1477 Project Proposed Action on groundwater and surface water quality including whether a water  
1478 quality evaluation criterion is likely to be exceeded. Surface water and groundwater evaluation  
1479 locations are points or lines on the landscape at which GoldSim generates model results that are  
1480 compared to applicable water quality evaluation criteria. These were identified during the  
1481 preparation of the FEIS to provide decisions-makers and the public with a discrete point from  
1482 which impacts can be understood and evaluated. The evaluation criteria are a basic and essential  
1483 component of this water resources impact assessment and were geographically located for the  
1484 purpose of environmental review.

1485 For each constituent at each evaluation location, GoldSim produces 500 predictions (or  
1486 realizations) of concentrations and orders them to generate a cumulative frequency distribution.  
1487 The 90<sup>th</sup> percentile value of the distribution is referred to as the P90 concentration. The 50<sup>th</sup>  
1488 percentile is the P50 concentration and the 10<sup>th</sup> percentile is the P10 concentration. The P90  
1489 annual maximum for a mine year is the highest P90 value over the 12 monthly timesteps that  
1490 comprise that year. The maximum P90 concentration for the simulation is the highest P90 value  
1491 for all of the mine years (200 years at the Mine Site and 500 years at the Plant Site). For non-  
1492 hardness based evaluation criteria, the modeling results are screened for further analysis by  
1493 comparing the maximum P90 concentration against the criterion value. If the maximum P90  
1494 concentration is less than the evaluation criterion, it is concluded that the constituent would not  
1495 cause an impact of concern at the evaluation location over the entire simulated time period and  
1496 no further assessment occurs. If the maximum P90 concentration is greater than the evaluation  
1497 criterion, it is retained for further evaluation. While the P50 concentration is considered the best-  
1498 estimate, the maximum P90 concentrations provides assurance that the FEIS is not  
1499 underestimating potential water quality impacts from the NorthMet Project Proposed Action.

1500 To further illustrate how the probabilistic modeling results are used in the FEIS, consider the  
1501 example of where the predicted maximum P90 concentration of a solute is exactly equal to the  
1502 evaluation criterion. In this case there is a minimum 90 percent probability that the actual  
1503 concentration would be below the criterion over the entire model simulation. This threshold,  
1504 however, does not imply and is not equivalent to saying that water quality criteria would be  
1505 exceeded 10 percent of the time.

1506 As an example of the screening process, consider cobalt at Partridge River station SW-004a.  
1507 Cobalt is a useful screening example, because it is expected to be released from Mine Site  
1508 contaminant sources at predicted concentrations significantly higher than background  
1509 concentrations already occurring in natural groundwater and surface water. Figure 5.2.2-19 is a  
1510 plot of predicted P10, P50, and P90 annual maximum cobalt concentrations at SW-004a. In this  
1511 FEIS, a constituent is concluded to not have a severe impact if its P90 concentrations are less  
1512 than its associated water quality evaluation criterion. As shown on Figure 5.2.2-19, the P90 plot  
1513 of annual maximum cobalt concentrations for all years is about 3 µg/L, which is lower than the  
1514 water quality evaluation criterion of 5 mg/L, so cobalt would be predicted to not have a  
1515 significant impact at this evaluation location. A closer inspection of the GoldSim output indicates  
1516 that the maximum P90 cobalt concentration of all mine years (2,400 timesteps) is 3.11 µg/L as  
1517 shown on the plot. The screening process would conclude that cobalt at SW-004a would not be  
1518 retained for further evaluation.

1519

1520  
1521

**Figure 5.2.2-19 GoldSim-predicted Annual Maximum Cobalt Concentrations at SW-004a**

1522 The P90 threshold was adopted in another mining NEPA document where probabilistic modeling  
1523 was used (Idaho Cobalt Project [USFS 2009b]). Regarding the selection of the maximum P90  
1524 threshold for initial screening the Co-lead Agencies retain the flexibility to consider other  
1525 modeling analyses and screening approaches for evaluating the significance of a particular  
1526 modeled impact.

1527 For the purposes of screening review, the first year of model data were excluded when  
1528 calculating maximum P10, P50, and P90 values. Solute concentrations between model cells can  
1529 take several timesteps to stabilize from the input initial conditions, and the predicted  
1530 concentrations for these initial timesteps may be unreliable and not representative of the  
1531 expected conditions. To avoid including these numerical artifacts in the screening analysis, the  
1532 first twelve timesteps of the model data (mine year 1) were not used to generate the maximum  
1533 P90 concentrations used for screening.

1534 The use of the P90 criterion for determining whether or not evaluation criteria are being met is  
1535 not equivalent to how water quality-based effluent limits (WQBELs) would be developed for  
1536 NPDES permitting. Appropriate WQBELs would be derived based on water quality standards  
1537 and implemented in the permit. Discharges would be evaluated during the NPDES permitting  
1538 stage and WQBELs applied according to 40 CFR 122.44(d).

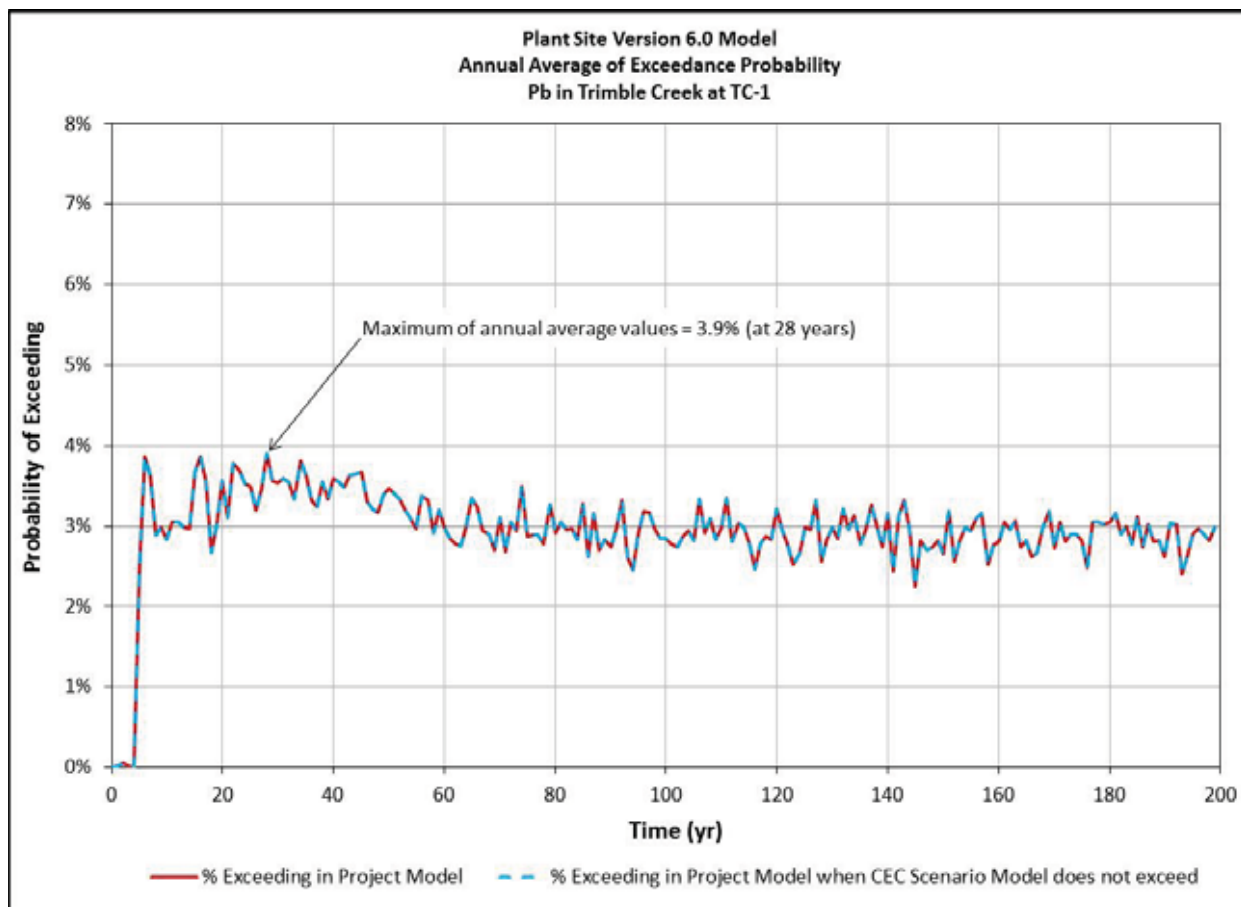

1539 Surface water chemical constituents with hardness-based evaluation criteria include cadmium,  
1540 chromium III, copper, lead, nickel, and zinc. The screening of these constituents requires special  
1541 considerations because hardness, and the associated evaluation criterion, could change from  
1542 monthly timestep to timestep during a model realization and also for the same timestep between  
1543 different realizations. It was therefore not possible to develop a single evaluation criterion to  
1544 which the GoldSim-predicted solute concentrations could be compared. The approach to  
1545 screening was therefore based on evaluating the frequency of occurrence of an exceedance for  
1546 each timestep that computed a solute concentration and hardness value, the latter dictating the  
1547 solute evaluation criterion for that timestep only. At the end of the GoldSim simulation, each  
1548 timestep would have 500 solute concentrations to compare to 500 evaluation criteria (one pair for  
1549 comparison for each realization). The total number of exceedances for the timestep was divided  
1550 by 500 and converted to a percent to determine the exceedance probability for that time step. For  
1551 each model year, the exceedance probability for the 12 associated (monthly) timesteps was  
1552 averaged and that was taken as the annual average exceedance probability for that mine year.

1553 As an example, Figure 5.2.2-20, shows a plot of the annual average exceedance probability for  
1554 lead at Plant Site evaluation location TC-1 (red line). Also shown (in blue) is a line representing  
1555 the probability of the NorthMet Project Proposed Action exceeding a criterion while the CEC  
1556 scenario does not exceed. If the highest value on this second curve is less than 5 percent, it was  
1557 concluded that the constituent at that location would not require further discussion and it was not  
1558 considered further in the FEIS. If the maximum value was greater than 5 percent, the constituent  
1559 at that location was retained for further evaluation. This includes an additional narrative that  
1560 evaluates the characteristics of the exceedances including the differences between NorthMet  
1561 Project Proposed Action and CEC scenario concentrations, the conservativeness of model  
1562 assumptions leading to the prediction of exceedances, and possible mitigation measures that can  
1563 be considered to reduce the frequency of exceedances. If the constituent is not retained for  
1564 further evaluation, then it is not discussed further in this FEIS and the quantification of impacts  
1565 provided in tables was determined to be sufficient for purposes of environmental review.

1566 For the example shown on Figure 5.2.2-20, the maximum annual probability is 3.9 percent, so  
1567 the constituent and location (in this case, lead at TC-1) would not be evaluated further. Note that  
1568 for the example shown, the annual probabilities of the NorthMet Project Proposed Action  
1569 exceeding when CEC does not (blue line) is visually very similar to the NorthMet Project  
1570 Proposed Action exceedance probabilities (red line) for each mine year meaning that, in this  
1571 case, the small probability of exceedances (less than 5 percent) is attributable to the NorthMet  
1572 Project Proposed Action and not to background, therefore further discussion is not provided.

1573

1574

1575

1576 **Figure 5.2.2-20** *Example of Exceedance Probability Plot for a Constituent with a*  
1577 *Hardness-Based Evaluation Criterion*

1578 Hardness-dependent evaluation criteria are affected month by month by the modeled  
1579 concentration of hardness. Therefore, the FEIS uses the frequency of exceedance approach  
1580 described in Section 5.2.2.2.3 for screening of surface water constituents with hardness-based  
1581 criteria.

1582 A 5 percent screening threshold was selected because in the judgment of the Co-Lead Agencies,  
1583 it is sufficiently conservative for purposes of identifying cases where additional discussion is  
1584 necessary to understand potential environmental effects. The 5 percent threshold is equivalent to  
1585 the NorthMet Project Proposed Action exceeding a criterion at a given evaluation location when  
1586 CEC scenario does not one month out of every twenty.

1587 If the frequency of exceedance is greater than 5 percent, the constituent is retained for further  
1588 evaluation in the FEIS. This includes an additional narrative that evaluates the characteristics of  
1589 the exceedances including the differences between NorthMet Project Proposed Action and CEC  
1590 scenario concentrations, the conservativeness of model assumptions leading to the prediction of  
1591 exceedances, and possible mitigation measures that can be considered to reduce the frequency of  
1592 exceedances. If the constituent is not retained for further evaluation, then it is not discussed  
1593 further in this FEIS and the quantification of impacts provided in tables was determined to be  
1594 sufficient for purposes of environmental review.

1595 ***CEC Scenario***

1596 The overall analysis of NorthMet Project Proposed Action effects on water quality also takes into  
1597 consideration the extent to which predicted water quality for the NorthMet Project Proposed  
1598 Action compares with modeled existing conditions. There are some processes, however, that  
1599 most water quality models, including the one used for the FEIS, do not fully capture, which  
1600 limits the ability to simply compare the predicted effects of the NorthMet Project Proposed  
1601 Action from water quality models with existing water quality for some constituents. These  
1602 include sulfate reduction between the LTVSMC Tailings Basin and the Embarrass River and  
1603 site-specific redox reactions (see Section 4.2.2.3.2 for more discussion of sulfate reduction in the  
1604 Embarrass River Watershed). For this reason, a CEC scenario was modeled within GoldSim.

1605 The CEC scenario draws from the same existing condition hydrologic and water quality dataset  
1606 in GoldSim that was used for modeling the NorthMet Project Proposed Action, but does not  
1607 introduce any NorthMet mine features or activities. Otherwise, both scenarios were modeled the  
1608 same way, using 500 Monte Carlo simulations for the same model durations and the results were  
1609 displayed in the same probabilistic manner.

1610 This CEC scenario model was intended to represent conditions in the absence of the NorthMet  
1611 Project Proposed Action and also in the absence of future activities that may improve water  
1612 quality under the Consent Decree between the MCPA and Cliffs Erie. The one exception is  
1613 ending Northshore discharge to the Partridge River in mine year 55, which is included in both  
1614 the NorthMet Project Proposed Action and CEC scenarios for the assessment of cumulative  
1615 effects. Modeling both scenarios in the same way allows for a direct comparison of predicted  
1616 water quality model results and facilitates an assessment of the extent to which implementation  
1617 of the NorthMet Project Proposed Action would result in changes in existing water quality.

1618 Note, however, that this modeled CEC scenario is not the same as the No Action Alternative, the  
1619 impacts of which are described in Section 5.2.2.4. The CEC scenario assumes one change in  
1620 baseline conditions. The only modeled source of constituent loading to the groundwater or  
1621 surface water that does not represent background sources is the Peter Mitchell Pit discharge to  
1622 the Partridge River, which is assumed to stop in approximately 2070 because it is expected to  
1623 occur. Other than this change the CEC scenario model does not include future expected  
1624 additional mitigation such as water quality mitigation at the existing LTVSMC Tailings Basin,  
1625 because these measures have not yet been determined. Nor does it try to account for climate  
1626 change. The No Action Alternative, on the other hand, is not static and anticipates for other  
1627 predictable changes in the NorthMet Project Proposed Action area, such as other planned  
1628 projects, required mitigation, and climate change.

1629 ***Comparison of NorthMet Project Proposed Action with the CEC Scenario***

1630 The analysis of the model results that follows (see Section 5.2.2.3) compares predicted solute  
1631 concentrations for both the NorthMet Project Proposed Action and CEC scenario to applicable  
1632 groundwater and surface water evaluation criteria. These comparisons are made at each of the  
1633 Mine Site and Plant Site groundwater and surface water evaluation locations (a combined total of  
1634 eight groundwater and 18 surface water evaluation locations) using the GoldSim P90  
1635 probabilistic results.

1636 **5.2.2.3 NorthMet Project Proposed Action**

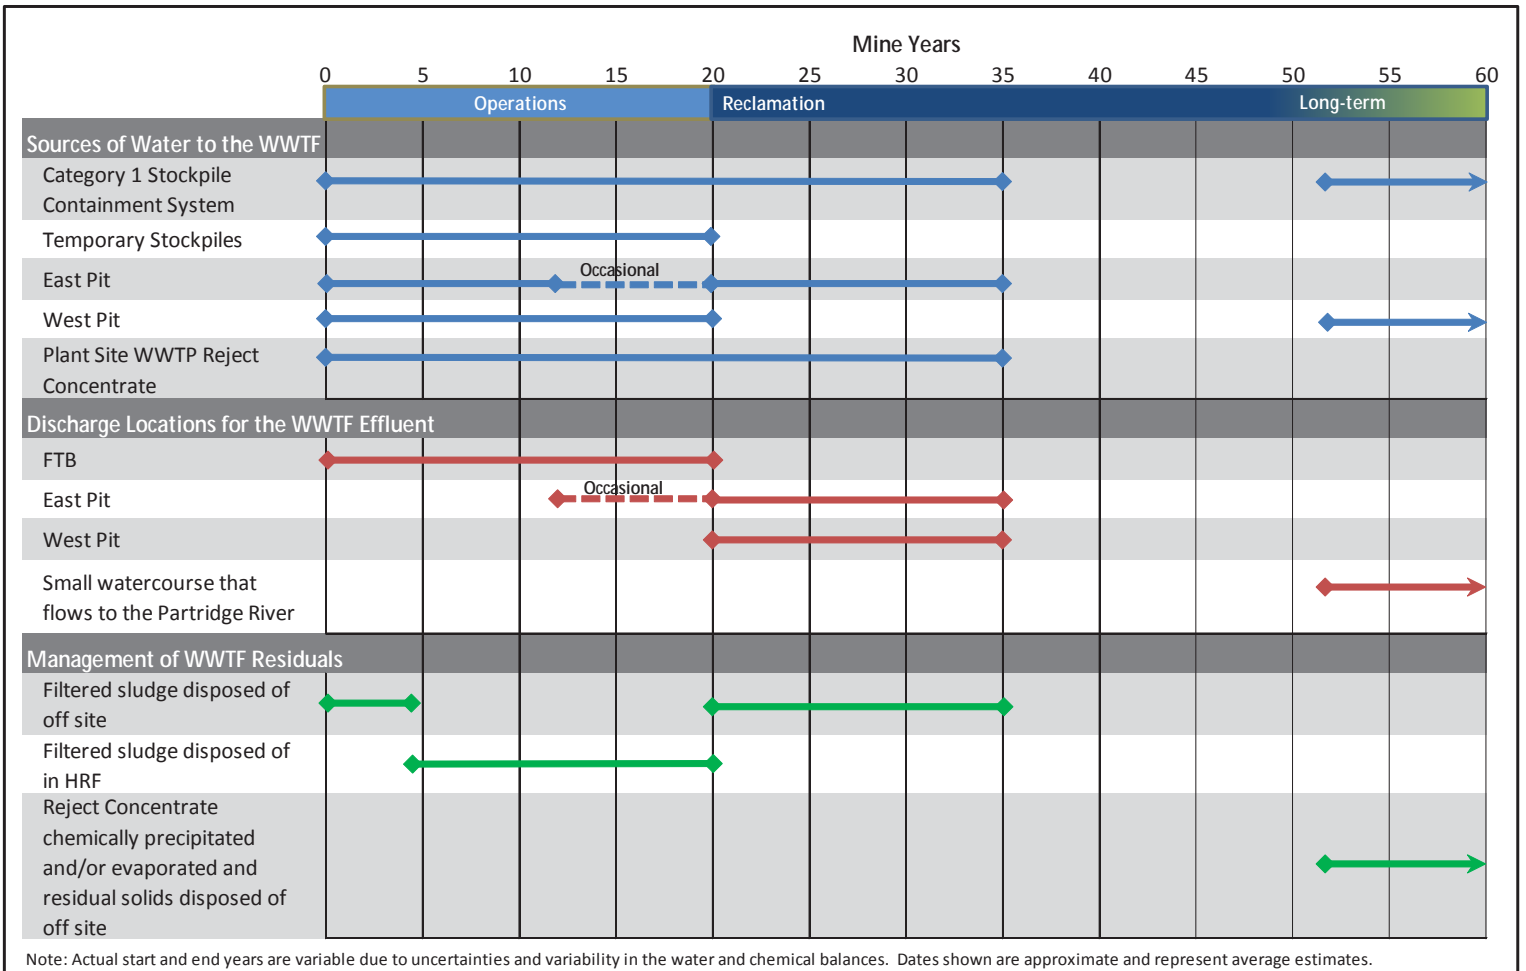

1637 This section discusses the potential environmental consequences of the NorthMet Project  
1638 Proposed Action on groundwater and surface water levels and quality at both the Mine Site and  
1639 Plant Site (Tailings Basin) and the Transportation and Utility Corridor. Figure 5.2.2-21 and  
1640 5.2.2-22 illustrate Plant Site and Mine Site water management timelines.

1641 **5.2.2.3.1 NorthMet Project Proposed Action Water Budget Overview**

1642 This section briefly describes the water budget under the NorthMet Project Proposed Action at  
1643 the Mine Site and Plant Site. Under the NorthMet Project Proposed Action, the following water  
1644 sources would have to be managed:

- 1645 • Stormwater runoff on mine facilities (e.g., waste rock stockpiles, mine pits, Tailings Basin);
- 1646 • Seepage from mine facilities into groundwater and surface water;
- 1647 • Pit lakes and saturated pit backfill, which include groundwater entering the mine pits;
- 1648 • Process plant makeup water withdrawn from Colby Lake;
- 1649 • Stream augmentation water from the Plant Site's WWTP;
- 1650 • Discharge of excess water from the WWTF and WWTP;
- 1651 • Transport and use of excess Mine Site water for process makeup at the Plant Site; and
- 1652 • Transport and use of excess Plant Site Water to accelerate re-flooding of the West Pit at the  
1653 Mine Site.

1654 An overall water process flow diagram, shown on Figures 5.2.2-10 and 5.2.2.12, illustrates the  
1655 principle NorthMet Project Proposed Action components and their relationship to surface water  
1656 and groundwater resources.

Note: Actual start and end years are variable due to uncertainties and variability in the water and chemical balances. Dates shown are approximate and represent average estimates.

This document is a working document. This document may change over time as a result of new information, further deliberation, or other factors not yet known to the Co-lead Agencies.

DRAFT

1665 **Operations (Year 0 to 20)**

1666 ***Mine Site***

1667 During operations, the West Pit (years 0-20), Central Pit (years 12-16) and East Pit (years 0-11)  
1668 would be dewatered due to pit inflows from groundwater. A process water pipeline would carry  
1669 this water to the WWTF West Equalization Basin. Temporary liners, underdrains and ditches  
1670 associated with the Category 2/3 Stockpile, Category 4 Stockpile, Ore Surge Pile, would capture  
1671 surface runoff and groundwater seepage and convey this contact water to lined ponds. Process  
1672 water pipelines would carry this water to the WWTF West Equalization Basin. The Category 1  
1673 Stockpile containment system, Rail Transfer Hopper pond liners and Haul Road pond liner  
1674 would capture contact water which would be directed to the WWTF East Equalization Basin.

1675 Initial construction activity involving wetland dewatering (effluent management) would be  
1676 addressed by construction stormwater management during permitting. Surface runoff from the  
1677 Overburden Storage and Laydown Area would drain to a process water pond. Pond water quality  
1678 and operational demands would determine if it is piped to the Central Pumping Station, to the  
1679 Tailings Basin or to the East Pit during filling.

1680 Interior ditches, exclusion dikes (including perimeter and rim pit dikes) would be used to manage  
1681 non-contact stormwater and prevent contact with mine wastes. Five sedimentation ponds would  
1682 be used to reduce total suspended solids and allow for controlled discharge off site. Runoff from  
1683 the covered Category 1 Stockpile would be managed as stormwater and discharged off site via a  
1684 sedimentation pond. The geomembrane cover construction would begin at mine year 14 and be  
1685 complete by mine year 21.

1686 Groundwater seepage through lined and unlined mine features would begin migrating toward the  
1687 Partridge River.

1688 A chemical precipitation WWTF would treat process water from the West and East equalization  
1689 ponds. Effluent would flow to the clay-lined Central Pumping Station Pond where it would be  
1690 blended with Overburden Storage and Laydown Area runoff. The Central Pumping Station  
1691 would then pump the treated water to the Tailings Basin or to the East Pit during filling (after  
1692 mine year 11). No water would be discharged off site.

1693 Filtered sludge from the chemical precipitation process would be sent off site for disposal or  
1694 stored at the Hydrometallurgical Residue Facility. The reject concentrate stream from the Plant  
1695 Site WWTP would be transported to the WWTF via rail tank cars where it would be added to the  
1696 West Equalization Basin.

1697 Beginning in year 11, after East Pit mining would be completed, the pit would be backfilled with  
1698 Category 2/3 and 4 waste rock from the temporary waste rock stockpiles and from ongoing  
1699 operations. The East Pit backfill would re-saturate with groundwater, in-pit runoff, direct  
1700 precipitation, and treated process water from the WWTF, to limit the oxidation of the sulfide  
1701 minerals in the pit walls and backfilled waste rock, and reduce the amount of metals leaching to  
1702 the pit water. Water would be maintained within 5 ft of the backfill surface (PolyMet 2015d).  
1703 During periods of high precipitation or during spring snowmelt, partial dewatering of the East Pit  
1704 (to the WWTF and ultimately to the Tailings Basin) may be required to allow placement of the  
1705 waste rock.

1706 Once backfilling of the East Pit is complete, the backfill would continue to saturate and the pore  
1707 water would be sent to the WWTF for treatment and returned to the pit to improve the pore water  
1708 quality. When the backfill water level rises above the top of bedrock (approximately mine year  
1709 20), it would release into the East Pit – Category 2/3 Surficial Flowpath. The affected  
1710 groundwater in this flowpath would migrate slowly towards the Partridge River.

1711 The pipeline between the WWTF and the East Pit would be left in place during and after backfill  
1712 re-saturation to manage the water elevation in the East Pit.

### 1713 ***Plant Site***

1714 During operations, the primary source of process water at the Plant Site would be the Tailings  
1715 Basin ponds, which would contain return water from the beneficiation plant, treated water from  
1716 the Mine Site WWTF and Plant Site WWTP, and water collected from the Tailings Basin  
1717 containment system. Colby Lake water would also be withdrawn. Direct precipitation and  
1718 stormwater runoff from the process areas at the Plant Site would also be directed to the Tailings  
1719 Basin pond. Tailings Basin pond water would be sent to the WWTP for treatment and discharged  
1720 to surface water for operational needs as necessary. The purpose of the WWTP would be to treat  
1721 water for discharge to the environment when the NorthMet Project Proposed Action has excess  
1722 water that could not be stored in the Tailings Basin pond. The WWTP would include an RO unit  
1723 or equivalent technology that would meet water quality targets. Containment systems would be  
1724 installed across the western, northwestern, northern, and eastern sides of the Tailings Basin to  
1725 collect water leaving the Tailings Basin as surface and surficial groundwater flow. During  
1726 operations, this water would be returned to the Tailings Basin pond for re-use. A small portion of  
1727 groundwater would bypass the containment system and enter into groundwater flowpath.  
1728 Groundwater would then emerge in surface waters north, northwest and west of the Tailings  
1729 Basin. On the southern side of the Tailings Basin, an existing seepage containment system would  
1730 be upgraded by PolyMet to achieve 100 percent capture of tailings surface and groundwater  
1731 seepage that otherwise would flow into Second Creek, a tributary of the Partridge River.  
1732 Improvements to capture efficiency of the existing dam may include lining the upstream dam  
1733 face with bentonite and injecting grout into the dam. A second dam could be constructed  
1734 approximately 500 ft downstream of the existing dam where the geography is more constricted.  
1735 This potential second dam may be earthen with a clay or concrete cutoff wall extending to  
1736 bedrock.

1737 The Tailings Basin containment systems would reduce flows to tributaries that extend from the  
1738 Tailings Basin. Flow would be increased through augmentation. A portion of the water collected  
1739 by the containment system and water from the Tailings Basin pond would be sent to the WWTP,  
1740 treated, and discharged to Unnamed Creek, Trimble Creek, and Second Creek in order to  
1741 maintain downstream hydrology and wetland function. Mud Lake Creek would be augmented  
1742 via a drainage swale on the eastern side of the Tailings Basin. Augmentation would restore flow  
1743 to  $\pm$  20 percent of existing or uncaptured flows to maintain existing hydrology, geomorphology,  
1744 aquatic communities, connectivity, water quality, and biology (Chisholm 2006).

1745 Tailings Basin pond elevation would be controlled by pumping any excess pond water to the  
1746 WWTP. An emergency overflow channel would be constructed as a backup means of controlling  
1747 pond elevation, but discharge from the emergency overflow would not be expected. The  
1748 emergency overflow is provided for protection of the dams in the rare event that freeboard within  
1749 the Tailings Basin is not sufficient to contain all stormwater. Such instances have the potential to

1750 occur in the event of a probable maximum precipitation rainfall event or some fraction thereof.  
1751 Probable maximum precipitation rainfall events are rare and such an event has a low likelihood  
1752 of being experienced during the life of the basin.

1753 Colby Lake water would be pumped to the Hydrometallurgical Plant and to the WWTP. Wet  
1754 hydrometallurgical residue would be pumped to the Hydrometallurgical Residue Facility. Leakage  
1755 from the Hydrometallurgical Residue Facility would be collected by the leakage collection  
1756 component of the double-liner system and returned to the Hydrometallurgical Residue Facility  
1757 flotation pond and from there it would be returned to the Hydrometallurgical Plant.

1758 Reject concentrate from the WWTP RO system would be sent to the Mine Site WWTF for  
1759 treatment by chemical precipitation.

### 1760 **Reclamation (Starting Year 21)**

#### 1761 ***Mine Site***

1762 The backfilled East Pit would continue to saturate and the pore water would be sent to the  
1763 WWTF for treatment and returned to the pit to improve the pore water quality. A wetland would  
1764 be established at the surface of the pit and water levels would be maintained by a gravity  
1765 overflow structure to the West Pit.

1766 West Pit reclamation would commence when mining activity ceases. Primary dewatering  
1767 systems would no longer be operated, and the West Pit would begin to flood naturally with  
1768 groundwater, precipitation, and surface runoff from the tributary watershed. Flooding would be  
1769 accelerated by delivery of treated water from both the Mine Site WWTF and the Plant Site  
1770 WWTP. Seepage through the Category 1 Stockpile containment system would also contribute  
1771 water to the West Pit. With the addition of water pumped from the Plant Site, West Pit flooding  
1772 is projected to be completed before the end of mine year 55. When the West Pit water level rises  
1773 above the top of bedrock, there would be a release of pit lake water into the West Pit Surficial  
1774 Flowpath. The affected groundwater in this flowpath would migrate slowly south towards the  
1775 Partridge River.

1776 Temporary stockpiles and unnecessary haul roads would be removed along with their associated  
1777 process water ponds. The WWTF would also receive low flow rates from the Category 1  
1778 Stockpile surface and groundwater seepage containment system.

1779 Reject concentrate from the Plant Site WWTP RO system would be treated at the Mine Site  
1780 WWTF and the resulting filtered sludge would be taken off site for disposal.

#### 1781 ***Plant Site***

1782 Plant Site reclamation would include building and structure demolition and equipment removal,  
1783 Tailings Basin reclamation, and Hydrometallurgical Residue Facility reclamation.

1784 During Tailings Basin reclamation, the pond bottom and beaches would be covered with a  
1785 bentonite layer to reduce the downward percolation from the pond, which would reduce the  
1786 amount of water collected by the Tailings Basin containment system. Most of the side slopes  
1787 and top (non-ponded) surfaces of the Tailings Basin would be amended with bentonite to reduce  
1788 meteoric infiltration and oxygen diffusion into the tailings, with the intent of reducing sulfide

1789 oxidation and associated release of soluble sulfate and metals. Tailings Basin cell 2W would be  
1790 re-vegetated to reduce meteoric infiltration (PolyMet 2015d).

1791 Water management would include maintenance of the pond and wetland within the reclaimed  
1792 Tailings Basin, stormwater management, and continued operation of the WWTP and the  
1793 containment systems. A wetland would be constructed on the pond perimeter.

1794 After bentonite amendment of tailings surfaces, establishment of the wetland, and continued  
1795 water treatment, the tailings pond water quality would improve over time. The pond and wetland  
1796 would continue to lose water via seepage, but at a reduced rate as compared to operations. The  
1797 reject concentrate stream from the WWTP would be sent to a distillation crystallizer to generate  
1798 a solid residual that would be transported offsite for disposal.

1799 Containment systems would continue to operate, although seepage rates would be progressively  
1800 reduced. The collected seepage would be pumped to the WWTP. During this period, the WWTP  
1801 effluent would be used for both West Pit flooding and stream augmentation (PolyMet 2015a).

1802 The WWTP and the containment system would be periodically inspected to ensure continuing  
1803 integrity. Monitoring of piezometers or other similar devices would continue for the purpose of  
1804 assessing the continued effectiveness of the containment system and to inform appropriate  
1805 mitigation and/or permitting of any potential release of seepage that may bypass the containment  
1806 system. The NPDES/SDS permit covering the facility would prohibit a point source water  
1807 discharge from the containment system that adds pollutants to waters of the U.S.

1808 Reclamation of the Hydrometallurgical Residue Facility would include removal of ponded water  
1809 from the cell surface, removal of pore water from the residue, construction of the cell cover  
1810 system, and establishment of vegetation and stormwater runoff controls. Once the  
1811 Hydrometallurgical Residue Facility is reclaimed, the volume of water draining from the facility  
1812 would decline and nearly cease if the cover system were effective. The facility would only  
1813 require periodic pumping of any remaining drainage to the WWTP and inspection of the  
1814 reclaimed cell to verify integrity of the reclamation systems.

### 1815 **Closure and Post-Closure Maintenance (after Reclamation is Complete)**

#### 1816 ***Mine Site***

1817 During this phase, the WWTF would be converted to a Reverse Osmosis (RO) system with a  
1818 distillation crystallizer to eliminate the liquid reject stream. The moist waste solids from this  
1819 system would be disposed of offsite. Pilot-testing has indicated that treated effluent from this  
1820 system would have sulfate concentrations less than 9 mg/L and meet water quality discharge  
1821 standards for all other regulated solutes (Barr 2013f). Effluent from the WWTF RO system  
1822 would be discharged to the West Pit Overflow Creek shown on Figure 5.2.2-23.

1823 Water levels in the East Pit would generally be controlled by passive wetland overflow to the  
1824 West Pit. Depending on seasonal weather conditions, there could be occasional pumped flows  
1825 from the wetland to the WWTF or of treated effluent from the WWTF to the wetland to further  
1826 control the water levels (PolyMet 2015d). In any event, saturated backfill in the East Pit would  
1827 continue to release groundwater to the East Pit – Category 2/3 Surficial Flowpath.

1828 After refill, the West Pit water level would be controlled by pumping to the WWTF to prevent  
1829 surface water overflow from the pit lake. However, release of pit lake water to the West Pit

1830 Surficial Flowpath would continue. The WWTF would also receive low flow rates from the  
1831 Category 1 Stockpile groundwater containment that would then be discharged to the West Pit  
1832 Overflow Creek shown on Figure 5.2.2-23.

1833 Perimeter dikes that would be no longer needed to provide access or separation from the areas  
1834 outside the Mine Site would be removed. The dike located north of the East Pit would remain in  
1835 place to minimize mixing of the Partridge River flows with the East Pit water and prevent gully  
1836 development on the northern side of the pit in the segments not protected by ditches (see Figure  
1837 5.2.2-23). In addition, the dike located north of the Category 1 Stockpile would remain in place  
1838 to allow access to groundwater monitoring locations. The Category 1 Stockpile would be  
1839 inspected on a regular basis and portions of the geomembrane liner and soil cover would be  
1840 replaced if necessary.

1841 Surface runoff would be routed away from the mine pits using a combination of existing and new  
1842 ditches (see Figure 5.2.2-23). Some portions of the pit rim dikes may be left in place, if needed to  
1843 prevent an uncontrolled flow to or from the pits and potential erosion of the pits walls. A more  
1844 detailed evaluation of this requirement would be conducted prior to mine closure.

1845 Stormwater pond outlet control structures would remain in place as necessary to manage water  
1846 resource effects. The outlet control structure on the stormwater pond located immediately north  
1847 of the East Pit and the Category 1 Stockpile would remain in place to minimize the mixing of the  
1848 Partridge River flows with the East Pit water and prevent gully development on the northern side  
1849 of the pit. The outlet control structures on the two stormwater ponds next to Dunka Road would  
1850 remain in place to direct water under the road and the railroad to a tributary to the Partridge  
1851 River along natural drainage paths. As a requirement of the NPDES/SDS stormwater permit  
1852 and/or Reclamation Plan for the facility, discharges from these outlet control structures would be  
1853 monitored as necessary to ensure that stormwater runoff to the Partridge River would meet water  
1854 quality discharge limits. For modeling purposes, it is assumed that the water quality of this  
1855 stormwater runoff is the same as the non-contact water for other portions of the watershed.

1856 The WWTF would continue to operate during closure and long-term maintenance, treating  
1857 excess water from the West Pit and discharging the effluent to the West Pit Overflow Creek. The  
1858 typical discharge rate from the WWTF is predicted to be about 300 gpm. The water balance  
1859 model predicts periodic temporary higher treatment/discharge rates (up to about 600 gpm) to  
1860 create additional freeboard prior to spring snowmelt. By pumping pit lake water to the WWTF,  
1861 the pit water level would be managed to always provide sufficient freeboard to absorb extreme  
1862 precipitation events without overflowing.

DRAFT

1869 ***Plant Site***

1870 At the beginning of closure, the WWTP RO system would be modified for multistage operation  
1871 and use of the distillation crystallization unit to eliminate the liquid reject stream. The moist  
1872 waste solids from this system would be disposed of off-site. Pilot-testing has indicated that  
1873 treated effluent from this system would meet water quality discharge standards for all regulated  
1874 constituents.

1875 During closure and long-term maintenance, the WWTP would continue to treat water collected  
1876 by the Tailings Basin containment systems. The treated effluent would be used for flow  
1877 augmentation to Unnamed Creek, Trimble Creek, and Second Creek. (PolyMet 2015a). Tailings  
1878 seepage bypassing the containment system (approximately 20 gpm) would continue to enter the  
1879 northern, northwestern, and western surficial flowpaths, and migrate slowly toward the  
1880 Embarrass River.

1881 ***Closure and Post-Closure Maintenance Objectives***

1882 The ultimate water resource closure objective is to transition from the mechanical treatment  
1883 provided by the WWTF and WWTP to non-mechanical treatment. Transition to the non-  
1884 mechanical treatment systems would begin after the performance of the non-mechanical  
1885 treatment methods have been proven. At the Mine Site, non-mechanical treatment systems would  
1886 be considered for long-term treatment of water from the Category 1 Stockpile surface and  
1887 groundwater seepage containment system and West Pit overflow. At the Plant Site, non-  
1888 mechanical treatment would be considered for tailings seepage collected by the Tailings Basin  
1889 containment systems. Descriptions of possible non-mechanical systems are presented in PolyMet  
1890 2015d. See section 5.2.2.3.5 for more information on the transition to non-mechanical systems.

1891 Long-term monitoring of the Hydrometallurgical Residue Facility would continue. Water  
1892 collected by the leak detection system (if any water) would be sent to the WWTP (for treatment.  
1893 Monitoring would continue and mitigation measures would be undertaken if there was any  
1894 indication of potential solute releases to groundwater or surface water.

1895 Surface water and groundwater would be monitored as required by relevant permits. The closure  
1896 and long-term maintenance activities would continue until monitoring indicated that the site  
1897 water quality had met the stipulated permit conditions for discontinuing these activities.

1898 **5.2.2.3.2 Partridge River Watershed**

1899 This section discusses the potential environmental consequences of the NorthMet Project  
1900 Proposed Action on groundwater and surface water hydrology and quality within the Partridge  
1901 River Watershed, which includes all of the Mine Site, Transportation and Utility Corridor,  
1902 processing plant and a small portion of the Tailings Basin that contributes flow via a surface seep  
1903 to the headwaters of Second Creek, which is a tributary to the Partridge River.

1904 **Effects on Groundwater Hydrology**

1905 This section discusses the effects of the NorthMet Project Proposed Action on groundwater  
1906 hydrology, specifically groundwater levels at the Mine Site. The NorthMet Project Proposed  
1907 Action would not result in any measurable effects on groundwater levels along the

1908 Transportation and Utility Corridor (other than as a result of the West Pit dewatering, which is  
1909 discussed as part of the Mine Site) or at the processing plant.

1910 The NorthMet Project Proposed Action would affect groundwater levels at the Mine Site during  
1911 operations by dewatering the active mine pits and pumping water to the Plant Site (years 0 to 11)  
1912 or to the East Pit and Tailings Basin (years 11 to 20). During years 20 to 52, water from the Plant  
1913 Site would be pumped to the West Pit to accelerate flooding and help return groundwater levels  
1914 to near pre-mining conditions.

### 1915 ***Inflow to Mine Pits***

1916 The expected rate of groundwater inflow to the East Pit and West Pit during operations was  
1917 estimated from MODFLOW modeling, similar to that performed for the DEIS. The model was  
1918 updated in several ways, including the following:

- 1919 • MODFLOW model was recalibrated using target groundwater baseflows of 0.41 cfs at SW-  
1920 002, 0.51 cfs at SW-003, and 0.92 cfs at SW-004 to reflect revisions from the XP-SWMM  
1921 model;
- 1922 • Groundwater elevations at monitoring wells MW-1 through MW-18 were included as targets  
1923 in the updated calibration;
- 1924 • A new calibration constraint was for surficial aquifer heads not to be significantly higher than  
1925 ground surface; and
- 1926 • The model was calibrated using higher values of hydraulic conductivity for Virginia  
1927 Formation.

1928 These updated estimates of groundwater inflow rates to the pits were used to develop the overall  
1929 water balance for the probabilistic model. Table 5.2.2-19 shows the MODFLOW-predicted  
1930 inflows to the pit (years 1 to 20) as well as outflows during closure, once the pits have flooded  
1931 (PolyMet 2015m).

1932 **Table 5.2.2-19 Groundwater Inflows at the Mine Pits Based on MODFLOW Results**

| Year                              | West Pit              |               | Central Pit                            |               | East Pit     |               |
|-----------------------------------|-----------------------|---------------|----------------------------------------|---------------|--------------|---------------|
|                                   | Inflow (gpm)          | Outflow (gpm) | Inflow (gpm)                           | Outflow (gpm) | Inflow (gpm) | Outflow (gpm) |
| 1                                 | 0                     |               | 0                                      |               | 220          |               |
| 2                                 | 60                    |               | 0                                      |               | 190          |               |

1936 **Extent of Groundwater Drawdown**

1937 Understanding the extent of groundwater drawdown, especially in the surficial material  
 1938 surrounding the NorthMet Project Proposed Action mine pits, is important in order to assess the  
 1939 potential effects on nearby surface water features such as wetlands. However, the complex  
 1940 geology with the presence of bedrock, surficial deposits, and wetland soils at the Mine Site  
 1941 makes it difficult to accurately quantify drawdown at any specific location. Site characterization  
 1942 data and MODFLOW calibration results indicate that the bulk hydraulic conductivity of bedrock  
 1943 is much lower than the bulk hydraulic conductivity of surficial materials. As a consequence, the  
 1944 bedrock tends to be saturated and overlain by a thin surficial aquifer that controls the local  
 1945 groundwater flow system. In a dewatering situation, the lower-permeability bedrock tends to  
 1946 remain saturated because it is subject to downward leakage from the overlying higher-  
 1947 permeability surficial aquifer (as long as the surficial aquifer contains groundwater). Unsaturated  
 1948 conditions in bedrock may occur very close to the pit wall, but not at moderate or large distances  
 1949 from the pit. Blasting during the mining operation is controlled to maintain pit wall integrity for  
 1950 safety considerations. Fractures and impacts to hydraulic conductivity due to blasting would not  
 1951 be expected to extend more than a few tens of feet from the pit walls. Water table drawdown in

1952 the surficial aquifer near the mine pits would be limited because it would be subject to meteoric  
1953 recharge and has a saturated thickness on the order of only 14 ft.

1954 Monitoring well response to pit dewatering at the Canisteo Pit, located approximately 65 miles  
1955 west of the NorthMet Project Proposed Action area in similar surficial geology, indicated  
1956 significant aquifer heterogeneity. Modeling of aquifer response at the Canisteo site using  
1957 MODFLOW resulted in differences between simulated and measured water levels ranging from  
1958 +28 ft to -4 ft (Jones 2002). The model clearly could not accurately estimate water level changes  
1959 of a few feet or less as would be desirable for assessing potential effects on nearby surface water  
1960 features such as wetlands. Therefore, it was concluded that it was not reasonable to attempt to  
1961 quantify drawdown at the Mine Site using the MODFLOW model.

1962 In lieu of using MODFLOW to estimate pit drawdown at the Mine Site, an analog approach was  
1963 developed using available well data from the Canisteo Pit, which is the only mine pit within the  
1964 Mesabi Iron Range that has an associated water balance study with well data that could be used  
1965 to assess potential drawdown effects. Sixteen Canisteo wells were used for the analog evaluation.  
1966 An additional shallow well near Kinney, Minnesota, adjacent to Minntac's West Pit, and one  
1967 deep bedrock well, also near Kinney, were also used for the evaluation. A comparison of the  
1968 hydrogeologic conditions at the Canisteo Mine Pit, the Kinney area wells, and the Mine Site  
1969 concluded that the geologic and hydrogeologic settings of the Mine Site are relatively similar to  
1970 the Canisteo and Minntac sites (Barr 2011i).

1971 The Canisteo Pit is not as deep as the proposed NorthMet mine pits. However, the surficial  
1972 deposits at the Canisteo site ranges from 50 to 100 ft thick, while the surficial deposits at the  
1973 Mine Site average only about 14 ft thick. Also, the underlying bedrock at the Canisteo site is  
1974 composed exclusively of the Biwabik Iron Formation, which generally has a higher hydraulic  
1975 conductivity than the Duluth Complex, Virginia Formation, and Giants Range Granite that  
1976 underlie surficial deposits at the Mine Site. Despite the difference in pit depths, it is interpreted  
1977 that there is potential for greater drawdown at the Canisteo site compared to the Mine Site.  
1978 Overall, the Canisteo data are believed to provide a reasonably conservative estimate of the  
1979 maximum extent of surficial aquifer drawdown that would result from the proposed PolyMet  
1980 mine pits.

1981 Water level data collected from monitoring wells over several years were used to characterize the  
1982 aquifer's response to the changing Canisteo Pit water level, and response to the approaching,  
1983 dewatered Minntac West Pit (ERM and MDNR 2011).

1984 The following were conclusions of the analog study:

- 1985 • Three wells within 700 ft of the Canisteo Pit showed a strong response to the rising pit water;
- 1986 • Six wells within 900 to 2,625 ft of the Canisteo Pit showed a measurable, but weak, response  
1987 to the rising pit water;
- 1988 • Seven wells within 660 to 3,500 ft of the Canisteo Pit showed no response to the rising water;
- 1989 • The deep bedrock well near Kinney showed an apparent, progressive water level drop when  
1990 the dewatered Minntac West Pit approached within about 1,000 ft of the well; and
- 1991 • The shallow well near Kinney did not show any measurable water level drop from June 2000  
1992 through March 2003 (when data collection stopped for safety reasons), during which time the  
1993 dewatered Minntac West Pit had advanced to within 900 ft of the well.

1994 Observations from the above discussed analog site show no clear, systematic relationship  
1995 between the proximity of wells to mine pits and effects on groundwater levels.

1996 Considering the analog site evaluation conclusions, the following guidelines for potentially  
1997 measurable drawdown can be used at the Mine Site:

1998 • 0 to 1,000 ft from the pit rim: groundwater drawdown from pit dewatering may occur and  
1999 may be measurable;

2000 • 1,000 to 1,700 ft from the pit rim: groundwater drawdown from pit dewatering may occur,  
2001 but may be difficult to distinguish from natural variations in background water levels;

2002 • 1,700 to 3,200-plus ft from the pit rim: groundwater drawdown from pit dewatering may  
2003 occur, but would likely only occur under certain hydrogeologic conditions, and may not be  
2004 discernible from natural variability; and

2005 • Beyond 3,200 ft from the pit: no drawdown effects would be expected.

2006 These guidelines are intended to help define zones of potential groundwater drawdown that  
2007 could be used to estimate potential indirect effects on nearby surface water features and wetlands  
2008 (see Section 5.2.3 for further discussion of this analog approach). They could also be used to  
2009 design a monitoring program to quantify actual effects, which could trigger appropriate  
2010 mitigation measures if warranted. Contingency mitigation options are discussed in the Water  
2011 Management Plan for the Mine Site (PolyMet 2015m). These guidelines have been expanded  
2012 considerably since the original analog study (see Section 5.2.3).

2013 There are few surface waterbodies within the 0 to 1,000 ft or the 1,000 to 1,700 ft zones, where  
2014 groundwater drawdown may occur and would potentially be distinguishable from natural  
2015 variations that could be affected by pit drawdown. The West Pit Outlet Creek is located within  
2016 these zones and would be affected by the WWTF discharge and other NorthMet Project  
2017 Proposed Action activities, as well. Yelp Creek and the headwaters of the Partridge River are  
2018 located to the north of the mine pits, but beyond the 0 to 1,000 ft zone. The proposed Category 1  
2019 Stockpile surface and groundwater seepage containment system, with its low-permeability cut-  
2020 off wall keyed into bedrock, would minimize effects of pit drawdown on these waterbodies.

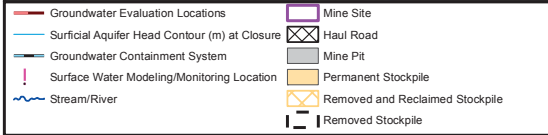

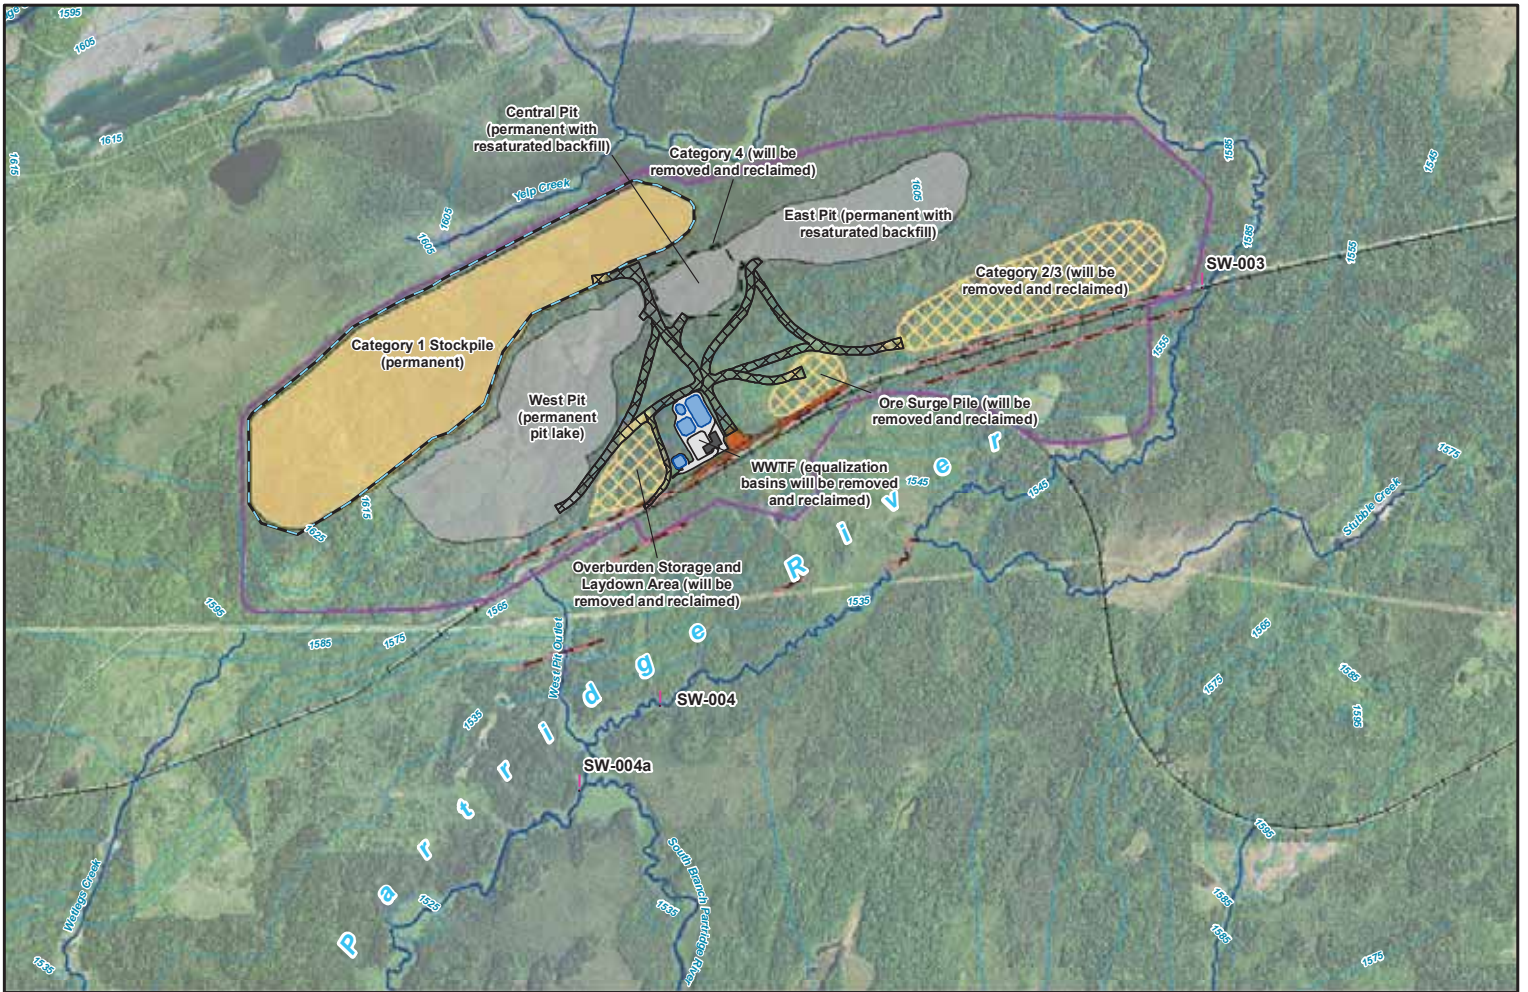

2021 Note that these guidelines would apply during mine operations and reclamation, but groundwater  
2022 drawdown associated with the mine pits should decline and essentially cease as the pits flood.  
2023 The actual steady-state water level in the East Pit would be established by an outlet structure  
2024 (invert at elevation 1,592 ft amsl) that would route surface overflows into the West Pit. The  
2025 water level in the West Pit would be controlled by operation of the WWTF. Long-term change in  
2026 on-site surficial aquifer groundwater levels (i.e., permanent drawdown) would be due to the  
2027 fixing of head boundaries to lower surface water levels controlled by pumped discharge by the  
2028 WWTF relative to existing conditions. There would be a permanent drawdown of a maximum of  
2029 about 20 ft immediately surrounding the West Pit lake, resulting from a closure groundwater  
2030 elevation of 1,579 ft versus existing groundwater elevation of approximately 1,600 ft, and about  
2031 10 ft immediately surrounding the East Pit, resulting from a closure groundwater elevation of  
2032 1,592 ft versus existing groundwater elevation of approximately 1,600 ft.

2033 ***Effects on Groundwater Quality in the Surficial Aquifer***

2034 The NorthMet Project Proposed Action could affect groundwater quality at the Mine Site by  
2035 leaching metals, sulfate, and other solutes from exposed waste rock, overburden, ore, WWTF  
2036 ponds and unsubmerged part of pit walls. Water affected by those contaminants could enter  
2037 groundwater system and migrate from mine facilities to the Partridge River.

2038 ***Potential Sources of Groundwater Impacts and Proposed Engineered Controls***

2039 The potential sources of groundwater impacts from the NorthMet Project Proposed Action within  
2040 the Partridge River Watershed include the waste rock stockpiles, the Overburden Storage and  
2041 Laydown Area, the Ore Surge Pile, the WWTF, and the mine pits (see Figure 5.2.2-24). Each of  
2042 these sources is briefly described below and key features are summarized in Table 5.2.2-20. Note  
2043 that the Category 2/3 Stockpile, the Overburden Storage and Laydown Area, and the Ore Surge  
2044 Pile, which are potential contaminant sources to groundwater, would only exist during mine  
2045 operations and would cease to exist after approximately mine year 20. Another potential  
2046 contaminant source, the WWTF equalization basins, would be removed at about mine year 55.  
2047 Most seepage from the permanent Category 1 Stockpile would be captured. Uncaptured seepage  
2048 would migrate to the West and East Pits, although a very small part of it would enter bedrock.  
2049 The mine pits would remain permanently and potentially serve as long-term sources of  
2050 contamination. The Category 4 Stockpile would exist until about year 11 and any seepage from  
2051 this stockpile would migrate as surface water or groundwater to the East Pit where it would be  
2052 collected as part of the pit dewatering system and pumped to the WWTF for treatment. After  
2053 year 11, material in the Category 4 Stockpile would backfill the combined East Central Pit.

This document is a working document. This document may change over time as a result of new information, further deliberation, or other factors not yet known to the Co-lead Agencies.

2056 **Table 5.2.2-20 Mine Site Solute Source Areas used in GoldSim**

| <b>Source Area</b>                  | <b>Active Source Period (mine years)</b>                                                 | <b>Engineered Features</b>                                                                                                                                                                                                                                                                                                                                                                  | <b>Chemical Mechanisms</b>                                                                                                                                                                                                                                                                                                                                                                                     |
|-------------------------------------|------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Category 1 Stockpile                | 0+                                                                                       | Geomembrane cover; perimeter surface and groundwater seepage containment system. Permanent mine feature.                                                                                                                                                                                                                                                                                    | Most solutes released from Category 1 Stockpile material at concentration caps. Seepage collected by containment system would be sent to the WWTF or the West Pit. Seepage not collected by containment system would migrate as groundwater to West and East Pits. A very small part of it would enter bedrock.                                                                                                |
| Category 2/3 Stockpile              | 0–20                                                                                     | Geomembrane underliner with seepage collection. Solid material would be sent to East Pit as backfill. Would be removed during reclamation.                                                                                                                                                                                                                                                  | Oxidation of Category 2/3 Stockpile material. Seepage collected above liner sent to WWTF. Seepage through liner would enter the underlying groundwater system.                                                                                                                                                                                                                                                 |
| Category 4 Stockpile                | 0–20                                                                                     | Geomembrane underliner with seepage collection. Solid material sent to East Pit as backfill. Would be removed during reclamation.                                                                                                                                                                                                                                                           | Oxidation of Category 4 Stockpile material. Seepage would migrate as groundwater to the East Pit.                                                                                                                                                                                                                                                                                                              |
| West Pit                            | Pit lake: 20+<br>Flow to groundwater flowpaths: 48+ <sup>(1)</sup>                       | Dewatered during mining, followed by flooding. Water level would reach top of bedrock at year 48. Maximum flooding would occur at about year 52, after which water level would be controlled by pumping to the WWTF.                                                                                                                                                                        | Oxidation of wall rock prior to flooding. Would receive affected water from East Pit. Receives treated (or blended) water from Plant Site WWTP during flooding period (20-52 years). Would receive treated water from Mine Site WWTF. Beginning in year 48, the West Pit water level would rise above the top of bedrock and begin to release pit lake water into the West Pit surficial groundwater flowpath. |
| East Pit                            | Flow to groundwater flowpath: 20+ <sup>(1)</sup><br>Flow to West Pit: 21+ <sup>(1)</sup> | Would merge with the Central Pit. Dewatered during mining. All Category 2, 3, and 4 waste rock, and some Category 1 waste rock, would be used as backfill. Water level in saturated backfill would reach top of bedrock at year 20. Maximum refill would occur at year 21, after which water level in saturated backfill would be controlled by overflow through a wetland to the West Pit. | Oxidation of wall rock prior to backfill saturation. Solute release from unsaturated and saturated backfill. Beginning in year 20, the water level in the East Pit saturated backfill would rise above the top of bedrock and begin release of pit water into the East Pit Cat 2/3 Surficial (groundwater) Flowpath. The East Pit would reach maximum refill at about year 21.                                 |
| Overburden Storage and Laydown Area | 0–20                                                                                     | Unlined facility, but with collection system for surface runoff. Would be removed during reclamation.                                                                                                                                                                                                                                                                                       | Leaching of overburden materials. Seepage would enter underlying groundwater system.                                                                                                                                                                                                                                                                                                                           |

| <b>Source Area</b> | <b>Active Source Period (mine years)</b> | <b>Engineered Features</b>                                                                                                                                                                                            | <b>Chemical Mechanisms</b>                                                                                                                                                                                                                                                                                                                                                       |
|--------------------|------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| WWTF Basins        | 0–33                                     | Precipitation/filtration treatment plant using equalization basins with leak detection system and geomembrane underliners. Would be removed during reclamation when water treatment plant converted to RO at year 33. | Receives water from West Pit (including East Pit overflow), Category 1 Stockpile, Category 2/3 Stockpile, Overburden Storage and Laydown Area, and Ore Surge Pile. Would receive reject concentrate from Plant Site WWTP. Seepage collected from leak detection system (if any) would be sent to WWTF. Seepage through underliner would enter the underlying groundwater system. |
| Ore Surge Pile     | 0–21                                     | Geomembrane underliner with seepage detection. Would be removed during reclamation.                                                                                                                                   | Oxidation of ore. Seepage collected from leak detection system (if any) would be sent to WWTF. Seepage through underliner would enter the underlying groundwater system.                                                                                                                                                                                                         |

2057 Source: PolyMet 2015d.

2058 <sup>1</sup> Based on deterministic GoldSim run with P50 inputs.

2059 All of these potential contaminant sources would be located at the Mine Site. The only potential  
 2060 contaminant sources along the Transportation and Utility Corridor or at the processing plant  
 2061 (both within the Partridge River Watershed) would be from spills, as there would be no surface  
 2062 stockpiles of waste rock, ore, or other potential solute sources in these areas. As mentioned  
 2063 previously, the South seep from the Tailings Basin at the headwaters of Second Creek is  
 2064 currently, and would continue to be, collected and pumped back to the Tailings Basin pond.  
 2065 PolyMet has committed to future upgrades to achieve 100 percent capture by this system if the  
 2066 NorthMet Project Proposed Action is approved.

2067 No effects on groundwater quality along the Transportation and Utility Corridor are anticipated  
 2068 during construction, operations, or closure as part of the NorthMet Project Proposed Action.

2069 ***Waste Rock Stockpiles***

2070 The NorthMet Project Proposed Action would generate about 308 million tons of waste rock  
 2071 over the 20 years of mine operations. This waste rock would be managed according to its  
 2072 geochemical properties. Four categories of waste rock were defined generally based on its sulfur  
 2073 content as summarized in Table 5.2.2-21.

2074 **Table 5.2.2-21 Summary of Waste Rock Stockpile Properties**

| Waste Rock Categorization | Sulfur Content (% S) <sup>1</sup>                                      | Approximate % of Waste Rock Total Mass <sup>4</sup> | Max Footprint (acres)  | Stockpile Duration | Bottom Liner System                                                                                                                         | Cover System                                             |
|---------------------------|------------------------------------------------------------------------|-----------------------------------------------------|------------------------|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------|
| Category 1                | %S ≤ 0.12                                                              | 70%                                                 | 508/526 <sup>(5)</sup> | Permanent          | No liner system; a surface and groundwater seepage containment system would collect water for pumping to the WWTF.                          | 3-ft engineered cover with a 40-mil geomembrane barrier. |
| Category 2                | 0.12 < %S ≤ 0.31                                                       | 24%                                                 | 180 <sup>(3)</sup>     | Temporary          | 12-inch compacted (1 x 10 <sup>-5</sup> cm/s) subgrade overlaid by 80-mil LLDPE geomembrane, covered by a 24-inch overliner drainage layer. | Stockpile would be completely removed and reclaimed.     |
| Category 3                | 0.31 < %S ≤ 0.6                                                        | 3%                                                  | 180 <sup>(3)</sup>     | Temporary          | 12-inch compacted (1 x 10 <sup>-5</sup> cm/s) subgrade overlaid by 80-mil LLDPE geomembrane, covered by a 24-inch overliner drainage layer. | Stockpile would be completely removed and reclaimed.     |
| Category 4 <sup>(2)</sup> | > 0.6 %S<br>Duluth Complex<br><br>0.4 ≤ %S ≤ 5.0<br>Virginia Formation | 3%                                                  | 57                     | Temporary          | 12-inch compacted (1 x 10 <sup>-6</sup> cm/s) subgrade overlaid by 80-mil LLDPE geomembrane, covered by a 24-inch overliner drainage layer. | Stockpile would be completely removed and reclaimed.     |

2075 Source: PolyMet 2015a.

2076 <sup>1</sup> In general, the higher the rock's sulfur content, the higher its potential for generating acid rock drainage or leaching heavy metals.

2077 <sup>2</sup> Includes all Virginia formation rock.

2078 <sup>3</sup> Max footprint is total for Category 2/3 waste rock.

2079 <sup>4</sup> Approximately 29% of waste rock that ultimately fills the East Pit (mostly Category 2 and 3) would be sent to the pit without prior stockpiling.

2080 <sup>5</sup> The Category 1 waste rock stockpile has a maximum footprint of 508 acres while active. It would reach this size by mine year 6. The stockpile would be re-graded as part of  
2081 reclamation with a final footprint of 526 acres in mine year 2.  
2082

2083 As Table 5.2.2-21 above indicates, the Category 1 Stockpile would be permanent. It would not  
2084 have a liner, but would be surrounded by a surface and groundwater seepage containment system  
2085 consisting of a cutoff wall (i.e., low-permeability hydraulic barrier) and a sub-surface drain that  
2086 would collect 90 to 94 percent of the seepage from the stockpile during mine operations and 94  
2087 percent after the mine's closure. This stockpile would be progressively reclaimed with an  
2088 engineered geomembrane cover system constructed from year 14 through 21. A maximum of 8  
2089 percent of seepage is estimated to bypass the containment system, during mine operations.  
2090 However, most of such uncaptured seepage would migrate with groundwater to the West Pit,  
2091 where it would be collected and pumped to the WWTF for treatment. Only about 2 percent of the  
2092 overall seepage during the mine operation period would bypass both the containment system and  
2093 the West Pit and East Pit.

2094 During reclamation and closure, the estimated bottom seepage from the Category 1 Stockpile  
2095 would be about 3 gpm. About 94 percent of that seepage would be captured by the containment  
2096 system and none of the seepage would bypass West Pit and East Pit.

2097 The Category 2/3 and 4 stockpiles would be constructed with an underliner system including a  
2098 compacted subgrade, an underdrain, an impermeable geomembrane liner, an overliner drainage  
2099 layer, and a leachate collection system. Drainage from these stockpiles would be collected on the  
2100 liner and routed to a lined sump for pumping to the WWTF for treatment. The GoldSim  
2101 modeling assumes, however, that some leachate seeps through tears/flaws in the Category 2/3  
2102 Stockpile geomembrane liner, reaches the groundwater table, and follows what is referred to as  
2103 the Category 2/3 Stockpile and East Pit Flowpath, ultimately discharging to the Partridge River.  
2104 Some leachate from the Category 4 Stockpile is also assumed to seep through the liner system,  
2105 but given its location adjacent to the East Pit, it is assumed that any uncollected seepage would  
2106 follow the hydraulic gradient to the East Pit, where it would be collected as part of the pit  
2107 dewatering system and pumped to the WWTF for treatment. Once mining of the East Pit is  
2108 completed (approximately year 11), the Category 2/3 and Category 4 waste rock would be  
2109 backfilled into the East Pit, the liner system would be removed, and the footprints of these  
2110 stockpiles revegetated per an approved reclamation plan. Once mining ceases in the East Pit,  
2111 waste rock would be directly deposited in the East Pit.

#### 2112 Overburden and Overburden Storage and Laydown Area

2113 The NorthMet Project Proposed Action would strip overburden as needed for mine development,  
2114 thereby minimizing the amount of exposed bedrock at any one time. About 32 percent of the  
2115 overburden would be stripped in the first 2 years of the mine life, with the balance being  
2116 removed by the end of year 11. Overburden present at the Mine Site is categorized into three  
2117 types: unsaturated overburden, saturated overburden, and peat (organic soils). Each type of  
2118 overburden would be managed in accordance with its characteristics.

2119 Saturated overburden is material that has been below the normal water table and not exposed  
2120 regularly to oxygen, so it is still potentially reactive if exposed to oxygen. Some of this material  
2121 would be used for construction purposes, but only for applications where it would be placed  
2122 below the water table or where any water contacting it would be collected and appropriately  
2123 treated. Saturated overburden not used for construction purposes would be commingled with  
2124 waste rock and placed in the temporary Category 2/3 or 4 stockpiles with a geomembrane liner.

2125 Unsaturated overburden is above the normal water table, and waste characterization studies  
2126 indicate that it has been exposed to oxygen for a sufficiently long period of time that it is now  
2127 non-reactive. This material would be used for construction purposes. To the extent that  
2128 unsaturated overburden exceeded immediate construction needs, it would be temporarily stored  
2129 in the unlined Overburden Storage and Laydown Area. Peat would also be used for reclamation  
2130 purposes, as appropriate, and any excess would be temporarily stored along with the unsaturated  
2131 overburden in the unlined Overburden Storage and Laydown Area for future use during  
2132 reclamation.

2133 Surface runoff from the Overburden Storage and Laydown Area is considered “process water,”  
2134 and would be captured in an unlined pond (Pond PW-OSLA) and monitored for quality. If the  
2135 Overburden Storage and Laydown Area water were of acceptable quality, it would be pumped to  
2136 the Central Pumping Station and discharged to the East Pit or the Tailings Basin, where the  
2137 destination would be based on variable project demand over time. If water in Pond PW-OSLA  
2138 required treatment, it would be pumped to the WWTF for treatment prior to delivery to the  
2139 Central Pumping Station.

2140 Since the Overburden Storage and Laydown Area would be unlined, the GoldSim model  
2141 assumes meteoric water would seep into the groundwater below the Overburden Storage and  
2142 Laydown Area and follow the Overburden Storage and Laydown Area Flowpath ultimately  
2143 discharging to the Partridge River. During operations, the estimated bottom seepage from the  
2144 Overburden Storage and Laydown Area would be about 14 gpm. The water quality of this  
2145 seepage was estimated based on the results of the Meteoric Water Mobility Procedures test for  
2146 peat and unsaturated overburden (PolyMet 2015q).

#### 2147 Ore Surge Pile

2148 An Ore Surge Pile would be constructed near the Rail Transfer Hopper to allow for temporary  
2149 storage of ore and a steady flow and uniform grade of ore to the processing plant. Ore would  
2150 pass into and out of this pile during operations to meet plant needs for efficient processing. The  
2151 Ore Surge Pile would have a geosynthetic underliner system identical in design to that for the  
2152 Category 4 Stockpile. Drainage from the Ore Surge Pile would be collected on the liner and  
2153 routed to a lined sump for pumping to the WWTF for treatment. The Ore Surge Pile, including  
2154 the liner system, would be removed at the completion of mining activities (at mine year 20) and  
2155 reclaimed.

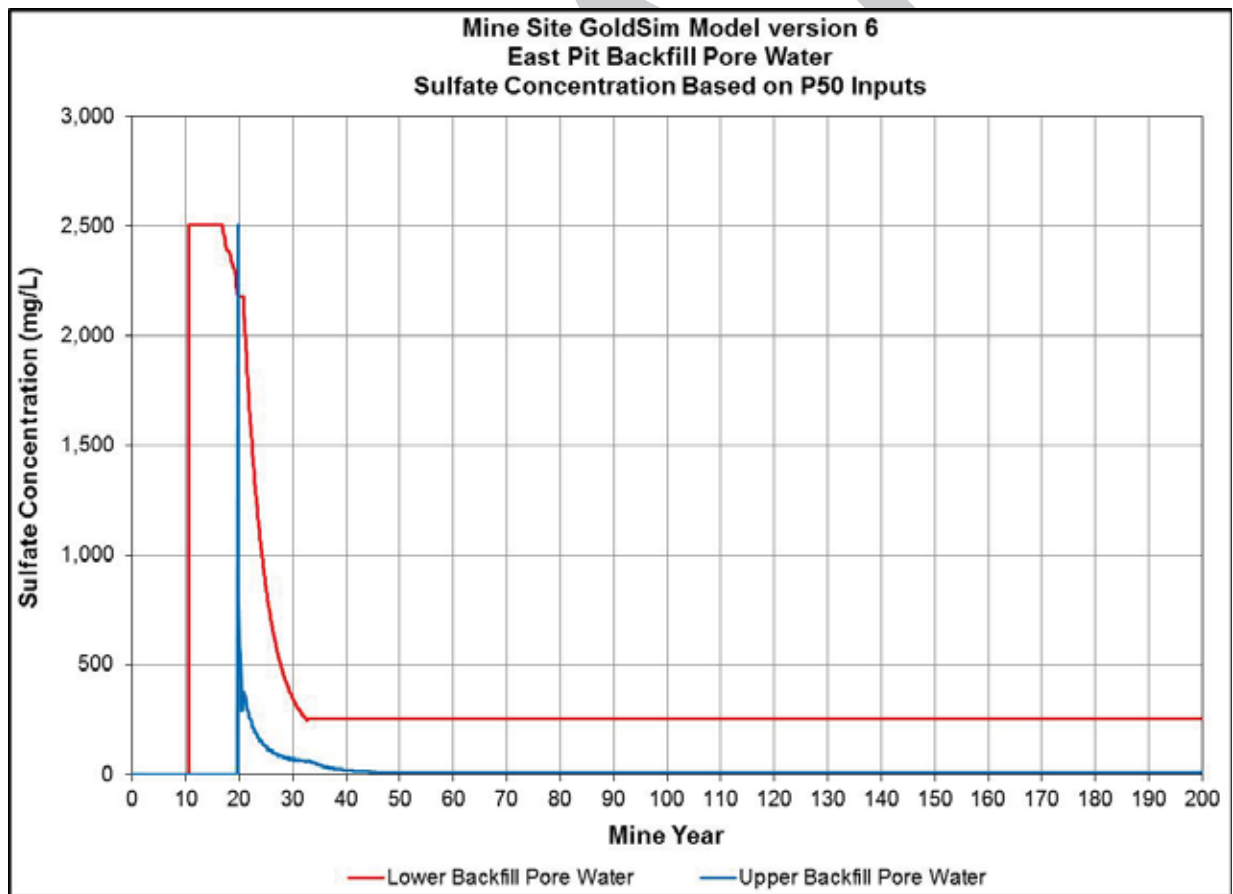

2156 The GoldSim modeling assumes that a small volume of leachate would seep through flaws in the  
2157 geomembrane liner, reach the groundwater table, and migrate along the Ore Surge Pile Flowpath,  
2158 ultimately discharging to the Partridge River.

#### 2159 East Pit

2160 During mining, the East Pit would be dewatered. In approximately year 10, mining of the East  
2161 Pit would be completed and backfilling would begin with stockpiled Category 2/3 and 4 waste  
2162 rock, and fresh waste rock (all categories) from the West Pit. During backfilling, natural  
2163 groundwater inflow to the pit would saturate the backfill. The pore water in the initially saturated  
2164 backfill would have relatively high solute concentrations (see Figure 5.2.2-25 for a representative  
2165 example based on sulfate), but once submerged, oxygen transport would be limited and there  
2166 would be a systematic decrease in oxidation and associated dissolution of sulfide minerals.

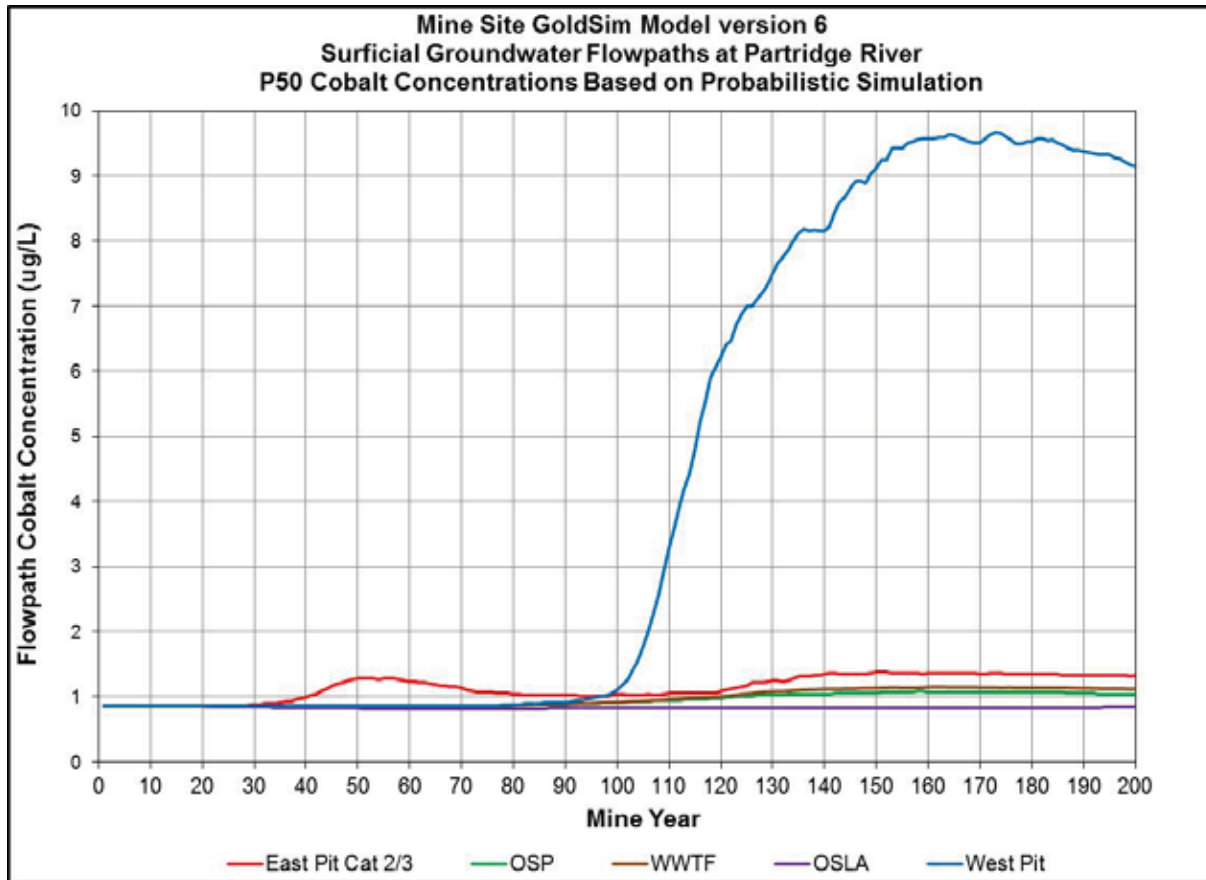

2167 Additional concentration reduction would be accomplished by pumping the East Pit backfill pore  
2168 water through the WWTP and re-injecting the treated effluent back into the backfill.

2169 Once the saturated water level in the backfill reaches the top of bedrock along the pit rim  
2170 (approximate elevation of 1,577 ft at year 20), some backfill pore water would begin to flow  
2171 from the pit into the surficial aquifer. The quality of the aquifer inflow would reflect the quality  
2172 of the pit lake water, which would gradually improve over time due to reclamation activities at  
2173 the Mine Site. This groundwater inflow would migrate south through the East Pit Category 2/3  
2174 Surficial Flowpath and ultimately release to the Partridge River. Since both the Category 2/3  
2175 Stockpile and the East Pit would share the same flowpath, the flowpath would experience two  
2176 concentration peaks, the first representing the arrival of solutes from the Category 2/3 Stockpile,  
2177 which would reach the Partridge River around year 35 and would peak around year 55, and the  
2178 second from the arrival of aquifer inflow from the East Pit, which would reach the Partridge  
2179 River around year 100 and peak around year 150. For cobalt, Figure 5.2.2-26 shows the dual  
2180 peak that would occur in the East Pit Cat 2/3 Surficial Flowpath at the Partridge River and  
2181 compares this response with peaks that would occur in the other surficial flowpaths.

2182

2185

2186 **Figure 5.2.2-26 P50 Cobalt Concentrations in Surficial Groundwater Flowpaths at the**  
2187 **Partridge River Based on GoldSim Probabilistic Simulation**

2188 West Pit

2189 Flooding of the West Pit would begin after the completion of mining in year 21. The water in the  
2190 West Pit is expected to contain dissolved oxygen with initial concentrations as high as 15 mg/L.  
2191 This oxygen would be initially reactive with the pit wall rock, but the reactivity would decrease  
2192 over time as the material exposed to water oxidizes. Groundwater flow in bedrock would be  
2193 towards the pit, so the only mechanism for oxygen to reach unoxidized rock beyond the pit wall  
2194 would be diffusion, and this would limit the rate of wall rock chemical reactions.

2195 Once the water in the flooded pit reaches the top of bedrock along the pit rim (approximate  
2196 elevation 1,550 ft at year 48), some of the pit lake water would begin to flow into the surficial  
2197 aquifer. The quality of this aquifer inflow would reflect the quality of the pit lake water, which is  
2198 predicted by GoldSim to improve over time due to: 1) dilution from rainfall and surface runoff  
2199 into the pit and 2) submergence of pit walls with an association decrease in the oxidation of  
2200 sulfide minerals. The groundwater inflow would migrate south along West Pit Surficial Flowpath  
2201 and ultimately release to the Partridge River. The initial arrival of West Pit solutes at the  
2202 Partridge River would occur at about year 105, and peak concentrations in groundwater  
2203 discharging to the river would occur at about year 160.

## 2204 Wastewater Treatment Facility

2205 The WWTF would treat influent water from a variety of sources (e.g., pit dewatering, stockpile  
2206 leachate collection, contact surface water, Plant Site RO concentrate). The only potential source  
2207 of groundwater contamination at the WWTF would be leakage from the two equalization basins  
2208 and from the Central Pumping Station. The equalization basin would have a geomembrane liner  
2209 system and would be designed to have a minimum of 3 ft of freeboard, in accordance with the  
2210 MPCA guidance (Meyer et al. 2009). Leakage from these basins through the liner system is  
2211 calculated differently than for the waste rock stockpile liner systems because these ponds would  
2212 have standing water above the underliner. Therefore, the hydraulic pressure on the liners would  
2213 be greater, and, in turn, more water would be expected to leak on a per-acre basis (i.e.,  
2214 approximately 5 gallons per acre per day) (PolyMet 2015m). The total volume of leakage from  
2215 the equalization basins, however, would be less than from the stockpiles, as the footprint of the  
2216 equalization basins would be smaller. This leakage would reach the groundwater table and  
2217 follow the WWTF Flowpath ultimately to the Partridge River.

## 2218 ***Groundwater Transport and Evaluation Locations***

2219 Solutes from each source area described above would be transported by groundwater along its  
2220 associated flowpath (see Figure 5.2.2-7). Each of these flowpaths has a groundwater evaluation  
2221 location where the GoldSim model predicts groundwater quality (see Figure 5-2.2-7). At each  
2222 evaluation location, the predicted water quality for the NorthMet Project Proposed Action is  
2223 compared with both the evaluation criteria and the predicted water quality for the CEC Scenario.  
2224 See Table 5.2.2-22 for a summary of solute fate and transport.

2225 The time at which contaminants leached from the Mine Site would begin to affect water quality  
2226 at the downgradient evaluation locations depends on the following four variables:

- 2227 • The time (i.e., year) when the source facility was constructed or began leaching  
2228 contaminants;
- 2229 • The rate at which contaminants move in groundwater (assumed to equal the groundwater  
2230 flow rate for all constituents except the four attenuated contaminants (arsenic, antimony,  
2231 copper, and nickel), which are assumed to migrate more slowly than the groundwater);
- 2232 • The distance between the source and the evaluation location; and
- 2233 • Mechanical dispersion, which tends to spread out the solute plume.

2234 Cobalt was generally used to illustrate groundwater transport at the Mine Site because the model  
2235 did not account for attenuation and it would enter the surficial flowpaths at concentrations higher  
2236 than baseline groundwater. As a consequence, the movement of solute fronts associated with this  
2237 solute is readily discernible on concentration-versus-time and concentration-versus-distance plots  
2238 for the modeled flowpaths. Transport of other non-attenuated solutes should be similar to cobalt,  
2239 but the changes in concentrations are not as visually noticeable as it is for cobalt.

2240 The estimated migration times for contaminant plumes to reach the evaluation locations are  
2241 presented in Table 5.2.2-22.

2242 **Table 5.2.2-22 P50 Solute Migration Times for Mine Site Groundwater Flowpaths Based on**  
 2243 **GoldSim Probabilistic Simulation**

| Surficial Groundwater Flowpath      | Solute Source Times |                | Solute Migration Times to Groundwater Evaluation Location <sup>1</sup> |                                           | Solute Migration Times to Partridge River <sup>1</sup> |                                           |
|-------------------------------------|---------------------|----------------|------------------------------------------------------------------------|-------------------------------------------|--------------------------------------------------------|-------------------------------------------|
|                                     | Start Mine Year     | Stop Mine Year | Initial Concentration Increase Mine Year                               | Peak Concentration <sup>5</sup> Mine Year | Initial Concentration Increase Mine Year               | Peak Concentration <sup>5</sup> Mine Year |

2244 Source: PolyMet 2014v.

2245 <sup>1</sup> For all constituents except arsenic, copper, nickel, and antimony, which are modeled with adsorption coefficients that greatly  
 2246 increase solute migration times.

2247 <sup>2</sup> Concentration decrease for most constituents.

2248 <sup>3</sup> Minimum concentration for most constituents.

2249 <sup>4</sup> Time when pit water level would rise above the top of bedrock and begin to release pit water into the adjacent surficial  
 2250 (groundwater) flowpath.

2251 <sup>5</sup> All modeled peak concentrations are below evaluation criteria.

2252 <sup>6</sup> River location used for groundwater evaluation location.

2253 Table 5.2.2-22 indicates that all of the contaminant plumes would reach the Partridge River  
 2254 within the 200-year modeled duration.

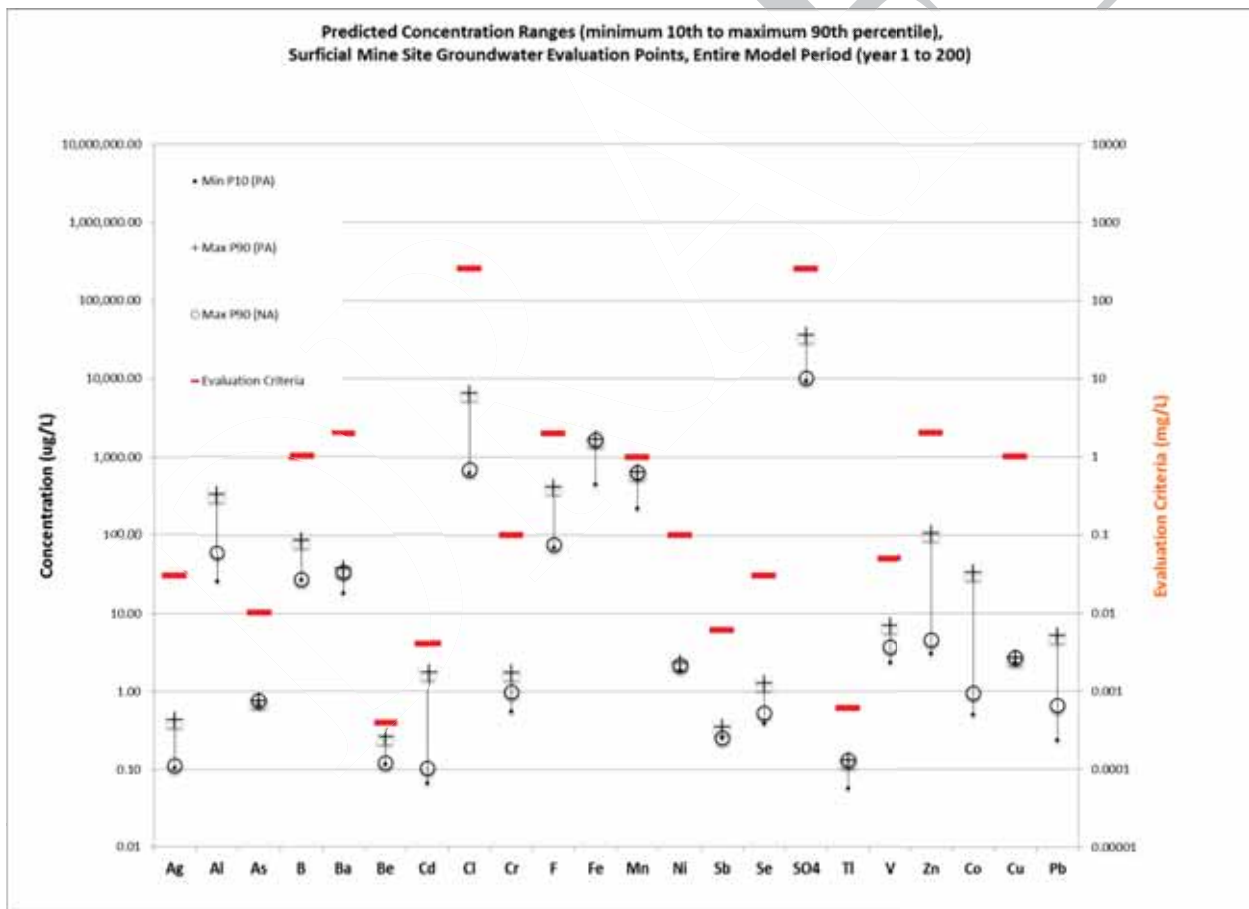

2255 ***Surficial Groundwater Quality at the Evaluation Locations***

2256 Model results were reviewed for all 29 solutes at the evaluation location within each of the five  
 2257 surficial flowpaths. A screening process was used to identify any constituents and locations that  
 2258 warranted a more robust examination because some modeled concentrations were above or equal  
 2259 to water quality evaluation criteria. The screening process involved comparing the single-highest  
 2260 monthly P90 water quality prediction from among the 2,388 months covered by the simulation  
 2261 (i.e., 12 months times 199 years, with the first year of simulation excluded for screening review  
 2262 due to potential numerical artifacts in the model results) for each constituent at each of the five  
 2263 evaluation locations. These NorthMet Project Proposed Action modeled values were compared  
 2264 with both the CEC scenario modeled values and the evaluation criteria discussed previously.

2265 The screening of maximum P90 groundwater concentrations of all modeled solutes indicated that  
 2266 none of the solutes at any of the five flowpaths were predicted to ever exceed the evaluation  
 2267 criteria. These results are shown in Table 5.2.2-23, which lists the maximum P90 values for each  
 2268 modeled constituent. These results are illustrated, along with the maximum P90 concentrations  
 2269 for the CEC scenario and the range in NorthMet Project Proposed Action model concentrations  
 2270 (lowest P10 to the highest P90 value over 200-year simulation and across all groundwater model-  
 2271 reporting points), in Figure 5.2.2-27. The proportional increase in the concentrations of each  
 2272 solute (i.e., the ratio of the maximum P90 value under the NorthMet Project Proposed Action

2273 scenario to the maximum P90 value under the CEC scenario) are listed in Table 5.2.2-23 and  
 2274 illustrated graphically in Figure 5.2.2-28. Note that if the values are the same, the relative change  
 2275 ratio would be 1; values greater than 1 indicate the ratio at which the NorthMet Project Proposed  
 2276 Action would result in an increase in solute concentrations relative to the CEC Scenario model  
 2277 results.

2278 When groundwater affected by mining reaches the Partridge River, the concentration of  
 2279 groundwater that exits from the flowpath into the river would be a mixture of water that entered  
 2280 the upgradient end of the flowpath, meteoric recharge along the flowpath, and background  
 2281 groundwater into which the contaminant front disperses. For most constituents both the meteoric  
 2282 and background groundwater concentrations are lower than the source concentration. This means  
 2283 there would be a reduction in concentration of these constituents by the time the original source  
 2284 water arrived at the Partridge River (PolyMet 2015m).

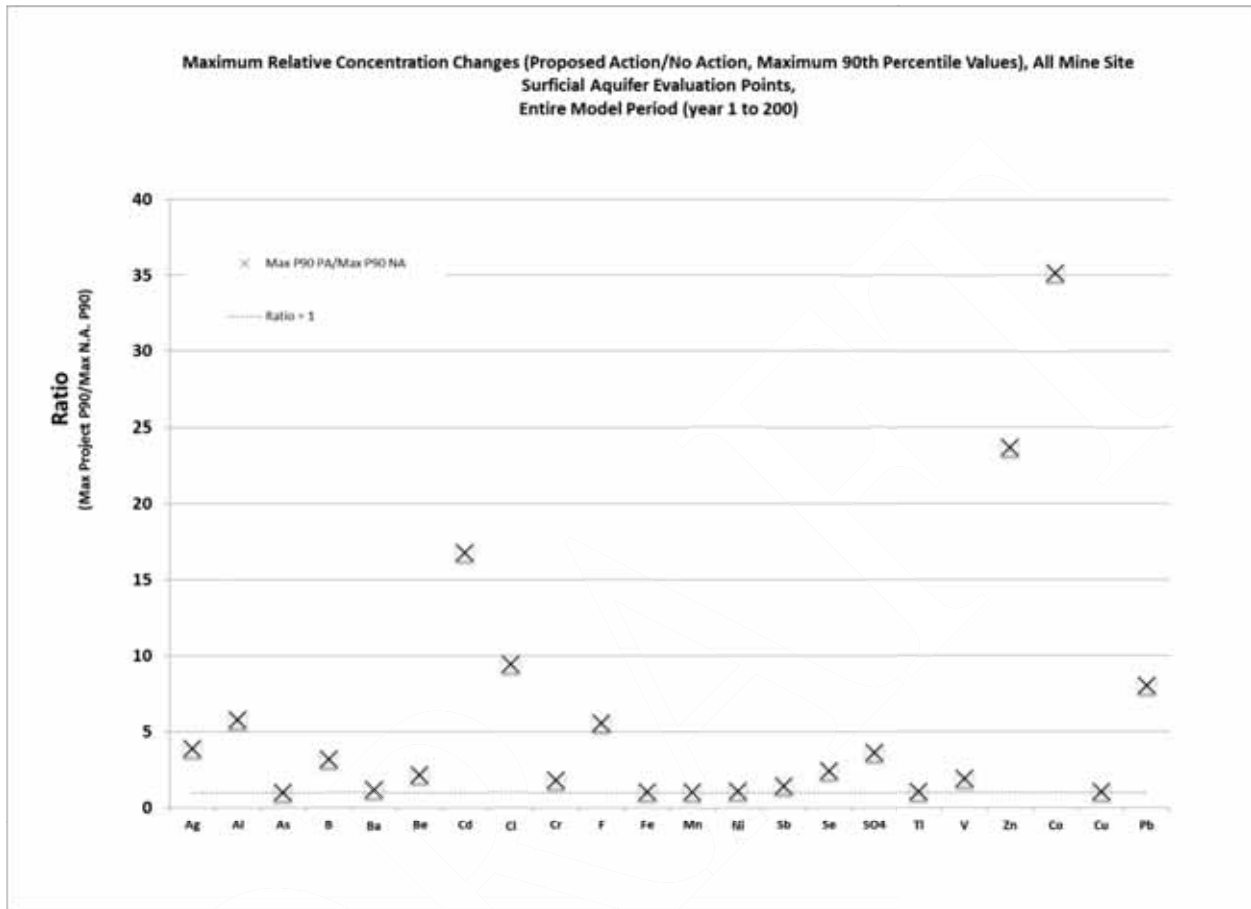

2285  
 2286 Note: Groundwater evaluation criteria plotted are listed in Table 5.2.2-2.

2304 ***Effects on Bedrock Groundwater Quality***

2305 At the Mine Site, the only mine-related solute sources to bedrock groundwater are flooded  
2306 backfill in the East Pit, ponded water in the West Pit, and seepage from the Category 1 Stockpile.  
2307 These waters are carried by two flowpaths to the south to the Partridge River. The East Pit  
2308 bedrock evaluation location is the property boundary and the West Pit evaluation location is the  
2309 old property boundary or current Mine Site project boundary.

2310 Predicted water quality in the bedrock was reviewed, but the solute load from these sources did  
2311 not reach the evaluation locations at the end of the 200-year model simulation because the  
2312 estimated travel time for groundwater between the mine pits and the bedrock evaluation  
2313 locations would be much longer (greater than 1,000 years). The effect of the NorthMet Project  
2314 Proposed Action on bedrock groundwater is considered negligible at the bedrock evaluation  
2315 locations.

2316 ***Saline Groundwater***

2317 Saline groundwater is known to occur in bedrock across the Canadian Shield (Fritz and Frap  
2318 1987; Morton and Ameal 1985). In general, the potential for encountering saline water increases  
2319 with depth, such that briny groundwater (defined as TDS greater than 35,000 mg/L) may be  
2320 nearly ubiquitous in bedrock at depths greater than approximately 3,000 ft throughout the Lake  
2321 Superior Basin in northeastern Minnesota (Morton and Ameal 1985), including the Duluth  
2322 Complex (Rouleau et al. 2003; Bottomley 1996). Brackish to saline groundwater is encountered  
2323 sporadically in deep (greater than 1,000 ft) bedrock wells in northeastern Minnesota and on the  
2324 Keweenaw Peninsula and in shallow (less than 300 ft) bedrock wells near Lake Superior (Morton  
2325 and Ameal 1985). Elevated salinity at depth does not appear to be caused by the bedrock itself,  
2326 as studies have found no particular relationship with rock type (Morton and Ameal 1985). One  
2327 study concluded that these “brines” were likely formed by the evaporation of seawater during  
2328 Devonian time about 359 to 419 million years ago (Bottomley 1996).

2329 The concern for water quality is whether excavation of the East Pit and West Pit could penetrate  
2330 zones of saline or briny groundwater or otherwise draw these waters to the surface, thereby  
2331 increasing the salinity of the pit water.

2332 The closest wells to the NorthMet Project Proposed Action area that are known to have  
2333 encountered saline groundwater are located 3.2 miles to the northeast of the East Pit at the  
2334 former AMAX test shaft at depths of approximately 1,200 to 1,400 ft bgs (elevation 200 to 400 ft  
2335 amsl) (Barr 2012m). The maximum depths of the East Pit and West Pit, however, are  
2336 approximately 630 and 700 ft bgs (elevation 800 to 900 ft amsl) or a minimum of 400 ft above  
2337 the elevation where saline water was observed.

2338 Bedrock groundwater sampling from the Mine Site also suggests that the pit excavations would  
2339 not encounter saline groundwater. Sampling from two exploratory boreholes, a water supply  
2340 well, and nine groundwater monitoring wells drilled at the Mine Site found a maximum chloride  
2341 concentration of 15.7 mg/L (this excludes a value of 93.1 mg/L from the initial sampling of  
2342 Observation Well-3, where the maximum value detected in subsequent monitoring was 0.81  
2343 mg/L) (Barr 2012m).

2344 Despite the absence of brine in current wells, the excavation and dewatering of the mine pits  
2345 would likely draw water up from deeper bedrock below the pits, which could contain elevated

2346 chloride concentrations. Bedrock conductivity, however, is much lower than the surficial aquifer,  
2347 and hydraulic analyses indicate that groundwater inflow to the West Pit would be dominated by  
2348 water from the surficial aquifer, which is predicted to comprise 64 percent of groundwater inflow  
2349 at end of mining and increase to 98 percent of inflow after the pit is fully flooded (PolyMet  
2350 2015m, Table 1-22b).

2351 Regionally, the Federal Hardrock Mineral Prospecting Permits Project ROD recognizes this as a  
2352 potential risk from exploration drilling (USFS 2012b), noting the possibility that “exploratory  
2353 drilling could cause pockets of brackish (i.e., salty) groundwater to reach freshwater supplying  
2354 drinking water wells.” This ROD concluded, in consultation with the MDH, that “this scenario is  
2355 considered unlikely,” but “that the risk is not zero” (USFS 2012b).

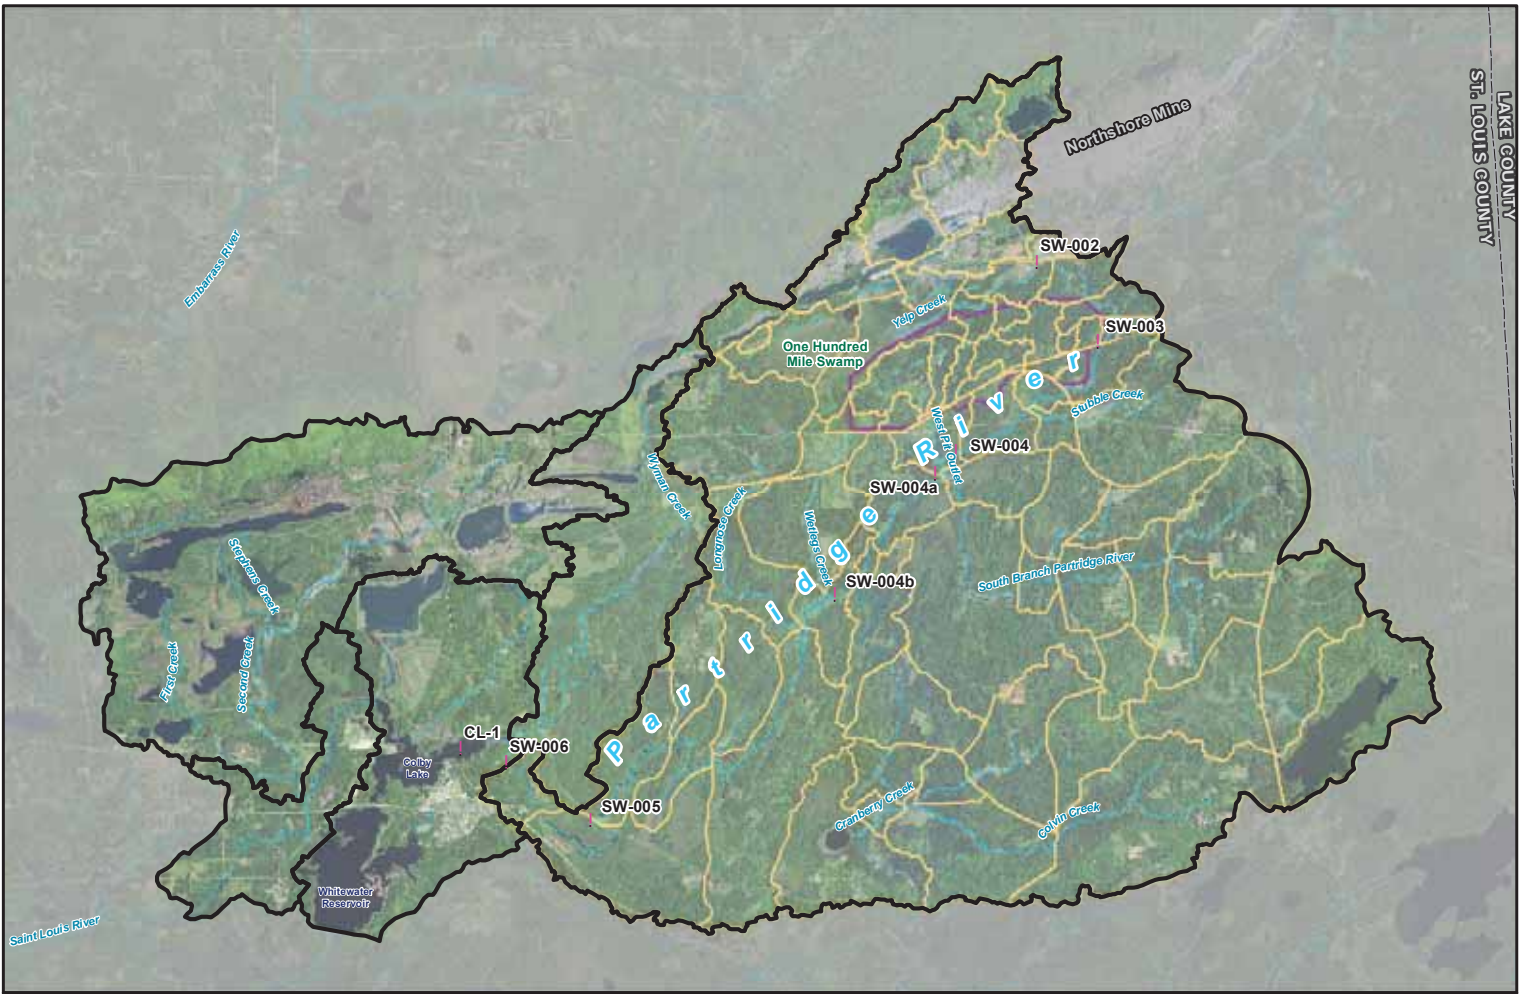

2356 Given that bedrock groundwater monitoring from 12 wells with depths up to 600 ft bgs at the  
2357 Mine Site did not reveal any elevated chloride concentrations, that the nearest known occurrence  
2358 of saline water is 3.2 miles from the Mine Site, and that the proposed pit floors would be at least  
2359 400 ft above the elevation where saline water is known to occur, the risk of encountering saline  
2360 water is considered low. If encountered, saline bedrock groundwater inflow to the pits would be  
2361 diluted by other water sources (surficial aquifer, and precipitation). In addition, any groundwater  
2362 inflow to the pit during operations would be collected as part of pit dewatering and pumped to  
2363 the WWTF for treatment. Finally, the chances of a perpetual elevated saline condition is  
2364 considered small because the pits would flood in closure, producing hydraulic head that would  
2365 inhibit groundwater upwelling.

### 2366 **Effects on Surface Water Hydrology in the Partridge River Watershed**

2367 This section describes the effects of the NorthMet Project Proposed Action on the surface water  
2368 hydrology of the Partridge River and its tributaries (see Figure 5.2.2-29). The NorthMet Project  
2369 Proposed Action could affect flows in the Partridge River and its tributaries by changing  
2370 drainage areas (e.g., alteration or reduction in watershed area), reducing groundwater baseflow  
2371 contributions during the dewatering and flooding of the East Pit and West Pit, and withdrawing  
2372 water from Colby Lake occasionally for use as makeup water at the processing plant during  
2373 operations .

### 2374 **Changes in Drainage Area**

2375 The NorthMet Project Proposed Action would result in changes to drainage areas in some  
2376 locations that would, in turn, affect streamflows. These changes would primarily include the  
2377 capture and retention of contact water at the Mine Site and during reclamation the use of this  
2378 water to flood the West pit. During mine operations and reclamation, surface water runoff from  
2379 much of the Mine Site would be retained within the site until the West Pit floods. This would  
2380 reduce the drainage area that currently provides surface water runoff to the Partridge River.  
2381 Table 5.2.2-25 shows the total watershed area and percent watershed area reduction at each  
2382 surface water evaluation location for selected time periods.

2387 Source: PolyMet 2015m, Attachment C.

2388 <sup>1</sup> Station SW-001 is upstream from the NorthMet Project Proposed Action area, and is thus unaffected by the NorthMet Project  
 2389 Proposed Action. Data from this station are used in the hydrologic modeling, but this FEIS does not estimate water quality at  
 2390 this station.

2391 The maximum watershed area reduction for any modeled location along the Partridge River  
 2392 would be 6.2 percent at SW-004, during year 11 of operations. A maximum long-term watershed  
 2393 area reduction of 2.1 percent would occur at SW-004a. Mine year 11 is presented as it is the  
 2394 predicted time of maximum change in watershed area. It represents the time when the combined  
 2395 East Central Pit has reached maximum areal extent (and has not been backfilled), and when the  
 2396 West Pit is open and approaching maximum areal extent.

2397 The reduced drainage areas were taken into consideration in the XP-SWMM modeling and are  
 2398 presented in the Mine Site Data Package (PolyMet 2015m) with key values presented in Table  
 2399 5.2.2-26 of this FEIS.

2400 ***XP-SWMM Modeling Results for the Partridge River***

2401 The flow parameters and water resources evaluation criteria, established in Section 5.2.2.1.2,  
 2402 were used to evaluate the effects on surface water hydrology in the Partridge River Watershed.  
 2403 The XP-SWMM model was run for the NorthMet Project Proposed Action and the CEC  
 2404 scenarios for selected years during operations, and reclamation and closure, to determine the  
 2405 changes to each parameter at each stream location. Given the relatively small watershed area  
 2406 changes (watershed area reductions would approximate flow reductions), only selected modeling  
 2407 results are presented here to demonstrate the range of potential hydrologic effects. Effects on  
 2408 Colby Lake were not evaluated with the XP-SWMM model; however, water-level changes to  
 2409 Colby Lake and Whitewater Reservoir are addressed in a subsequent section of the FEIS. Table  
 2410 5.2.2-26 summarizes the XP-SWMM results for selected flow parameters and stream locations.  
 2411 Modeled annual daily mean flow is also shown as a percentage of existing conditions in Figure  
 2412 5.2.2-30.

DRAFT

2421  
 2422

Source: Barr 2015i

2423 **Figure 5.2.2-30 Project Impact on Partridge River Annual Daily Mean Flow, shown as**  
 2424 **Modeled Flows Over Time as a Percent of Existing Conditions**

2425 It is apparent from Table 5.2.2-26 that almost all effects on streamflow during the year of  
 2426 maximum watershed reduction (mine year 11) would be in the form of streamflow reductions.  
 2427 The largest modeled effect, about an 8 percent reduction, would occur during low-flow  
 2428 conditions. After the West Pit is filled with water, discharge from the WWTF to the West Pit  
 2429 Outlet Creek would more than compensate for the reduced low flows at some locations. The  
 2430 maximum modeled effect is at location SW-004a, just downstream of where the WWTF  
 2431 discharge would enter the Partridge River. Here, the annual minimum 3-day flow and average  
 2432 annual 30-day low flow would increase by about 38 and 22 percent, respectively. The actual  
 2433 flow increases would be on the order of 0.78 and 0.54 cfs, respectively. The NorthMet Project  
 2434 Proposed Action would have little effect on high flows, as shown for the mean April flows and  
 2435 the annual maximum 3-day flows.

2436 Modeling predicts that annual daily mean flow would change by 5 percent or less during  
 2437 operations and reclamation, and return to within approximately 1 percent of existing flow  
 2438 conditions in closure and long-term maintenance, as shown in Figure 5.2.2-30.

2439 Changes in hydrology can affect stream geomorphology. PolyMet conducted a Level I  
 2440 Geomorphic Survey of the Partridge River from its headwaters to Colby Lake (Barr 2005) to

2441 determine the stability of the river under existing conditions, evaluate its sensitivity to hydrologic  
2442 change, and indicate how restoration may be approached if a portion of the stream becomes  
2443 unstable. The Geomorphic Survey found the Upper Partridge River to be stable, with no  
2444 evidence of erosion except in its headwaters (see Figure 4.2.2-7). Its steep reaches are well-  
2445 armored and the flatter reaches tend to have well-vegetated shorelines. As indicated in Table  
2446 5.2.2-26, the NorthMet Project Proposed Action would reduce flow in the Upper Partridge River  
2447 during mine operations by 1.8 to 7.8 percent depending on evaluation location and flow  
2448 parameter, with less of an effect (2.0 to 5.3 percent) on higher flows. Flows would return to  
2449 nearly pre-NorthMet Project Proposed Action conditions during closure, except at surface water  
2450 stations downstream of WWTF discharge points where river flows would be higher.

2451 No erosion or significant geomorphic changes are expected in the Upper Partridge River due to  
2452 the NorthMet Proposed Action for the following reasons:

- 2453 • The Geomorphic Survey of the Upper Partridge River found it to be stable;
- 2454 • The NorthMet Project Proposed Action would not directly disturb the river banks;
- 2455 • High flows (e.g., bank-full flows), which are important in shaping geomorphic processes,  
2456 would only be reduced by a maximum of five percent during operations which is within the  
2457 range of natural variability; and
- 2458 • Most streamflows would return to near pre-NorthMet Project Proposed Action conditions  
2459 after closure.

#### 2460 ***Effects on the Hydrology of the Partridge River Tributary Streams***

2461 The NorthMet Project Proposed Action is not expected to have any measurable effects on surface  
2462 water hydrology of the tributary streams along the Transportation and Utility Corridor. Flow data  
2463 collection and monitoring of the Partridge River tributary streams would be conducted for  
2464 permitting

2465 Flow in the West Pit Outlet Creek would be modified due to reduction of drainage area,  
2466 interception of groundwater by the West Pit, and discharge of the WWTF effluent during closure  
2467 and long-term maintenance. The XP-SWMM model estimates an average annual flow of 1.2 cfs  
2468 at the approximate location of the future WWTF discharge under existing conditions. The  
2469 estimated average annual flow at this location in closure and long-term maintenance is increased  
2470 to 1.4 cfs primarily due to the WWTF discharge (PolyMet 2015m).

2471 A geomorphic survey of the West Pit Outlet Creek between Dunka Road and the Partridge River  
2472 found no evidence of erosion, downcutting or channel widening. The survey concluded that  
2473 because the creek has a well-developed floodplain and substantial and continuous bank  
2474 vegetation, it would be tolerant to moderate changes in hydrology (Barr 2005).

#### 2475 ***Effects on Colby Lake and Whitewater Reservoir Water Levels***

2476 The effect of the NorthMet Project Proposed Action on water levels in Colby Lake is related to  
2477 changes in Partridge River inflow and water withdrawals to the Plant Site during operations.

2478 The XP-SWMM modeling for SW-006, just upstream of Colby Lake, shows minor reductions in  
2479 Partridge River low flows during operations (2.7 percent reduction in the 30-day low flow, which  
2480 is equivalent to about 0.14 cfs). On an annual average basis, inflow to Colby Lake would be

2481 reduced about 1.7 percent during operations (in mine year 11) and have virtually no change  
2482 during closure (see Table 5.2.2-26 for SW-006) (PolyMet 2015m).

2483 NorthMet Project Proposed Action makeup water demand from Colby Lake during operations  
2484 would vary between 260 and 1,760 gpm (0.6 and 3.9 cfs) with an average annual demand of 760  
2485 gpm (1.7cfs). After operations complete, makeup water from Colby Lake would no longer be  
2486 withdrawn (PolyMet 2015a).

2487 Combining the flow reduction at SW-006 with the rate of process makeup water removed from  
2488 Colby Lake provides an estimate of the total reduction in flow to Colby Lake. The maximum  
2489 predicted reduction to average annual flow due to the NorthMet Project Proposed Action at SW-  
2490 006 is 1.7 percent, occurring during mine year 11, which corresponds to an average annual flow  
2491 reduction of 600 gpm (1.3 cfs) (Table 5.2.2-26). The average and maximum Colby Lake annual  
2492 withdrawal rates during operations are 760 gpm (1.7 cfs) and 1,750gpm (3.9 cfs). Therefore, the  
2493 estimated annual average reduction in flow to Colby Lake is 1,360 gpm (3.0 cfs) with a  
2494 maximum withdrawal rate of 2,350 gpm (5.2 cfs). The NorthMet Project Proposed Action DEIS  
2495 (MDNR and USACE 2009) evaluated two potential Colby Lake withdrawal rates, 3,500 gpm  
2496 and 5,000 gpm. The model assumed transfer of water from Whitewater Reservoir in order to  
2497 maintain water levels above the critical outflow elevation of 1,439 ft at all times in Colby Lake,  
2498 which is required under MDNR Water Appropriation Permit 1949-0135.

2499 The evaluation criterion for Colby Lake and Whitewater Reservoir is an assessment of the annual  
2500 mean, maximum, and minimum lake level changes from existing conditions. At a 3,500 gpm  
2501 withdrawal rate and average flow conditions, the average Colby Lake drawdown over the  
2502 modeled period was 0.01 ft, with an average annual water level fluctuation of about 3.6 ft,  
2503 compared to 3.9 ft for zero withdrawal. Whitewater Reservoir would also be affected by water  
2504 withdrawals, as it is used to help maintain water levels in Colby Lake. Under this 3,500 gpm  
2505 withdrawal and average flow conditions scenario, drawdown on Whitewater Reservoir was  
2506 predicted to be about 0.4 ft with a maximum annual fluctuation of about 4.2 ft, compared to  
2507 about 2.9 ft for zero withdrawal (PolyMet 2015m). Environmental consequences of the  
2508 drawdown on wetlands and aquatic resources are discussed in Sections 5.2.3 and 5.2.6,  
2509 respectively.

2510 It is reasonable to assume that the effects of PolyMet's proposed withdrawal of less than 3,500  
2511 gpm would be no worse on Colby Lake and Whitewater Reservoir water levels than this modeled  
2512 3,500 gpm withdrawal. These anticipated effects on water levels are well within the range  
2513 experienced during the former LTVSMC taconite mining operations.

#### 2514 ***Effects on the Hydrology of the Lower Partridge River***

2515 Existing flow conditions in the Lower Partridge River can be estimated by examining the flow  
2516 record (i.e., 1942 to 1982) at USGS gaging station 04016000, which was located approximately  
2517 1.5 miles downstream of Colby Lake. Historic hydrologic alterations to Partridge River  
2518 watershed area caused by former LTVSMC operations are likely present in the USGS flow data,  
2519 while alterations from the present Mesabi Nugget operations are not considered. Notwithstanding  
2520 these effects, the historic flow records can be used to provide a reasonable estimate of NorthMet  
2521 Project Proposed Action effects on the Lower Partridge River.

2522 The record shows average monthly flows varying from about 17 cfs during February to about  
2523 333 cfs during May, with an average annual flow of about 112 cfs. As described above, the

2524 maximum effect of the NorthMet Project Proposed Action on streamflow into Colby Lake would  
2525 be a net reduction in flow of about 3.0 to 4.2 cfs during operations, which would represent about  
2526 a 2.7 to 3.8 percent decrease in the average annual flow at the gage site. This withdrawal cannot  
2527 simply be subtracted from each month to estimate effects on low or high flows because of  
2528 required transfer of water from Whitewater Reservoir when Colby Lake drops to elevation  
2529 1,439.0. Given this requirement to supplement low flows by transferring water from the  
2530 reservoir, it is expected that effects on low flows at the gage station would be negligible. Effects  
2531 on high flows would be less than on average flows, and would proportionately diminish as the  
2532 flow increases. Note that high flows downstream of Colby Lake would also be substantially  
2533 reduced because of water transfers to the reservoir during high runoff periods, which reflects  
2534 existing operating procedures. Therefore, the NorthMet Project Proposed Action is expected to  
2535 have negligible effects on flow in the Lower Partridge River. Note that during closure, once the  
2536 West Pit floods, the hydrology of the Partridge River is expected to return to relatively normal  
2537 conditions with no net change in average annual flow at SW-006 (Table 5.2.2-26).

### 2538 ***Effects on the Hydrology of Second Creek***

2539 Second Creek is the only Lower Partridge River tributary stream that could be notably affected  
2540 by the NorthMet Project Proposed Action. The current estimated average seepage rate is about  
2541 230 gpm (Table 5.2.2-42). Historically, seepage from the southern side of the Tailings Basin  
2542 entered the headwaters of Second Creek. In July 2011, a seepage collection system was installed,  
2543 which returned most of the south-side seepage to the Tailings Basin pond. Under the NorthMet  
2544 Project Proposed Action, the seepage collection system would be upgraded to ensure essentially  
2545 100 percent capture of the southern side surface seepage. If seepage were observed to bypass the  
2546 existing dam, a second dam could be constructed approximately 500 ft downstream of the  
2547 existing system, in an area where the Second Creek headwaters valley is more constricted and  
2548 any remaining subsurface seepage would have come to the surface. This potential second dam  
2549 could be constructed as an earthen dam with a clay or concrete cutoff wall (extending to bedrock  
2550 if necessary) in order to achieve 100 percent capture of the surface seepage. As part of its  
2551 streamflow augmentation plan (PolyMet 2015j), PolyMet would discharge WWTP effluent to the  
2552 headwaters of Second Creek at a rate equal to a minimum of 80 percent of the uncaptured south-  
2553 side seepage rate, or at least 184 gpm, to compensate for interception of the south-side seepage.  
2554 The effects of the NorthMet Project Proposed Action on Second Creek streamflow would be  
2555 minimal.

### 2556 ***Effects on Surface Water Quality***

2557 The NorthMet Project Proposed Action would affect the water quality of the Partridge River and  
2558 its tributaries that drain the Mine Site, Transportation and Utility Corridor, and the processing  
2559 plant area. PolyMet proposes to treat and re-use water, resulting in no direct surface water  
2560 discharges to the Partridge River until the West Pit completely refills by approximately year 52.  
2561 The West Pit would not be allowed to overflow until its water quality meets water quality based  
2562 effluent limits. During operations, reclamation, and closure and post-closure maintenance there  
2563 would be continuous augmentation at the Plant Site to Second Creek, which is a tributary of the  
2564 Partridge River. Several other potential pathways for surface water quality effects include  
2565 domestic wastewater, non-contact stormwater runoff, and seepage from waste rock stockpiles.

2566 PolyMet proposes to manage domestic wastewater by providing portable facilities serviced by a  
2567 supplier at the Mine Site. These portable facilities would be designed to adequately manage the  
2568 domestic wastewater requirements of the NorthMet Project Proposed Action, so this potential  
2569 contaminant source is not discussed further.

2570 The other predicted effects of the NorthMet Project Proposed Action on surface water quality in  
2571 the Upper Partridge River, Colby Lake, and the Lower Partridge River are discussed below.

### 2572 ***Effects on the Upper Partridge River***

2573 Water quality in the Upper Partridge River (upstream of Colby Lake) is already affected by  
2574 discharges from the Northshore Mine. As mentioned above, PolyMet does not propose any  
2575 surface water discharges to the Upper Partridge River until the West Pit floods around year 52.  
2576 However, non-contact stormwater runoff, unrecoverable groundwater seepage from the five  
2577 groundwater flowpaths (i.e., from the waste rock stockpiles, pits, Ore Surge Pile, WWTF, and  
2578 Overburden Storage and Laydown Area), and the WWTF discharge would all serve as  
2579 contaminant sources to the Upper Partridge River. Each of these sources is discussed below and  
2580 then the predicted overall effect of these sources on water quality in the Upper Partridge River is  
2581 evaluated.

### 2582 ***Non-contact Stormwater Runoff***

2583 PolyMet proposes to collect non-contact stormwater runoff from undisturbed and reclaimed  
2584 vegetated areas within the Mine Site and route it to the Partridge River via existing drainage  
2585 patterns to the extent possible. Stormwater quality is not expected to differ significantly from  
2586 existing conditions because it would not contact any reactive rock, but there would be the  
2587 potential for increased suspended solids. PolyMet would provide sedimentation ponds at the  
2588 outlet locations to manage suspended solids prior to discharge to surface waterbodies (see  
2589 Figures 3.2-5, 3.2-6, 3.2-7, and 3.2-8). These sedimentation ponds should be adequate to manage  
2590 suspended solids, but monitoring of the discharge is recommended as part of any NPDES/SDS  
2591 permit (see Section 4.1.3.5 for a discussion of recommended monitoring measures).

### 2592 ***Unrecovered Groundwater Seepage from Liner Leakage and Pit Seepage***

2593 The WWTF equalization basins, Ore Surge Pile, Category 2/3 Stockpile, and Category 4  
2594 Stockpile would all have compacted soil and geomembrane liners. Percolating water above the  
2595 liner would be collected and pumped to the WWTF for treatment.

2596 Some water is predicted to leak through the liners as a result of tears or defects in the  
2597 geomembrane liners and this effect is included in the GoldSim model. The quantity of water  
2598 leaking through the liners is determined by the liner design and effectiveness. The Hydrologic  
2599 Evaluation of Landfill Performance model was used to help estimate liner leakage, including the  
2600 use of uncertainty analysis for three key input variables (i.e., liner slope, subgrade permeability,  
2601 and frequency of liner defects) (PolyMet 2015m).

2602 The proposed liner systems would be installed in accordance with the proposed design using  
2603 rigorous quality control measures consistent with industry standards. Current construction  
2604 practices and improvements in electrical leak detection surveys should be able to achieve the  
2605 proposed design criteria (i.e., defects/acre, overliner slope, and subgrade permeability). Concerns  
2606 regarding geomembrane liners primarily relate to the potential for differential settlement to cause

2607 tears and for it to degrade over time. These concerns are tempered by the fact that all of the  
 2608 proposed liner systems would be temporary. The Ore Surge Pile and Category 2/3 and 4  
 2609 stockpiles would be removed, including the liners, by year 21. The WWTF equalization basins  
 2610 would remain in use while the East Pit is being treated in reclamation and closure and post-  
 2611 closure maintenance until approximately year 33.

2612 Because the Category 4 waste rock stockpile would be surrounded by mine pits and its footprint  
 2613 later becomes the Central Pit, any liner leakage from the stockpile would not enter a groundwater  
 2614 flowpath, and would instead be assumed to enter the East Pit and contribute to the flow that must  
 2615 be dewatered from the pit during operations.

2616 During reclamation and closure and post-closure maintenance, small volumes of water are  
 2617 predicted to flow from the pits into the downgradient surficial groundwater. These untreated pit  
 2618 releases would include East Pit backfill pore water into the East Pit Category 2/3 Surficial  
 2619 Flowpath (beginning year 20) and West Pit lake water into the West Pit Surficial Flowpath  
 2620 (beginning year 48). These releases to surficial groundwater would continue in perpetuity.  
 2621 Groundwater in these flowpaths would flow downgradient and eventually reach the Partridge  
 2622 River.

2623 Liner leakage from the Overburden Storage and Laydown Area, WWTF, Ore Surge Pile, and  
 2624 Category 2/3 Stockpile would also follow groundwater flowpaths that eventually reach the  
 2625 Partridge River, but would only be temporary sources. The leakage/seepage flow rates associated  
 2626 with these solute sources are generally low and are summarized in Table 5.2.2-27. For P50  
 2627 inputs, depending on the flowpath, the initial concentration change in groundwater discharging to  
 2628 the Partridge River would occur at 8 to 85 years after the start of mining and peak  
 2629 concentrations would occur in the range of 20 to 155 years (see Table 5.2.2-22). After peak  
 2630 concentrations were achieved, the groundwater concentrations would gradually decrease over  
 2631 many tens to hundreds of years. Note that for the Overburden Storage and Laydown Area  
 2632 flowpath, most solutes would experience a decrease in concentration downgradient of the source.

2633 **Table 5.2.2-27 Pit Outflow and Liner/Equalization Basin Leakage into Groundwater**  
 2634 **Flowpaths (Based on GoldSim Deterministic Run with P50 Inputs)**

| Contaminant Source                  | Flow Rate (gpm)     | Duration of Source (Mine Years) | Mine Year when Solute Plume First Arrives at Partridge River |
|-------------------------------------|---------------------|---------------------------------|--------------------------------------------------------------|
| East Pit                            | 3.75 <sup>(1)</sup> | 20+                             | 100                                                          |
| Category 2/3 Stockpile              | 0.0193              | 0–20                            | 35                                                           |
| Ore Surge Pile                      | 0.00116             | 0–21                            | 90                                                           |
| WWTF Equalization Basins            | 0.0138              | 0–33                            | 85                                                           |
| Overburden Storage and Laydown Area | 14.0                | 0–20                            | 30 <sup>(2)</sup>                                            |
| West Pit                            | 6.09 <sup>(1)</sup> | 48+                             | 105                                                          |

2635 <sup>1</sup> Pit water into groundwater flowpath.  
 2636 <sup>2</sup> Concentration decrease.

2637 Category 1 Stockpile Seepage

2638 During operations, the Category 1 Stockpile would be uncovered. Infiltration would percolate to  
 2639 the bottom of the stockpile, where it would be collected by the surface and groundwater seepage  
 2640 containment system. As the stockpile footprint is expanded, the total seepage during operations

2641 would increase up to a maximum annual rate of 290 and 440 gpm. Most of this seepage would be  
2642 collected and sent to the WWTF for treatment. An estimated maximum rate of 20 to 30 gpm  
2643 would pass below the containment system and be drawn by gravity into the dewatered West Pit.

2644 The Category 1 Stockpile would have a permanent cover consisting of a synthetic cover  
2645 (geomembrane) overlain by a compacted soil and vegetated growth medium, which would be  
2646 installed progressively during operations, starting in mine year 14 and planned to be completed  
2647 by the end of year 21. During reclamation and closure and post-closure maintenance, the total  
2648 seepage rate from the stockpile is estimated to be about 2.75 gpm. About 2.59 gpm of this  
2649 seepage would be collected by the surrounding surface and groundwater seepage containment  
2650 system and sent to the WWTF for treatment. About 0.16 gpm would pass below the containment  
2651 system and migrate as bedrock groundwater into the West Pit. None of the seepage would flow  
2652 directly into any of the surficial flowpaths.

### 2653 Wastewater Treatment Facility Discharges

2654 PolyMet proposes a WWTF at the Mine Site to treat affected water from the sources summarized  
2655 in Table 5.2.2-28. This table presents P90 (high-end) estimated average Mine Site process water  
2656 flow rates by source for the indicated design year (which are years 14, 25, and 75 for operations,  
2657 reclamation, and closure and post-closure maintenance, respectively). Details regarding some of  
2658 these WWTF influent sources are discussed below. The process water at the Mine Site would be  
2659 combined into three waste streams for treatment at the WWTF. Construction water would be  
2660 treated in a construction water stream and would only be needed through approximately year 11.  
2661 Process water containing relatively high levels of metals and sulfate (drainage from the  
2662 temporary Category 2/3 Stockpile and Category 4 Stockpile liners and the temporary Ore Surge  
2663 Pile liner) would be stored in the West Equalization Basin and routed to the chemical  
2664 precipitation treatment train. Process water containing relatively low concentrations of metals  
2665 and sulfate (drainage from haul roads, the Rail Transfer Hopper, pit dewatering, and Category 1  
2666 Stockpile drainage) would be stored in the East Equalization Basin and routed to the filtration  
2667 treatment train. The WWTF effluent would be conveyed to the Central Pumping Station pond to  
2668 be blended with the Overburden Storage and Laydown Area runoff prior to being pumped  
2669 through the Treated Water Pipeline for use at the Tailings Basin or used to supplement flooding  
2670 of the East Pit after approximately year 11 (PolyMet 2015r).

2671 **Table 5.2.2-28 P90 Mine Site Process Water Flows to the Wastewater Treatment Facility**

| Source                              | 90 <sup>th</sup> Percentile Estimated Average Annual Flow (gpm) |                          |                                                   |
|-------------------------------------|-----------------------------------------------------------------|--------------------------|---------------------------------------------------|
|                                     | Operations <sup>2</sup>                                         | Reclamation <sup>3</sup> | Closure and Post-Closure Maintenance <sup>4</sup> |
| East Pit                            | 1,035                                                           | 1,750 <sup>(5)</sup>     | --                                                |
| Central Pit                         | 55                                                              | --                       | --                                                |
| West Pit                            | 365                                                             | --                       | 400                                               |
| Haul Roads and Rail Transfer Hopper | 65                                                              | --                       | --                                                |
| Category 1 Stockpile                | 375                                                             | 10                       | 10                                                |
| Category 2/3 Stockpile              | 145                                                             | --                       | --                                                |
| Ore Surge Pile                      | 25                                                              | --                       | --                                                |
| Category 4 Stockpile                | 0                                                               | --                       | --                                                |
| WWTP Reject Concentrate             | 145                                                             | 175                      | --                                                |
| Total <sup>1</sup>                  | 2,065                                                           | 1,925                    | 405                                               |

2672 Source: PolyMet 2015d, Table 2-1.

- 2673 <sup>1</sup> Flows are rounded to the nearest 5 gpm; column values do not sum to 90<sup>th</sup> percentile total value due to probabilistic modeling  
 2674 (P90 of totals is not equivalent to the total of the P90s).  
 2675 <sup>2</sup> Estimates based on PolyMet 2015m for year 14 (Design Year), 90<sup>th</sup> Percentile.  
 2676 <sup>3</sup> Estimates based on PolyMet 2015m for year 25, 90<sup>th</sup> Percentile.  
 2677 <sup>4</sup> Estimates based on PolyMet 2015m for year 75, 90<sup>th</sup> Percentile.  
 2678 <sup>5</sup> Flow value is total of East Pit and Central Pit.

2679 Actual flow rates would vary both daily and seasonally throughout the 20 years of mine  
 2680 operations. Peak influent flows to the WWTF are anticipated to occur during spring snowmelt.  
 2681 Because influent flow rates to the WWTF would vary significantly over the life of the NorthMet  
 2682 Project Proposed Action and within any given year, the WWTF design includes two equalization  
 2683 basins that would store influent when flows exceed the WWTF's treatment capacity. The WWTF  
 2684 equalization basins are designed for the spring snowmelt, when the Mine Site would be at its  
 2685 maximum area. In the event of an extreme event (e.g., 100-year storm), excess water would  
 2686 remain in the initially dewatered mine pits, which essentially have unlimited storage capacity,  
 2687 with mine operations in the pits temporarily shut down (see PolyMet 2015r). Even during an  
 2688 extreme event, no untreated water would be discharged to a natural water body.

2689 The WWTF process design for operations and reclamation includes chemical precipitation and  
 2690 nano-membrane separation. During mine operations, the treated effluent from the WWTF would  
 2691 be mixed with the runoff collected from the Overburden Storage and Laydown Area in the  
 2692 Central Pumping Station pond, where it would be pumped either to the Tailings Basin pond (for  
 2693 re-use as process water at the Beneficiation Plant) or to help re-saturate the East Pit backfill  
 2694 (after mining would be completed in year 11). The pH in the East Pit backfill would be  
 2695 monitored and adjusted by the addition of alkaline water from the WWTF as backfilling  
 2696 progresses to maintain near-neutral conditions in the backfill pore water. During mine  
 2697 reclamation, the WWTF would primarily be used for treating East Pit backfill surface water and  
 2698 to accelerate flooding of the West Pit.

2699 During mine closure and post-closure reclamation, the WWTF would be used to treat water  
 2700 collected from the Category 1 Stockpile containment system and pumped water from the West  
 2701 Pit. Since the West Pit would now be flooded, the WWTF would begin in closure and post-  
 2702 closure maintenance to discharge effluent to the West Pit Outlet Creek, a natural intermittent  
 2703 stream that flows to the Partridge River just upstream of SW-004a. The treated effluent would

2704 need to meet applicable effluent limits. During closure and post-closure maintenance, the  
2705 existing WWTF nano-membrane system would be converted to an RO system with an  
2706 evaporator/spray dryer or equivalent unit. Reject concentrate from the primary membrane  
2707 separation unit would continue to be treated with existing secondary membrane separation and  
2708 chemical precipitation equipment, or would be evaporated and the residual solids disposed  
2709 offsite.

2710 Table 5.2.2-29 presents the target WWTF effluent concentrations for the different mine phases.  
2711 Pilot-testing of a WWTF with RO demonstrated that all of the target closure effluent  
2712 concentrations could be achieved with the planned WWTF design (Barr 2013f).

DRAFT

2720 **Comparison of Contaminant Sources**

2721 The GoldSim model enables the identification of “culpability,” or the relative contribution of  
 2722 various contaminant sources to the overall contaminant load at a specific evaluation location.  
 2723 Table 5.2.2-30 presents an illustrative example of the culpability analysis using two  
 2724 representative solutes of interest (copper and sulfate) at evaluation location SW004a during  
 2725 representative years for operations, reclamation, and closure and post-closure maintenance  
 2726 periods. The culpability identifies 12 sources of copper and sulfate at this evaluation location. In  
 2727 addition to the eight NorthMet Project Proposed Action-related sources (i.e., five surficial  
 2728 aquifer flowpaths, two bedrock flowpaths, and the WWTF discharge), three non-NorthMet  
 2729 Project Proposed Action-related sources are identified (i.e., background groundwater, non-  
 2730 contact stormwater runoff, and the Northshore Mine discharge).

2733 Source: PolyMet 2014v.

2734 GW = Groundwater.

2735 <sup>1</sup> Includes NorthMet Project Proposed Action-related loading and loading associated with meteoric recharge into the flowpath.

2736 As Table 5.2.2-30 indicates, the primary source of contaminant load for both copper and sulfate  
 2737 at SW-004a for operations, reclamation, and closure and post-closure maintenance phases are the

2738 non-NorthMet Project Proposed Action-related sources (background groundwater, surface water,  
2739 and Northshore Mine discharge). In addition, the WWTF discharge represents an important  
2740 source of copper in closure and post-closure maintenance, and a minor source of sulfate.

2741 ***Evaluation of Surface Water Quality for the Upper Partridge River***

2742 Results of the GoldSim water quality modeling were reviewed for 29 constituents at the seven  
2743 Partridge River surface water evaluation locations listed in Table 5.2.2-31. Station SW-001,  
2744 upstream of SW-002, is not an evaluation location because its water chemistry is essentially the  
2745 same as that of the Northshore Mine discharge. The screening process described previously for  
2746 constituents without hardness-based evaluation criteria (see Section 5.2.2.2.3) was applied to 23  
2747 constituents to identify constituents and locations that warranted a more robust examination. The  
2748 screening process involved comparing the single-highest monthly P90 water quality prediction  
2749 (maximum P90 concentration) for the NorthMet Project Proposed Action to the associated  
2750 evaluation criterion, excluding the first year of simulation as discussed previously. The bold  
2751 entries in Table 5.2.2-31 identify constituents and locations with maximum P90 values that  
2752 exceed the associated evaluation criterion and are retained for further evaluation. These include  
2753 sulfate (SW-005 and SW-006) and aluminum (all evaluation locations).

2754 Table 5.2.2-30 shows that the maximum P90 solute concentrations for the NorthMet Project  
2755 Proposed Action are similar to the corresponding CEC scenario modeled values for most of the  
2756 constituents. Some of the NorthMet Project Proposed Action maximum P90 values—such as  
2757 those for antimony, cadmium, cobalt, copper, nickel, vanadium, and zinc at SW-004a, SW-004b,  
2758 SW-005, and SW-006, and sulfate and lead at SW-004a and SW-004b—are noticeably higher  
2759 than the CEC scenario maximum P90 values, but the NorthMet Project Proposed Action values  
2760 for these constituents all remain well below the applicable evaluation criteria.

2761 While listed in Table 5.2.2-31, six constituents with hardness-based evaluation criteria  
2762 (cadmium, chromium III, copper, lead, nickel, and zinc) were screened using a different  
2763 methodology because the associated evaluation criteria could not be described by single values;  
2764 this methodology was previously discussed in Section 5.2.2.2.3. Using this methodology, Table  
2765 5.2.2-32 summarizes the initial screening of Mine Site surface water constituents that have  
2766 hardness-based evaluation criteria. As shown, the probability of the NorthMet Project Proposed  
2767 Action exceeding the evaluation criterion, when CEC does not, is less than 5 percent for all  
2768 constituents and locations. As a consequence, all of the Mine Site surface water constituents with  
2769 hardness-based evaluation criteria are not considered further in this FEIS.

2770 **Table 5.2.2-31 Mine Site Surface Water – Maximum P90 Solute Concentration Over Entire 200-Year Simulation with Initial Screening of Constituents without Hardness-Based Evaluation Criteria**

| Parameter           | Partridge Evaluation Criteria | Units | SW-002                           |              | SW-003                           |              | SW-004                           |              | SW-004a                          |              | SW-004b                          |              | SW-005                           |              | SW-006                           |              |

Notes: Bold value indicates exceedance of the evaluation criterion.

<sup>1</sup> Sulfate 10 mg/L, wild rice evaluation criterion applies at SW-005 and SW-006

<sup>2</sup> Parameter has a hardness-based evaluation criterion and is screened using a different procedure (see Table 5.2.2.32)

2782

2783 Table 5.2.2-33 below compares the maximum P50 and P90 for NorthMet Project Proposed  
2784 Action and the CEC Scenario modeled concentrations for selected representative solutes of  
2785 interest during mine operations, reclamation, and closure and post-closure maintenance at SW-  
2786 004a, which is the evaluation location where the NorthMet Project Proposed Action would have  
2787 its greatest effects on water quality for most constituents. As these data show, the water quality is  
2788 predicted to be essentially the same for the CEC scenario and the NorthMet Project Proposed  
2789 Action modeled values for operations and reclamation. This result is not unexpected, as most of  
2790 the groundwater contaminant source loads would not reach the Partridge River at the end of the  
2791 reclamation period, and WWTF effluent discharge to the Partridge River would not begin until  
2792 about year 48. By year 200 in closure and post-closure maintenance, which reflects when effects  
2793 would have peaked and would be decreasing, the WWTF would be discharging and all  
2794 groundwater contaminant source loads would have reached the Partridge River (except  
2795 negligible contributions from the bedrock flowpaths), the predictions for the NorthMet Project  
2796 Proposed Action for some constituents (e.g., nickel and zinc) are higher than for the CEC  
2797 Scenario, but remain below applicable evaluation criteria.

2801 <sup>1</sup> NorthMet Project Proposed Action  
 2802  
 2803  
 2804

2805 The screening presented in Tables 5.2.2-31 and 5.2.2-32 indicate that sulfate (at SW-005 and  
2806 SW-006) and aluminum (all evaluation locations) have the potential to cause impacts to Mine  
2807 Site surface water and require a higher level of evaluation. More detailed analyses for these  
2808 constituents are provided in subsequent FEIS sections.

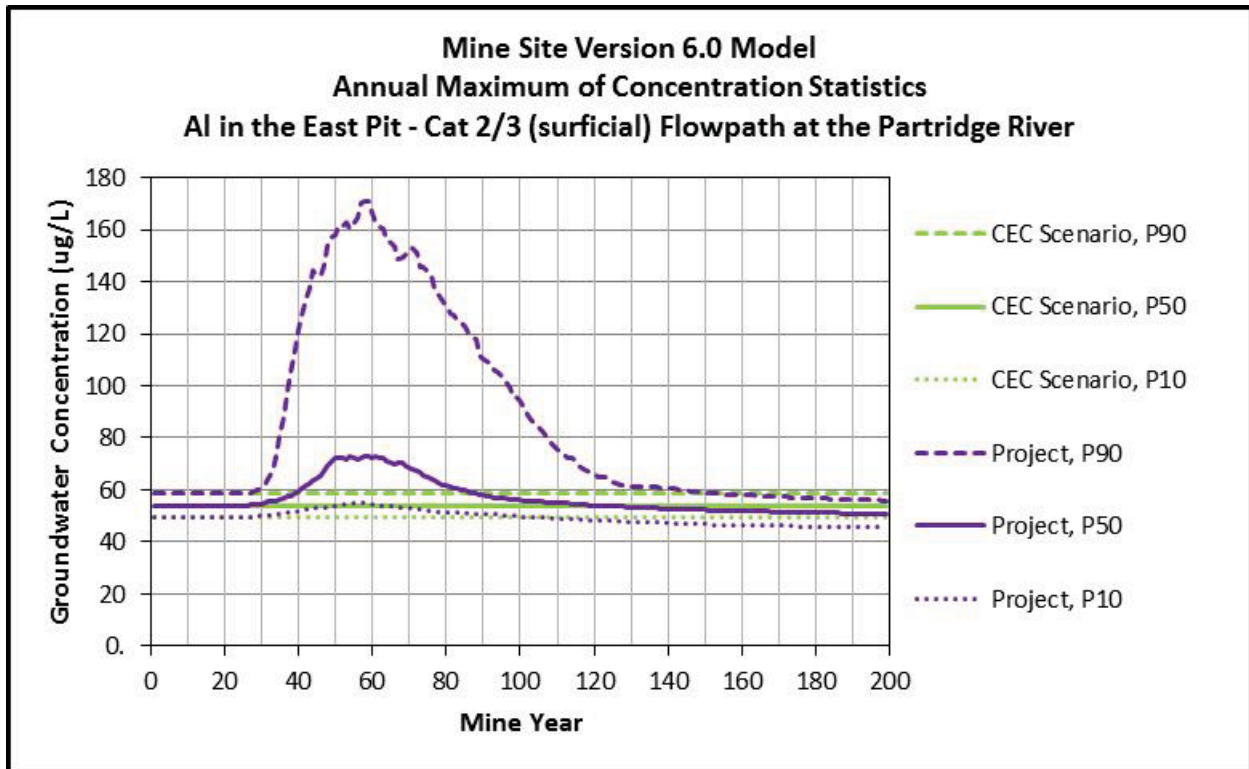

2809 Aluminum in the Partridge River

2810 Model results indicate that the maximum P90 concentration of aluminum in the Partridge River  
2811 for the modeled NorthMet Project Proposed Action would exceed the evaluation criterion (125  
2812 µg/L) at all seven evaluation locations along the Upper Partridge River. Aluminum maximum  
2813 P90 concentrations for NorthMet Project Proposed Action conditions range from 305.6 to 313.3  
2814 µg/L at the various evaluation locations (see Table 5.2.2-31).

2815 Potential sources of aluminum from the NorthMet Project Proposed Action include the East Pit –  
2816 Category 2/3 Stockpile, the Ore Surge Pile, the WWTF Equalization Basins, the Overburden  
2817 Storage and Laydown Area, and the West Pit. For each Mine Site contaminant source, the  
2818 primary constituent migration pathway would be transport as groundwater in the surficial aquifer  
2819 and eventual release of affected groundwater to the Partridge River. The groundwater flowpath  
2820 that provides groundwater release to the Partridge River with P90 aluminum concentrations  
2821 above the surface water quality evaluation criterion of 125 µg/L is the East Pit – Category 2/3  
2822 Stockpile flowpath, which shows a “pulse” in aluminum concentrations that would peak at about  
2823 175 µg/L between years 25 and 125 (see Figure 5.2.2-31). As the evaluation criterion is not  
2824 applicable to groundwater, this pulse in aluminum concentrations would only be a concern if it  
2825 was measurable upon release to the Partridge River. Figure 5.2.2-32 shows the modeled monthly  
2826 aluminum concentration for years 56 to 62 at SW-004, the first surface water evaluation location  
2827 downstream of the East Pit – Category 2/3 Stockpile flowpath contribution, and captures the  
2828 peak of the pulse shown in Figure 5.2.2-31. As evidenced by the CEC Scenario and the  
2829 NorthMet Project Proposed Action modeled concentrations being coincident in Figure 5.2.2-32,  
2830 groundwater flow from the East Pit – Category 2/3 Stockpile is sufficiently diluted upon  
2831 reaching the Partridge River such that effects from the NorthMet Project Proposed Action are not  
2832 discernible.

2841 **Figure 5.2.2-32 Monthly Aluminum Concentrations at SW-004**

2842 As shown in Table 5.2.2-31 comparing the modeled CEC scenario concentrations in the Upper  
2843 Partridge River with the modeled NorthMet Project Proposed Action concentrations indicates  
2844 that although aluminum concentrations in the Upper Partridge River would exceed the evaluation  
2845 criterion the concentrations are predicted to be about the same as they would be under the CEC  
2846 scenario. Therefore, it is predicted that the NorthMet Project Proposed Action would not have a  
2847 measurable adverse effect on aluminum concentrations in the Upper Partridge River. In addition,  
2848 as indicated in Figure 5.2.2-33, the concentrations of aluminum in background surface runoff  
2849 (i.e., non-contact water) exceed the evaluation criterion of 125  $\mu\text{g/L}$  approximately 20 percent of  
2850 the time. This suggests that the modeled aluminum exceedances are attributable to background  
2851 surface runoff, which is naturally high in aluminum, and not to effects related to the NorthMet  
2852 Project Proposed Action.

2857 *Surface Runoff*

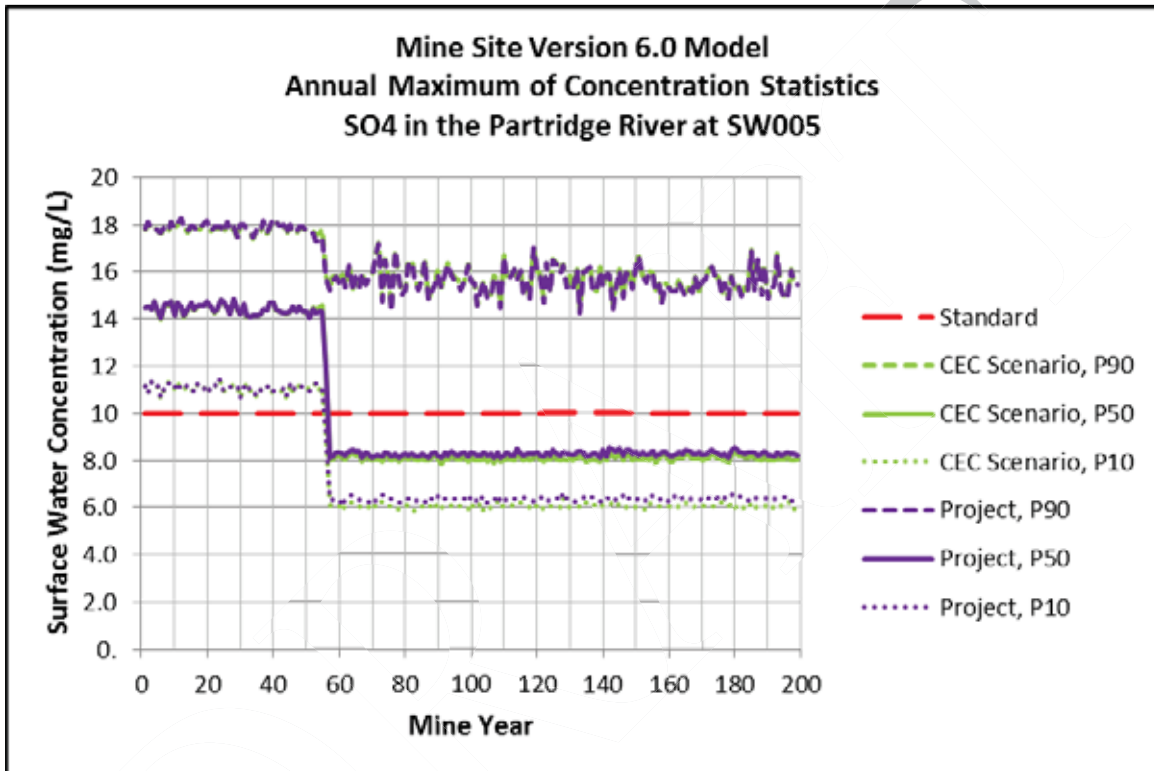

2858 *Sulfate in the Partridge River*

2859 Evaluation locations SW-005 and SW-006 are located in portions of the Partridge River that the  
2860 MPCA has recommended as being waters used for the production of wild rice, and therefore  
2861 subject to the 10 mg/L wild rice sulfate evaluation criterion. As shown by bold font in Table  
2862 5.2.2-31, the maximum P90 sulfate concentrations at SW-005 and SW-006 for the NorthMet  
2863 Project Proposed Action are 18.3 and 17.6 mg/L, respectively, which exceed the 10 mg/L  
2864 criterion. The CEC scenario, however, would also exceed the wild rice evaluation criterion, so  
2865 the NorthMet Project Proposed Action's compliance with the evaluation criterion requires  
2866 further evaluation. The analysis below focuses on SW-005 because the NorthMet Project  
2867 Proposed Action would have greater effects (higher sulfate concentrations) at this location  
2868 compared to SW-006. Inspection of the GoldSim outputs verifies that predicted sulfate  
2869 concentrations at SW-006 are always slightly lower than at SW-005 due to dilution effects.

2870 SW-005 shows a dramatic reduction in sulfate concentration after mine year 55 (see Figure  
2871 5.2.2-34. Up to this time, the Northshore Mine is modeled as continuously discharging 2.6 cfs of  
2872 mine water to the Partridge River with a sulfate concentration of 28 mg/L. After mine year 55,  
2873 there would no longer be a Northshore Mine discharge, but the WWTF would begin to  
2874 discharging approximately 0.67 cfs to the West Pit Overflow Creek with a sulfate concentration

2875 of 9 mg/L. As a consequence, the sulfate chemical load from affected water discharged to the  
2876 river would decrease after mine year 55, but P90 sulfate concentrations would still exceed the  
2877 evaluation criterion.

2878

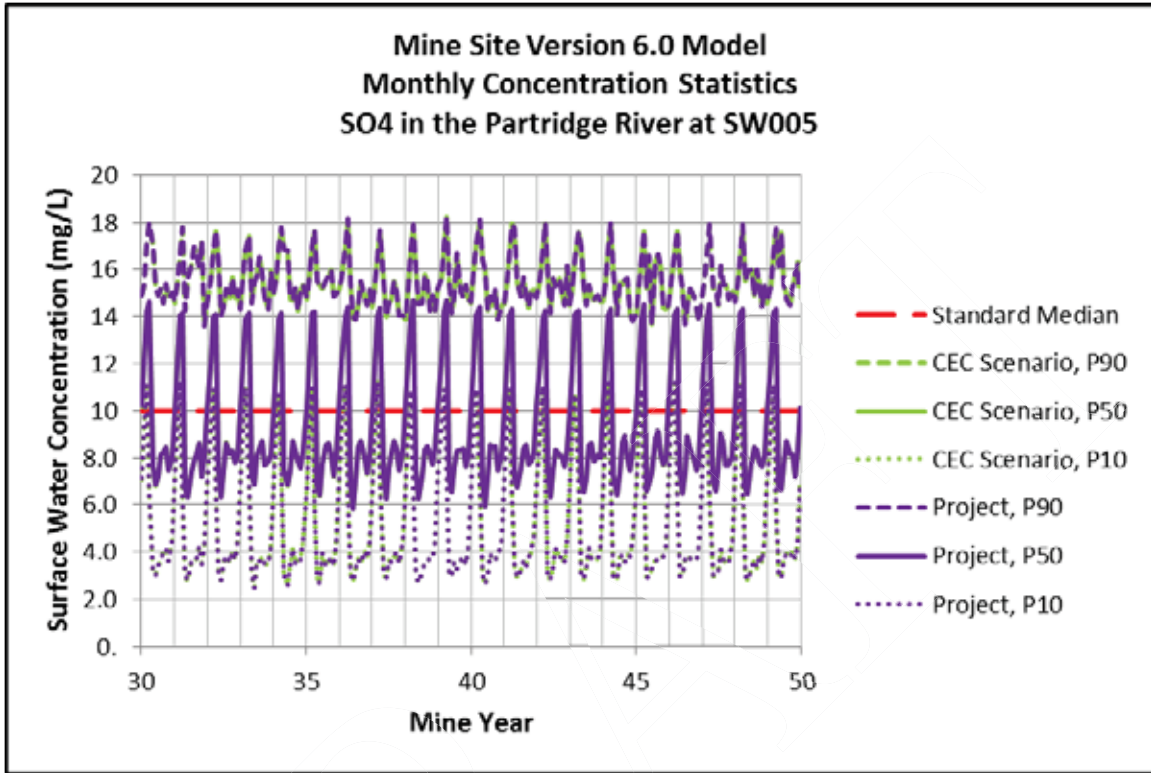

2879

2880 **Figure 5.2.2-34 Maximum P90 of Annual Sulfate Concentration at SW-005**

2881 Monthly sulfate concentrations in the Partridge River would fluctuate with higher concentrations  
2882 tending to occur during winter low flows as well as lower concentrations during the spring and  
2883 summer when increased runoff occurs. For example, Figure 5.2.2-35 shows monthly sulfate  
2884 concentrations for a representative time period (mine years 30-50) when the Northshore Mine  
2885 discharges to the Partridge River and the WWTF discharges to the West Pit, but not to the river..  
2886 Figure 5.2.2-36 is plot for Mine Years 140-160 when the WWTF discharges to the Partridge  
2887 River, all groundwater plumes have reached the River, and the Northshore Mine no longer  
2888 discharges to the River. As can be seen on both figures, sulfate concentrations fluctuate on an  
2889 annual basis, with highest concentrations during low-flow conditions (typically January and  
2890 February) when there is less dilution from surface runoff, which typically has low sulfate  
2891 concentrations.

2900 **Figure 5.2.2-36 GoldSim-Predicted Sulfate Concentrations at SW-005 for Mine Years**  
 2901 **140 -160 when the WWTF Discharges to the Partridge River, Groundwater Plumes have**  
 2902 **Reached the River, and Northshore No Longer Discharges to the River**

2903 To investigate sulfate at SW-005 in more detail, GoldSim results were evaluated on a timestep-  
 2904 by-timestep basis for both P50 concentrations and P90 concentrations, leading to the summary in  
 2905 Table 5.2.2-34. The table indicates the following:

- 2906 • **Time period 0 to 55 years:** During this period, sulfate concentrations at SW-005 would  
 2907 always exceed the evaluation criterion at the P90 level for both the CEC and NorthMet  
 2908 Project Proposed Action scenarios, but under both scenarios this is attributable to background  
 2909 runoff, background groundwater and the Northshore Mine discharge. The NorthMet Project  
 2910 Proposed Action would have negligible effect on sulfate concentrations in the Partridge River  
 2911 during this period because it would not have any surface discharges during this time and only  
 2912 groundwater from the Overburden Storage and Laydown Area and Category 2/3 Stockpile  
 2913 flowpaths would have reached the Partridge River (initially contributing sulfate load to the  
 2914 river in years 30 and 35, respectively). For all conditions and timesteps, the NorthMet Project  
 2915 Proposed Action would not contribute more than 0.1 mg/L to the sulfate concentration in the  
 2916 Partridge River.
- 2917 • **Time period 55 to 200 years:** During this period, sulfate concentrations at SW-005 would  
 2918 still always exceed the evaluation criterion at the P90 level for both the CEC and NorthMet  
 2919 Project Proposed Action scenarios, but would be at lower concentrations than during the  
 2920 Year 0 to 55 period because Northshore Mine's discharge would cease. The NorthMet  
 2921 Project Proposed Action's contribution to the sulfate loading increases noticeably because  
 2922 the WWTF begins discharging in Year 55 and the NorthMet Project Proposed Action

2923 groundwater from other flowpaths (in addition to the OSLA and East Pit-Category 2/3  
2924 Stockpile flowpaths) begins to reach the Partridge River. The WWTF would discharge at a  
2925 sulfate effluent target of 9 mg/L so it would not contribute to any exceedances of the  
2926 evaluation criterion, rather it would provide dilution. The groundwater flowpaths would  
2927 contribute small volumes, but higher sulfate concentrations to the Partridge River.

2928 Overall, the NorthMet Project Proposed Action would account for approximately 3 percent of the  
2929 sulfate loadings to the Partridge River at SW-005. The primary sources of sulfate loads would  
2930 continue to be background runoff and background groundwater. The GoldSim model results  
2931 indicate that the NorthMet Project Proposed Action would increase exceedances of the  
2932 evaluation criterion less than 2 percent of the time and the maximum magnitude of this increase  
2933 would be 0.1 mg/L (Table 5.2.2-34). It should be noted that the GoldSim results show that the  
2934 evaluation criterion would be met essentially all the time under the NorthMet Project Proposed  
2935 Action Scenario at the P50 level.

2936 GoldSim results predict that for all situations where a theoretical impact could be attributed to  
2937 the NorthMet Project Proposed Action, the expected increase in sulfate concentration at SW-005  
2938 (and SW-006) would be less than or equal to 0.1 mg/L, and this would be superimposed on  
2939 typical annual fluctuations of several mg/L. A practical consequence of this result is that the  
2940 effects of the NorthMet Project Proposed Action would likely not be identifiable by the proposed  
2941 post-operations field monitoring program.

2942 The small sulfate increases are explained by the small amounts of impacted and untreated water  
2943 leaving the Mine Site, which only occur as groundwater. For P50 predictions during all phases of  
2944 the NorthMet Project Proposed Action, the maximum amount of impacted and untreated  
2945 groundwater leaving the site is 0.031 cfs (14 gpm). The maximum impact to the Partridge River  
2946 would occur when this affected groundwater is released to the Partridge River during low-flow  
2947 conditions. At SW-005, the average annual 1-day low flow is estimated to be 6.9 cfs (3,100 gpm)  
2948 when Northshore is discharging (up to year 55) and 5.0 cfs (2,240 cfs) when only the WWTF  
2949 discharges to the Partridge River (after year 55). Given the contrast between groundwater and  
2950 river flows, it is apparent that the mass loading associated with groundwater flow from the Mine  
2951 Site is far too small to impart a noticeable impact on sulfate concentrations in the Partridge  
2952 River.

2953 **Table 5.2.2-34 GoldSim Predicted Sulfate Concentrations at SW-005**

| Time Period (myr)       | Description                                                                            | Units | Based on P50 Values | Based on P90 Values |
|-------------------------|----------------------------------------------------------------------------------------|-------|---------------------|---------------------|
| 0 – 55 <sup>(1)</sup>   | Percentage of time that PA concentration > 10 mg/L                                     | %     | 29.0                | 100.0               |
|                         | Percentage of time that CEC concentration > 10 mg/L                                    | %     | 28.9                | 100.0               |
|                         | Percent of time that PA concentration > 10 mg/L <b>and</b> CEC concentration ≤ 10 mg/L | %     | 0.3                 | 0.0                 |
|                         | Maximum (PA concentration – CEC concentration)                                         | mg/L  | 0.05                | 0.09                |
| 55 – 200 <sup>(2)</sup> | Percentage of time that PA concentration > 10 mg/L                                     | %     | 0.2                 | 100.0               |
|                         | Percentage of time that CEC concentration > 10 mg/L                                    | %     | 0.2                 | 100.0               |
|                         | Percent of time that PA concentration > 10 mg/L <b>and</b> CEC concentration ≤ 10 mg/L | %     | 0.0                 | 0.0                 |
|                         | Maximum (PA concentration – CEC concentration)                                         | mg/L  | 0.27 <sup>(3)</sup> | 0.10                |

2954 PA = NorthMet Project Proposed Action

2955 <sup>1</sup> Northshore discharges 2.6 cfs with sulfate concentration of 28 mg/L; no WWTF discharge.

2956 <sup>2</sup> WWTF discharges at average rate of 0.67 cfs with sulfate concentration of 9 mg/L; no Northshore discharge.

2957 <sup>3</sup> All PA and CEC concentrations are below the wild rice sulfate evaluation criterion of 10 mg/L.

2958 Given the low probability that sulfate concentrations from the NorthMet Project Proposed Action  
 2959 would be greater than predicted and identifiable from field data, a number of contingency  
 2960 measures could be implemented and adapted as necessary to decrease NorthMet Project  
 2961 Proposed Action effects on the Partridge River. As discussed in Section 5.2.2.3.5, these  
 2962 contingency mitigation measures could include: 1) changes in WWTF effluent sulfate  
 2963 concentration and flow rate, 2) installation of surface and groundwater seepage containment  
 2964 systems, and 3) installation of non-mechanical groundwater treatment systems.

2965 **Effects on Surface Water Quality in the Upper Partridge River Tributary Streams**

2966 This section discusses the effects on surface water quality in the four Upper Partridge River  
 2967 tributary streams: West Pit Outlet Creek, Wetlegs Creek, Longnose Creek, and Wyman Creek.  
 2968 Surface water quality in these creeks would be affected by ore spillage from the rail cars that  
 2969 would transport ore from the Mine Site to the processing plant during operations. Ore would  
 2970 range in size from 48 inches down to small gravel and dust.

2971 Based on observations at other mining operations using similar side-dump rail cars, it is assumed  
 2972 that spillage is most likely to occur along the first 1,000 meters of rail from the Rail Transfer  
 2973 Hopper (PolyMet 2015q).. The railway does not cross any streams along this stretch. Rainfall  
 2974 contacting the spilled ore would have the potential to release contaminants, but the relatively  
 2975 small volume of material and dilution from other sources are expected to result in surface water  
 2976 quality meeting the evaluation criteria (PolyMet 2015q). During closure, there may be residual  
 2977 effects on surface water quality from the spilled ore, although the small quantity of expected  
 2978 spilled material would become rapidly depleted of sulfide materials compared to the much larger  
 2979 waste rock stockpiles (PolyMet 2015q).

2980 Three potential ways that ore could be released to the environment during transport via rail car  
 2981 include: 1) ore spillage through the hinge gap, 2) ore spillage through the door gap, and 3) dust  
 2982 from the top of the car. To guard against possible adverse effects from spilled ore, PolyMet plans  
 2983 to refurbish the ore cars, tightening or replacing the couplings and linkages to minimize gaps  
 2984 along the hinges and joint areas where spillage could occur (PolyMet 2014a). The quantity of ore

2985 that could potentially spill through the door and hinge gaps of a refurbished ore car is estimated  
 2986 to be 0.20 tons per year. This is a 97 percent reduction from the originally calculated value of  
 2987 6.14 tons per year of unrefurbished cars.

2988 Water quality monitoring is recommended downstream from the rail line on the Partridge River  
 2989 tributary streams to check for any potential deteriorations of water quality over time from ore  
 2990 spillage, and, if detected, adaptive water management measures would be implemented. Dust  
 2991 could be mitigated by spraying water on the loaded ore prior to transport. If significant  
 2992 accumulation of ore spillage occurs, it would be removed.

2993 The West Pit Outlet Creek would also receive effluent from the WWTF during closure, which is  
 2994 estimated at an annual average discharge rate of 0.65 cfs. The WWTF is designed to meet all  
 2995 surface water quality standards with its discharge.

2996 ***Effects on Surface Water Quality in Colby Lake and Whitewater Reservoir***

2997 Screening for Colby Lake constituents with hardness-based criteria is shown in Table 5.2.2-32;  
 2998 as indicated, there are no hardness-based constituents that require further evaluation. Table 5.2.2-  
 2999 35 provides maximum P90 concentrations for Colby Lake along with the initial screening results  
 3000 for constituents that do not have hardness-based evaluation criteria. As indicated by bold entries,  
 3001 aluminum, arsenic, iron, and manganese have maximum P90 concentrations that exceed their  
 3002 associated evaluation criteria, and these are retained for further evaluation.

3003 ***Table 5.2.2-35 Colby Lake – Maximum P90 Solute Concentration Over Entire 200-Year***  
 3004 ***Simulation with Initial Screening of Constituents without Hardness-Based***  
 3005 ***Evaluation Criteria***

| Parameter           | Colby Lake Evaluation Criteria | Units | CEC Scenario | NorthMet Project Proposed Action | % Change from CEC Scenario |
|---------------------|--------------------------------|-------|--------------|----------------------------------|----------------------------|
| <b>General</b>      |                                |       |              |                                  |                            |

Source: PolyMet 2014v

Note: Bold value indicates exceedance of the evaluation criterion.

<sup>1</sup> Parameter has a hardness-based evaluation criterion and is screened using a different procedure (see Table 5.2.2-32).

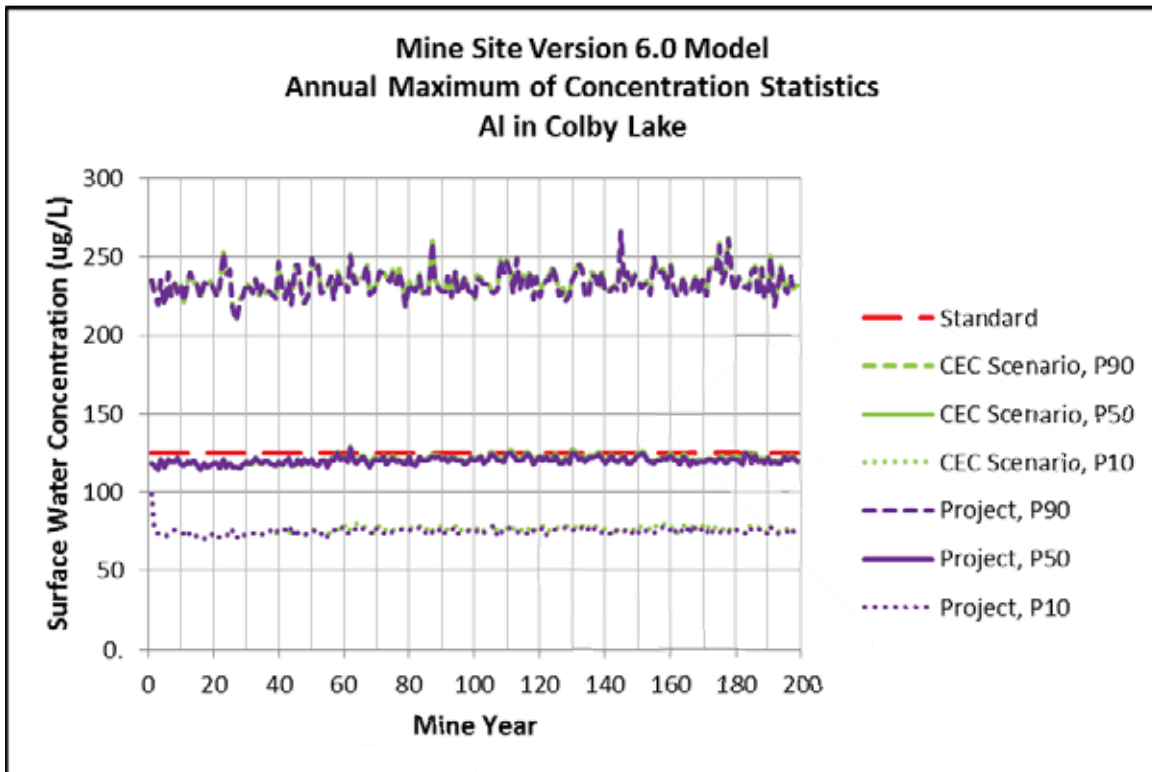

3006 Table 5.2.2-35 above also shows the percent change from the CEC scenario model results. The  
 3007 percent change can appear quite large, but the absolute change is quite small, especially when  
 3008 compared with the evaluation criteria. A good example is nickel, which has a maximum P90  
 3009 value that increases 22.9 percent, but the absolute increase is approximately 1 µg/L, and the  
 3010 NorthMet Project Proposed Action maximum P90 value (5.43 µg/L) is still well below the  
 3011 evaluation criteria (43.3 µg/L). Note that for aluminum, iron, and manganese, the maximum P90  
 3012 concentration for CEC is lower than the comparable value for the NorthMet Project Proposed  
 3013 Action. For Arsenic, the CEC value is higher, but only by 0.9 percent. The four solutes retained  
 3014 for further analysis are discussed in the following sections.

3015 Aluminum

3016 Model results indicate that the maximum P90 concentration of aluminum (266 µg/L) would  
 3017 exceed the evaluation criteria (125 µg/L) in Colby Lake, just as it is predicted to exceed along  
 3018 most of the Partridge River (see Figure 5.2.2-37).

3019

3020  
3021 Source: PolyMet 2014v.

3022 **Figure 5.2.2-37 Colby Lake Annual Maximum Aluminum Concentrations**

3023 Higher aluminum concentrations would typically occur between April and November, when  
3024 surface runoff would contribute proportionately more to river flow than groundwater baseflow.  
3025 Concentrations of aluminum in background surface non-contact water would exceed the water  
3026 quality standard approximately 20 percent of the time, whereas aluminum in groundwater would  
3027 almost never exceed the evaluation criteria.

3028 As indicated in Table 5.2.2-35 and Figure 5.2.2-37, the NorthMet Project Proposed Action would  
3029 not cause Colby Lake aluminum to increase in comparison to the CEC scenario. For P10, P50,  
3030 and P90 annual maximum curves on Figure 5.2.2-37, the NorthMet Project Proposed Action  
3031 curves are nearly identical to the CEC curves. In Table 5.2.2-33, the maximum P90  
3032 concentration for the Proposed Action (310.2  $\mu\text{g/L}$ ) is slightly less than the comparable P90 for  
3033 CEC (314.9  $\mu\text{g/L}$ ). The conclusion is that aluminum would likely exceed the evaluation criterion  
3034 in Colby Lake, but the NorthMet Project Proposed Action would not cause concentrations to be  
3035 noticeably higher than what would occur without the NorthMet Project Proposed Action.

3036 Further, aluminum has not been an issue for the City of Hoyt Lakes. For municipal drinking  
3037 water, the City treats raw water from Colby Lake with high aluminum and produces drinking  
3038 water that meets applicable regulatory standards. The City is not required to monitor for  
3039 aluminum, as there is no human health-based drinking water standard for aluminum.

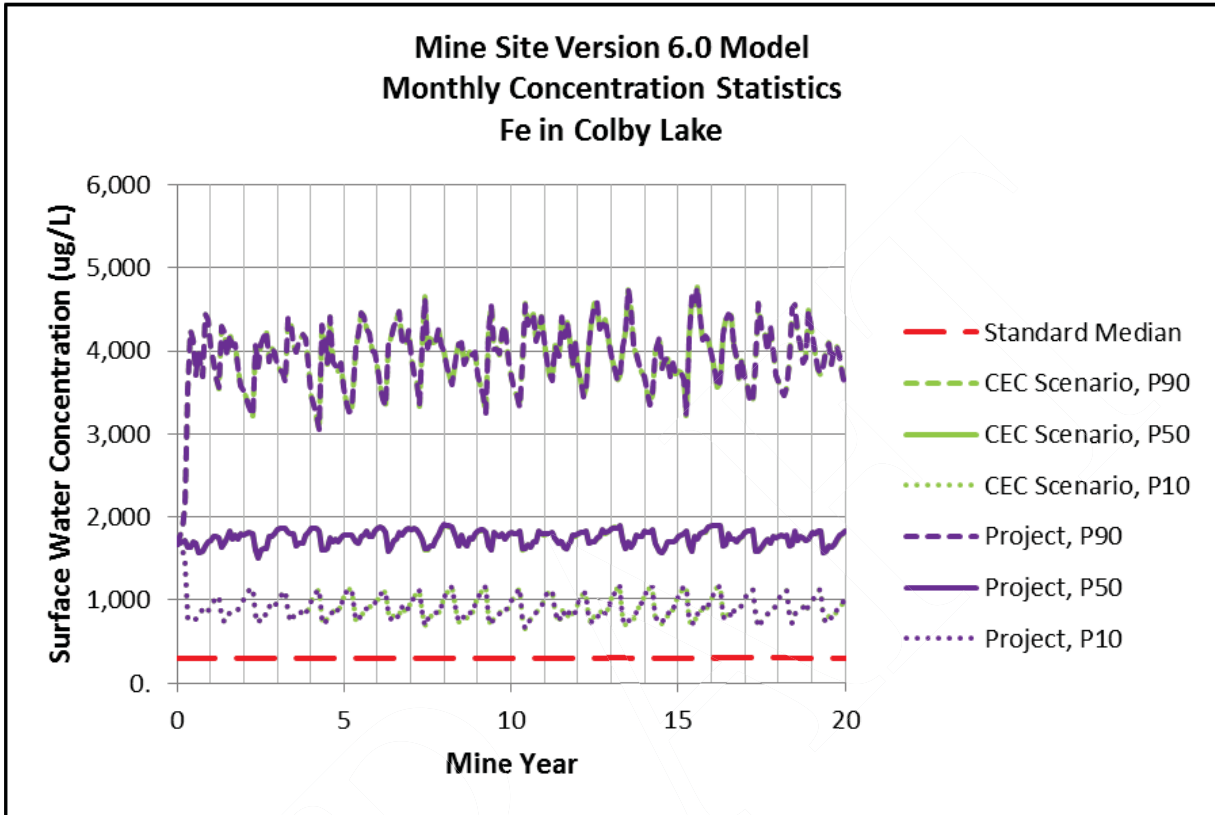

3040 Iron and Manganese

3041 Because Colby Lake is used as a drinking water source by the City of Hoyt Lakes, the USEPA  
3042 sMCL evaluation criteria apply: 300 µg/L for iron and 50 µg/L for manganese. Measured  
3043 background iron and manganese concentrations in Colby Lake are high and usually exceed their  
3044 respective evaluation criteria. Over 90 percent of the background iron samples exceed the iron  
3045 evaluation criteria and approximately 80 percent of the manganese samples exceed the  
3046 manganese criteria.

3047 As shown by bold font in the initial screening Table 5.2.2-35 for Colby Lake, the GoldSim-  
3048 predicted maximum P90 concentrations for iron and manganese exceed the applicable evaluation  
3049 criterion and therefore require further evaluation. Table 5.2.2-36 shows GoldSim-predicted  
3050 maximum P50 and maximum P90 concentrations for three NorthMet Project Proposed Action  
3051 phases; operations, reclamation, as well as closure and long-term maintenance. The following  
3052 observations are made from this table:

- 3053 • All maximum P50 and maximum P90 values for iron and manganese exceed the applicable  
3054 evaluation criterion for both the NorthMet Project Proposed Action and CEC scenarios.
- 3055 • For manganese, all maximum P50 and maximum P90 values for the NorthMet Project  
3056 Proposed Action are lower than the comparable CEC scenario. It is therefore concluded that  
3057 the NorthMet Project Proposed Action would not cause a manganese impact to Colby Lake  
3058 above and beyond what would occur without the NorthMet Project Proposed Action.
- 3059 • For iron, the maximum P50 and maximum P90 values for the NorthMet Project Proposed  
3060 Action are lower than the comparable CEC scenario for the reclamation phase and the  
3061 closure and long-term maintenance phase, but not for the operations phase. Iron for the  
3062 operations phase therefore requires further evaluation.

3063 Figure 5.2.2-38 is a plot of GoldSim-predicted monthly P10, P50, and P90 iron concentrations  
3064 for iron in Colby Lake during the operations phase (0 to 20 years). Inspection of this figure  
3065 shows that the P10, P50, and P90 lines for the NorthMet Project Proposed Action are either  
3066 identical or extremely close to the comparable lines for the CEC Scenario. Given this result and  
3067 the observations made in Table 5.2.2-36, it is concluded that the NorthMet Project Proposed  
3068 Action would not cause an iron impact to Colby Lake above and beyond what would occur  
3069 without the NorthMet Project Proposed Action.

3080

3081

3082 Arsenic

3083 As shown by bold font in Table 5.2.2-35, the maximum P90 concentration for arsenic in Colby  
3084 Lake (2.46 µg/L) exceeds the evaluation criterion for that constituent at that location (2 µg/L).  
3085 As a consequence, the GoldSim-predicted arsenic in Colby Lake was identified as requiring  
3086 further evaluation.

3087 GoldSim model output indicates that the dominating chemical controls on arsenic concentrations  
3088 in Colby Lake are natural surface runoff, natural groundwater baseflow, and contaminant sources  
3089 contributing directly to Colby Lake, all of which are not related to the NorthMet Project  
3090 Proposed Action. While much less important, other sources include Northshore discharge which  
3091 operates for mine years 0 to 55 and WWTF discharge to the Partridge River, which begins about  
3092 mine year 52.

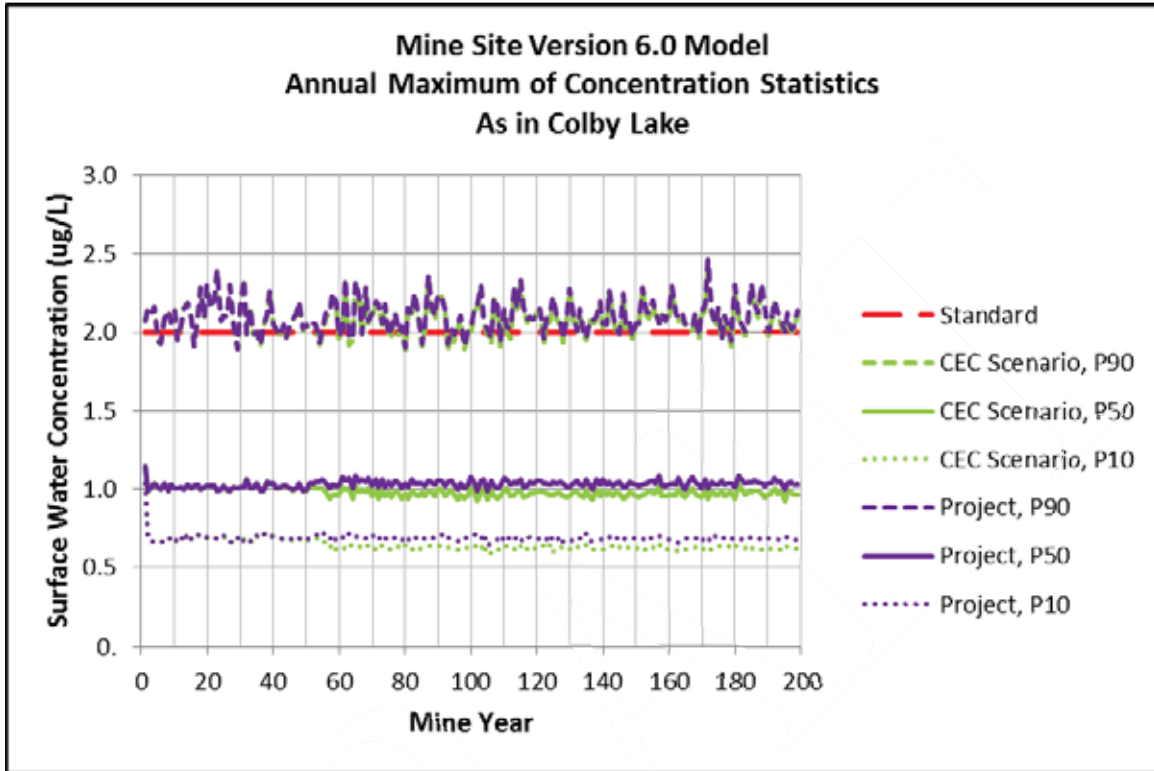

3093 To investigate the source and significance of arsenic exceedances in more detail, Figure 5.2.2-40  
3094 is a plot of the predicted P10, P50, and P90 of annual maximum arsenic concentrations for years  
3095 0 to 200 (purple lines). Also shown (in red) is the Colby Lake arsenic evaluation criterion of 2  
3096 µg/L. As observed on the plot, the NorthMet Project Proposed Action concentrations are  
3097 virtually identical to CEC concentrations up to mine year 52. After that time, the NorthMet  
3098 Project Proposed Action concentrations are slightly higher than the CEC concentrations;  
3099 however, the difference is less than about 0.05 mg/L. The slight increase in NorthMet Project  
3100 Proposed Action concentrations after year 52 results from the partially offsetting effects of: 1)  
3101 ending of low-concentration (1.33 µg/L) Northshore discharge to the Partridge River that  
3102 provides a dilution effect in the Lake and 2) the beginning of WWTF discharge to the Partridge  
3103 River with an arsenic concentration of 4 mg/L, which increases the arsenic concentration in the  
3104 Lake. This increase in loading from the WWTF is only partially offset by the decrease from the  
3105 cessation of the Northshore discharge, so the overall result is a slight increase in Colby Lake  
3106 arsenic after year 52. Also observed on Figure 5.2.2-40 is that only the annual maximum P90  
3107 concentrations exceed the standard.

3108 Figure 5.2.2-41 compares *monthly* P10, P50 and P90 concentrations with the evaluation criteria  
3109 for a representative time period after the beginning of mine-affected groundwater emerge in the  
3110 Partridge River. As can be seen on the graph, when the P90 concentrations are predicted to  
3111 exceed the standard (most notably during mine years 141 and 145), the NorthMet Project  
3112 Proposed Action concentrations are virtually identical to the CEC concentrations. An analysis of  
3113 other time periods showed a similar result. This observation indicates that for conditions where  
3114 the arsenic standard would be exceeded in Colby Lake, the NorthMet Project Proposed Action  
3115 would not cause higher concentrations compared to what would occur for CEC. It is therefore  
3116 concluded that the NorthMet Project Proposed Action would not cause arsenic exceedances in  
3117 Colby Lake above and beyond what would occur without the NorthMet Project Proposed Action.

3118 Finally, pilot testing of RO treatment concluded that arsenic is effectively removed by the  
3119 greensand filter producing filter effluent with arsenic concentrations that were well below the  
3120 Class 2B water quality standard for all three sampling events (Barr 2013f). Therefore, the  
3121 assumed modeled effluent concentrations of the WWTF may be higher than what would actually  
3122 be produced.

3131 **Figure 5.2.2-41 Colby Lake Monthly Arsenic Concentration Statistics**

3132 Whitewater Reservoir

3133 The NorthMet Project Proposed Action is predicted to have negligible effects on water quality in  
3134 Whitewater Reservoir because only high Partridge River flows would be diverted into the  
3135 reservoir from Colby Lake, which would coincide with the periods when any contaminants from  
3136 the NorthMet Project Proposed Action would be diluted and because the water quality of Colby  
3137 Lake is predicted to meet evaluation criteria, prior to dilution, except for the three parameters  
3138 (i.e., aluminum, iron, and manganese) that are explained above.

3139 **Water Quality Effects in the Lower Partridge River**

3140 Although not specifically modeled, water quality in the Lower Partridge River would be  
3141 expected to reflect the water quality condition of water flowing out of Colby Lake. As discussed  
3142 above, under the NorthMet Project Proposed Action Colby Lake water is predicted to meet all  
3143 water quality evaluation criteria other than for aluminum, arsenic, iron, and manganese, which  
3144 are attributable to natural background conditions. The contaminant load in flow from Colby Lake  
3145 attributable to the NorthMet Project Proposed Action would be further diluted downstream as the  
3146 watershed area increases. The NorthMet Project Proposed Action would not result in any new  
3147 surface water discharges (other than stormwater runoff from the processing plant area and  
3148 Second Creek flow augmentation) or groundwater seepage that would affect the water quality of  
3149 the Lower Partridge River that are not already accounted for in predicted upstream water quality.

3150 These contaminant loads from the NorthMet Project Proposed Action, however, could contribute  
3151 to cumulative effects in combination with contaminant loading from other projects. See Section  
3152 6.2.2.

3153 Surface water currently seeps at a rate of approximately 227 gpm from the existing LTVSMC  
3154 Tailings Basin to the headwaters of Second Creek. This seepage is currently partially blocked by  
3155 a cutoff berm and trench and collected in a sump and pumped back to the Tailings Basin pond.  
3156 Under the NorthMet Project Proposed Action, this seepage is predicted to continue during mine  
3157 operations (550 gpm), reclamation, and closure and long-term maintenance (80 gpm). The  
3158 NorthMet Project Proposed Action would install an engineered containment system south of the  
3159 Tailings Basin designed to ensure that 100 percent of the seepage is captured during operations  
3160 and closure and post-closure maintenance, this seepage would continue to be pumped to either  
3161 the Tailings Basin pond or the WWTP. To mitigate the reduction of flow to Second Creek, under  
3162 the NorthMet Project Proposed Action, WWTP effluent would be used to augment flow to  
3163 Second Creek in closure at a minimum flow rate equal to about 80 percent of the uncaptured  
3164 flow rate (or about 184 gpm). Since the effluent from the WWTP is designed to meet surface  
3165 water quality standards, this discharge is not expected to cause any exceedance of water quality  
3166 evaluation criteria.

3167 ***NorthMet Project Proposed Action Solute Contribution Over Time***

3168 The NorthMet Project Proposed Action is predicted to meet most groundwater and surface water  
3169 quality evaluation criteria at evaluation locations for all mine phases (operations, reclamation,  
3170 and closure and post-closure maintenance). There is value, however, in understanding how the  
3171 NorthMet Project Proposed Action would contribute to the solute load in the Partridge River  
3172 over time.

3173 The NorthMet Project Proposed Action would contribute contaminant loads to the Partridge  
3174 River from seven groundwater sources: Overburden Storage and Laydown Area, Ore Surge Pile,  
3175 Category 2/3 Stockpile, WWTF equalization basins, East Pit, West Pit, and the Category 1  
3176 Stockpile (which provides seepage to the West Pit and bedrock flowpaths). As shown in Table  
3177 5.2.2-37, four of these sources are temporary and would not be present during closure. The  
3178 loadings from these features would not occur after the feature is removed and the associated peak  
3179 concentrations in groundwater reaching the Partridge River would occur before 200 years. The  
3180 East Pit, West Pit, and Category 1 Stockpile are permanent features that would continue to  
3181 provide contaminant loading for a minimum of 200 years. Also contributing contaminant loads  
3182 to the Partridge River would be the WWTF effluent discharge, which would continue to operate  
3183 during closure and post-closure maintenance.

3185 **Table 5.2.2-37 Estimated Times for Affected Water to Reach the Partridge River**

| Source                                                                   | Flow Rate from Source into Surficial GW Flowpath <sup>3</sup> (gpm) | Time Period that Source is Active <sup>3</sup> (Mine Year) | Time for Peak Loading at Partridge River <sup>4</sup> (Mine Year) |
|--------------------------------------------------------------------------|---------------------------------------------------------------------|------------------------------------------------------------|-------------------------------------------------------------------|
| Overburden Storage and Laydown Area                                      | 14.0                                                                | 0 to 20                                                    | 60 <sup>(1)</sup>                                                 |

<sup>4</sup> Based on P50 results for GoldSim probabilistic run.

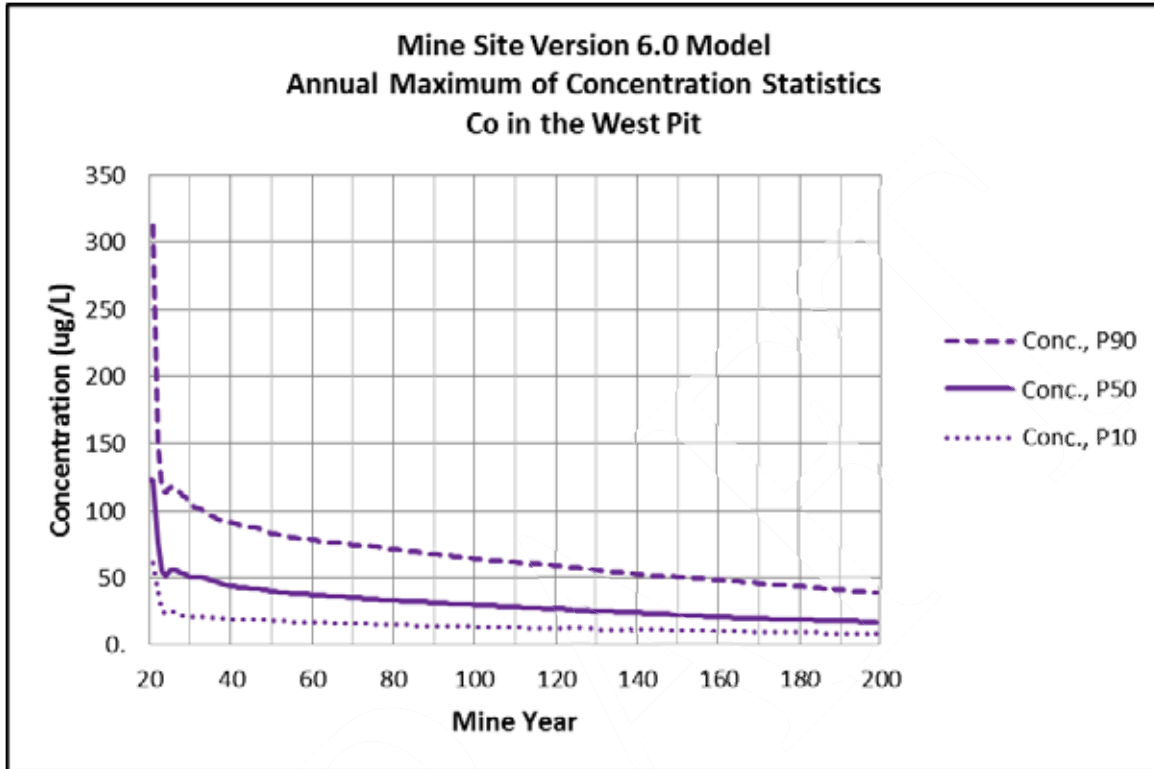

3186  
 3187  
 3188  
 3189

3190 GW = Groundwater

3191 The backfilled East Pit, Category 1 Stockpile, and flooded West Pit would be the only permanent  
 3192 mine features and would continue to contribute solute load to the surficial aquifer that eventually  
 3193 releases to the Partridge River. The small volume of seepage from the Category 1 Stockpile that  
 3194 would not be captured by the containment system would contribute solutes to the West Pit. This  
 3195 seepage would be expected to reduce in quantity over time as the Category 1 Stockpile  
 3196 geomembrane and vegetative cover is established, although concentrations are not expected to  
 3197 improve because most solutes are at their concentration caps.

3198 Under the NorthMet Project Proposed Action, the water levels would be controlled by water  
 3199 pumped to the WWTF for treatment. The WWTF is considered a long-term facility that would  
 3200 require ongoing maintenance.

3201 The water quality of both mine pits, however, is predicted to improve over time as the pits  
 3202 become flooded, thereby effectively eliminating oxidation of the pit walls, the primary source of  
 3203 solutes, except for the upper few feet where water levels may fluctuate. Figures 5.2.2-42,  
 3204 5.2.2-43, and 5.2.2-44 show how the water quality in the West Pit is predicted to improve over  
 3205 time for three representative solutes: cobalt, nickel, and sulfate. It is expected that eventually the  
 3206 solute concentrations in the pits would stabilize to more or less steady-state values, although the  
 3207 timeframe for this would likely be greater than 200 years as indicated by Figures 5.2.2-42 to  
 3208 5.2.2-44, which show solute concentrations continuing to decrease at year 200, although still  
 3209 above water quality standards. These predicted improvements in water quality suggest that the  
 3210 WWTF may not need to operate permanently, but that at some point, non-mechanical treatment  
 3211 systems may be sufficient to meet water quality based effluent limits.

3224 **Post-Closure Maintenance**

3225 The only long-term sources of solutes from the NorthMet Project Proposed Action would be  
3226 groundwater seepage from the East Pit and West Pit (which includes Category 1 Stockpile  
3227 seepage), with a combined total flow rate of about 10 gpm and the WWTF effluent discharge of  
3228 about 290 gpm.

### 3229 Mine Site Sensitivity Analyses

3230 The sensitivity of the GoldSim Model was evaluated for changes to groundwater baseflow rates  
3231 and climate change to determine what effect they have on model predictions. The following  
3232 sections summarize the sensitivity analysis findings for the Mine Site.

### 3233 Groundwater Baseflow Sensitivity Analysis

3234 Groundwater baseflow calculated from the data collected at SW-003 beginning from 2011 is up  
3235 to 3.5 times higher than values used in the Mine Site MODFLOW baseline model and assumed  
3236 in the Mine Site GoldSim probabilistic model simulations. Although this new value is not  
3237 considered representative of the long-term, average groundwater baseflow, a sensitivity analysis  
3238 was carried out to evaluate how changing the value of groundwater baseflow as a target in the  
3239 model calibration influences its predictions (note: “target” is a value the model is calibrated to).

3240 As part of that sensitivity analysis, the Mine Site MODFLOW baseline model was recalibrated  
3241 using groundwater baseflow about four times higher than in the baseline model (e.g., it was  
3242 increased from 0.5 to 2 cfs at SW-003). Recognizing the purpose of the sensitivity analysis is to

3243 evaluate the impacts of different groundwater baseflow values, the Co-lead Agencies  
3244 accomplished chose a hypothetical maximum flow derived in part from the gage SW- 003 at  
3245 Dunka Road. The suggested value for this purpose is 2.0 cfs, which is slightly higher than the 1.8  
3246 cfs low-flow value determined by the MDNR using hydrograph separation for the December  
3247 2011 to March 2012 winter period. The recalibration was accomplished by increasing hydraulic  
3248 conductivity and aquifer recharge, as compared to the groundwater baseflow calibration.  
3249 Relative to the FEIS base modeling, the new, higher baseflow MODFLOW model version  
3250 simulates:

- 3251
- Faster groundwater movement;
  - Slightly higher groundwater inflow rates into the West Pit and associated faster pit flooding and
  - Moderately higher groundwater inflow rates into the East Pit and associated faster backfill saturation (Barr 2015d, Appendix K).

3252

3253

3254

3255

3256 The recalibrated MODFLOW model sensitivity version does not predict a groundwater flow rate  
3257 between the Central and West Pit via bedrock that is significantly different from the predictions  
3258 of the baseline model.

3259 To develop water quality predictions, the results of the recalibrated MODFLOW model  
3260 simulations were used as inputs to the new, higher baseflow version of the GoldSim model.  
3261 Because the adjustment of the estimated groundwater baseflow in the Partridge River changes  
3262 the ratio of groundwater to surface water runoff in the river, the calibration process for  
3263 determining distributions for surface water quality was repeated for this sensitivity analysis as  
3264 well.

3265 Results of the GoldSim groundwater baseflow high rate scenario were compared with the best-  
3266 estimate scenario to evaluate the degree to which predicted the NorthMet Project Proposed  
3267 Action impacts are sensitive to baseflow and other related model inputs.

3268 Results from the FEIS Goldsim model run predicts that higher peak contaminant concentrations  
3269 would occur sooner than predicted by a baseline model for some constituents. However, these  
3270 peaks remain below evaluation criteria for most parameters. Those simulation results show that,  
3271 although the estimated concentrations in the groundwater and surface water are sensitive to the  
3272 assumed value of baseflow, the NorthMet Project Proposed Action's ability to comply with the  
3273 applicable groundwater and surface water quality standards is not.

3274 The comparison of the baseline and new version (higher baseflow) models indicate that the  
3275 increased contaminant loadings at the upgradient end of the flowpaths (due to higher  
3276 groundwater flow rates) are offset by: (1) increased dilution from recharge water along the  
3277 flowpath, and (2) increased dilution in the river from higher baseflows during winter low-flow  
3278 conditions. In other words, for low (i.e., winter) streamflow conditions, the higher contaminant  
3279 mass loading into the river was offset by dilution associated with the higher river groundwater  
3280 baseflows.

3281 Despite a conservative nature of this high baseflow version of the GoldSim model, its predicted  
3282 contaminant concentrations remain below the applicable groundwater and surface water quality  
3283 evaluation criteria (Barr 2015d, Appendix K).

3284 This sensitivity analysis indicates that the Mine Site GoldSim model is relatively insensitive to  
3285 changes in the Partridge River groundwater baseflow variable. By analogy, it is considered that  
3286 the Plant Site GoldSim model is also insensitive to changes in groundwater baseflow in the  
3287 Embarrass River variable.

### 3288 ***Climate Change Sensitivity Analysis***

3289 The potential effects of a climate change upon the predictions of a GoldSim probabilistic model  
3290 (the Project Model) were evaluated by running the “climate change sensitivity analysis”. The  
3291 ranges of precipitation and temperature input parameters were varied following the guidance  
3292 provided by Co-Lead Agencies (Kellogg 2011). In summary, the Climate Change Sensitivity  
3293 Analysis Model was set by increasing: 1) the mean annual temperature by 2.0 to 5.2 degrees  
3294 Celsius, 2) the mean annual precipitation from 28.1 to 29.8 in/yr, and 3) the mean annual open  
3295 water evaporation by 6.5 percent. The parameter values were linearly increased from mine year 1  
3296 to mine year 60 and, then, were kept constant. Such modified model was used to run 200-year  
3297 predictive simulations, similar to the Project Model.

3298 The impacts of the modeled changes upon chemical concentrations in the East Pit pore water and  
3299 West Pit Lake were analyzed for lead, sulfate, copper, and iron. The simulation results showed  
3300 that the greatest changes would occur during closure and long-term maintenance (approximately  
3301 mine year 45 and beyond). Lead concentrations in East and West Pits would change very little.  
3302 The largest increase in sulfate concentration of 10.3 percent would occur in the East Pit wetland,  
3303 but would change little outside of that wetland. The pattern of simulated changes in  
3304 concentration for copper is similar to sulfate with the maximum change of 15 percent for the East  
3305 Pit wetland. No significant changes in iron concentrations were simulated for any part of the  
3306 modeled domain (Barr 2015d).

3307 Climate change would affect water quality in the stock pile drainage in similar ways to the mine  
3308 pit water. The largest simulated change concentration was 5.1 percent for lead, 0.9 percent for  
3309 sulfate, 0.3 percent for copper, and 0.2 percent for iron.

3310 The changes in dewatering volumes for the Pits were simulated to be very small, the largest for  
3311 the period of closure and long-term maintenance: 5.2 gpm. Likewise, the simulated changes in  
3312 leakage flows from the stockpiles were very small.

3313 The rates of flow from the Pits to aquifers and contaminant concentrations in groundwater were  
3314 not much affected by the simulated climate change. Surface water quality also did not change  
3315 much. There is likely to be an increase in the amount of water that would need to be treated by  
3316 the WWTF.

### 3317 **5.2.2.3.3 Embarrass River Watershed**

3318 This section discusses potential environmental effects of the NorthMet Project Proposed Action  
3319 on groundwater and surface water hydrology and quality within the Embarrass River watershed.  
3320 The solute-generating NorthMet Project Proposed Action features in the Embarrass River  
3321 Watershed are the Tailings Basin, the WWTP discharge, the Hydrometallurgical Residue  
3322 Facility, and (much less significantly) domestic sewage treatment systems and/or potable water  
3323 treatment backwash systems. These potential hydrologic and contaminant sources and their  
3324 predicted effects on groundwater and surface water hydrology and quality are evaluated below.

3325 PolyMet expects that the Hydrometallurgical Plant would begin operation between mine years 3  
3326 to 5. Residue would be transported to the Hydrometallurgical Residue Facility as a mixture of  
3327 solids and water. The solids would settle out into the Hydrometallurgical Residue Facility, and  
3328 the water would be returned to the Hydrometallurgical Plant for reuse. However, losses would  
3329 occur during processing and through evaporation or storage within the pores of the deposited  
3330 residue. The discharge from the Hydrometallurgical Plant to the pond is expected to be a  
3331 constant 223 gpm through operations. Average annual flows from the Hydrometallurgical  
3332 Residue Facility to the Hydrometallurgical Plant during operations range from 182 to 219 gpm  
3333 (PolyMet 2015i). Precipitation falling within the drainage area of the Hydrometallurgical  
3334 Residue Facility pond would be managed as process water.

3335 The design of the Hydrometallurgical Residue Facility is based on State of Minnesota Rule  
3336 requirements, expected residue generation rates, hydrology within the Hydrometallurgical  
3337 Residue Facility, geotechnical considerations and Hydrometallurgical Residue Facility operating  
3338 plans. Additional design considerations include the potential for water treatment plant solids  
3339 (gypsum) to be disposed of within the Hydrometallurgical Residue Facility and the relocation of  
3340 coal ash from the existing closed Coal Ash Landfill near the Tailings Basin. PolyMet 2014c).

3341 The Hydrometallurgical Residue Facility would have a double geomembrane liner with a  
3342 leachate collection system between the liners. The upper liner would consist of an 80-mil Linear  
3343 Low Density Polyethylene geomembrane. This liner would serve as the primary barrier to  
3344 leakage from the Hydrometallurgical Residue Facility. Its thickness was selected by PolyMet for  
3345 durability and to resist ice impacts in the event of any temporary shutdowns of the  
3346 hydrometallurgical process in winter months. The leakage collection layer would consist of a  
3347 continuous layer of Geocomposite Drainage Net. The leakage collection layer would collect any  
3348 leakage that passes through defects in the upper liner. The leakage collection layer is included in  
3349 the liner system because even with application of industry-standard quality control procedures  
3350 during installation of the upper liner, some installation defects can remain. The leakage  
3351 collection layer directs leakage to a sump which then pumps it back to the Hydrometallurgical  
3352 Residue Facility pond. The lower liner would consist of 60-mil Linear Low Density or High  
3353 Density Polyethylene above a Geosynthetic Clay Liner. The lower composite liner would  
3354 provide a virtually leak-free barrier to prevent leakage that may pass through the upper liner  
3355 from leaving the Hydrometallurgical Residue Facility (PolyMet 2014c).

3356 The amount of water pumped from the leak collection system would be monitored on a long-  
3357 term basis. For this reason, if the amount of pumpage were to increase or if there were any other  
3358 indications of increased leakage, appropriate repairs and mitigation measures would be  
3359 undertaken. For these reason, it is assumed for purposes of the FEIS that the leakage from this  
3360 facility into underlying groundwater or adjacent surface water would be negligible and therefore  
3361 is not further evaluated. Details on the design and operation of this facility are in Chapter 3. A  
3362 detailed Residue Management Plan for this facility would be required during permitting  
3363 (PolyMet 2014r).

### 3364 **Effects on Groundwater Hydrology**

3365 This section discusses the environmental consequences of the NorthMet Project Proposed Action  
3366 on groundwater hydrology within the Embarrass River Watershed, specifically from the Tailings  
3367 Basin and associated engineering controls. There are no other NorthMet Project Proposed Action  
3368 area facilities within the Embarrass River Watershed that would affect groundwater hydrology.

3369 As discussed in Chapter 3, PolyMet proposes to re-use the existing LTVSMC Tailings Basin.  
3370 Seepage from the existing LTVSMC Tailings Basin has decreased since LTVSMC operations  
3371 ended in 2001, reaching a current steady state of approximately 2,820 gpm with 2,590 gpm  
3372 migrating within the Embarrass River Watershed. Once the seepage reaches the toe of the  
3373 Tailings Basin, it divides between flow that remains as groundwater (referred to as groundwater  
3374 seepage) and flow that exceeds the hydraulic capacity of the aquifer and upwells to the surface  
3375 (referred to as surface seepage). Under existing conditions, about 200 gpm of Tailings Basin  
3376 seepage remains as groundwater and about 2,390 gpm upwells to the surface and ultimately  
3377 contributes to surface water flow in the Embarrass River. The Tailings Basin seepage reaches the  
3378 Embarrass River via its tributaries (Mud Lake Creek, Trimble Creek, and Unnamed Creek) and  
3379 by flow through wetlands. On the southern side of the Tailings Basin, most of the seepage is  
3380 collected and returned to the Tailings Basin. Some of this seepage is not captured and migrates to  
3381 the Second Creek, a tributary of the Partridge River (PolyMet 2015j).

3382 Groundwater seepage from the Tailings Basin flows in three flowpaths to the Embarrass River  
3383 identified as the north, northwest, and west flowpaths (see Figure 5.2.2-9). On the eastern side of  
3384 the Tailings Basin, because of the presence of bedrock outcrops, natural groundwater flow is  
3385 toward the Tailing Basin. Essentially all of the groundwater that flows south toward Second  
3386 Creek in the Partridge River Watershed would be captured and pumped back into the Tailings  
3387 Basin.

3388 The addition of tailings and changes in water management due to the NorthMet Project Proposed  
3389 Action would result in increased seepage from the Tailings Basin relative to existing legacy  
3390 LTVSMC seepage. As Table 5.2.2-38 indicates, seepage is predicted to increase from the current  
3391 approximately 2,820 gpm to a maximum of 3,880 gpm during operations. Most of this seepage  
3392 would travel to the north, northwest, and west of the Tailings Basin and could affect groundwater  
3393 levels in those areas.

3394 **Table 5.2.2-38 Tailings Basin Seepage**

| TB Toe             | Continuation of Existing Conditions |               |                      |                   | Maximum Rates for Mine Years 0–25 <sup>(1)</sup> |               |                        |                       | Long-Term Maintenance  |            |               |                   |                       |                   |

3406

DRAFT

3407 The NorthMet Project Proposed Action would increase Tailings Basin seepage rates by 1,060  
3408 gpm. The hydraulic capacity of the surficial aquifer would not change. This increase in  
3409 upwelling could have a significant effect on downgradient wetlands and waterways. Therefore,  
3410 PolyMet proposed that the containment system would wrap around the northeastern, northern,  
3411 western, and eastern sides of the Tailings Basin. This system is designed to capture 100 percent  
3412 of the surface seepage and 100 percent of the groundwater seepage, but is conservatively  
3413 modeled to collect 100 percent of surface seepage and only 90 percent of the groundwater  
3414 seepage on the northern, northwestern, and western sides to account for imperfect construction of  
3415 the cutoff wall at the bedrock (see Figure 5.2.2-14 and Figure 5.2.2-15). As Table 5.2.2-37  
3416 indicates, the net effect of the containment system would be to decrease groundwater seepage  
3417 from the Tailings Basin downgradient of the containment system from approximately 200 to 20  
3418 gpm. This decrease in groundwater seepage would be mitigated by a proposed flow  
3419 augmentation program, which is described later in this section.

3420 As Table 5.2.2-38 indicates, seepage from the Tailings Basin to the Embarrass River watershed  
3421 is predicted to decrease from the estimated current rate of 2,820 gpm to about 1,620 gpm at  
3422 closure under the NorthMet Project Proposed Action (about a 42 percent decrease). The surface  
3423 and groundwater seepage containment system would remain in place, which would capture all  
3424 but an estimated 20 gpm of Tailings Basin seepage. The decrease in groundwater seepage would  
3425 not be expected to have a significant effect on groundwater or wetlands downgradient of the  
3426 surface and groundwater seepage containment system because of the proposed flow  
3427 augmentation, which would maintain hydrology within  $\pm 20$  percent of existing conditions.  
3428 There would be sufficient natural recharge to maintain saturation in the surficial (unconsolidated)  
3429 unit. The effects of the containment system on surface water hydrology are discussed later in this  
3430 section.

### 3431 **Effects on Groundwater Quality**

3432 The NorthMet Project Proposed Action could affect surficial groundwater quality within the  
3433 Embarrass River Watershed by leaching metals, sulfate, and other solutes from the NorthMet  
3434 Tailings Basin. However, current conditions at the Tailings Basin are already affecting the  
3435 groundwater. The following two paragraphs offer a summary comparison between the current  
3436 conditions and the conditions projected to take effect as a result of the NorthMet Project  
3437 Proposed Action.

### 3438 ***Current Conditions***

3439 Under current conditions, the seepage emerging from the LTVSMC Tailings Basin at its  
3440 northern, northwestern, and western toes feeds groundwater (at a rate of about 200 gpm) and  
3441 surface waters at a rate of about 2,390 gpm). All the seepage-affected groundwater and surface  
3442 water migrates to the Embarrass River via its tributaries, through wetlands and via migration  
3443 along the northern, northwestern, and western groundwater flowpaths (see Figure 5.2.2-9).  
3444 Tailings seepage from its southern toe is collected and returned to the Tailings Basin, such that  
3445 this seepage does not affect the environment. Groundwater flows toward the Tailings Basin at its  
3446 eastern toe, so the seepage in that part of the toe does not affect the environment either.

3447 ***Proposed NorthMet Project Proposed Action Conditions***

3448 The only untreated Tailing Basin water entering the surrounding environment would be  
3449 groundwater by passing the northern, northwestern, and western parts of the containment system  
3450 at a rate of 20 gpm. This 20 gpm represents a conservative engineering assumption (actual rate  
3451 may be lower). This signifies a 90 percent reduction of the groundwater flow rates occurring  
3452 under current conditions (20 gpm vs. 180 gpm). Most of the seepage-affected groundwater  
3453 bypassing the containment system would flow along the north, northwest, and west flowpaths  
3454 towards the Embarrass River and would affect downgradient groundwater quality (see Figure  
3455 5.2.2-9).

3456 ***Effects on Groundwater Quality***

3457 Several sources would contribute solutes to the Tailings Basin, including both the existing  
3458 LTVSMC tailings and NorthMet Project Proposed Action tailings themselves, Mine Site process  
3459 water (which could be pumped to the Tailings Basin through year 11, and possibly through year  
3460 20 depending on the NorthMet Project Proposed Action water budget), Colby Lake makeup  
3461 water, and a negligible amount of watershed runoff.

3462 The contribution from the Mine Site (to the Tailings Basin's water quality) would be influenced  
3463 by the predictions of stockpile leachate and mine pit water quality and the ability of the WWTF  
3464 to achieve design effluent concentrations prior to pumping to the Tailings Basin.

3465 Some solutes can be released from tailings by direct dissolution of minerals, but solutes of  
3466 concern are primarily released by oxidation of sulfide minerals in the tailings. The oxidation rate  
3467 in tailings, and thus the rate of solute release, is typically limited by the rate that atmospheric  
3468 oxygen can diffuse into the facility. The diffusion of oxygen and the rate of oxidation and  
3469 associated solute release would depend strongly on the tailing's moisture content, where higher  
3470 moisture content corresponds to lower rates of oxygen diffusion and associated oxidation and  
3471 contaminant release. Thus, the unsaturated tailings in the embankment and beach areas are  
3472 expected to have higher oxidation rates than the saturated tailings below the pond.

3473 Laboratory testing indicated that average sulfur concentration in the NorthMet tailings would be  
3474 0.12 percent, which is low enough to ensure that the tailings would not produce acidic leachate.  
3475 Pore water metal concentrations could increase dramatically if pH were to decrease, especially  
3476 for nickel and cobalt (SRK 2007c). The oxyanions (arsenic, antimony, and selenium), however,  
3477 tend to have increasing solubility with higher pHs.

3478 Testing of tailings containing 0.2 percent sulfur by the MDNR from the nearby Babbitt prospect  
3479 within the Duluth Complex did not result in acidic leachate because silicate weathering was  
3480 sufficient to neutralize the acid produced. Humidity cell test results for NorthMet Project  
3481 Proposed Action tailings have tended to support the research by the MDNR and the results from  
3482 the Babbitt Deposit (Day 2008). Leachate showed an initial decline in pH, but has subsequently  
3483 remained between 6.0 and 7.8 with no trend toward lower pHs.

3484 Solutes released by oxidation (primarily sulfate and metals) would be mobilized and flushed  
3485 from the tailings by percolating water. The rate of percolation would depend on the net  
3486 infiltration of meteoric water at the tailing's surface and the rate of pond leakage. The seepage  
3487 from the NorthMet Project Proposed Action tailings would pass through the underlying existing  
3488 LTVSMC tailings (i.e., previous taconite tailings). These underlying tailings may attenuate to

3489 some extent the metals leached from the NorthMet Project Proposed Action tailings, or may  
3490 contribute additional solutes to seepage, or both.

3491 The Tailings Basin pond would receive 1) treated Mine Site process water (during mine  
3492 operations); 2) tailings slurry water from Processing Plant (during mine operations); 3) captured  
3493 untreated seepage from Tailings Basin's toes; 4) rainfall, snowmelt, and local storm runoff; 5)  
3494 filtered backwash from the WWTP; 6) sewage treatment effluent; and 7) treated water from  
3495 WWTP.

3496 The Tailings Basin pond, in turn, would become a primary source of contaminants due to the  
3497 pond's infiltration into the tailings. Therefore, the chemical composition of the Tailings Basin's  
3498 pond water (becoming a permanent feature of the Tailings Basin) would be an important  
3499 influence upon the quality of water that would be discharged from the WWTP and seep from the  
3500 Tailings Basin.

3501 Consequently, PolyMet proposes to use the WWTP to treat the pond water during reclamation,  
3502 and as necessary during closure, to improve the pond's water quality. The presence of the pond  
3503 in closure would provide benefits as it would create a saturated layer that would permanently  
3504 reduce oxygen diffusion and associated solute release in the underlying tailings.

### 3505 ***Engineering Controls***

3506 The LTVSMC Tailings Basin is not lined. Several tailings and water management options were  
3507 considered in the development of the NorthMet Project Proposed Action (Chapter 3 alternatives  
3508 section). The NorthMet Project Proposed Action does not include a liner for the Tailings Basin. .  
3509 In lieu of a liner, PolyMet proposes the following engineering controls to reduce the release and  
3510 transport of solutes from the Tailings Basin (see Figure 5.2.2-22):

- 3511 • Collection of Tailings Basin's seepage by surface and groundwater seepage containment  
3512 system;
- 3513 • Installation of bentonite amendment of the existing tailings dam to reduce infiltration;
- 3514 • Installation of bentonite amendment of the Tailings Basin's beaches to reduce infiltration and  
3515 oxygen diffusion into Tailings;
- 3516 • Installation of bentonite amendment of pond bottom to reduce leakage into Tailings; and
- 3517 • Mechanical treatment of the collected tailings seepage and pond water by the WWTP.

### 3518 ***Tailings Basin Containment System***

3519 The containment system would be installed prior to plant operations and would consist of a  
3520 surface water and groundwater collection system along the outside perimeter of the Tailings  
3521 Basin where seepage has the potential to enter the surficial aquifer (see Figure 3.2-28). The  
3522 design includes a hydraulic barrier (cutoff wall) that would be keyed into bedrock, and a  
3523 collection trench and drain pipe installed on the upgradient side (see Figure 5.2.2-14 and 5.2.2-  
3524 15). Above the hydraulic barrier would be a berm to stop surface seeps from leaving the site. The  
3525 trench and piping would convey the collected seepage to several pumping stations, which would  
3526 pump the seepage during operations to either the Tailings Basin pond for re-use, or to the  
3527 WWTP for treatment prior to discharge. The containment system would continue to operate  
3528 during reclamation, and closure and long-term maintenance, although in those phases, the

3529 seepage could not be re-used as process water, but would be treated at the WWTP and used to  
3530 accelerate filling of the West Pit (during reclamation) and for streamflow augmentation (during  
3531 reclamation and closure). Figure 5.2.2-14 illustrates the functioning of the proposed containment  
3532 systems along the north-, northwest-, and west toes, while Figure 5.2.2-15 shows the functioning  
3533 of the systems at the east toe. It is designed to capture all of the Tailings Basin groundwater and  
3534 surface water seepage, the containment system is assumed for purposes of impact evaluation to  
3535 capture:

- 3536 • 100 percent of the Tailings Basin's surface seepage;
- 3537 • 100 percent of the groundwater approaching the containment system from the Tailings  
3538 Basin's east and south toes; and
- 3539 • 90 percent of the groundwater approaching the containment systems from the Tailings  
3540 Basin's north, northwest and west toes (PolyMet 2015d).

3541 During operations, the maximum flows collected by the containment system would be 3,680  
3542 gpm originating as surface seepage and 180 gpm as groundwater seepage. During closure, the  
3543 collection rates would be 1,420 gpm of surface seepage and 180 gpm of groundwater seepage.

#### 3544 Wastewater Treatment Plant

3545 PolyMet proposes a WWTP to treat the Tailings Basin pond's water and tailings seepage  
3546 collected by the surface and groundwater seepage containment systems. The WWTP would treat  
3547 water throughout the entire mine life (operations, reclamation, and closure and long-term  
3548 maintenance). The WWTP would treat all Tailings Basin seepage except the small quantity  
3549 (approximately 20 gpm on average) that would bypass the containment systems. The WWTP  
3550 would discharge treated effluent to augment streamflow during operations. During reclamation,  
3551 some WWTP effluent would be pumped to the West Pit to accelerate its flooding. The level of  
3552 water treatment at the WWTP would be sufficient to meet surface water evaluation criteria.

#### 3553 Bentonite-amended Tailings Cover

3554 For the NorthMet Project Proposed Action during operations, PolyMet would cover the tailings  
3555 dam embankments with a 12-inch-thick bentonite-amended soil layer, as allowed by construction  
3556 activities. On top of the bentonite-amended layer would be an 18-inch-thick vegetated soil cover.  
3557 After operations cease in year 20, PolyMet would place a similar two-layer cover on top of the  
3558 dry tailings beaches. The objective of the cover system would be to 1) reduce infiltration of  
3559 meteoric water and 2) maintain the bentonite layer at a high saturation to limit oxygen diffusion  
3560 into the tailings.

#### 3561 Bentonite-amended Pond Bottom

3562 PolyMet would also place a bentonite layer at the bottom of the tailings pond to reduce  
3563 downward leakage of pond water into the tailings. The thickness and effective hydraulic  
3564 conductivity of the bentonite layer would be designed to achieve a pond seepage flux of 6.5 in/yr  
3565 or less.

3566 ***Groundwater Transport and Evaluation Locations***

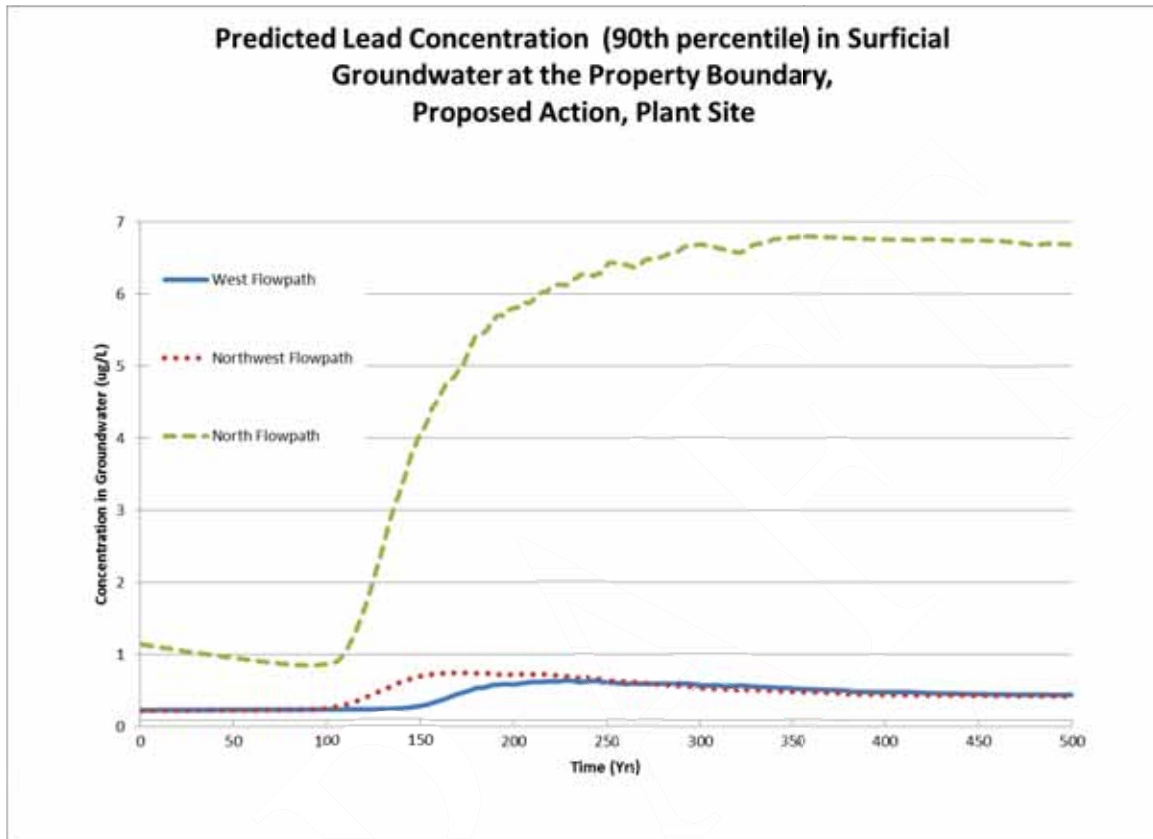

3567 Groundwater flow and solute transport away from the Tailings Basin towards the Embarrass  
3568 River is tracked in three groundwater surficial flowpaths: north, northwest, and west (see Figure  
3569 5.2.2-9). Within each flowpath there is a groundwater evaluation location, coincident with the  
3570 property boundary, along which predicted solute concentrations are compared to the groundwater  
3571 evaluation criteria to assess potential effects. Because solute effects on surface water are of  
3572 interest, the solute concentrations at locations where groundwater releases to surface water  
3573 (generally at or close to the Embarrass River) are also tracked in the model because it helps to  
3574 interpret the surface water chemistry in the Embarrass River and its tributary streams.

3575 For the North, Northwest, and West Surficial flowpaths, the time at which contaminants leached  
3576 from the Tailings Basin would begin to affect water quality at their respective evaluation  
3577 locations depends on the following variables:

- 3578 • The amount of affected water that would seep past the Tailings Basin containment system.  
3579 GoldSim conservatively assumes that 10 percent of the approaching groundwater would  
3580 bypass the system and this would begin at time zero. Note that the analysis assumes that all  
3581 tailings surface seepage is captured. The rate at which contaminants would move in  
3582 groundwater would be the same as the groundwater seepage velocity downgradient of the  
3583 containment system for all but four constituents (arsenic, antimony, copper, and nickel).  
3584 Because no attenuation values are used for the constituents other than arsenic, antimony,  
3585 copper, and nickel—the modeled rate of groundwater transport would be faster than the actual  
3586 rate of transport in the ground. Note that this velocity would increase in the downgradient  
3587 direction due to meteoric recharge that would add flow to the groundwater system. Transport  
3588 of the four attenuated constituents would be 10 to 100 times slower than the groundwater  
3589 flow because of sorption.
- 3590 • The distance between the location of solute release (Tailings Basin containment system) and  
3591 the flowpath evaluation location.
- 3592 • The effects of hydrodynamic dispersion, which tends to spread out the leading edge of the  
3593 solute plume.

3594 To ensure that the water quality modeling would identify the potential effects on groundwater  
3595 and surface water, a 500-year GoldSim probabilistic (Monte Carlo) simulation was performed.  
3596 Lead was used to illustrate groundwater transport at the Plant Site because it is not attenuated  
3597 and would enter the surficial flowpaths at concentrations higher than baseline groundwater. As a  
3598 consequence, the movement of solute fronts associated with this constituent is readily discernible  
3599 on concentration-versus-time and concentration-versus-distance plots for the modeled flowpaths.  
3600 Transport of other non-attenuated solutes should be similar to lead, but the change in  
3601 concentrations is not always as visually noticeable as it is for lead. Based on the GoldSim results,  
3602 P90 lead concentrations at the evaluation locations and at locations where groundwater would  
3603 release to surface water are shown on Figures 5.2.2-45 and 5.2.2-46, respectively.

3608

3609

3610 **Figure 5.2.2-46 Predicted P90 Lead Concentrations at the Locations of Groundwater**  
3611 **Release to Surface Water Based on the GoldSim Probabilistic Simulation for the Plant Site**

3612 **Surficial Groundwater Quality at the Evaluation Locations**

3613 Results of a 500-year GoldSim water quality modeling simulation were reviewed for all 29  
3614 solutes at all three surficial flowpath evaluation locations. A screening process was used to  
3615 identify any constituents and locations that warranted a more robust examination because of  
3616 potential exceedances of water quality evaluation criteria. That process involved comparing the  
3617 maximum P90 water quality prediction from among the 5,988 months covered by the simulation  
3618 (i.e., 12 months times 499 years, with the first year of simulation excluded for screening review  
3619 due to potential numerical artifacts in the model results) for each constituent at each of the three  
3620 evaluation locations. These NorthMet Project Proposed Action modeled values were compared  
3621 with both CEC Scenario modeled values and the evaluation criteria (discussed previously). Each  
3622 contaminant that was identified as exceeding the numerical evaluation criteria was then  
3623 evaluated in more detail to understand the details and context of the potential exceedance.

3624 Table 5.2.2-39 presents the maximum P90 values for the NorthMet Project Proposed Action  
3625 Scenario and the CEC Scenario in comparison with the groundwater evaluation criteria. Figure  
3626 5.2.2-47 illustrates the range of model predictions for each solute (minimum P10 to maximum  
3627 P90 values) over the 500-year simulation. Figure 5.2.2-48 illustrates the relative difference  
3628 between the NorthMet Project Proposed Action and CEC Scenarios. If the values were the same,  
3629 the relative change ratio would be 1; values greater than 1 indicate that the NorthMet Project  
3630 Proposed Action would result in higher solute concentrations compared to the CEC Scenario.  
3631 Conversely, values less than 1 indicate that the NorthMet Project Proposed Action would result  
3632 in lower solute concentrations than the CEC Scenario.

3633

DRAFT

3637 Bold faced numbers exceed Groundwater Evaluation Criteria

3638 <sup>1</sup> References for the groundwater evaluation criteria are summarized in Table 5.2.2-2; concentrations that exceed the evaluation criteria are in bold.

3639 <sup>2</sup> The evaluation criterion differs by location based on background water quality (see Table 5.2.2-1).

DRAFT

3644 Bold-faced numbers in the screening table (Table 5.2.2-38) indicate which of the 29 model-  
3645 simulated constituents were identified as having NorthMet Project Proposed Action maximum  
3646 P90 concentrations (over 500 years) that exceed evaluation criteria at evaluation locations in the  
3647 Plant Site surficial groundwater flowpaths:

- 3648 • Fluoride in North Flowpath at property boundary
- 3649 • Sulfate in Northwest Flowpath at property boundary
- 3650 • TDS in North Flowpath at property boundary
- 3651 • TDS in Northwest Flowpath at property boundary
- 3652 • TDS in West Flowpath at property boundary
- 3653 • Manganese in Northwest Flowpath at property boundary
- 3654 • Manganese in West Flowpath at property boundary

3655 These four constituents and associated evaluation locations are listed in Table 5.2.2-40. In this  
3656 table, maximum P50 and P90 concentrations for the NorthMet Project Proposed Action are  
3657 compared with analogous values associated with the CEC for three phases of the GoldSim 500-  
3658 year simulation (operations, reclamation, and post-closure maintenance). In all cases the  
3659 NorthMet Project Proposed Action maximum P90 concentration of a phase is lower than the  
3660 comparable maximum P90 concentration for CEC.

3661 A further evaluation was performed by conducting a timestep-by-timestep analysis of the  
3662 GoldSim results. The analysis indicated that over the 500-year simulation, there were no  
3663 (monthly) timesteps for which the NorthMet Project Proposed Action P90 contaminant  
3664 concentration was higher than the evaluation criterion and higher than the P90 concentration for  
3665 CEC. The same result occurred when the comparison was made with P50 concentrations.

3666 This assessment of the GoldSim results provides strong evidence that the NorthMet Project  
3667 Propose Action would not cause impacts to Plant Site groundwater quality above and beyond  
3668 what would occur without the NorthMet Project Proposed Action.

3687 **Effects on Surface Water Hydrology in the Embarrass River Watershed**

3688 This section describes the effects of the NorthMet Project Proposed Action on the surface water  
 3689 hydrology of the Embarrass River and its tributaries. The effects of the NorthMet Project  
 3690 Proposed Action on surface water hydrology, especially in the three tributary streams draining  
 3691 the Tailings Basin (i.e., Mud Lake Creek, Trimble Creek, and Unnamed Creek) are complex, as  
 3692 some project features/engineering controls would tend to increase flows while others would  
 3693 decrease flows and change over time. For example, during mine operations, the NorthMet  
 3694 Project Proposed Action would increase seepage from the Tailings Basin toe as a result of  
 3695 tailings deposition, but nearly all of this seepage would be captured by the containment system;  
 3696 this reduction in flow would, in turn, be mitigated by the proposed streamflow augmentation  
 3697 with treated water or the construction of a swale. The NorthMet Project Proposed Action would  
 3698 also slightly modify some watershed areas within the Embarrass River, which would affect  
 3699 streamflows. These NorthMet Project Proposed Action effects on surface water hydrology are  
 3700 described in more detail below.

3701 The State of Minnesota aims to maintain existing flows to which streams and aquatic habitat  
 3702 have adapted. This may or may not be a pre-mining flow regime. In the case of the NorthMet  
 3703 Project Proposed Action where the existing LTVSMC tailings basin seeps water, containing the

3704 seeps creates a need to discharge clean water within a range of existing flows to maintain  
3705 existing hydrology, geomorphology, aquatic communities, connectivity, water quality, and  
3706 biology (Chisholm 2006).

3707 ***Mud Lake Creek Watershed Alteration***

3708 The Tailings Basin has a contributing watershed immediately to the east of Cell 1E that provides  
3709 groundwater and surface water flow into the Tailings Basin. The East Dam would be constructed  
3710 to enable tailings deposition into Cell 1E. The watershed that currently drains into Cell 1E would  
3711 be rerouted via a constructed drainage swale to drain to the headwaters of Mud Lake Creek. In  
3712 addition, a containment facility with a cut-off wall would be constructed adjacent to the east  
3713 embankment, and this would divert groundwater east of the Tailings Basin into the swale as well  
3714 (see Figure 5.2.2-49). There would be no need for augmentation to Mud Lake Creek because of  
3715 the additional runoff water diverted to the stream (PolyMet 2015j). Figure 5.2.2-49 shows the  
3716 approximate location of the drainage swale. Construction of the swale diversion would increase  
3717 the Mud Lake Creek Watershed area at MLC-3 from 1.34 mi<sup>2</sup> to 2.24 mi<sup>2</sup> (PolyMet 2015j,  
3718 Appendix B).

3719 ***Effects on Embarrass River Tributary Streamflow***

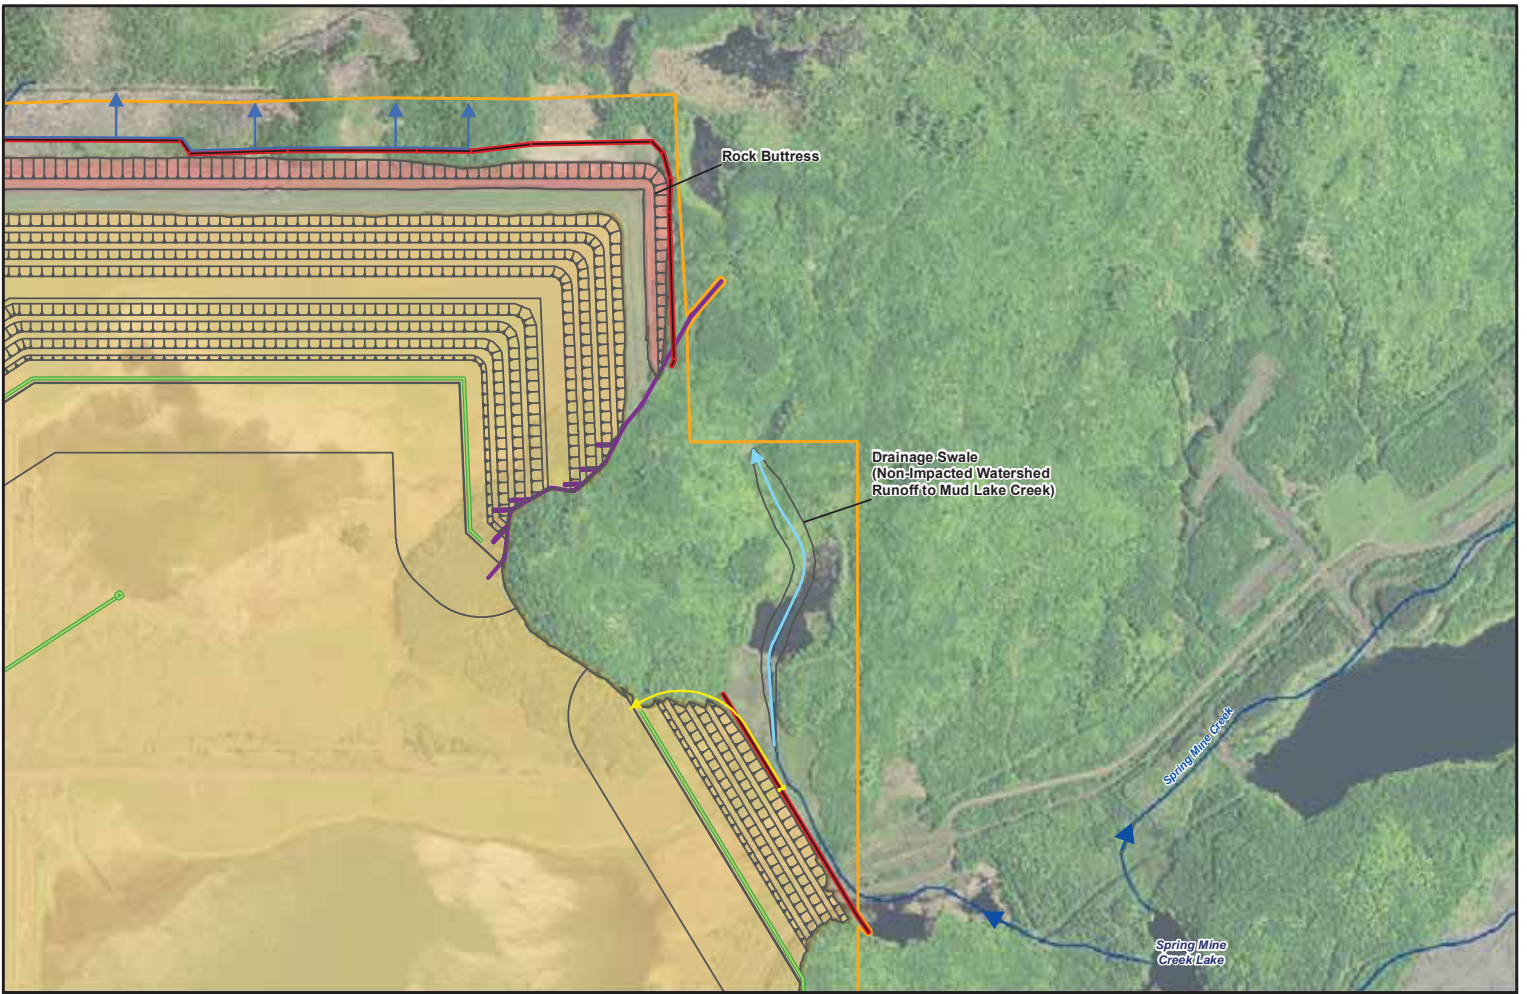

3720 The NorthMet Project Proposed Action includes construction of surface water and groundwater  
3721 seepage containment systems along the sides of the Tailing Basin. The containment system on  
3722 the North, Northwest and West sides would capture all surface seepage and nearly all  
3723 groundwater Tailings Basin seepage that would flow away from the Tailings Basin. In addition, a  
3724 containment system would be constructed along the east embankment to prevent westward  
3725 flowing groundwater and surface water fed by Spring Mine Lake from draining into the Tailings  
3726 Basin. A gravel-filled trench would collect 100 percent of surface and groundwater tailings  
3727 seepage that would occur as the Tailings Basin is raised. Seepage and local runoff captured by  
3728 these systems would be pumped back into the Tailings Basin pond or to the WWTP. As  
3729 indicated in Table 5.2.2-38, the containment systems would capture nearly all seepage entering  
3730 the tributary streams. WWTP-treated effluent would be used to restore streamflows in the  
3731 affected tributaries. This is referred to as augmentation.

DRAFT

3740 PolyMet has proposed to augment flow by distributing treated effluent from the WWTP among  
 3741 Unnamed Creek and Trimble Creek to maintain average annual flow to within 20 percent of  
 3742 existing conditions to maintain existing aquatic ecology. To ensure there would be enough  
 3743 treated effluent from the WWTP to augment the tributary streamflow, water from Colby Lake  
 3744 and if required, the optional Hydrometallurgical Residue Facility Wick Drain System, would be  
 3745 sent to the WWTP to be treated to increase the treated effluent available. Volumes for  
 3746 withdrawal are shown in Table 5.2.2-41.

3747

3748 **Table 5.2.2-41 Plant Site Water Appropriation During Operations**

| <b>Water Source Location</b>                                       | <b>Source Water</b> | <b>90th Percentile Maximum Estimated Daily Volumes (Million Gallons per Day)</b> | <b>90th Percentile Maximum Estimated Annual Volume (Million Gallons per Year)</b> |
|--------------------------------------------------------------------|---------------------|----------------------------------------------------------------------------------|-----------------------------------------------------------------------------------|
| Colby Lake                                                         | Surface Water       | 15.1 MGD (Mine Year 1)                                                           | 1,300 MGY (Mine Year 1)                                                           |
| Hydrometallurgical Residue Facility Wick Drain System <sup>1</sup> | Groundwater         | TBD in permitting                                                                | TBD in permitting                                                                 |

3749 Source: PolyMet 2015i

3750 <sup>1</sup> The Hydrometallurgical Residue Facility wick drain system is an optional feature of the Hydrometallurgical Residue Facility  
 3751 and, if required, would tie into the FTB Containment System for collection. Appropriation quantities for the wick drain system  
 3752 would be determined in permitting, if required.

3753 The total flow required from the WWTP effluent to augment Trimble Creek, Unnamed Creek  
 3754 and Second Creek after construction of the Mud Lake Creek drainage swale would range from  
 3755 1,698 to 3,442 gpm (Table 5.2.2-42) (PolyMet 2015j). Table 5.2.2-41 shows the minimum  
 3756 required and maximum allowable (plus or minus 20 percent of existing average annual tributary  
 3757 streamflow) augmentation that would be discharged on an average annual basis to each of the  
 3758 three tributaries for operations, reclamation and long-term maintenance. The discharge locations  
 3759 would be downstream of the surface and groundwater seepage containment system. Depending  
 3760 on site conditions, the augmentation water would be piped directly to the stream channels or  
 3761 released from a distribution pipe that parallels the North and Northwest containment system,  
 3762 whereas West of the Tailings Basin, augmentation flow to Unnamed Creek would be via a single  
 3763 discharge near the current SD-006 discharge.

3765 **Table 5.2.2-42 WWTP Flow Requirements for Stream Augmentation**

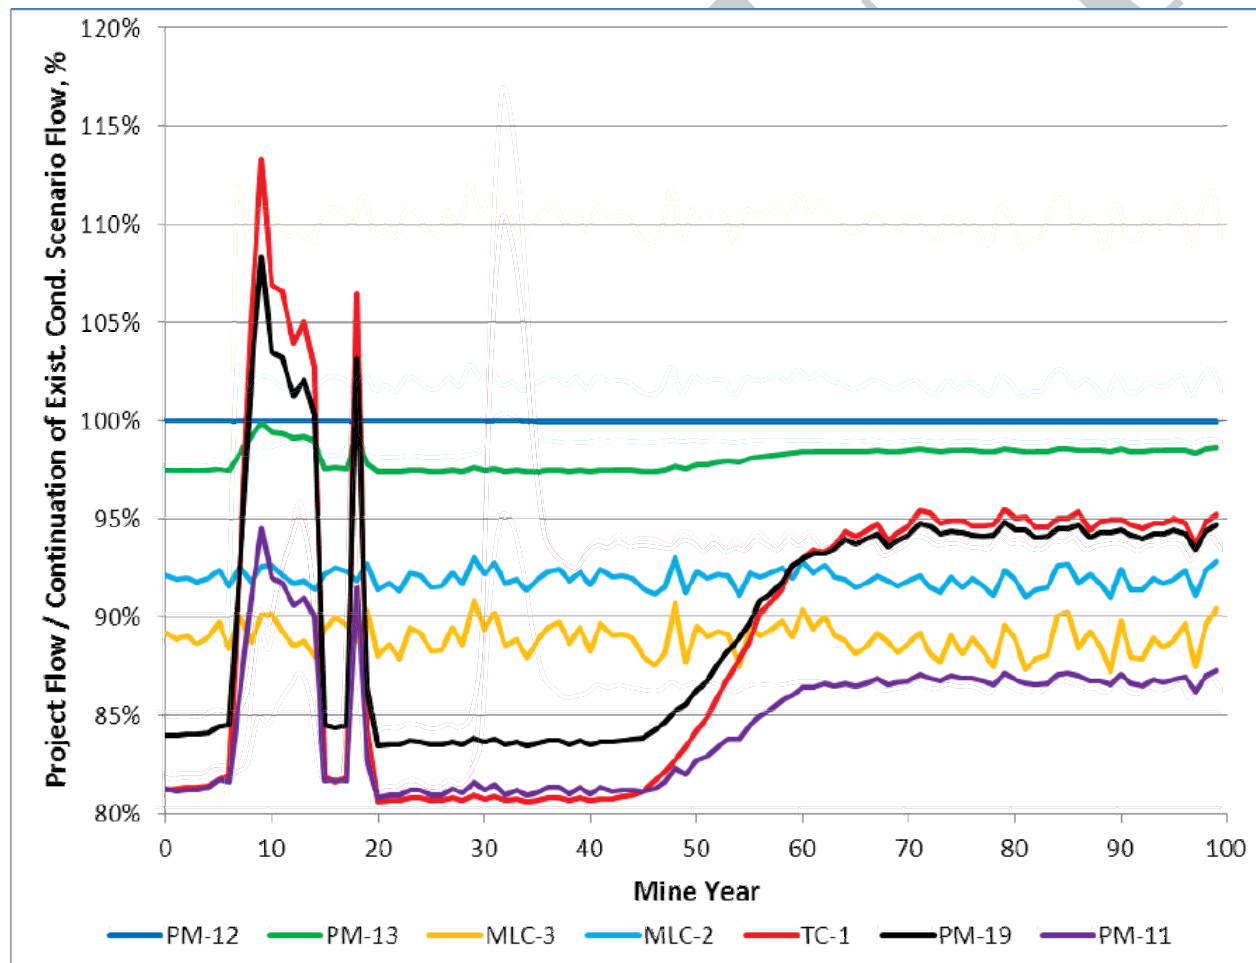

| <b>Description</b>                     | <b>Trimble Creek (gpm)</b> | <b>Unnamed Creek (gpm)</b> | <b>Second Creek (gpm)</b> |
|----------------------------------------|----------------------------|----------------------------|---------------------------|
| Minimum Requirement from WWTP          | 1,178                      | 336                        | 184                       |
| Maximum Allowable from WWTP            | 2,066                      | 836                        | 276                       |
| Expected Flows from WWTP - Operations  | 1,190 – 1,890              | 340 – 540                  | 185 – 295 <sup>1</sup>    |
| Expected Flows from WWTP - Reclamation | 1,180                      | 336                        | 184                       |

|                                                                 |       |     |     |
|-----------------------------------------------------------------|-------|-----|-----|
| Expected Flows from WWTP<br>- Closure and Long-Term Maintenance | 1,485 | 423 | 232 |
|-----------------------------------------------------------------|-------|-----|-----|

3766 Source: PolyMet 2015i, Table 2-3

3767 <sup>1</sup> Note the highest modeled flows to Second Creek did exceed the maximum allowable by about 20 gpm due to the simplified  
 3768 distribution of WWTP effluent in the modeling and the tight target flow range at SD-026. However, the high flow rate (295  
 3769 gpm) is within the observed flows at SD026 from July 1999 through September 2014 (range is from less than 10 gpm to nearly  
 3770 2,500 gpm).  
 3771

3772 Figure 5.2.2-50 shows the predicted effectiveness of the proposed flow augmentation in  
 3773 maintaining annual average Embarrass River tributary streamflow within 20 percent of the CEC  
 3774 Scenario. The graph only shows up to year 100 because the results are steady beyond that point.

3775  
 3776 Source: PolyMet 2015j, Figure 6-82.

3777 **Figure 5.2.2-50 Average Annual Embarrass River and Tributary Flows in the NorthMet**  
 3778 **Project Proposed Action Model (Percent of CEC Scenario)**

3779 Hydrologic fluctuations throughout operations and reclamation would be due to changes in the  
 3780 available amount of WWTP effluent. At no time, however, would tributary flow change by more  
 3781 than the 20 percent from existing flows.. Upstream of the NorthMet Project Proposed Action, at  
 3782 PM-12, the projected flow remains unchanged. Results for Mud Lake Creek show that starting in

3783 mine year 0 – upon construction of the drainage swale that would direct additional runoff into  
3784 Mud Lake Creek the minimum required flow – 80 percent of existing conditions, is met at MLC-  
3785 3 and MLC-2. Figure 5.2.2-50 shows that flow at MLC-3 and MLC-2 are relatively constant,  
3786 indicating that the drainage swale is effective in preventing hydrologic impacts to Mud Lake  
3787 Creek (PolyMet 2015j). Trimble Creek and Unnamed Creek show the effects of varying  
3788 quantities of WWTP discharge, but at all times the NorthMet Project Proposed Action  
3789 augmented stream flows are within 20 percent of the annual average CEC scenario. The effect of  
3790 the NorthMet Project Proposed Action would decrease with distance downstream, as can be seen  
3791 at PM-13, where the maximum change in flow would be approximately 3 percent in the annual  
3792 average flow during operations, with a closure and long-term maintenance decrease of less than  
3793 2 percent (PolyMet 2015j).

### 3794 ***Effects on Surface Water Quality***

3795 As shown on Figure 5.2.2-50, Embarrass River tributaries that would be affected by mine  
3796 facilities include Unnamed Creek, Trimble Creek, and Mud Lake Creek. These tributaries  
3797 currently receive Tailings Basin seepage with its associated water quality. Because the tributaries  
3798 discharge into the Embarrass River, their flow rates and water quality affect Embarrass River  
3799 concentrations.

3800 Results of the GoldSim water quality modeling were reviewed for all 29 solutes at five tributary  
3801 streams (i.e., MLC-2, MLC-3, TC-1, PM-19, and PM-11) and three Embarrass River (i.e., PM-  
3802 12, PM-12.2, and PM-13) evaluation locations (see Table 5.2.2-43). Model results for the  
3803 NorthMet Project Proposed Action and CEC scenario are essentially identical at stations PM-12  
3804 and PM-12.2, the two stations that are up stream of the NorthMet Project area and thus would not  
3805 be affected by the NorthMet Project Proposed Action (see Table 5.2.2-43). The differences in  
3806 water quality between these two stations can be attributed to a significant chemical load (notably  
3807 sulfate) that enters the Embarrass River just upstream of PM-12.2 via a tributary stream  
3808 originating at the 5NW Pit.

3809 A screening process was used to identify any constituents and locations that warranted a more  
3810 robust examination because of potential exceedances of water quality evaluation criteria (see  
3811 Table 5.2.2-40 for the Embarrass River tributary streams evaluation locations and Table 5.2.2-41  
3812 for the Embarrass River mainstem evaluation locations). The screening process involved  
3813 comparing the single-highest monthly P90 water quality prediction from among the 5,988  
3814 months covered by the simulation (i.e., 12 months times 499 years, with the first year of  
3815 simulation excluded for screening review due to potential numerical artifacts in the model  
3816 results) for each constituent for each of the eight evaluation locations. If the maximum P90  
3817 concentration exceeded the evaluation criteria, the screening process identified it for further  
3818 analysis.

3819 Tables 5.2.2-44 and 5.2.2-45 show that the maximum P90 concentrations for the NorthMet  
3820 Project Proposed Action would not exceed the applicable evaluation criteria, with the following  
3821 exceptions:

- 3822 • The aluminum criterion would be exceeded at all locations except TC-1 (on Trimble Creek)  
3823 for both the CEC scenario and the NorthMet Project Proposed Action;
- 3824 • The 10 mg/L wild rice sulfate criterion would be exceeded at PM-13 for both the CEC  
3825 scenario and the NorthMet Project Proposed Action.

3826 More detailed discussion of these constituents is provided in subsequent subsections of this  
3827 FEIS.

3828 Table 5.2.2-43 screens metals with hardness-based evaluation criteria. It was not possible to  
3829 develop a single evaluation criterion to which the GoldSim-predicted solute concentrations could  
3830 be compared. The approach to screening was therefore based on evaluating the frequency of the  
3831 occurrence of an exceedance for each timestep. A 5 percent frequency of exceedance criterion  
3832 was used for metals with hardness-dependent evaluation criteria. The 5 percent threshold was  
3833 selected because it is sufficiently conservative for purposes of identifying solutes where  
3834 additional discussion is necessary to understanding potential environmental effects. The bolded  
3835 value for lead and PM-11 is the only value that exceeded the frequency of exceedance threshold  
3836 of 5 percent. Lead is discussed further below.

3838 Source: GoldSim output file: "SW\_NonDEg\_Timeseries\_PlantSite.xlsx" (NorthMet GoldSim model, version 6)

3839 CEC = Continuation of Existing Conditions solute concentration

3840 CRT = Hardness-based evaluation criterion

3841 PA = NorthMet Project Proposed Action solute concentration

3842 Bolded values indicate constituents with {PA > CRT and CEC ≤ CRT} probability greater than 5%, retained for further evaluation.

3843 <sup>1</sup> Maximum of annual average values from Barr exceedance plots (see PolyMet 2015, Attachment J) or other GoldSim outputs

3844

DRAFT

3846 Table 5.2.2-46 below compares the P50 and P90 modeled concentrations for the NorthMet  
3847 Project Proposed Action and the CEC Scenario for selected key constituents during mine  
3848 operations, reclamation, and closure and post-closure maintenance at PM-13, which is the most  
3849 downstream evaluation location that would reflect all NorthMet Project Proposed Action-related  
3850 contaminant loadings. As these data show, the sulfate concentrations would decrease for the  
3851 NorthMet Project Proposed Action relative to the CEC Scenario across all three probability  
3852 values and all three mine phases.

3853 Current Tailings Basin seepage with high sulfate concentrations reaches the Embarrass River,  
3854 affecting sulfate concentrations at PM-13. Under the NorthMet Project Proposed Action, nearly  
3855 all of this seepage would be collected and prevented from reaching the river, and the flow is  
3856 replaced by treated WWTP effluent with a low sulfate load. As a result, the sulfate load to the  
3857 Embarrass River is reduced, as reflected by lower sulfate concentrations at PM-13 under the  
3858 NorthMet Project Proposed Action compared with the CEC Scenario. However, this reduction is  
3859 not sufficient to meet the 10 mg/L wild rice sulfate evaluation criterion that applies at PM-13.

3860 Comparison of GoldSim-predicted CEC scenario and NorthMet Project Proposed Action  
3861 conditions at PM-13 for arsenic, copper, lead, nickel, and zinc indicates that NorthMet Project  
3862 Proposed Action concentrations of these metals would all be higher than CEC Scenario  
3863 concentrations during all phases. The reason for increased PM-13 concentrations for these metals  
3864 is that concentrations of these metals in the WWTP effluent, which is used for stream  
3865 augmentation, would be higher than the concentrations in the existing LTVSMC Tailings Basin  
3866 seepage (assumed for CEC scenario). As a consequence, there would be an increase in solute  
3867 loading to the Embarrass River during operations and closure and post-closure maintenance  
3868 when compared to the CEC scenario.

3873 Notes:  
3874 For each constituent at each location, the maximum solute concentration over the entire 500-year simulation period is recorded for each of 500 realizations of the Monte Carlo run. At the end of the Monte Carlo run, there is a list of 500 maximum concentration values for each constituent at each  
3875 location. Each list is converted to a cumulative frequency distribution. Each value in this table is the 90th percentile concentration from the associated distribution.

3876 Bold value indicates exceedance of the evaluation criterion.

3877 <sup>1</sup> Parameter has a hardness-based evaluation criterion and is screened using a different procedure (see Table 5.2.2.43)

3895 ***Aluminum in Surface Waters of the Embarrass River Watershed***

3896 As shown by bold font in screening Tables 5.2.2-44 and 5.2.2-45, the maximum P90 values for  
3897 aluminum would exceed the 125 µg/L water quality criterion at nearly all surface water  
3898 evaluation locations for both the NorthMet Project Proposed Action and CEC scenarios. The  
3899 exceedances are shown for Embarrass River stations PM-12, PM12.2, and PM-13, and for  
3900 tributary stations MLC-2 and MLC-3 on Mud Lake Creek, PM-19 on Trimble Creek, and PM-11  
3901 on Unnamed Creek (map locations are shown on Figure 5.2.2-9). These screening level  
3902 exceedances indicate the need for further evaluation of aluminum in surface waters at the Plant  
3903 Site.

3904 Based on GoldSim results, Table 5.2.2-47 was developed to provide a better analysis of  
3905 aluminum at surface water evaluation locations. For three different phases of the project,  
3906 maximum P90 values of annual maximum aluminum concentrations are listed for both the  
3907 NorthMet Project Proposed Action and CEC scenarios. The three NorthMet Project Proposed  
3908 Action phases considered are operations (mine years 1 to 20), reclamation (years 21 to 56), and  
3909 post-closure maintenance (years 56 to 200). Inspection of GoldSim outputs indicated that  
3910 predicted surface water concentrations were generally stable or decreasing after 200 years due to  
3911 depletion of the chemical sources at the Tailings Basin, so mine years 201-500 were not included  
3912 in the evaluation. Highlighted in the table are conditions where 1) the CEC value is *lower* than  
3913 the evaluation criterion (yellow) and 2) where the NorthMet Project Proposed Action  
3914 concentration exceeds the criterion while the comparable CEC concentration does not (blue).  
3915 Based on Table 5.2.2-47, the following observations are made:

- 3916 • All maximum P50 values of annual aluminum for the three operating phases are below the  
3917 125 µg/L aluminum evaluation criterion. Most maximum P90 values of annual aluminum for  
3918 the three operating phases are above the aluminum evaluation criterion. The maximum P90  
3919 values of annual aluminum are on average 66 µg/L higher than corresponding P50 values.
- 3920 • For the P90 values, the maximum difference between NorthMet Project Proposed Action  
3921 concentrations and comparable CEC concentrations is most significant for Mud Lake Creek  
3922 (46 µg/L), but relatively small for the other tributary streams (5 µg/L for Trimble Creek and  
3923 9 µg/L for Unnamed Creek). The difference for the Embarrass River is very small (2 µg/L).
- 3924 • There is only one case where the NorthMet Project Proposed Action concentration exceeds  
3925 the evaluation criterion while the analogous CEC concentration is below the criterion. This  
3926 occurs at PM-19 (Trimble Creek) for the maximum P90 of annual aluminum during the  
3927 operations phase. However, closer inspection of the table shows that the NorthMet Project  
3928 Proposed Action concentration of 129 µg/L is just above the criterion (125 µg/L) and is only  
3929 5 µg/L higher than the corresponding CEC concentration of 124 µg/L, which is just below  
3930 the criterion.

3931

|                                                            | PM-19               | 125                  | 129                     | 124 | 130                       | 125 | 130                                     | 126 |
| Unnamed Creek                                              | PM-11               | 125                  | 156                     | 147 | 158                       | 148 | 158                                     | 151 |
|                                                            | PM-12               | 125                  | 178                     | 178 | 181                       | 181 | 182                                     | 182 |
| Embarrass River                                            | PM-12.2             | 125                  | 171                     | 171 | 175                       | 175 | 175                                     | 175 |
|                                                            | PM-13               | 125                  | 172                     | 170 | 174                       | 170 | 176                                     | 174 |

3934 Note:  
 3935 All concentrations are in mg/L.

3936 Based on an evaluation of the above observations in Table 5.2.2-47, it is generally concluded that  
 3937 the NorthMet Project Proposed Action is not the cause for the exceedances of the aluminum  
 3938 evaluation criterion at the P90 level in surface water at the Plant Site. There is only one case  
 3939 where the predicted NorthMet Project Proposed Action concentration is above the criterion while  
 3940 the analogous CEC concentration is below, but the difference between the two values is only 5  
 3941 µg/L, which is within the range of measurement error and is not considered significant.

3942 The fact that predicted maximum P90 concentrations are on average 66 µg/L higher than  
 3943 analogous P50 concentrations is explained by the cumulative probability distribution for surface  
 3944 runoff concentration used as input to the GoldSim model. Evaluation of the GoldSim outputs  
 3945 shows that predicted aluminum concentrations in surface water are dominated by mass loading  
 3946 from surface runoff and the loading from other sources (including all project-related chemical  
 3947 sources) is minor. As such there is no real link between the NorthMet Project Proposed Action  
 3948 and predicted P90 aluminum concentrations in surface water, which are commonly above the  
 3949 aluminum evaluation criterion.

3950 Unlike the other Embarrass River tributaries, aluminum concentrations in Mud Lake Creek are  
 3951 predicted to be significantly higher for the NorthMet Project Proposed Action compared to the  
 3952 CEC scenario. What makes Mud Lake Creek different from the other tributaries is that under the  
 3953 NorthMet Project Proposed Action its drainage area above MLC-3 (2.24 mi<sup>2</sup>) would be larger  
 3954 than for CEC (1.36 mi<sup>2</sup>). This is because for the CEC, surface water and groundwater flowing  
 3955 toward the east toe of the Tailings Basin are assumed to continue to migrate through the Tailings  
 3956 Basin footprint and not provide any surface flow or groundwater to Mud Lake Creek. Under the

3957 NorthMet Project Proposed Action, a seepage containment system with barrier wall would be  
3958 constructed along the East Toe, which would capture 100 percent of Tailings Basin seepage and  
3959 divert surface flow and upwelling groundwater to the Mud Lake Creek via the constructed swale.  
3960 Since aluminum in surface water tends to be dominated by surface runoff, there would be a  
3961 greater aluminum load to Mud Lake Creek under the NorthMet Project Proposed Action  
3962 compared to the CEC. The larger Mud Lake Creek watershed area under the NorthMet Project  
3963 Proposed Action is responsible for the higher associated modeled aluminum concentrations. The  
3964 higher aluminum concentrations in Mud Lake Creek are related to natural surface runoff and not  
3965 to chemical sources associated with chemical sources from the NorthMet Project Proposed  
3966 Action.

### 3967 ***Lead in Surface Water at PM-11***

3968 As shown in initial screening Table 5.2.2-50, the 7.13 percent frequency of exceedance for lead  
3969 at PM-11 (when the CEC scenario does not exceed) is greater than the 5 percent threshold, so  
3970 lead was retained for further consideration. Examination of GoldSim outputs show that when  
3971 lead concentrations at PM-11 are predicted to exceed associated hardness-based evaluation  
3972 criteria, the flow at PM-11 is dominated by WWTP discharges. In GoldSim, the WWTP effluent  
3973 lead concentration is assumed to be 3 µg/L, which is the water quality standard for lead at the  
3974 hardness of the discharge. Pilot testing of the proposed WWTP processes (Barr 2013f) has  
3975 indicated that the WWTP is capable of discharging lead at lower concentrations, so the 3 µg/L  
3976 concentration used in GoldSim is likely a higher value than what would actually be achieved. In  
3977 addition, if necessary engineering modifications to the proposed WWTP could be made to ensure  
3978 that WWTP effluent would have lead concentrations less than or equal to 2 µg/L. See Section  
3979 5.2.2.3.5 for a brief description of what adaptive mitigation measures could be made to achieve a  
3980 lead effluent concentration of 2 µg/L.

3981 To investigate the effect on WWTP effluent lead concentration on surface water concentrations  
3982 at PM-11, a subsidiary GoldSim simulation (PolyMet 2015s) was performed for which the only  
3983 change to the inputs was lowering the assumed WWTP effluent lead concentration from 3 to 2  
3984 µg/L. In making this change, the predicted frequency of lead exceedance at PM-11 (when the  
3985 CEC scenario does not exceed) was reduced to 1.3 percent, which is substantially less than the 5  
3986 percent screening threshold. Given that pilot testing shows that 2 µg/L lead concentration is  
3987 achievable in the WWTP effluent, it is likely that actual lead concentrations at PM-11 would  
3988 have acceptably low frequencies of exceedance. If however, the proposed WWTP generates  
3989 effluent with higher lead concentrations than expected, adaptive engineering measures could be  
3990 invoked at the WWTP to lower the frequency of lead exceedances (see Section 5.2.2.3.5).

### 3991 ***Sulfate in Surface Water in the Embarrass River***

3992 For the Embarrass River, the only surface water evaluation location that has a sulfate evaluation  
3993 criterion is PM-13, because it has been identified as a MPCA staff-recommended wild rice  
3994 production water. Therefore, a sulfate evaluation criterion of 10 mg/L was established for the  
3995 FEIS. As shown in screening Table 5.2.2-45, the GoldSim maximum P90 concentration at PM-  
3996 513 for the CEC scenario is 179 µg/L, which is well above 10 mg/L. Given that existing sulfate  
3997 at PM-13 is above the evaluation criterion, the MPCA developed a set of specific water quality  
3998 criteria for sulfate at the Plant Site. These are each evaluated at the end of this section.

3999 As with the previous sections, Table 5.2.2-48 shows predicted maximum P50 and P90 annual  
 4000 sulfate concentrations at PM-13, and PM-12 and PM-12.2 for comparison. The table provides the  
 4001 following observations:

- 4002 • At PM-12 and PM-12.2, there is virtually no change in sulfate between CEC scenario and  
 4003 NorthMet Project Proposed Action conditions.
- 4004 • In progressing downstream from PM-12 to PM-12.2, there is generally a large increase in  
 4005 sulfate concentrations.
- 4006 • The GoldSim-predicted PM-13 sulfate concentrations for both the NorthMet Project  
 4007 Proposed Action and the CEC scenario are significantly higher than historically measured  
 4008 sulfate at PM-13.
- 4009 • At PM-13, the concentration for the NorthMet Project Proposed Action is generally about  
 4010 100 µg/L less than the associated CEC scenario.
- 4011 • At PM-13, there are no cases (both the NorthMet Project Proposed Action and CEC) where  
 4012 sulfate is below the 10 mg/L wild rice evaluation criterion.

4013 **Table 5.2.2-48 Maximum P50 and Maximum P90 of Annual Sulfate Concentrations for**  
 4014 **Different Project Phases**

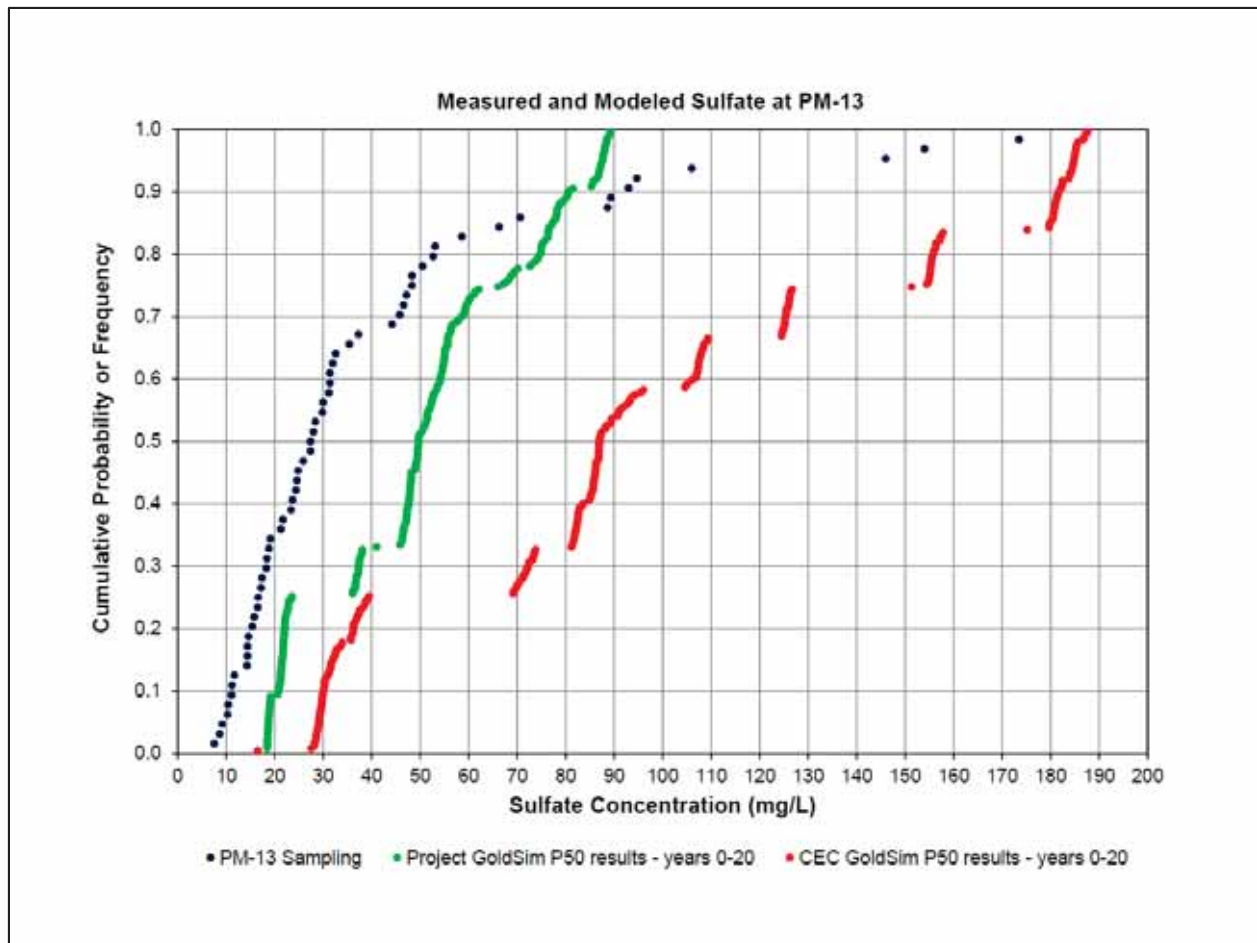

| Evaluation Location                                                | Evaluation Criterion | Operations (years 2-20) |      | Reclamation (years 21-55) |      | Post-Closure Maintenance (years 56-200) |      |
|--------------------------------------------------------------------|----------------------|-------------------------|------|---------------------------|------|-----------------------------------------|------|
|                                                                    |                      | PA                      | CEC  | PA                        | CEC  | PA                                      | CEC  |
| <b>a. Maximum P50 of Annual Concentrations from GoldSim Output</b> |                      |                         |      |                           |      |                                         |      |
| PM-12                                                              | n/a                  | 5.6                     | 5.6  | 5.7                       | 5.7  | 5.7                                     | 5.7  |
| PM-12.2                                                            | n/a                  | 294                     | 294  | 294                       | 294  | 294                                     | 294  |
| PM-13                                                              | 10                   | 89                      | 188  | 89                        | 185  | 90                                      | 185  |
| <b>b. Maximum P90 of Annual Concentrations from GoldSim Output</b> |                      |                         |      |                           |      |                                         |      |
| PM-12                                                              | n/a                  | 12.6                    | 12.6 | 14.0                      | 14.0 | 14.3                                    | 14.3 |
| PM-12.2                                                            | n/a                  | 367                     | 367  | 368                       | 368  | 371                                     | 371  |
| PM-13                                                              | 10                   | 113                     | 209  | 114                       | 217  | 114                                     | 217  |

4015 Notes:  
 4016 PA = NorthMet Project Proposed Action  
 4017 All concentrations are in mg/L.

4018 Explanations for these observations are provided below.

4019 First, the similarity of CEC scenario and the NorthMet Project Proposed Action is reasonable for  
 4020 PM-12 and PM-12.2 because these evaluation locations are upstream of all mine facilities and  
 4021 would not be expected to exhibit any effects from the NorthMet Project Proposed Action. Also,  
 4022 the increase in sulfate at PM-12.2 is explained by surface discharge from Pit 5NW, which enters  
 4023 the Embarrass River just upstream of PM-12.2 and has sulfate concentrations of about 1,000  
 4024 mg/L. The chemical sulfate load from Pit 5NW largely controls the magnitude of sulfate in  
 4025 downstream portions of the Embarrass River including PM-13.

4026 As discussed in Section 4.2.2.3.2, the current increase in the Embarrass River chloride load in  
4027 going from PM-12.2 (upstream of Plant Site) to PM-13 (downstream of Plant Site) provides  
4028 reasonable evidence that nearly all surface seepage from the northern, northwestern, and western  
4029 sides of the LTVSMC Tailings Basin is reaching the Embarrass River. It is estimated that this  
4030 surface seepage is about 2,400 gpm and has an average sulfate concentration of about 230 mg/L,  
4031 so that the associated sulfate load leaving the Tailings Basin is about 3,000 kg/day. However the  
4032 plot of sulfate load in the Embarrass River (see Figure 4.2.2-55) indicates that between PM-12.2  
4033 and PM-13, the sulfate load increases by only about 200 kg/day. In Section 4.2.2.3.2, it is  
4034 hypothesized that there is a natural process that sequesters sulfate in wetlands between the  
4035 Tailings Basin and the Embarrass River and this explains the reduced sulfate load from the  
4036 Tailings Basin to the Embarrass River. For conservativeness, the GoldSim model was  
4037 programmed to *not* consider any loss of chemical load in surface flow between the Tailings  
4038 Basin and the Embarrass River. As consequence, the model would be expected to overestimate  
4039 sulfate concentrations at PM-13, with the difference being greater for CEC scenario for which  
4040 there is no capture of the Tailings Basin surface seepage. This effect is illustrated on Figure  
4041 5.2.2-51, which uses cumulative probability to compare GoldSim predicted sulfate with  
4042 measured sulfate at PM-13. The figure shows that GoldSim-predicted sulfate concentrations for  
4043 both the NorthMet Project Proposed Action and the CEC scenario are greater than measured  
4044 sulfate at PM-13. In recognition of GoldSim's tendency to overestimate sulfate concentrations at  
4045 PM-13, evaluation of the NorthMet Project Proposed Action is oriented toward comparing the  
4046 *difference* between the NorthMet Project Proposed Action and CEC scenario values, rather than  
4047 focusing on the magnitude of predicted concentrations.

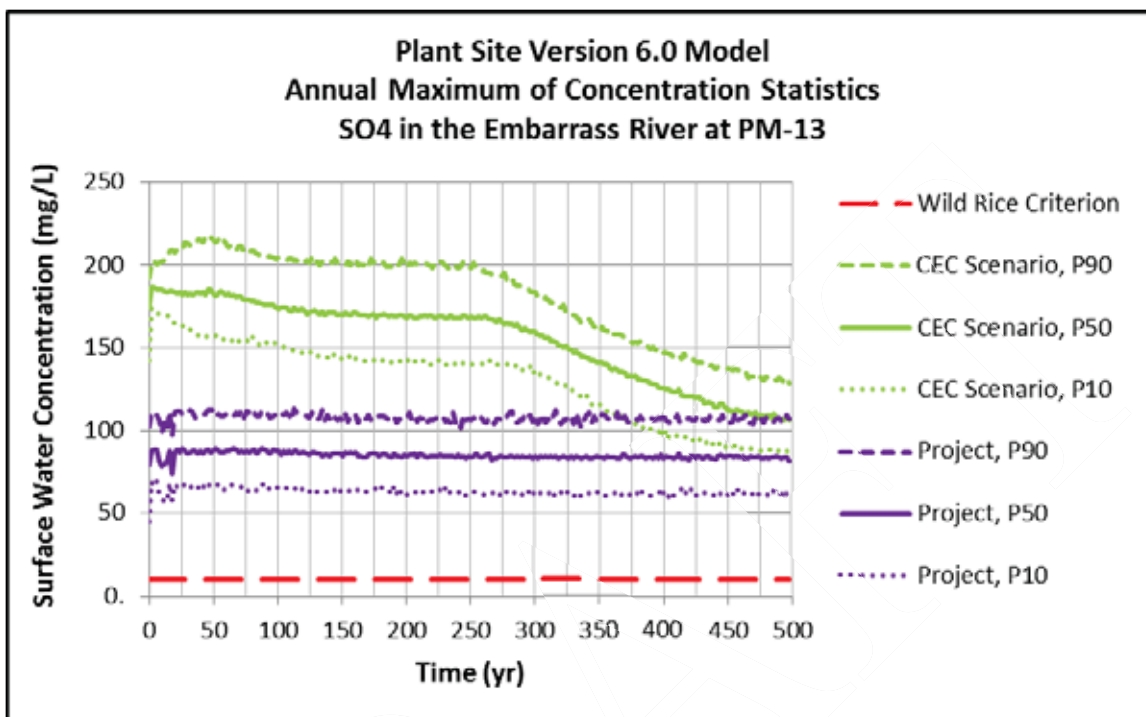

4048

4049  
4050

**Figure 5.2.2-51 Comparison of Measured and Modeled Sulfate Concentrations at PM-13**

4051 Figure 5.2.2-52 shows GoldSim-predicted annual maximum sulfate concentrations at PM-13. For  
4052 P10, P50, and P90 plots, the model predicts that sulfate at PM-13 would be substantially reduced  
4053 under the NorthMet Project Proposed Action compared to the CEC scenario. Although the model  
4054 may overestimate the magnitude of sulfate concentrations, the relative reduction in  
4055 concentrations at PM-13 is apparent. This result is explained by the engineering controls  
4056 associated with the NorthMet Project Proposed Action. Currently there is about 2,400 gpm of  
4057 surface seepage leaving the northern, northwestern, and western sides of the Tailings Basin that  
4058 contains sulfate concentrations of about 230 mg/L. Under the CEC scenario, all Tailings Basin  
4059 seepage reaches the Embarrass River and contributing its sulfate load to the Embarrass River.  
4060 Under the NorthMet Project Proposed Action, nearly all of the surface seepage would be  
4061 collected by the seepage containment system and sent to the WWTP. To augment the flow loss,  
4062 at least 80 percent of the captured flow rate would be discharged to the tributaries after treatment  
4063 has reduced the sulfate concentration to 9 mg/L. The result is that a substantial reduction in  
4064 sulfate load to the Embarrass River would occur under the NorthMet Project Proposed Action  
4065 and this explains the lower sulfate concentrations at PM-13 when compared to the CEC scenario.

4066

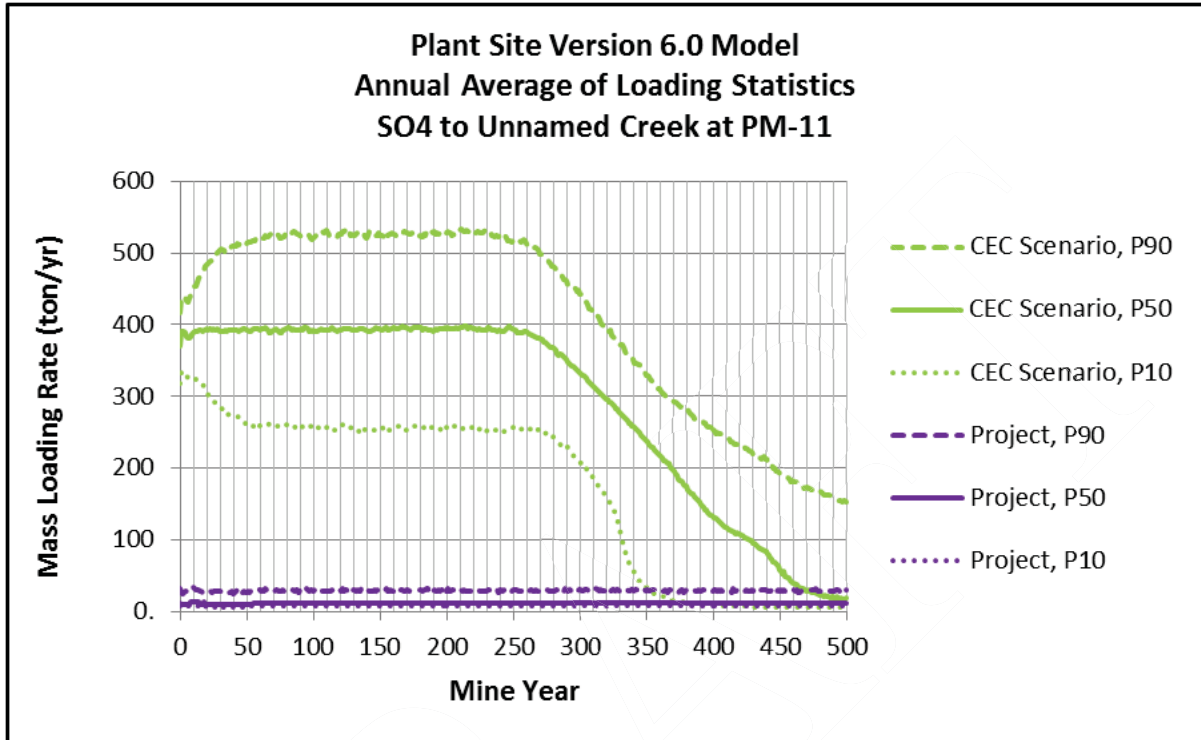

4067

**Figure 5.2.2-52 Maximum Annual Sulfate Concentrations at PM-13**

4068 The effect of the NorthMet Project Proposed Action on sulfate concentrations in the Embarrass  
4069 River Watershed is of concern because MPCA has recommended waters within and downstream  
4070 from Embarrass Lake, the northernmost tip of Wynne Lake, and the segment of the Embarrass  
4071 River from Sabin Lake to the Highway 135 bridge, as waters used for the production of wild rice  
4072 (see Figure 5.2.2-1). Given that current sulfate concentrations at PM-13 are almost always higher  
4073 than the 10 mg/L wild rice sulfate evaluation criterion, the MPCA has developed three  
4074 supplemental water quality criteria for sulfate at the Plant Site (MPCA 2011d), which are each  
4075 discussed below.

4076 Criterion 1: No increase in sulfate-loading from existing conditions would occur at PM-11  
4077 (Unnamed Creek), PM-19 (Trimble Creek), and MLC-2 (Mud Lake Creek)

4078 Figures 5.2.2-53, 5.2.2-54, and 5.2.2-55 show GoldSim-predicted sulfate loading at PM-11,  
4079 PM-19, and MLC-2, respectively, based on annual maximum values. As shown, the sulfate-  
4080 loading at these three locations would be reduced under the NorthMet Project Proposed Action  
4081 compared to the CEC scenario. The decrease is predicted to occur for P10, P50, and P90  
4082 concentrations. The model therefore predicts that this criterion would be met under the NorthMet  
4083 Project Proposed Action.

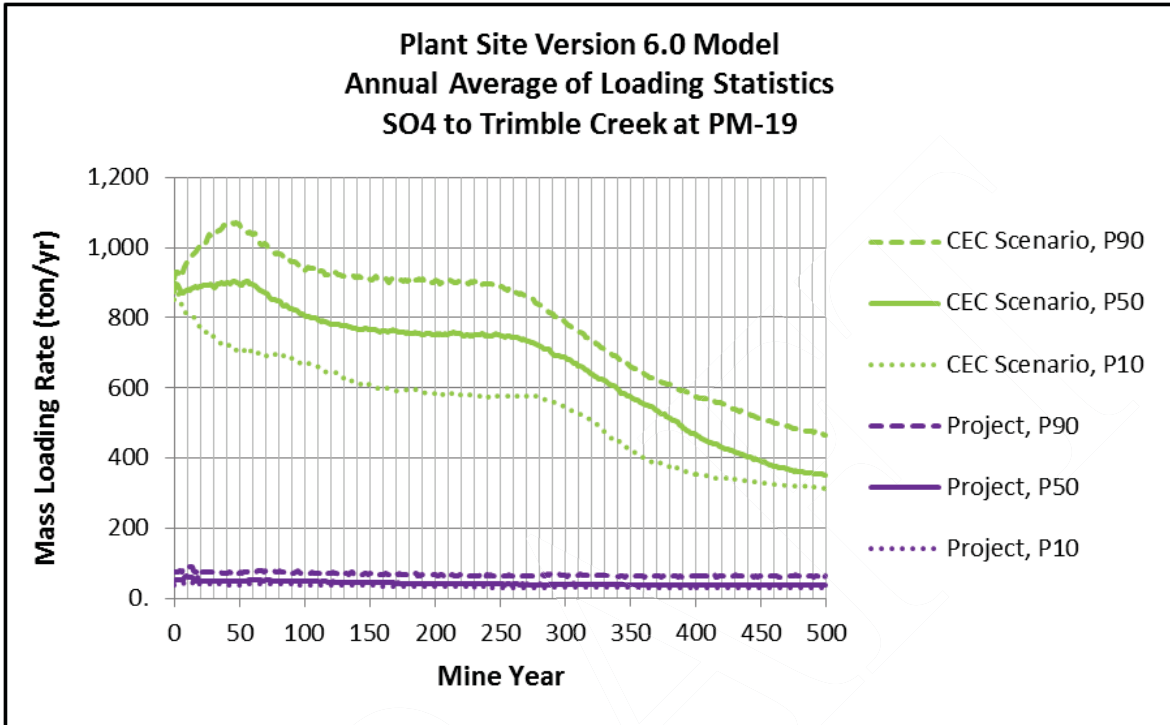

4084

4085

4086

*Figure 5.2.2-55 Maximum Annual Sulfate Loading at MLC-2*

4091

4092

4093 **Figure 5.2.2-56 Maximum Annual Sulfate Concentrations at PM-12.2 and PM-13**

4094 Criterion 2: The concentration of sulfate in the Embarrass River at PM-13 would decrease from  
4095 existing condition

4096 Figure 5.2.2-52 shows GoldSim-predicted sulfate at PM-13 for the NorthMet Project Proposed  
4097 Action and the CEC scenario. For P90, P50, and P10 values, the sulfate concentrations at PM-13  
4098 would be reduced under the NorthMet Project Proposed Action. As discussed previously, this  
4099 concentration reduction under the NorthMet Project Proposed Action would result from the  
4100 capture of tailings seepage with high sulfate by the seepage containment system and the  
4101 discharge of most of this water to the Embarrass River with much lower sulfate due to treatment  
4102 by the WWTP. The model therefore predicts that this criterion would be met under the NorthMet  
4103 Project Proposed Action.

4104 Criterion 3: No statistically significant increase in sulfate would occur in the Embarrass River  
4105 from upstream of the facility (e.g., PM-12.2) to downstream of the facility (e.g., PM-13)

4106 Figure 5.2.2-56 compares GoldSim-predicted annual maximum sulfate concentrations at PM-  
4107 12.2 with concentrations at PM-13. There are no NorthMet Project Proposed Action activities  
4108 that would affect concentrations at PM-12.2, so this figure serves as a basis for determining  
4109 downstream sulfate changes for Proposed Action conditions. Figure 5.2.2-56 shows that under  
4110 the NorthMet Project Proposed Action, sulfate concentrations would substantially decrease in  
4111 progressing downstream from PM-12.2 to PM-13, so this criterion would be met under the  
4112 NorthMet Project Proposed Action.

4113 ***Plant Site Model Sensitivity Analyses***

4114 The sensitivity of the GoldSim Model was evaluated for changes to groundwater recharge rates  
4115 and climate change. The following sections summarize the sensitivity analysis findings for the  
4116 Plant Site.

4117 ***Recharge to Groundwater Sensitivity Analysis***

4118 A sensitivity analysis was performed to assess to what extent the model predictive simulation  
4119 results depend on the definition of recharge (to groundwater) used to set up the NorthMet Plant  
4120 Site water quality model. This analysis showed that changing the distribution used for aquifer  
4121 recharge from triangular to lognormal and correlating recharge to precipitation in GoldSim  
4122 model simulations does result in minor changes to 10th percentile, 50th percentile, and 90th  
4123 percentile of the model calculated groundwater and surface concentrations. However, the  
4124 changes are minimal. Further, the estimation of the potential to exceed an applicable  
4125 groundwater and surface water standards is not sensitive to these model input changes (Barr  
4126 2015d).

4127 ***Climate Change Sensitivity Analysis – Plant Site***

4128 The potential effects of a climate change upon the predictions of both the GoldSim probabilistic  
4129 models developed for the Plant Site, the Plant Site NorthMet Project Proposed Action Model and  
4130 No Action Plant Site NorthMet Project Proposed Action Model, were evaluated by running the  
4131 “climate change sensitivity analysis”. The ranges of precipitation and temperature input  
4132 parameters were varied following the guidance provided by Co-Lead Agencies (Kellogg 2011).  
4133 The sensitivity of the model predictions to changes in values of those parameters was  
4134 quantitatively assessed at the toes of the Tailings Basin and qualitatively assessed at other  
4135 locations within the model domain. In summary, the Climate Change Sensitivity Analysis Model  
4136 was set by increasing: (1) the mean annual temperature by 2.0 to 5.2 degrees Celsius, (2) the  
4137 mean annual precipitation from 28.1 to 29.8 in/yr, and (3) the mean annual open water  
4138 evaporation by 6.5 percent. The parameter values were linearly increased from mine year 1 to  
4139 mine year 60 and, then, were kept constant. Such modified model was used to run 200-year  
4140 predictive simulations, similar to the NorthMet Project Proposed Action Models.

4141 The impacts of the modeled changes upon contaminant concentrations in seepage water at the  
4142 toes were analyzed for lead, sulfate, copper, and iron. Lead concentrations would change most at  
4143 the west and northwest toes, up to 13 percent. Similarly, the largest increase in sulfate  
4144 concentrations, up to 15 percent, would occur at the west and northwest toes. The largest  
4145 increase in copper concentrations, up to 12 percent, would occur, again, at the west and  
4146 northwest toes. Finally, The largest increase in iron concentrations, up to 15 percent, would also  
4147 occur at the west and northwest toes.

4148 Seepage at the toes is expected to increase slightly due to the increased infiltration through the  
4149 Tailings Basin. Climate change is not expected to cause significant changes in groundwater  
4150 quality. Likewise, surface water quality in the Embarrass River and its tributaries is expected to  
4151 be minimally affected by the NorthMet Project Proposed Action under climate change  
4152 conditions. All water leaving the Tailings Basin’s footprint would be treated by the WWTP,  
4153 except for approximately 21 gpm of seepage that is conservatively expected to escape the  
4154 Containment System. Runoff from the exterior of the East Dam is relatively inert.

4155 It is likely that the amount of water that would need treatment at the WWTP would increase  
4156 under climate change conditions. This is because the increase in precipitation would be slightly  
4157 greater than the amount of water lost to increased evaporation (Barr 2015d).

#### 4158 **5.2.2.3.4 Mercury**

4159 Mercury can be released to surface water or groundwater through mobilization of mercury stored  
4160 in rock, soil, peat, and vegetation, and can also be deposited to surface water through  
4161 atmospheric dry deposition and precipitation. Methylmercury, which is an organic form of  
4162 mercury, accumulates in fish and is toxic to humans and wildlife at concentrations above a  
4163 toxicity threshold. Current scientific understanding of the factors and mechanisms affecting  
4164 mercury methylation and bioaccumulation is limited. Mercury concentrations in fish sampled  
4165 from downstream lakes presently trigger advice to limit fish consumption. An increase in  
4166 mercury in fish tissue would be counter to statewide efforts to reduce mercury concentrations in  
4167 fish.

4168 Mercury was not included in the GoldSim model for either the Mine Site or the Plant Site, as  
4169 insufficient data and unique modeling requirements for mercury dynamics prevented modeling  
4170 mercury like the other solutes. Regardless, the NorthMet Project Proposed Action would still  
4171 need to demonstrate that the mercury evaluation criteria would be protected (see Section 5.2.2.1).  
4172 Details of the overburden management, which includes peat, is included in Section 5.2.2.3.2.  
4173 Adaptive management has also been identified within the FEIS process that could reduce  
4174 mercury concentrations if necessary (see Section 5.2.2.3.5). Therefore, a simple mass balance  
4175 model estimation method was used. This simple estimation method was preferred over a detailed  
4176 mechanistic model because it incorporated the important input and removal processes for  
4177 mercury, was very transparent with regard to data inputs, and allowed for easy assessment of the  
4178 effects of changing parameter values on mercury concentrations. For the Mine Site, this method,  
4179 in combination with analog data from existing natural and mine pit lakes in the region, was used  
4180 to assess future mercury concentrations in the West Pit lake and in the overflow water (PolyMet  
4181 2015m). A similar mass balance approach was used for the Plant Site to estimate future mercury  
4182 concentrations released from the Tailings Basin.

4183 The NorthMet Project Proposed Action and project area watershed information used to assess the  
4184 potential effects on average annual mercury loading and concentrations at the Plant Site and  
4185 Mine Site (Upper Embarrass River and Upper Partridge River, respectively) were also used in  
4186 assessing the potential effects from the NorthMet Project Proposed Action on mercury loading in  
4187 the St. Louis River (Barr 2015f).

4188 This section discusses mercury from only a water-concentration perspective; the potential effects  
4189 of the NorthMet Project Proposed Action on the bioaccumulation of methylmercury in fish are  
4190 discussed in Section 5.2.6. Cumulative effects are discussed in Section 6.2.3.3.4 and 6.2.3.5.4.

#### 4191 **Direct Release of Mercury to the Partridge River Watershed**

4192 The NorthMet waste rock and ore contain trace amounts of mercury. Laboratory analysis of  
4193 humidity cell leachates from waste rock samples found average total mercury concentrations  
4194 between 5 and 7 ng/L, with concentrations unrelated to rock type or sulfur content (SRK 2007b).  
4195 Separate 36-day batch tests using local rainfall (12 ng/L total mercury) found that contact with  
4196 Duluth Complex rock actually decreased total mercury concentrations to between 1.9 and 3.2  
4197 ng/L as a result of adsorption (SRK 2007b). . Therefore, the data suggest that most of the

4198 mercury present in rainfall or released by sulfide oxidation is typically adsorbed by other  
 4199 minerals present in the mine waste rock. The primary NorthMet Project Proposed Action-related  
 4200 source of mercury to the Partridge River would be the WWTF discharge.

4201 As discussed previously, there would be no surface water discharges to the Partridge River or its  
 4202 tributaries from the Mine Site until approximately year 52, when the West Pit would be flooded  
 4203 and the overflow would be directed to the WWTF for treatment and discharge. The WWTF  
 4204 discharge would be subject to the Great Lakes Initiative standard for mercury (1.3 ng/L).  
 4205 Mercury concentrations in the West Pit were estimated two ways: using analog data from other  
 4206 natural lakes and mine pit lakes in northeastern Minnesota, and using a mass balance approach.

4207 The West Pit, like seepage/headwater lakes (e.g., lakes with no significant inflowing streams),  
 4208 would receive most of its water from precipitation and direct runoff from the surrounding  
 4209 watershed. Water balance modeling estimates that 70 percent of the West Pit inflow after  
 4210 reclamation would be from precipitation. Therefore, natural seepage/headwater lakes and  
 4211 existing mine pits in the vicinity of the NorthMet Project Proposed Action area can provide an  
 4212 analog for mercury concentrations that would occur in the West Pit at the time of overflow. Of  
 4213 particular significance are the Dunka Pit Lakes. Because the Dunka Pit intersects the Duluth  
 4214 Complex, the mercury concentration data from the Dunka Pit Lakes are considered an important  
 4215 indicator of potential total mercury concentrations for the West Pit at closure. Data from 16 mine  
 4216 pit lakes and five natural headwater/seepage lakes in northeastern Minnesota were evaluated. As  
 4217 Table 5.2.2-49 shows, despite the fact that the primary source of inflow to these lakes/pits was  
 4218 precipitation, which averages about 13 ng/L based on the annual average mercury concentration  
 4219 from the National Atmospheric Deposition Program for the Fernberg Road Monitoring Site  
 4220 (2010-2011); (PolyMet 2015m), only two of the lakes/pits had average total mercury  
 4221 concentrations above the Great Lakes standard of 1.3 ng/L (Pit 2W at 1.61 ng/L and Pit 9S at  
 4222 1.87 ng/L).

4223 **Table 5.2.2-49 Total Mercury Concentration Data from Natural Lakes and Mine Pits in**  
 4224 **Northeastern Minnesota**

| Lake/Pit Type | Number of Lakes/Pits | Minimum Mercury Concentration (ng/L) | Average Mercury Concentration (ng/L) | Maximum Mercury Concentration (ng/L) | Number with Avg Concentration >1.3 ng/L |
|---------------|----------------------|--------------------------------------|--------------------------------------|--------------------------------------|-----------------------------------------|
| Natural Lakes | 5                    | 0.34                                 | 0.66                                 | 1.73                                 | 0                                       |
| Pit Lakes     | 16                   | 0.5                                  | 0.97                                 | 2.55                                 | 2                                       |

4225 Source: PolyMet 2015m.

4226 A mass balance approach was also used to evaluate potential mercury concentrations in the West  
 4227 Pit. For this evaluation, unless otherwise specified, ‘mercury’ refers to total mercury. Elemental  
 4228 mercury was not a part of the evaluation process, as no elemental mercury releases are  
 4229 anticipated from mining or processing operations. Mass balance models range from simple  
 4230 spreadsheet-based formats to more complex such as the GoldSim model. An important  
 4231 consideration in the selection of a water quality model is the complexity of the chemical being  
 4232 assessed and the available data, and the consideration that a complex situation may not require a  
 4233 complex water quality model (Loucks et al. 2005). The MPCA’s spreadsheet-based model allows  
 4234 reviewers to focus on key inputs and their impact on model behavior and results. Furthermore,  
 4235 the use of a separate spreadsheet model for mercury enabled the specification of assumptions that

4236 were specifically conservative for mercury but that were not necessarily conservative for other  
4237 contaminants, for example the depth of the mixing zone (Barr 2015f).

4238 The mass balance took into consideration average inflows and estimated potential mercury inputs  
4239 from precipitation, atmospheric dry deposition, groundwater inflow, Category 1 Stockpile  
4240 drainage, other stormwater runoff within the Mine Site, supplemental water from the Plant Site  
4241 WWTP, collected seepage from the Tailings Basin, and inflows from the East Pit (see Table  
4242 5.2.2-50). The mass balance also took into consideration the loss of mercury via burial (i.e., loss  
4243 due to settling), evasion/volatilization, and outflow (i.e., pumping to the WWTF for treatment  
4244 and discharge). Category 1 Stockpile drainage was assumed to be unaltered by the waste rock in  
4245 the stockpile (i.e., no adsorption of mercury to the waste rock), which is a conservative  
4246 assumption as there is evidence that waste rock likely adsorbs mercury from precipitation. The  
4247 mass balance model conservatively assumed that mixing only occurred in the upper 30 ft of the  
4248 water column, as this would limit the volume of water available to dilute the mercury-loading.

4251 Source: PolyMet 2015m, Table 6-15.

4252 <sup>1</sup> Precipitation volume from monitoring stations within 30 miles of the NorthMet Project Proposed Action area based on mean  
4253 annual precipitation (1981-2010 climate normal); annual average Hg concentration from the National Atmospheric Deposition  
4254 Program for the Fernberg Road Site (MN18) (2010-2011). Total atmospheric deposition is assumed to equal 12,500 nanograms  
4255 per square meter per year (ng/m<sup>2</sup>/yr) (Swain et al. 1992). Dry deposition is set equal to the difference between total and wet  
4256 deposition and represents about 25% of total deposition.

4257 <sup>2</sup> Flow estimate from GoldSim Modeling results.

4258 <sup>3</sup> Estimate of Hg concentration based on NorthMet Project Proposed Action data.

4259 <sup>4</sup> Burial rate for mercury is lower (more conservative) than initial estimate according to the burial regression equation discussed  
4260 in PolyMet 2015m.

4261 <sup>5</sup> Volatilization rate is estimated based on the low end of the range of values discussed PolyMet 2015m.

4262 Based on the input values from Table 5.2.2-50 above, the estimated average mercury  
4263 concentration of the West Pit during flooding (years 20 to 52) would initially be approximately  
4264 0.3 ng/L, and after flooding (after year 52) would stabilize at approximately 0.9 ng/L.

4265 It should be noted that the West Pit overflow would be treated by the WWTF using RO or  
4266 equivalent technology known to remove mercury and would meet water quality targets prior to  
4267 discharge. Therefore, the actual mercury concentrations in the WWTF effluent discharge are

4268 expected to be less than the concentrations predicted for the West Pit lake (i.e., less than 0.9  
4269 ng/L), although an effluent mercury concentration of 1.3 ng/L was assumed for purposes of  
4270 estimating mercury concentrations in the WWTF discharge. Table 5.2.2-51 provides a summary  
4271 of the initial mass balance results, with the largest input of mercury to the West Pit coming from  
4272 atmospheric deposition (about 66 percent of total estimated inputs), and the largest loss of  
4273 mercury attributed to burial (about 92 percent of total mercury inputs).

4274 The Overburden Storage and Laydown Area would not be lined, but would have a compacted  
4275 soil bottom. Unsaturated overburden and peat would be temporarily stored at the Overburden  
4276 Storage and Laydown Area until it is utilized for reclamation purposes. Mercury release from  
4277 decomposed organic material is thought to occur relatively rapidly and dissolved mercury would  
4278 be transported in solution with precipitation that falls on the Overburden Storage and Laydown  
4279 Area (PolyMet 2015r). Stormwater runoff from the Overburden Storage and Laydown Area  
4280 would be considered process water which would be routed to the process water pond and  
4281 eventually collected and routed to the Tailings Basin for years 1 to 11, where much of the  
4282 mercury would be sequestered in the tailings through sorption. In years 12 to 20, the Overburden  
4283 Storage and Laydown Area stormwater runoff would be collected and routed to help flood the  
4284 East Pit, where most of the remaining mercury would be sequestered with waste rock at depth  
4285 (e.g., through settling and other chemical processes within the pit). Because peat removal from  
4286 the areas to be mined would be completed between years 5 to 11, any potential release of  
4287 mercury from stored peat materials would have occurred or would be ending by the time water is  
4288 routed from the Overburden Storage and Laydown Area pond to the East Pit beginning in year  
4289 12. After year 20, the Overburden Storage and Laydown Area would be closed, reclaimed, and  
4290 material removed or covered by a geomembrane cover, and therefore would no longer serve as a  
4291 potential source of mercury. The potential for mercury release from peat decomposition in the  
4292 Overburden Storage and Laydown Area is included in the mass balance as part of the Process  
4293 Water input.

4294 The mercury load from the Mine Site would slightly decrease during closure and long-term  
4295 maintenance, because a portion of the flow that is currently watershed yield (total mercury  
4296 concentration of 3.6 ng/L) would be captured in the West Pit lake and discharged via the WWTF  
4297 at a conservatively assumed total mercury concentration of 1.3 ng/L. Flows from the Mine Site  
4298 in closure and long-term maintenance are not expected to change from existing conditions;  
4299 therefore, the change in total mercury concentration from 3.6 ng/L to 1.3 ng/L for a portion of  
4300 the flow from the Mine Site results in reduced loading to the Partridge River (Barr 2015g).  
4301 Therefore, the NorthMet Project Proposed Action is predicted to result in a net decrease in  
4302 mercury-loading to the Partridge River from 24.2 to 23.0 grams per year, primarily due to a  
4303 decrease in natural runoff and a proportional increase in water discharged from the West Pit via  
4304 the WWTF (with a total mercury concentration of 1.3 ng/L).

4305 **Table 5.2.2-51 Summary of Estimated Mercury-Loading (Inputs)<sup>1</sup> and Losses (Outputs) for**  
 4306 **the West Pit Lake (Mine Year 20 to about Mine Year 52)**

| Parameters                                                                      | Annual Average Load of Mercury (nanograms) | Percent of Summed Inputs | Comments                                                                                                                                                           |

4308 NE = Not estimated for this analysis.

4309 <sup>1</sup> Reasonably conservative estimates of mercury concentrations and average annual flow estimates from GoldSim modeling were  
 4310 used to estimate mercury-loading.

4311 **Direct Release of Mercury to the Embarrass River Watershed from the Tailings Basin**

4312 The Plant Site would receive inputs of mercury from two primary sources: residual trace  
 4313 concentrations in the tailings and process consumables, with some minor contributions from  
 4314 Mine Site process water, which would be pumped to the Tailing Basin pond through year 11  
 4315 (and possibly through year 20, but is dependent on the NorthMet Project Proposed Action's  
 4316 water balance). As discussed in Section 5.2.2.3.1, all process make up water used for stream  
 4317 augmentation would be treated at the WWTP prior to discharge. Mercury would be released  
 4318 from the Tailings Basin via seepage, discharge from the WWTP, and volatilization from the  
 4319 Tailings Basin pond (this mechanism is discussed in Section 5.2.7, Air Quality). As with the

4320 Mine Site, mercury was not included in the GoldSim model, but a mass balance approach was  
4321 used to estimate future mercury concentrations.

4322 Several studies have been conducted by state agencies regarding the release of mercury from  
4323 taconite ore processing and tailings facilities. Berndt (2003) concluded that wet and dry  
4324 deposition of mercury was the major source of dissolved mercury in taconite tailings pond water,  
4325 rather than the actual tailings themselves. Further, Berndt found that taconite tailings appear to  
4326 be a sink for mercury in full-scale actual tailings basins in northern Minnesota, at least similar to  
4327 other media like soils, as evidenced by lower mercury concentrations in waters seeping from  
4328 tailings basins (specifically at U.S. Steel's Minntac Mine and Northshore Mining's Northshore  
4329 Mine) than in either precipitation input or pond water in the tailings basin. The loss of mercury  
4330 through adsorption to solids in the tailings basin and subsequent burial in the sediments results in  
4331 an overall permanent retention of mercury within the basin and decreases the mercury load  
4332 released to receiving waters. Berndt (2003) demonstrates that mercury released to surface waters  
4333 during taconite processing is insignificant with respect to mercury concentrations found in local  
4334 precipitation and existing background surface waters. This finding is supported by surface water  
4335 monitoring around the existing LTVSMC Tailings Basin, which found mercury concentrations in  
4336 surface water seepage to be consistent with baseline levels (see Table 4.2.2-4), generally  
4337 averaging less than 2.0 ng/L. The overall average total mercury concentration at two discharge  
4338 locations at the Tailings Basin (SD-026 and SD-004) over a 9-year period was 1.0 ng/L,  
4339 indicating relatively low mercury concentrations in the existing LTVSMC Tailings Basin  
4340 seepage. All monitoring results were well below average concentrations in precipitation, so most  
4341 mercury appears to be sequestered in the LTVSMC tailings through adsorption (see Table 4.2.2-  
4342 4).

4343 A mass balance model was developed to aid in estimating potential release of mercury from the  
4344 Plant Site. All major inputs of mercury were included in the mass balance model. The major  
4345 outputs of mercury include the hydrometallurgical residue, air emissions from the  
4346 hydrometallurgical process, the tailings, and the ore concentrate. The vast majority of the  
4347 mercury is predicted to remain in the concentrate, with only about 8 percent predicted to be sent  
4348 to the Tailings Basin via the tailings and process water. Process and tailings water samples from  
4349 a pilot study conducted with NorthMet ore were found to have mercury concentrations of 11.2  
4350 and 0.7 ng/L, respectively. Mercury loadings to the Tailings Basin are estimated to be 16.2  
4351 pounds per year (lbs/yr), with about 15.8 lbs/yr from solids and about 0.4 lbs/yr from process  
4352 water. For comparison, this is significantly less than the 610 lbs/yr estimated average mercury-  
4353 loading to the existing LTVSMC tailings basin during LTVSMC operations.

4354 In 2006, Northeast Technical Services, Inc. (NTS) conducted a bench study using NorthMet  
4355 tailings to determine the rate of mercury adsorption by the tailings. The study utilized large-  
4356 volume shake flask tests to evaluate mercury adsorption of tailings over time (PolyMet 2015j).  
4357 The concentration of dissolved mercury in a treatment flask containing process water and  
4358 NorthMet tailings decreased from 3.3 ng/L (at time 0) to 0.9 ng/L (at 480 minutes). Although the  
4359 exact mechanisms behind the adsorption process are not yet clearly understood, the ability of  
4360 NorthMet tailings to adsorb mercury, in combination with the proven ability of the underlying  
4361 taconite tailings to adsorb mercury, is expected to result in an overall increase in the adsorption  
4362 of mercury and subsequent lower concentrations of mercury at the Tailings Basin with the  
4363 addition of the NorthMet tailings. Although adsorption was not explicitly included in the mass  
4364 balance model, its effects are observed in the mercury concentrations in runoff from the existing

4365 LTVSMC tailings, and are therefore assumed in the modeled future concentrations in Tailings  
 4366 Basin seepage.

4367 In summary, the Tailings Basin is predicted to receive less loading of mercury (about 2 to 3  
 4368 percent) and less flow than the existing LTVSMC Tailings Basin historically received, while  
 4369 retaining the adsorption benefits of the LTVSMC tailings, as well as the demonstrated mercury  
 4370 adsorption capability of the NorthMet tailings. For these reasons, it is reasonable to conclude that  
 4371 the seepage from the NorthMet tailings should have similar or lower mercury concentrations as  
 4372 the LTVSMC tailings seepage, which has averaged about 1.0 ng/L. Therefore, the total mercury  
 4373 concentration in seepage from the Tailings Basin is expected to be less than the Great Lakes  
 4374 Initiative standard of 1.3 ng/L.

4375 During long-term maintenance, the Tailings Basin seepage would be captured and pumped to  
 4376 the WWTP for treatment. The WWTP would also receive water from the Tailings Basin pond, as  
 4377 well as stormwater runoff from the basin. The discharge from the WWTP, like the discharge  
 4378 from the WWTF, would be subject to the Great Lakes Initiative standard of 1.3 ng/L. The  
 4379 estimated mercury concentration and flow rate for each of these influent streams is shown in  
 4380 Table 5.2.2-52. As this table shows, the combined influent streams are estimated to have a  
 4381 mercury concentration of 1.3 ng/L prior to treatment.

4382 **Table 5.2.2-52 Estimated Mercury Concentration of the Combined Inflows to the Plant Site**

4384 Source: Table 6-8, PolyMet 2015j.

4385 The WWTP would use a greensand filtration process followed by RO unit or equivalently  
 4386 performing technology that would meet water quality targets. RO treatment or equivalently  
 4387 performing technology that would meet water quality targets are known to remove mercury,  
 4388 particularly when the influent is pre-treated, and this potential additional removal of mercury is  
 4389 not accounted for in mass balance calculations, which adds a level of overestimation to the mass  
 4390 balance results. Any reduction in mercury by the WWTP would reduce discharge concentration;  
 4391 therefore, the total mercury concentration in the WWTP discharge is expected to meet the  
 4392 evaluation criteria of 1.3 ng/L.

4393 The NorthMet Project Proposed Action is predicted to result in a net increase in mercury  
 4394 loadings to the Embarrass River of up to 0.2 grams per year (from 22.3 to 22.5 grams per year),  
 4395 which is about a 1 percent increase. This increase is primarily attributable to:

- 4396 • The redirection of surface runoff diverted via the drainage swale constructed east of the  
 4397 Tailings Basin East Dam directly to Mud Lake Creek (at an assumed mercury concentration  
 4398 of 3.5 ng/L, versus a seepage concentration of 1.0 ng/L); and
- 4399 • The Tailings Basin containment systems, which would collect seepage from the Tailings  
 4400 Basin, with an estimated mercury concentration of 1.0 ng/L, and route it to the WWTP,

4401 which would discharge with an assumed mercury concentration of 1.3 ng/L,, which is  
4402 considered conservative in that the WWTP and the greensand filter are expected to remove  
4403 some mercury from the effluent.

#### 4404 **Enhanced Mercury Methylation**

4405 Virtually all dispersal of mercury in the environment (especially atmospheric dispersal) occurs in  
4406 inorganic form (Fitzgerald and Clarkson 1991), but nearly all of the mercury accumulated in fish  
4407 tissue (more than 95 percent) is organic methylmercury (Bloom 1992). Thus, methylation is a  
4408 key step in bioaccumulation and the uptake of mercury by aquatic biota. Methylmercury can be a  
4409 product of the methylation of inorganic mercury by sulfate-reducing bacteria, a process that can  
4410 be stimulated by increased sulfate concentrations in aquatic systems where sulfate is limiting  
4411 (Gilmour et al. 1992; Krabbenhoft et al. 1998), although recent research has shown that  
4412 numerous other types of bacteria can methylate mercury (Gilmour et al. 2013). Although, as  
4413 described above, the NorthMet Project Proposed Action is expected to result in a negligible  
4414 release of inorganic mercury to groundwater or surface waters and is predicted to meet the 1.3  
4415 ng/L discharge evaluation criteria, the potential effects of the NorthMet Project Proposed Action  
4416 on mercury methylation must be evaluated. Bacteria that cause mercury methylation require an  
4417 anoxic environment, and consequently methylation occurs in sediments rather than in the water  
4418 column. Therefore, methylation is unlikely to occur in the Partridge River or Embarrass River.

4419 There are several factors that influence mercury methylation, including total available mercury,  
4420 organic carbon, temperature, micronutrients required by sulfate-reducing bacteria, sulfate  
4421 loadings (over the range for which sulfate may be a limiting factor for sulfate-reducing bacteria),  
4422 lack of oxygen, and certain hydrologic conditions. The NorthMet Project Proposed Action is  
4423 expected to have little or no effect on most of these factors, but the effects on sulfate  
4424 concentrations and hydrologic conditions warrants further discussion and are discussed below. .

#### 4425 **Sulfate Loadings**

4426 Research indicates that sulfate-reducing bacteria are the primary mercury methylators in aquatic  
4427 systems, especially in wetlands (Compeau and Bartha 1985). Biologically available sulfate is  
4428 believed to be one of several limiting factors for the methylating bacteria (Jeremiason et al. 2006;  
4429 Watras et al. 2006). Adding sulfate to aquatic systems where sulfate is limiting can therefore  
4430 stimulate sulfate-reducing bacteria activity, leading to increased mercury methylation as the  
4431 sulfate is consumed (Gilmour et al. 1992; Harmon et al. 2004; Branfireun et al. 1999; Branfireun  
4432 et al. 2001). Recent research in northern Minnesota suggests that increased atmospheric sulfate-  
4433 loading to a peatland can result in increased mercury methylation and export (Jeremiason et al.  
4434 2006), but other research suggests that this effect is not linear and diminishes at higher loads  
4435 where sulfate may no longer be limiting (Mitchell et al. 2008). Heyes et al. (2000) reported a  
4436 significant positive correlation between methylmercury and sulfate in a poor fen ( $R^2 = 0.765$ ,  
4437  $p = 0.005$ ) and in a bog ( $R^2 = 0.865$ ,  $p = 0.022$ ).

4438 Many studies have shown that wetlands can be sinks for mercury and sources of methylmercury  
4439 to surrounding watersheds (St. Louis et al. 1996). Galloway and Branfireun (2004) found that  
4440 wetlands were an important site of sulfate reduction and methylmercury production. Balogh et al.  
4441 (2004) and Balogh et al. (2006) concluded that increases in methylmercury in several Minnesota  
4442 rivers during high-flow events was likely the result of methylmercury transport from surrounding  
4443 wetlands to the main river channel. A recent study by the MDNR found little, if any, correlation

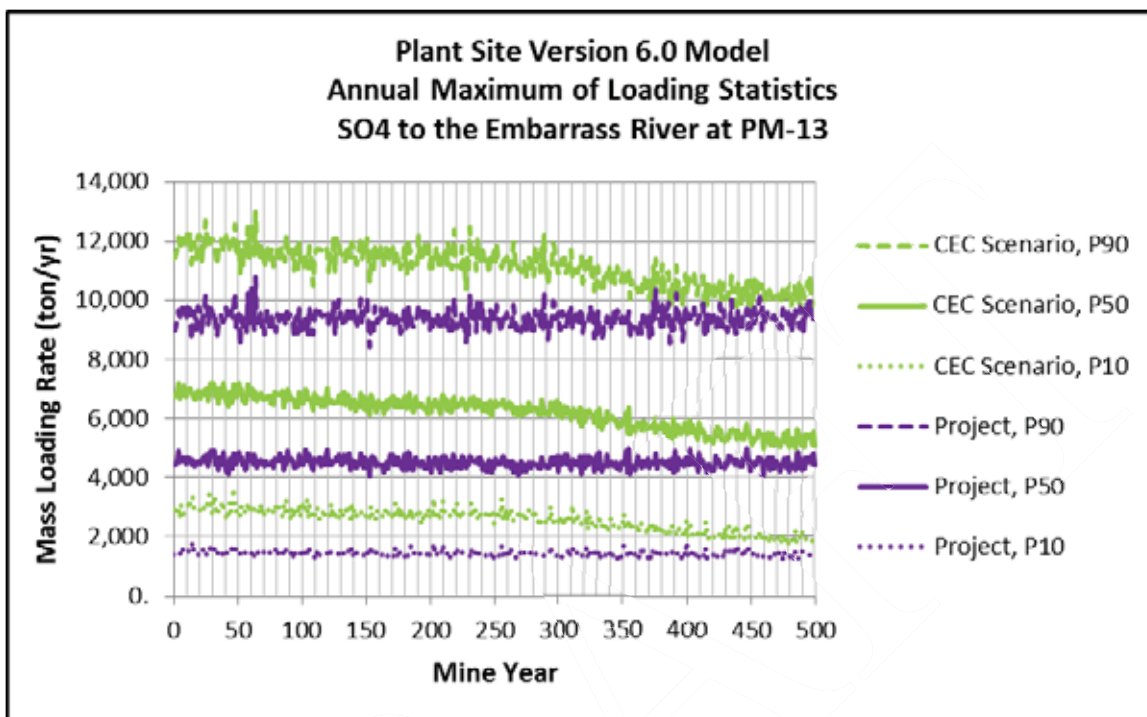

4444 between total mercury or methylmercury and sulfate concentrations in northeastern Minnesota  
4445 streams (Berndt and Bavin 2012a; Berndt and Bavin 2012b; Berndt et al. 2014). Instead, the  
4446 study found strong correlations between mercury and dissolved organic carbon concentrations  
4447 and total wetland area. Overall, these studies suggest that most mercury methylation, at least in  
4448 the St. Louis River Basin, primarily occurs within wetlands rather than in stream channels and  
4449 the methylmercury is flushed to rivers from wetlands during storm events.

4450 The MPCA and MDNR recognize the important role of sulfate in methylmercury production, as  
4451 well as the uncertainties regarding site-specific relationships between sulfate discharges and  
4452 water body impairment. The MPCA has set forth a strategy (MPCA 2006a) for addressing the  
4453 effects of sulfate on methylmercury production that encompasses technical, policy, and  
4454 permitting issues. The strategy acknowledges that the technical basis does not exist to establish  
4455 sulfate concentration limits. The strategy, however, sets forth steps the MPCA can take to  
4456 improve the technical basis for controlling sulfate discharges and establishes guidance for  
4457 considering potential sulfate effects during environmental review and NPDES permitting. The  
4458 strategy focuses on avoiding “discharges,” which could include groundwater seepage, to “high-  
4459 risk” situations. These high-risk areas include wetlands, low-sulfate water (less than 40 mg/L)  
4460 where sulfate may be a limiting factor in the activity of sulfate-reducing bacteria, and waters that  
4461 flow to a downstream lake that may stratify, all or most of which apply to the area downstream  
4462 of the WWTP and the WWTF discharges.

4463 In response to this policy, as well as to comply with sulfate standards that apply to waters  
4464 recommended as supporting the production of wild rice, PolyMet has proposed several  
4465 significant changes to the NorthMet Project Proposed Action design from that proposed in the  
4466 DEIS. These changes would significantly reduce sulfate loadings, and include a surface and  
4467 groundwater seepage containment system around the Category 1 Stockpile and a WWTF to treat  
4468 the West Pit overflow at the Mine Site and a containment system around the Tailings Basin and  
4469 a WWTP to treat tailings seepage at the Plant Site.

4470 As a result of the design changes at the Mine Site, the NorthMet Project Proposed Action is  
4471 predicted to increase the sulfate load by less than 2 percent in the Partridge River watershed, but  
4472 maintain the same maximum P90 concentration (19.4 mg/L) as the CEC scenario. Effluent from  
4473 the WWTF would be discharged at a water quality based effluent limit concentration that  
4474 protects the sulfate standard for waters used for the production of wild rice (10 mg/L), beginning  
4475 when the West Pit is predicted to flood around year 55. Sulfate concentrations in this range  
4476 coupled with the oxygenated hydrologic environment to which the effluent would be discharged  
4477 would not be expected to promote mercury methylation.

4478 As a result of the design changes at the Plant Site, the NorthMet Project Proposed Action is  
4479 predicted to significantly decrease sulfate loadings to the wetlands north of the Tailings Basin  
4480 and to the Embarrass River, primarily because the containment system would capture nearly all  
4481 Tailings Basin seepage and ultimately route it to the WWTP, which would treat the seepage and  
4482 discharge the effluent at a target concentration of 10 mg/L as part of the Embarrass River  
4483 tributary streams flow augmentation. However, as summarized in Section 5.2.2.3.3, the reduction  
4484 is not sufficient enough to meet the 10 mg/L wild rice sulfate evaluation criterion that applies at  
4485 PM-13. Nevertheless, the net effect of these engineering controls would be a reduction in sulfate  
4486 loadings relative to the CEC Scenario model results at PM-13 (see Figure 5.2.2-57).

4489 **Figure 5.2.2-57 Range of Annual Sulfate Loading Rates to the Embarrass River at**  
 4490 **PM-13 – CEC Scenario versus NorthMet Project Proposed Action**

4491 ***Hydrologic Changes and Water Level Fluctuations***

4492 Methylation of environmental mercury by sulfate-reducing bacteria is also stimulated by drying  
 4493 and rewetting associated with hydrologic changes and water level fluctuations (Gilmour et al.  
 4494 2004; Selch et al. 2007). Drying (and subsequent increase in exposure to oxygen) of substrate  
 4495 containing reduced sulfur species (sulfides and organic sulfur) oxidizes those species into sulfate,  
 4496 which is remobilized and available to sulfate-reducing bacteria upon rewetting of the substrate.  
 4497 This mechanism stimulates production of methylmercury in sediments exposed to wetting and  
 4498 drying cycles (Gilmour et al. 2004) and probably accounts for some of the elevated  
 4499 methylmercury concentrations observed in releases from wetlands during high-flow events  
 4500 (Balogh et al. 2006). Thus, hydrologic changes and water level fluctuations can potentially  
 4501 stimulate mercury methylation and enhance bioaccumulation. The effect of the NorthMet Project  
 4502 Proposed Action would decrease with distance downstream, as can be seen at PM-13, where the  
 4503 maximum change in flow would be approximately 3 percent in the annual average flow during  
 4504 operations, with a closure and long-term maintenance decrease of less than 2 percent (PolyMet  
 4505 2015j).

4506 ***Mercury Summary***

4507 Based on the above analysis, the NorthMet Project Proposed Action would have negligible  
 4508 effects on hydrologic changes or water level fluctuations in the Partridge River and Embarrass  
 4509 River, would maintain relatively low sulfate loadings and concentrations to the Partridge River,

4510 would significantly reduce sulfate loadings to the Embarrass River, and would meet the Great  
4511 Lakes Initiative mercury standard for discharges.

4512 Overall, mercury loadings are predicted to increase slightly in the Embarrass River (1 percent),  
4513 and decrease in the Partridge River (5 percent). Overall, the changes in total mercury  
4514 concentrations associated with the NorthMet Project Proposed Action in closure and long-term  
4515 maintenance at the respective Mine Site and Plant Site are estimated to be too small to  
4516 distinguish from natural background variability in the Partridge River and the Embarrass River  
4517 using available laboratory methods (Barr 2015g).

4518 The NorthMet Project Proposed Action and project area watershed information used to assess the  
4519 potential effects on average annual mercury loading and concentrations at the Plant Site and  
4520 Mine Site (Upper Embarrass River and Upper Partridge River, respectively) were also used in  
4521 assessing the potential effects from the NorthMet Project Proposed Action on mercury loading in  
4522 the St. Louis River. The result would be a net decrease in overall mercury loadings (1.0 grams  
4523 per year) with no detectable change in mercury concentrations to the St. Louis River as a result  
4524 of the NorthMet Project Proposed Action (Barr 2015g).

#### 4525 **5.2.2.3.5 Proposed and Recommended Mitigation Measures**

4526 PolyMet has proposed or agreed to measures to avoid, minimize, or mitigate potential  
4527 environmental effects. These measures are considered part of the NorthMet Project Proposed  
4528 Action (see Section 3.2) and include design changes since the DEIS, including fixed engineering  
4529 controls, PolyMet would be required by its permits to monitor water quality and quantity to  
4530 refine modeling and to predict future conditions for consideration in permit renewals. In the  
4531 event that monitoring coupled with modeling identifies the potential for water quality  
4532 exceedances, PolyMet has proposed adaptive engineering controls and contingency mitigation  
4533 that could be implemented to prevent exceedances of water quality standards. An overview of  
4534 the evolution of the NorthMet Project Proposed Action with respect to alternatives analysis is  
4535 provided in Section 3.2.3.3. PolyMet commits to monitoring and management through  
4536 application of facility management plans that form the NorthMet Project Proposed Action; these  
4537 plans are listed in Section 3.2.2.

#### 4538 **NorthMet Project Proposed Action Design Changes**

4539 PolyMet has proposed several significant improvements to the design of the NorthMet Project  
4540 Proposed Action for this FEIS from the NorthMet Project Proposed Action as described in the  
4541 DEIS (October 2009), which would avoid or minimize effects on water resources. These are  
4542 described in Table 3.2-16.

#### 4543 **Fixed Engineering Controls**

4544 PolyMet has proposed several fixed engineering controls that would decrease effects on water  
4545 resources from the NorthMet Project Proposed Action. These fixed engineering controls are not  
4546 expected to be modified during the life of the NorthMet Project Proposed Action and would be  
4547 included as part of the NorthMet Project Proposed Action's financial assurance package. The  
4548 fixed engineering controls include the following:

- 4549 • Ditches, perimeter and pit rim, and sedimentation basins to separate and control stormwater  
4550 and process waters;

- 4551 • Pipes, pumps, and lined process water ponds to separate and control stormwater and process  
4552 waters;
- 4553 • Geomembrane liners, underdrain systems, sumps, and overflow ponds, for temporary storage  
4554 of Category 2/3 Category 4 and Ore Surge Pile rock;
- 4555 • Category 1 Stockpile hydraulic barrier and drain pipe which would collect surface and  
4556 groundwater seepage that would then be pumped to the WWTF, enabling the capture and  
4557 treatment of nearly all Category 1 Stockpile seepage;
- 4558 • Treated Water Pipeline and Central Pumping Station to allow the re-use of water at the  
4559 processing plant and zero liquid discharge during operations at the Mine Site;
- 4560 • Haul Roads designed for the collection and separation of stormwater from road surfaces;
- 4561 • Tailings Basin for the collection and control of NorthMet tailings and re-use of process  
4562 water;
- 4563 • Bentonite amended Tailings Basin beaches (during reclamation) and embankment face  
4564 (during operations) to reduce both water and oxygen intrusion into the tailings during  
4565 reclamation;
- 4566 • Tailings Basin containment system to collect, surface and groundwater seepage on the  
4567 western, northwestern northern, eastern and southern sides of the Tailings Basin and pump it  
4568 back to the Tailings Basin pond or to the Plant Site WWTP;
- 4569 • Hydrometallurgical Residue Facility for collection, control, and storage of  
4570 hydrometallurgical residue and re-use and recycle of process water. This facility would have  
4571 a double geomembrane liner with a leakage collection system that would return any leachate  
4572 to the Hydrometallurgical Residue Facility pond;
- 4573 • Colby Lake pump house, pipeline from Colby Lake to the Plant Site reservoir; and
- 4574 • Tailings Basin streamflow augmentation system to maintain stream flows within  $\pm 20$  percent  
4575 of existing flows using WWTP effluent.

#### 4576 **Adaptive Water Management Plan**

4577 Adaptive management is a system of management practices, based on clearly defined outcomes  
4578 and monitoring requirements, that assesses whether management actions are meeting the desired  
4579 outcomes, and, if not, prescribes potential actions that would ensure the defined outcomes are  
4580 met. In the case of the NorthMet Project Proposed Action, PolyMet has developed an Adaptive  
4581 Water Management Plan (AWMP), which includes adaptive engineering controls and  
4582 contingency mitigation measures (PolyMet 2015d). Adaptive engineering controls may have  
4583 their design, operation, or maintenance modified before or after their installation based on  
4584 measured and modeled water quality during and after operations. Monitoring data in particular  
4585 are important because not all questions about water management can be answered by GoldSim  
4586 (i.e., transport time for constituent load in the Category 1 stockpile). Certain model assumptions  
4587 may not be applicable to all potential project feature modifications. If water quality were better  
4588 or worse than predicted, adaptive engineering controls would be adjusted accordingly, or  
4589 contingency mitigation implemented with the approval of regulatory agencies.

4590 **Adaptive Engineering Controls**

4591 Adaptive engineering controls would be included as part of the permit to mine financial  
4592 assurance package and would include the following:

4593 • Mine Site WWTF – The WWTF would be upgraded to a RO process or equivalently  
4594 performing technology that would meet water quality targets during closure and long-term  
4595 maintenance to manage influent sulfate concentrations. The WWTF is an adaptive  
4596 engineering control because its operating configuration, process unit requirements and  
4597 capacity can be modified to treat varying influent streams and discharge requirements.  
4598 WWTF construction plans include a phased build-out of the capacity to meet the Mine Site’s  
4599 P90 maximum flow requirements (year 14). Therefore, greater capacity could be achieved  
4600 sooner if necessary. The WWTF processes could be adapted depending on actual water  
4601 quality conditions encountered during the NorthMet Project Proposed Action phases and  
4602 estimated by water quality monitoring and model updating. Treatment performance issues  
4603 that could occur from changes in influent water quality could be addressed by making  
4604 adjustments to operating conditions (PolyMet 2015d). In addition, the WWTF effluent,  
4605 which would include calcium carbonate generated from the WWTF re-carbonation/calcite  
4606 precipitation system, would be used to help flood the East Pit, while also contributing some  
4607 alkalinity to help maintain near-neutral pH in the pit water. Lime could also be added to the  
4608 East Pit during waste rock backfilling if additional alkalinity were needed (Adaptive Water  
4609 Management Plant, v7, Feb 2015).

4610 • Adaptive management would be implemented as necessary based on monitoring for total  
4611 mercury to determine whether the treated water could be discharged to surface waters, or  
4612 whether some additional treatment is needed. Adaptive management strategies would include  
4613 pretreatment modifications such as a chemical scavenger addition ahead of the greensand  
4614 filter units to obtain additional metals, the use of tighter RO membranes for the primary RO  
4615 system, treatment of some portion of the Vibratory Shear Enhanced Process (VSEP)  
4616 permeate by the primary RO system to further remove some dissolved constituents, and  
4617 addition of polishing treatment units for removal of trace metals (e.g., ion exchange).

4618 • If future modeling, informed by the results of the monitoring, predicted that the NorthMet  
4619 Project Proposed Action would not protect surface waters, then adaptive mitigation measures  
4620 could be implemented to decrease NorthMet Project Proposed Action effects on the Partridge  
4621 River prior to an actual effect occurring (PolyMet 2015d). Possible adaptive measures that  
4622 could be implemented include the following:

4623 – Modify the WWTF design to generate cleaner effluent. For example, pilot-testing of the  
4624 proposed RO unit resulted in average sulfate removal rates of 99.8 percent with average  
4625 and maximum sulfate concentrations observed in the effluent of 3.7 and 6.9 mg/L,  
4626 respectively, for the blended (RO and vibratory shear enhanced processing) streams,  
4627 which is below the 9 mg/L value assumed for modeling purposes during closure (Barr  
4628 2013f). Given that the WWTF would have an annual average discharge of approximately  
4629 300 gpm, as compared to about 78 gpm from the three groundwater sources of sulfate, a  
4630 small decrease in the actual sulfate concentration in the WWTF effluent could offset the  
4631 loading from the three groundwater sources.  
4632

4633 – Increase the WWTF discharge in closure. Poly Met could temporarily increase the volume  
4634 of the WWTF (which is operating below its actual capacity) effluent discharge during  
4635 low-flow conditions, which would help further dilute concentrations in the Partridge  
4636 River.

4637 • Category 1 Stockpile Cover System – Poly Met proposes to install a geomembrane cover  
4638 system, in lieu of the originally proposed evapotranspiration cover, to reduce the load of the  
4639 constituents that would reach the West Pit via drainage from the Category 1 Stockpile.  
4640 Construction of the Category 1 Stockpile cover system would be progressive, starting in year  
4641 14 and being fully constructed by the end of year 21. Under the NorthMet Project Proposed  
4642 Action, the Category 1 Stockpile would be the only permanent waste rock stockpile. Water  
4643 quality modeling indicates that for many constituents, this stockpile would be the largest  
4644 source of constituent load to the West Pit. The Category 1 Stockpile cover system would be  
4645 the primary engineering control that limits constituent loading from the Category 1 Stockpile  
4646 to the West Pit.

4647 The design of the Category 1 Stockpile cover system could be adapted up to the point of  
4648 construction, depending on the actual water quality conditions encountered during the  
4649 NorthMet Project Proposed Action phases and estimated by water quality monitoring and  
4650 model updating. Design options, which would need to be approved by the MPCA and  
4651 MDNR, include:

- 4652 – Increased or decreased thickness of the geomembrane material to modify the potential for  
4653 defects to be created during installation and to modify the life of the geomembrane;
- 4654 – Increased or decreased soil cover thickness above the geomembrane material to modify  
4655 water storage capacity;
- 4656 – Increased or decreased soil hydraulic conductivity of the granular drainage layer above  
4657 the geomembrane to modify lateral drainage capacity;
- 4658 – Increased or decreased uninterrupted slope length to modify lateral drainage capacity;
- 4659 – Modified soil type and/or thickness below the geomembrane to modify leakage rate  
4660 through potential geomembrane defects; and/or
- 4661 – Including a geosynthetic clay liner below the geomembrane to modify leakage rate  
4662 through potential geomembrane defects.

4663 After installation of the cover system, post-installation adjustments, such as modifying  
4664 vegetation density and erosion of the cover system, could be made if approved by the MPCA  
4665 and MDNR (Poly Met 2015d).

4666 • Plant Site WWTP – The WWTP would treat process water. A RO treatment plant it proposed  
4667 or equivalently performing technology that would meet water quality targets. Because the  
4668 plan for construction of the WWTP envisions a phased build-out of the capacity that would  
4669 be needed when the maximum flow occurs, variations in quantity can easily be addressed by  
4670 either accelerating or delaying the installation of the additional equipment that is planned for  
4671 the expansion of the WWTP.

4672 • Treatment performance issues that could occur from changes in influent water quality can be  
4673 addressed by making adjustments to operating conditions. At times throughout the year, it is

- 4674 expected that the WWTP would have excess hydraulic capacity, which can be used to  
4675 • improve treatment performance, for example by reducing the recovery rates for the  
4676 membrane separation processes or increasing the hydraulic retention times in the chemical  
4677 precipitation processes.
- 4678 • Other examples of how the WWTP can be adapted during the Project to modify treatment  
4679 performance include:
- 4680 – Selection of alternative membranes for either the Reverse Osmosis (RO) or the Vibratory;  
4681 – Shear Enhanced Processing (VSEP) process units to modify the removal efficiencies of  
4682 some parameters across these systems;  
4683 – Chemical addition to increase metals removal by the WWTP; and  
4684 – Softening pretreatment.

4685 Adaptive management would be implemented as necessary based on monitoring for total  
4686 mercury to determine whether the treated water could be discharged to surface waters, or  
4687 whether some additional treatment is needed. Adaptive management strategies would include  
4688 pretreatment modifications such as chemical scavenger addition to obtain additional metals;  
4689 the use of tighter RO membranes for the primary RO system; treatment of some portion of  
4690 the VSEP permeate by the primary RO system to further remove some dissolved  
4691 constituents; and addition of polishing treatment units for removal of trace metals (e.g., ion  
4692 exchange).

- 4693 • Tailings Basin Pond Bottom Cover – During reclamation, PolyMet proposes to deposit  
4694 granular or pelletized bentonite into the Tailings Basin pond, which would then settle and  
4695 form a cover. This cover would reduce the diffusion of oxygen and water percolation into the  
4696 tailings, thereby reducing oxidation and the resultant production of contaminants. In addition,  
4697 the seepage through the tailings would be reduced, resulting in less flow being collected in  
4698 the Tailings Basin surface and groundwater seepage containment system, and then treated.

4699 The Tailings Basin pond bottom cover thickness or the percent of bentonite in the pellets or  
4700 grains or both can be changed if monitored water quantity or quality suggested that  
4701 modifications were needed to meet water resource objectives. This modification can occur  
4702 before or after installation to modify performance.

4703 In addition, the bentonite amended layer could be excavated from portions of the pond  
4704 bottom to modify performance. Any design modifications would need to be approved by the  
4705 MPCA and MDNR (PolyMet 2015d).

#### 4706 **Contingency Mitigation**

4707 Contingency mitigation measures are feasible options that could be undertaken should  
4708 engineering controls (fixed or adaptive) be unable to ensure compliance with applicable water  
4709 quality standards. These contingency measures were not included in GoldSim modeling, as  
4710 current model results at the P90 confidence level did not show these measures were needed to  
4711 meet or not cause or contribute to an exceedance of the evaluation criteria. If monitoring or  
4712 refined modeling were to indicate that contingency mitigation would be needed, these measures  
4713 would be employed as appropriate and approved by the MPCA and MDNR. The contingency  
4714 mitigation measures would not be initially included in the financial assurance package, but, if

4715 required in the future, these measures would be added to the financial assurance package. These  
4716 contingency mitigation measures would address the following situations (PolyMet 2015r; 2015i):

- 4717 • A pattern of overflows of the process water sumps or ponds developed – In all the process  
4718 water sumps and ponds, there would be excess capacity designed as a safety factor ranging  
4719 from approximately 30 to 270 percent of required capacity. Additional capacity could be  
4720 developed by expanding the pond areas.
- 4721 • Streams along the railroad corridor between the Mine Site and Plant Site showed degradation  
4722 in water quality as a result of material spilled from the rail cars – Catchment areas could be  
4723 developed adjacent to the tracks at stream crossings to minimize the amount of material that  
4724 reaches the streams.
- 4725 • Groundwater downgradient of lined infrastructure had compliance issues – Interception wells  
4726 could collect groundwater flows affected by a leak from one of the liner systems or by the  
4727 OSLA. Interception wells would only be needed while groundwater was affected by the  
4728 temporary mine features.
- 4729 • West Pit water quality was not as expected – This could be addressed by reducing the  
4730 contaminant load from the West Pit walls or the East Pit using methods such as low-  
4731 permeability soil barriers or a PRB, adding water with lower concentrations of contaminants  
4732 to the West Pit by routing additional stormwater to the West Pit, or treating the West Pit  
4733 either by pumping West Pit water to the WWTF for treatment or treating the West Pit Lake  
4734 in situ with iron salts, fertilizer, or other methods tailored to the contaminant.
- 4735 • If East Pit or West Pit groundwater inflows are greater than expected due to faults, use of a  
4736 grout curtain to control groundwater flow into pits and eventually out of pits when they are  
4737 filled with water or water and rock would be evaluated (PolyMet 2014l).
- 4738 • New surface seepage locations emerged as the Tailings Basin was developed – The surface  
4739 and groundwater seepage containment system or the Tailings Basin south surface seepage  
4740 management system could be expanded to collect seepage from any new seepage locations.
- 4741 • Tailings Basin pond water quality was worse than expected – This could be addressed by  
4742 several methods, including: reducing solute load delivered to the Tailings Basin pond by  
4743 incorporating additional treatment at the Mine Site WWTF; sending all or a portion of the  
4744 water from the surface and groundwater seepage containment system and Tailings Basin  
4745 south surface seepage management systems to the WWTP for treatment before being  
4746 returned to the Tailings Basin pond; sending pond water to the WWTP for treatment before  
4747 being returned to the Tailings Basin pond; or treating the Tailings Basin pond in situ with  
4748 iron salts, fertilizer, or other methods tailored to the constituent of concern.
- 4749 • Groundwater or surface water downgradient of the Tailings Basin has compliance issues –  
4750 This could be addressed by several methods, including inspecting the containment system  
4751 around the Tailings Basin for breaches and repaired or using interception wells to collect  
4752 groundwater flows affected by a breach, or improving Tailings Basin pond water quality (see  
4753 above).

4754

4755 ***Future Transition from Mechanical to Non-Mechanical Treatment Systems***

4756 The NorthMet Project Proposed Action would rely upon mechanical treatment to achieve water  
4757 resource objectives as long as needed; however, the goal would be to transition to non-  
4758 mechanical treatment—which would be a low-maintenance, low-energy treatment system—to  
4759 ensure attainment of water resources objectives, including compliance with applicable  
4760 groundwater and surface water standards, during the closure phase.

4761 State of Minnesota Non-Ferrous Rules allow for maintenance after closure, known as “post-  
4762 closure maintenance” (*Minnesota Rules* 6132.3200, subp. 2.E.6.). While “closure” is defined in  
4763 the Rules to mean, “...the process of terminating and completing final steps in reclaiming any  
4764 specific portion of a mining operation.” Post-closure maintenance includes those activities  
4765 required to “sustain reclamation” after closure (*Minnesota Rules* 6132.0100). Both of these  
4766 maintenance methods can meet the goals of *Minnesota Rules* 6132.3200, subpart 1. It is  
4767 important to recognize that the goals in the Non-Ferrous Rules are not requirements.

4768 When mining activities cease, a permittee is required to initiate “closure” of the mine. As part of  
4769 the closure process, reclamation of the mining area must be completed. If continued maintenance  
4770 is needed following closure of the mine to sustain the reclamation, the permittee is responsible  
4771 for “post-closure maintenance.” To ensure that reclamation is completed and sustained, the Non-  
4772 Ferrous Rules require the permittee to provide financial assurance in amounts sufficient to pay  
4773 for both closure and post-closure maintenance. A permittee cannot be released from its  
4774 responsibilities, including financial assurance requirements, until there is no longer a need for  
4775 post-closure maintenance.

4776 The permit to mine would require PolyMet to present a plan for eventual transition from  
4777 mechanical water treatment to non-mechanical water treatment. PolyMet plans to test non-  
4778 mechanical water treatment technologies during mine operations and following closure and then  
4779 transition from mechanical to non-mechanical water treatment technologies as soon as the  
4780 company can demonstrate that that these technologies would treat water to the required water  
4781 quality standards. PolyMet estimates that it can transition to non-mechanical water treatment at  
4782 the Tailings Basin immediately after mine closure and at the Mine Site several decades after  
4783 mine closure.

4784 Non-mechanical treatment systems, which are described below, would be designed and pilot-  
4785 tested before being implemented to treat water from the Category 1 Stockpile surface and  
4786 groundwater seepage containment system, the West Pit Overflow, the Tailings Basin seepage  
4787 containment system, and the Hydrometallurgical Residue Facility.

4788 ***Category 1 Stockpile Groundwater Containment Non-mechanical Treatment System***

4789 PolyMet proposes to install a Category 1 Stockpile groundwater containment non-mechanical  
4790 treatment system at the Mine Site to replace the mechanical treatment of the water collected by  
4791 the containment system during the closure and long-term maintenance phase of the NorthMet  
4792 Project Proposed Action. The system would likely include two PRBs, which are flow-through  
4793 treatment systems, for metal precipitation and solids removal. The PRBs would reduce  
4794 constituent loading through physical, chemical, and/or biological treatment processes including:  
4795 biochemical reduction of sulfate to sulfide using sulfate-reducing bacteria, sorption to solid-  
4796 phase surfaces such as iron oxides or organic matter, chemical precipitation to convert dissolved-  
4797 phase constituents to solid-phase particles, and physical filtering of solid-phase particles. The

4798 PRBs would ideally be located where they could take advantage of gravity flow. The locations  
4799 would be dependent on the final hydraulic plan for discharge from the Category 1 Stockpile  
4800 surface and groundwater seepage containment system into the West Pit (PolyMet 2015d).

#### 4801 ***West Pit Overflow Non-mechanical Treatment System***

4802 PolyMet proposes to install a West Pit overflow non-mechanical treatment system at the Mine  
4803 Site to replace the pumping of West Pit lake water to the WWTF during the closure and long-  
4804 term maintenance phase of the NorthMet Project Proposed Action. It is expected to be a multi-  
4805 stage system with a constructed wetland for metal (copper, cobalt, nickel, and lead) precipitation  
4806 and solids removal, a PSB for metal sorption, and an aeration pond to provide time for water  
4807 exiting the PSB to re-equilibrate with the atmosphere and to increase the concentration of  
4808 dissolved oxygen before the water would be discharged. The proposed design and operation of  
4809 any non-mechanical system at the Mine Site would be adapted as necessary to effectively treat  
4810 actual flows and to meet all applicable regulatory requirements (PolyMet 2015d).

#### 4811 ***Tailings Basin Non-mechanical Treatment System***

4812 PolyMet proposes to install a Tailings Basin non-mechanical treatment system to replace the  
4813 mechanical treatment of the water draining through the Tailings Basin and collected in the  
4814 Tailings Basin seepage containment system and the south seepage management system during  
4815 the closure and long-term maintenance phase of the NorthMet Project Proposed Action. In  
4816 closure and long-term maintenance, seepage flow to the east would be less than 1 gpm.  
4817 Provisions to adaptively manage this low-volume flow from the eastern segment of the  
4818 containment system would be included in the development of the Non-Mechanical Treatment  
4819 System. During closure and long-term maintenance, any water collected by the  
4820 Hydrometallurgical Residue Facility leakage collection system would also be routed to this  
4821 treatment system. The Tailings Basin non-mechanical treatment system would consist of a  
4822 constructed wetland for metals precipitation, sulfate load reduction, and solids removal and PSBs  
4823 for polishing (i.e., additional removal of metals, if needed). It would be constructed by rebuilding  
4824 the natural wetlands between the Tailings Basin and the containment system as a vertical, up flow  
4825 constructed wetland system with PSB systems at the outer perimeter within the access road. The  
4826 total flow for the Tailings Basin non-mechanical treatment system is expected to be 1,200 gpm,  
4827 which would include flows at the northern, northwestern, western, and southern toes (PolyMet  
4828 2015d).

#### 4829 ***Tailings Basin Pond Overflow Post-mechanical Treatment Options***

4830 During the initial portion of the closure and long-term maintenance period, Tailings Basin pond  
4831 water would be pumped to the WWTP to prevent overflow. A monitoring program would  
4832 document changes in pond water levels and water quality over time. One goal of the NorthMet  
4833 Project Proposed Action during closure and long-term maintenance would be to allow overflow  
4834 of the tailings pond. This could only be done after demonstrating that water in the Tailings pond  
4835 was stormwater and that it complied with applicable standards. The Tailings Basin closure  
4836 overflow structure would be embedded into bedrock of the hillside east of Cell 2E during  
4837 reclamation. This structure would likely be modified to serve as a stormwater overflow, which  
4838 would allow water discharged to enter the Mud Lake Creek Watershed (PolyMet 2015d).

4839 **5.2.2.3.6 Monitoring**

4840 Monitoring would be a critical component of the NorthMet Project Proposed Action to better  
 4841 understand impacts and to inform facility operation and maintenance and the selection and  
 4842 implementation of possible adaptive or contingency mitigation measures. The NorthMet Project  
 4843 Proposed Action includes PolyMet’s proposed water quality and quantity monitoring plan.  
 4844 Overviews of the water monitoring plans at the Mine Site and Plant Site, with PolyMet proposed  
 4845 monitoring locations and frequencies, are presented in the sections below. The specifics of  
 4846 monitoring—including specific locations, frequencies, and parameters—would be finalized  
 4847 during the permitting process after a detailed evaluation. An NPDES permit would be required  
 4848 for any point source water discharge that adds pollutants to waters of the U.S.

4849 **Partridge River Watershed**

4850 Water monitoring within the Partridge River Watershed would be used on a continual basis to  
 4851 document compliance with permit conditions, annually validate and update water models, and  
 4852 provide input to optimize operations including any adaptive engineering controls or contingency  
 4853 mitigation measures. Depending on the component (i.e., water flow, elevation, or quality)  
 4854 monitoring frequency would range from continuously to quarterly (PolyMet 2015r). An  
 4855 overview of PolyMet’s proposed water monitoring plan within the Partridge River Watershed is  
 4856 in Table 5.2.2-53.

4857 **Table 5.2.2-53 Overview of Monitoring Plans within the Partridge River Watershed**

| Monitoring Plan Component |                                            | Purpose                                                                                                                                                       | Summary                                                                                                                    | General Locations                                                                                                                                                  |
|---------------------------|--------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Internal<br>Streams       | Pit water                                  | Compare water balance with expected conditions. Define future pumping requirements and evaluate trends in pit water quality.                                  | Continuous flow monitoring and monthly water quality sampling at up to four sumps <sup>1</sup>                             | Stations installed to monitor flows and water quality from each pit sump                                                                                           |
|                           | Stockpile drainage                         | Compare water balance with expected conditions. Define future pumping requirements, and evaluate trends in stockpile drainage water quality.                  | Continuous flow monitoring and monthly water quality sampling from up to 12 locations <sup>1</sup>                         | Stations installed to monitor drainage from each stockpile liner and each stockpile underlain and the two Category 1 Waste Rock Stockpile containment system sumps |

| Treated Water Pipeline flows     | Compare water balance with expected conditions                                                                                                 | Flow monitoring and water quality sampling at the inlet and outlet                                                                                                                      | Inlet and outlet of the Treated Water Pipeline                                                                                                                                                                                                                   |
| Stormwater                       | Stormwater                                                                                                                                     | Evaluate trends in stormwater quality.                                                                                                                                                  | Flow monitoring and water quality sampling at pond outlets <sup>1</sup>                                                                                                                                                                                          |
| Groundwater                      | Surficial aquifer                                                                                                                              | Evaluate groundwater level and water quality trends in the surficial aquifer.                                                                                                           | 33 sampling locations sampled approximately April, July, and October                                                                                                                                                                                             |
|                                  | Bedrock                                                                                                                                        | Evaluate groundwater level and water quality trends in the bedrock.                                                                                                                     | Number of wells are yet to be determined, with sampling approximately April, July, and October                                                                                                                                                                   |
| Wetlands                         | Wetlands                                                                                                                                       | Evaluate potential effects of mining operations on wetlands and determine if potential indirect impacts from the mining operations have occurred or if additional mitigation is needed. | Surficial aquifer monitoring wells installed downgradient of each stockpile and pit<br>Bedrock monitoring well locations are to be determined<br>Continuation of baseline monitoring program                                                                     |
| Surface Water                    | Partridge River and tributaries                                                                                                                | Evaluate trends in surface water quality and flow.                                                                                                                                      | Number of piezometers and sampling frequency to be determined<br>Monthly sampling of flow and water quality at nine sampling locations during non-frozen conditions<br>Partridge River, Longnose Creek, Wetlegs Creek, Wyman Creek, and West Pit Overflow Creek, |

| <b>Monitoring Plan Component</b>    | <b>Purpose</b>                                                                                           | <b>Summary</b>                                                                                          | <b>General Locations</b>            |
|-------------------------------------|----------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------|-------------------------------------|
| Colby Lake and Whitewater Reservoir | Evaluate trends in water quality of Colby Lake and water levels for Colby Lake and Whitewater Reservoir. | Water quality and water level sampling at one location for each water body during non-frozen conditions | Colby Lake and Whitewater Reservoir |

4858 Source: PolyMet 2015r.

4859 <sup>1</sup> Cumulative flow volume would be measured, with values recorded on a monthly basis. Water quality monitoring would occur  
 4860 during non-frozen conditions.

4861 Proper placement of waste rock and overburden in the appropriate stockpile and for ultimate  
 4862 disposal would be important to achieve the NorthMet Project Proposed Action’s predicted water  
 4863 quality. PolyMet has developed a Rock and Overburden Management Plan for monitoring and  
 4864 testing of waste rock during mine operations. The USEPA, MDNR, and MPCA have agreed that  
 4865 they will review this Plan and include requirements for waste rock testing and monitoring to  
 4866 ensure it is properly categorized and managed during permitting.

4867 The MDNR would require a Spilled Ore Plan as part of the Permit to Mine for monitoring the  
 4868 extent of spillage and identifying appropriate mitigation measures.

4869 The Co-Lead Agencies recommend a robust monitoring program during all phases of mining to  
 4870 provide evidence of the presence or absence of hydrologically significant faults. If identified,  
 4871 mitigation can be employed to minimize flow through the faults.

4872 **Embarrass River Watershed**

4873 Water monitoring within the Embarrass River Watershed would be used on a continual basis to  
 4874 document compliance with permit conditions, annually validate and update water models, and  
 4875 provide input to optimize operations of adaptive engineering controls. Depending on the  
 4876 component (i.e., water flow, elevation, or quality) monitoring is proposed to occur continuously,  
 4877 monthly, or three times a year in the first month of non-freezing quarters (PolyMet 2015i). An  
 4878 overview of PolyMet’s proposed water monitoring plan at the Plant Site is in Table 5.2.2-54.

4879

4880 **Table 5.2.2-54 Overview of Monitoring Plans for the Embarrass River Watershed**

| <b>Monitoring Plan Component</b>  |                                              | <b>Purpose</b>                                                                                                                    | <b>Summary</b>                                                                                                                  | <b>General Locations</b>                                                                                             |
|-----------------------------------|----------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------|
| Internal Process<br>Water Streams | Tailings Basin pond                          | Monitor pond water levels and trends in Tailings Basin pond water characteristics over time                                       | Daily water level (WL) monitoring and water quality (WQ) monitoring                                                             | WL monitoring location TBD; WQ monitoring at pond barge                                                              |

| Stormwater                        | Stormwater                                   | Monitor stormwater quality and quantity                                                                                           | Monthly (during non-frozen conditions, April through October) flow rate and WQ monitoring                                       | Stormwater control features                                                                                          |
| Surface Discharges                | WWTP                                         | Demonstrate acceptable effluent characteristics                                                                                   | Continuous flow monitoring of WWTP effluent, and monthly WQ monitoring and monthly total flow monitoring at discharge locations | WWTP effluent                                                                                                        |
| Surface Water                     | Embarrass River and tributaries              | Evaluate trends in surface water quality and flow                                                                                 | Monthly sampling of flow and water quality                                                                                      | Embarrass River, Mud Lake Creek, Trimble Creek, and Unnamed Creek                                                    |
|                                   | Second Creek                                 | Evaluate trends in surface water quality and flow                                                                                 | Monthly sampling of flow and water quality                                                                                      | Second Creek downstream of seepage barrier                                                                           |
|                                   | Colby Lake intake                            | Evaluate water quantity use over                                                                                                  | Continuous flow monitoring at intake,                                                                                           | Colby Lake intake                                                                                                    |

| Monitoring Plan Component |          | Purpose                                                                                                                                                                                         | Summary                                                                          | General Locations                                             |
|---------------------------|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------|---------------------------------------------------------------|
| Groundwater               | General  | Evaluate groundwater quality and water level trends over time                                                                                                                                   | Monitoring wells sampled during non-frozen conditions (April, July, and October) | Existing monitoring wells installed around the Tailings Basin |
| Wetlands                  | Wetlands | Evaluate potential effects of processing plant operations on wetlands and determine if the potential indirect impacts from these operations have occurred or if additional mitigation is needed | Number of piezometers and sampling frequency yet to be determined                | Continuation of the baseline monitoring program               |

4881 Source: PolyMet 2015i.

4882 WQ = Water Quality; WL = Water Level

4883 Piezometers or other measurement devices would be installed on opposite sides of the  
 4884 containment system to monitor head differential to verify that hydraulic gradient have been  
 4885 reversed which would show that the containment system is achieving complete capture.  
 4886 Additionally, permit(s) would require a robust monitoring program during all phases of mining  
 4887 to provide evidence of the presence or absence of hydrologically significant faults. If identified,  
 4888 mitigation would be employed to minimize flow through the faults.

#### 4889 5.2.2.4 NorthMet Project No Action Alternative

4890 Under the NorthMet Project No Action Alternative, the NorthMet Project Proposed Action  
 4891 would not occur and, therefore, the environmental effects associated with the NorthMet Project  
 4892 Proposed Action, as described in Section 5.2.2, would not occur. Although under the No Action  
 4893 Alternative, the NorthMet Project Proposed Action, including the proposed Tailings Basin  
 4894 seepage collection and water treatment engineering controls, would not occur, the No Action  
 4895 Alternative would not be static. Under the No Action Alternative, water quality would continue  
 4896 to be maintained by generally effective existing natural ecosystem functions. Under the  
 4897 NorthMet Project Proposed Action, these functions would be provided by the WWTP or WWTF  
 4898 (or alternative, if developed) and this reflects a substantial shift in how water quality is  
 4899 maintained.

4900 In the Partridge River Watershed, there are actions occurring as part of the Cliffs Erie Consent  
 4901 Decree that would be expected to result in improvements to the water quality of Second Creek  
 4902 and the Lower Partridge River, but there are also other proposals for mining and mineral  
 4903 processing, and mitigative actions under other existing water quality permits, that could also  
 4904 affect the water quality of these waterbodies, but which cannot be predicted at this time.

4905 In the Embarrass River Watershed, it is anticipated that the water quality of the existing  
 4906 LTVSMC Tailings Basin seepage would improve over time as a result of natural attenuation  
 4907 and/or possible additional mitigation measures at some point in the future pursuant to new permit  
 4908 requirements or other state or federal remediation requirements. Other actions are underway to

4909 improve the water quality of the Area 5NW Pit overflow, which contributes a high sulfate load to  
4910 the Embarrass River. At this time, the exact nature, timing, and effectiveness of these measures  
4911 are unknown and, therefore, not quantifiable in this FEIS, but it is reasonable to expect that water  
4912 quality within the Embarrass River could improve over time, absent other unforeseen activities  
4913 that could affect water quality. In addition, climate change would be likely to affect the  
4914 hydrology and, indirectly, the water quality, of the NorthMet Project Proposed Action area as the  
4915 result of predicted increases in mean annual temperature and mean annual precipitation.

4916 Therefore, there are several factors that could dynamically affect the hydrology and water quality  
4917 of the Partridge and Embarrass River watersheds in the future, but in ways that cannot be  
4918 quantified with any reasonable level of confidence at this time. It should be noted that PolyMet  
4919 did analyze the effects of climate change on water quality and quantity estimates for the  
4920 NorthMet Project Proposed Action by conducting a sensitivity analysis. As described in Section  
4921 5.2.2.3, the GoldSim model was used to evaluate the CEC scenario for comparison with the  
4922 NorthMet Project Proposed Action. The CEC scenario represents future conditions without the  
4923 NorthMet Project Proposed Action, including all proposed facilities, but is not synonymous with  
4924 the No Action Alternative because it does not account for other foreseeable changes within the  
4925 NorthMet Project area.

DRAFT

### 1 **5.2.3 Wetlands**

2 This section describes the potential environmental consequences of the NorthMet Proposed  
3 Action to wetland resources, including the potential direct and indirect effects. Discussions are  
4 also included on actions taken to avoid or mitigate wetland impacts, proposed wetland mitigation  
5 options, and wetland monitoring plans.

#### 6 **Summary**

7 The NorthMet Project Proposed Action would result in direct impacts and indirect effects on  
8 wetland resources at the Mine Site, along the Transportation and Utility Corridor, at the Plant  
9 Site, and around the Mine Site (Area 1) and north of the Plant Site (Area 2). This section  
10 describes these effects within each of these areas and provides a summary of the effects over the  
11 operational life of the facility.

12 Direct wetland impacts would result from mining-related activities involving filling, excavation,  
13 a combination of filling and excavation, and installation of a containment system within the  
14 wetland boundary, and therefore these wetlands would be permanently lost. The NorthMet  
15 Project Proposed Action would directly affect 913.8 acres of wetlands located within the  
16 NorthMet Project area. The Mine Site would be subject to the majority of the direct wetland  
17 impacts. The direct wetland impacts within the entire NorthMet Project area would occur in  
18 the following wetland types: coniferous bog (56 percent), shrub swamp (12 percent),  
19 coniferous swamp (9 percent), shallow marsh (8 percent), deep marsh (8 percent), sedge/wet  
20 meadow (4 percent), hardwood swamp (1 percent), and open bog (1 percent). The majority of  
21 the direct impacts would occur as a result of a combination of filling and excavation (65  
22 percent).

23 Wetlands directly impacted within the Mine Site would result in a combined effect area of 758.2  
24 acres. These direct wetland impacts would be caused by fill (10 percent), excavation (12  
25 percent), or a combination of fill and excavation (78 percent). The Transportation and Utility  
26 Corridor would directly affect 7.2 acres of wetlands, all of which would be directly filled.  
27 Approximately 148.4 acres of wetlands within the Plant Site would be directly impacted. These  
28 wetlands impacts would be caused by fill (12 percent), excavation (31 percent), excavation and  
29 fill (less than 1 percent), and the containment system (58 percent).

30 Compensatory mitigation is required for the 913.8 acres of wetlands that would be directly  
31 impacted. In addition, compensatory mitigation for the 26.9 acres of wetland fragmentation  
32 would be provided up front. The overall wetland mitigation strategy for the NorthMet Project  
33 Proposed Action is to compensate for unavoidable wetland impacts in-place, in-kind where  
34 possible and in-advance of impacts when feasible in order to replace lost wetland functions. Off-  
35 wetland mitigation projects would be implemented to fulfill the requirements for compensatory  
36 mitigation. PolyMet's current mitigation proposal includes the following:

- 37 • Off-site mitigation including:
- 38 – Aitkin Site – 808.3 acres of wetland restoration and 83.2 acres of upland buffer;
  - 39 – Hinckley Site – 286.2 acres of wetland restoration and 91.2 acres of upland buffer; and
  - 40 – Zim Site – 508.2 acres of wetland restoration and preservation and 22.7 acres of upland  
41 buffer.

42 USACE St. Paul wetland compensatory mitigation replacement ratios are based on three factors:  
43 in-place versus out-of-place, in-kind versus out-of-kind, and in-advance versus concurrent. The  
44 2009 USACE St. Paul District's policy states a base compensation ratio of 1.5:1, and a minimum  
45 of 1:1, with a provision for a case-by-case determination of higher ratios to account for factors  
46 including difficult-to-replace, rare and/or exceptional wetlands/aquatic resources. Therefore, per  
47 the 2009 policy, the District Engineer may determine that a higher compensation ratio of 2:1 (or  
48 higher) would be required to offset losses of wetlands that would be difficult to replace and/or  
49 provide an exceptional level of functions. The USACE St. Paul District has not made a final  
50 determination of the compensation ratios that would be required for the NorthMet Project  
51 Proposed Action. The final decision on compensatory mitigation ratios would be determined at  
52 the time of the DA permit decision pursuant to Section 404 of the CWA based on current District  
53 guidance. PolyMet would ultimately need to satisfy both the federal and state mitigation  
54 requirements. The number of mitigation credits to be earned by replacement wetlands would be  
55 determined during permitting by the appropriate agencies reviewing the wetland mitigation plan.  
56 This would be based on the extent to which the sites meet the target goals established during  
57 permitting. These include, among other things, restoration of wetland appropriate hydrology and  
58 the establishment of a target plant community or type. The NorthMet Project Proposed Action is  
59 estimated to directly affect 913.8 acres. Depending on the location, type, and timing of  
60 compensatory mitigation, the minimum required amount of replacement wetlands for direct  
61 impacts could range from 913.8 acres up to 1,827.6 acres (i.e., 1:1 up to 2:1 compensation  
62 ratios). In addition, compensatory mitigation for the 26.9 acres of wetland fragmentation would  
63 also be provided up front.

64 The USACE has concluded that the mitigation sites selected and the wetland credits generated at  
65 the three mitigation sites would be acceptable for use in compensating for direct wetland losses.  
66 The USACE has not made a final decision on the mitigation ratios that would be required to  
67 compensate for direct wetland impacts; if fully successful, it is likely these three mitigation sites  
68 would generate sufficient credits to compensate for the 940.7 acres of wetlands directly  
69 impacted. In the event that not all of the credits generated by these sites are utilized to  
70 compensate for direct wetland impacts, any excess credits could be used to compensate for  
71 indirect losses (USACE 2015a). The current proposed mitigation presented below shows that  
72 PolyMet could have an excess of mitigation credits from the three mitigation sites if the  
73 mitigation sites are successful and meet the performance standards. However, it is understood  
74 that mitigation sites sometimes are not fully successful; contingency plans (discussed below)  
75 would be developed for the NorthMet Project Proposed Action and approved during permitting.  
76 The USACE encourages the development of mitigation for foreseeable indirect effects, which  
77 the current proposed mitigation plan appears to achieve.

78 Financial assurances for the direct wetland impact mitigation would be required until success of  
79 the mitigation sites can be assured. While this wetland mitigation would be expected to be  
80 approved and constructed in advance of any authorized wetland impacts, it is unclear whether  
81 these sites would be well enough established for financial assurances to be waived. The USACE  
82 would also consider the application of financial assurances for potential indirect wetland effects  
83 and monitoring. Both the USACE and state would require consideration of financial assurances  
84 during the permitting process.

85 Off-site wetland compensation of 1,602.7 acres could provide 1,513.3 wetland mitigation credits.  
86 In addition, a total of 197.1 acres of upland buffer areas are proposed to be established with

87 native vegetation around the wetland restoration areas. In accordance with USACE guidelines,  
88 credit for the upland buffer areas would be at a 4:1 ratio, resulting in an additional 49.3 credits.  
89 The total off-site mitigation could provide 1,562.5 wetland mitigation credits. Compensatory  
90 ratios determined in permitting may vary from these assumptions. The determination of final  
91 mitigation credits required to offset the impacts of the proposed NorthMet Project Proposed  
92 Action would be determined during permitting.

93 Finally, post-closure establishment of 101.8 acres of wetland on-site would likely occur during  
94 reclamation of the Mine Site; this establishment is not included in the mitigation credits  
95 discussed above as credit is not being requested at this time. The generation of wetland credits in  
96 these areas has the potential to be used on a contingency basis, but compensatory credit would  
97 not be considered at this time for a variety of reasons including the fact that any restoration  
98 efforts would not occur for many years.

99 Potential indirect wetland effects from the NorthMet Project Proposed Action would result from  
100 one or more of the following six factors: 1) wetland fragmentation, 2) changes in wetland  
101 hydrology resulting from changes in watershed area, 3) changes in wetland hydrology due to  
102 groundwater drawdown resulting from open pit mine dewatering, 4) changes in wetland  
103 hydrology from groundwater drawdown resulting from operation of the Plant Site, including  
104 groundwater seepage containment, 5) changes in stream flow near the Mine Site and Plant Site,  
105 as well as associated effects on wetlands abutting the streams, and 6) changes in wetland water  
106 quality related to atmospheric deposition of dust and rail car spillage associated with Mine Site  
107 and Plant Site operations. The change in wetland hydrology from groundwater drawdown at the  
108 Mine Site was assessed by two different methodologies; therefore, total indirect wetland effects  
109 were provided based on both approaches. The NorthMet Project Proposed Action could  
110 indirectly affect up to either 7,694.2 acres of wetlands located within and around the NorthMet  
111 Project area, based on the method of wetlands crossing analog impact zones, or up to 6,568.8  
112 acres of wetlands located within and around the NorthMet Project area, based on the method of  
113 wetlands within analog impact zones (PolyMet 2015b).

114 Regardless of the method used, wetland mitigation for potential indirect wetland effects would  
115 be determined by the agencies during permitting. If the NorthMet Project Proposed Action were  
116 to be permitted, wetland monitoring for hydrology and vegetation would be conducted to identify  
117 if future indirect effects to wetlands would occur. Wetland hydrology and vegetation would be  
118 monitored, and additional monitoring locations may be considered during permitting. A  
119 component of the monitoring plan would be based on those wetlands that would have a high  
120 likelihood of indirect effects as a result of groundwater drawdown. If the monitoring were to  
121 determine that indirect wetland effects had occurred, additional compensation could be required  
122 if determined necessary by the permitting agencies. In the event that the required wetland  
123 monitoring identified additional indirect effects, permit conditions would likely include a plan  
124 for adaptive management practices to be implemented, such as expanded monitoring and  
125 hydrologic controls. Additionally, compensatory mitigation may be required if additional  
126 impacts are identified during annual reporting. Permit conditions would likely include an  
127 adaptive management plan to account for any additional impacts that may be identified in the  
128 annual monitoring and reporting.

129 **5.2.3.1 Methodology and Evaluation Criteria**

130 Wetland effects for the NorthMet Project Proposed Action include direct, indirect, and  
131 cumulative effects. As previously mentioned, a Wetland IAP Workgroup was formed, and based  
132 on this workgroup, effects were assessed using agency-prescribed methods as presented in the  
133 Wetland Analysis Work Plan (PolyMet 2011b) and using the wetland types and acreages  
134 identified in the report *NorthMet Project Wetland Data Package Version 7* (PolyMet 2015b).  
135 Methods used to evaluate direct impacts and indirect effects are described below; cumulative  
136 effects are described in Chapter 6.

137 **5.2.3.1.1 Direct Wetland Impacts Methodology and Evaluation Criteria**

138 Direct wetland impacts for the NorthMet Project Proposed Action were determined through a  
139 GIS analysis of the areas that would be directly disturbed by mining features and operations,  
140 such as mine pits, stockpiles, and access roads. The area of analysis for the direct impacts  
141 included the Mine Site, Transportation and Utility Corridor, and Plant Site.

142 Direct impacts would result from mining-related activities such as filling or excavation of  
143 wetlands, and therefore, these wetlands would be permanently lost. Wetlands within the  
144 NorthMet Project area were identified using the Eggers and Reed (1997, 2014) community  
145 classification system, as described in Section 4.2.3. The analysis for the direct wetland impacts  
146 included identification of wetland type, total wetland acreage, total acres of direct effect, type of  
147 direct effect (i.e., fill, excavation, etc.), and the quality of each wetland to be impacted by the  
148 NorthMet Project Proposed Action.

149 **5.2.3.1.2 Potential Indirect Wetland Effects Methodology and Evaluation Criteria**

150 Wetlands that are not filled or excavated, but have a reduced function or value, would be  
151 considered indirectly affected. The most likely types of indirect effect on the functions and  
152 values of remaining wetlands at the Mine Site include wetland fragmentation from NorthMet  
153 Project area elements such as open pits, stockpiles, and haul roads; and indirect hydrological  
154 effects that may result in a conversion of one wetland type to another or the conversion of a  
155 wetland to an upland. Other indirect effects could result from changes in wetland watershed  
156 areas (during operation and post-closure); groundwater drawdown resulting from open pit mine  
157 dewatering; groundwater drawdown resulting from operation of the Tailings Basin, including  
158 groundwater seepage containment system; changes in streamflow near the Mine Site and  
159 Tailings Basin and associated effects on wetlands abutting the streams (during operation and  
160 post-closure); and changes in wetland water quality related to atmospheric deposition of dust and  
161 rail car spillage associated with the Mine Site and the Tailings Basin operations.

162 Potential indirect wetland effects from drawdown were estimated using the analog method.  
163 Various models, some of which were associated with impact analysis of other environmental  
164 resources such as air, groundwater, and surface water that affect wetland resources were also  
165 used in estimating potential indirect wetland effects.

166 Each analysis was completed using the same set of wetlands that were not directly impacted;  
167 therefore, there are wetlands that may be potentially indirectly affected by more than one type of  
168 assessed source. The potential indirect wetland affects for each wetland cannot be summed  
169 across the analysis as this would likely result in double-counting of wetland acres. The results of  
170 the analyses and assessments identify areas to be monitored for wetland effects.

171 Wetland acreage by wetland type was calculated using GIS analysis with 500-ft radius  
172 increments beginning at the mine pits and continuing out to a total radius of 10,000 ft (for a total  
173 of 20 increments); and 500-ft radius increments beginning at the Plant Site and continuing out to  
174 the Embarrass River. The area of analysis for the indirect effects extended beyond the NorthMet  
175 Project area component boundaries and included Area 1 and Area 2, as identified in Section  
176 4.2.3. The analysis did not include wetlands identified as directly impacted. Additionally,  
177 wetlands in the Northshore Mine and areas directly north of the Northshore Mine have been  
178 excluded from the evaluation (PolyMet 2011b).

179 Noise and dust effects on wildlife that utilize the wetland habitat are discussed in Section 5.2.5  
180 (Wildlife Section).

181 Additional description of the specific methods used to assess individual indirect effects is  
182 provided below.

183 The indirect effects analyses performed for the EIS were not performed to characterize impacts  
184 but were done to inform where monitoring should take place for those areas that were identified  
185 as having a potential for indirect wetland effects. The Co-lead Agencies agree that multiple  
186 factors can affect whether a wetland would experience indirect effects due to a project. This  
187 FEIS quantitatively assessed all potential indirect wetland effects. Indirect wetland effects from  
188 the NorthMet Project Proposed Action were assessed as a result from one of the following six  
189 factors: 1) wetland fragmentation; 2) changes in wetland hydrology from changes in watershed  
190 area; 3) changes in wetland hydrology from groundwater drawdown resulting from open pit mine  
191 dewatering; 4) changes in wetland hydrology from groundwater drawdown resulting from  
192 operation of the Plant Site, including groundwater seepage containment; 5) changes in stream  
193 flow near the Mine Site and Plant Site, as well as associated effects on wetlands abutting the  
194 streams; and 6) change in wetland water quality related to atmospheric deposition of dust and rail  
195 car spillage associated with Mine Site and Plant Site operations. The methodology and criteria  
196 used for assessing potential indirect wetland effects are described in detail below. The  
197 monitoring and mitigation for potential indirect effects would be determined during permitting.  
198 Section 5.2.3.3 of this FEIS includes a detailed discussion on the monitoring and mitigation plan  
199 for the indirect wetland effects. The proposed wetland impact, avoidance, minimization,  
200 mitigation and monitoring plan presented in this FEIS would be reviewed, modified as required,  
201 and approved during permitting; therefore, this information could change during permitting.

202 While the Co-lead Agencies believe that the analog method used in the SDEIS to assess potential  
203 indirect effects from mine dewatering is adequate, this FEIS has been updated with a more  
204 conservative approach to address concerns raised by the Bands. Section 5.2.3.2.2 of this FEIS  
205 has been updated to make a more conservative assumption of the potential indirect effects for all  
206 bog communities within the zero to 1,000-ft analog zone such that all bogs are reclassified from  
207 the “no effect” category to “low likelihood” category of wetland hydrology effects. The complex  
208 mixes of bedrock, surficial deposits, and wetland soils at the Mine Site impede the ability to  
209 reasonably model and accurately assess the potential effect of pit dewatering on wetlands. In  
210 light of this modeling limitation, wetlands were divided into zones based on distance from the  
211 open pit. The closer a wetland was to the pit during dewatering, the greater the water table  
212 drawdown would be and the greater potential there would be for hydrologic effects on overlying  
213 wetlands. These impact assessment methodologies are presented below and in Section 5.2.2.3.2.

214 The Co-lead Agencies are not relying solely on the potential impact zones determined in the  
215 analog method for this FEIS, but would be monitoring wetlands for potential indirect effects. In  
216 the event that the required wetland monitoring identifies additional indirect effects, permit  
217 conditions would likely include a plan for adaptive management practices to be implemented.  
218 Additional compensatory mitigation would be required if indirect wetland impacts were  
219 identified during monitoring and annual reporting.

220 When an agency is evaluating reasonably foreseeable significant adverse effects on the human  
221 environment in an EIS and there is incomplete or unavailable information because the overall  
222 costs of obtaining it are exorbitant or the means to obtain it are not known, NEPA directs the  
223 agency to 1) make it clear that such information is lacking, 2) discuss the relevance of the  
224 lacking information, and 3) discuss any information relevant to evaluation the future impacts. In  
225 these cases, NEPA also directs the agency to evaluate these impacts based upon theoretical  
226 approaches or research methods generally accepted in the scientific community provided that the  
227 analysis of the impacts is supported by credible scientific evidence, is not based on pure  
228 conjecture, and is within the rule of reason.

229 The Co-lead Agencies believe this is the case for evaluating indirect wetland effects. The Co-  
230 lead Agencies have thoroughly considered throughout the development of the EIS and through  
231 the Wetland IAP Working Group how to assess potential indirect wetland effects. As a result,  
232 strengths and weaknesses of the approach used, as well as other suggested approaches, have been  
233 carefully considered. The Co-lead Agencies ultimately decided that the use of the analog method  
234 and the 20 percent metric described in this section as factors considered in identifying potential  
235 indirect effects to wetlands is a credible and reasonable approach consistent with the  
236 requirements of NEPA.

### 237 **Potential Indirect Wetland Effects Resulting from Wetland Fragmentation**

238 For each wetland that would not be directly impacted at the Mine Site, along the Transportation  
239 and Utility Corridor, or at the Plant Site, an estimate of indirect wetland effects (wetland acres by  
240 wetland type, and type of effect) from wetland fragmentation by NorthMet Project area features  
241 (e.g., open pits, stockpiles, haul roads) was determined based on an analysis of the various  
242 factors that may contribute to fragmentation. A wetland may be fragmented as the result of direct  
243 impacts that may split a wetland resource area into multiple parts. These fragmented parts could  
244 potentially be isolated from other wetlands and would no longer have any adjacent upland  
245 watershed area, which could result in the loss of functions in the wetland fragments. While a  
246 wetland may be fragmented by direct impacts, this does not necessarily mean the remaining  
247 fragmented part of the wetland resource area would be affected. These fragmented parts  
248 therefore required further evaluation to determine if these areas would remain viable and/or  
249 would retain its functions (PolyMet 2015b; PolyMet 2015j).

250 The evaluation (PolyMet 2015b; PolyMet 2015j) to determine if a wetland resources area would  
251 remain viable included the following criteria: change in the size of remaining wetland, wetland  
252 type, source of hydrology, direction of flow in the area, location in the current watershed,  
253 location in the future watershed, and connectivity to other wetlands. The criteria used are  
254 described below:

- 255 • **Size of Remaining Wetland:** Wetland fragments that were identified using GIS as having  
256 less than about 0.5 acres in size were determined too small to retain their functions. These  
257 wetlands were determined for the analysis to be considered fragmented.
- 258 • **Wetland Type:** The wetland types for the wetland fragments that were greater than 0.5 acres  
259 in size were reviewed to determine if they were bogs versus non-bogs. Ombrotrophic bogs  
260 that would become fragmented were not identified as indirectly impacted by fragmentation  
261 because they would maintain their functions because their sole source of hydrology is  
262 precipitation (see below). Minerotrophic bogs and small non-bog wetlands that were  
263 fragmented were further evaluated to determine their hydrologic sustainability.
- 264 • **Source of Hydrology:** Wetlands were further subclassified as ombrotrophic (solely  
265 precipitation-fed) or somewhat minerotrophic (receives surface and/or groundwater inputs).  
266 The hydrology of ombrotrophic bogs is solely supported by precipitation; therefore, these  
267 wetlands are not dependent on the watershed size to maintain their functions and were not  
268 identified as indirectly impacted by fragmentation. The hydrology of minerotrophic bogs and  
269 non-bog wetlands is primarily supported by shallow groundwater systems that are connected  
270 within different scales: wetland watershed, local (e.g., Mine Site) watershed, or regional  
271 watershed. Therefore, these minerotrophic bogs and non-bog wetlands were further evaluated  
272 because they are considered to be dependent on their watershed size to maintain their  
273 functions, and their watersheds would be altered due to construction of project infrastructure.
- 274 • **Direction of Flow in the Area:** The Mine Site is located in the Upper Partridge River  
275 watershed, and water on the Mine Site eventually drains to the Partridge River. Under this  
276 criterion, PolyMet evaluated the locations of the minerotrophic bogs and non-bog wetlands  
277 relative to the sub-watersheds on each side of the Mine Site groundwater divide, which is  
278 generally located from southwest to northeast near the northern boundary of the Mine Site.  
279 Under existing conditions, water in the northernmost area of the Mine Site generally drains  
280 (flows) north and water in the southern area of the Mine Site generally drains (flows) south.  
281 There are several sub-watersheds on each side of the divide. Based on the location of  
282 predicted wetland fragments on the Mine Site, their locations within the sub-watersheds in  
283 relation to direct impacts within that same sub-watershed and the direction of flow were  
284 noted. A wetland is more likely to retain its function if the fragment that remains is located in  
285 the upper portion of its sub-watershed than in the lower portion. Ultimately, if the area of the  
286 wetland's watershed is modified, it could result in a change to the equivalent flow (expressed  
287 as ac-ft/yr per acre of wetland), a measure of hydrologic support.
- 288 • **Determination of the Wetland's Current Watershed:** The current watersheds for  
289 ombrotrophic bog wetlands were not analyzed because they are not dependent on watershed  
290 area for their hydrology as they are precipitation-fed. The current (existing) conditions  
291 include the wetlands and watersheds, which represent the existing and relatively undisturbed  
292 conditions in the Mine Site area. The watersheds for the minerotrophic bogs and non-bog  
293 wetlands are the land areas that contribute surface water to the wetlands (upland areas and  
294 wetland areas). For each minerotrophic bog and non-bog wetland in the analysis, GIS was  
295 used to determine the acreage of its watershed area. The location of each minerotrophic bog  
296 and non-bog wetland in its current (existing) watershed was compared with its location in the  
297 future watershed.

- 298 • **Location of the Minerotrophic Bog and Non-bog Wetland Fragment in the Wetland's**  
299 **Future Watershed:** During operations, some watershed areas would be directly impacted by  
300 the NorthMet Project Proposed Action and would no longer be considered as tributary areas  
301 to the minerotrophic bogs and non-bog wetlands. Using the same methodology as in the  
302 previous criteria, for each minerotrophic bog and non-bog wetland in the analysis, GIS was  
303 used to determine the acreage of upland area and wetland area within its watershed area. As a  
304 result, the amount of water potentially contributed by the watershed to support the hydrology  
305 of the remaining wetland may also change (increase or decrease). If the wetland fragments  
306 had a change in equivalent yield of  $\pm 20$  percent, the minerotrophic bogs and non-bog  
307 wetlands were further determined to have a potential for indirect impacts. Depending on the  
308 results of the other criteria, the minerotrophic bog and non-bog wetland fragments were  
309 either considered to be indirectly affected or included as a monitoring location in the wetland  
310 hydrology monitoring plan.
- 311 • **Connectivity to Other Wetlands:** Each wetland fragment was evaluated based on its  
312 location, adjacency to upland, and adjacent infrastructure characteristics to determine if it  
313 would be expected to maintain its functions. Some of the wetland fragments as a result being  
314 divided by Mine Site infrastructure would become isolated from other wetlands; therefore, no  
315 longer located within or adjacent to an intact, relatively undisturbed upland. These wetland  
316 fragments were not expected to maintain their functions. However, other wetland fragments  
317 would still be hydrologically connected to wetlands and would be located within or adjacent  
318 to an intact, relatively undisturbed upland. For example, these fragmented wetlands would be  
319 located in the vicinity of the haul roads on the Mine Site. Construction of the haul roads  
320 would require excavation and fill with blasted rock that would allow groundwater  
321 connectivity for wetlands on either side of the haul road.

### 322 **Potential Indirect Wetland Effects Resulting from a Change in Watershed Area**

323 For each wetland that would not be directly impacted, but would have NorthMet Project area  
324 elements affect its watershed, an estimate of the change in watershed area (acreage and percent  
325 gain or loss) was calculated for the following conditions: pre-NorthMet Project Proposed Action,  
326 during operation when the maximum amount of watershed has been removed, and at closure and  
327 long-term maintenance. For those non-directly affected wetlands that would have changed  
328 watershed areas (during operation and post-closure), an estimate of indirect wetland effects  
329 (wetland acres by wetland type and type of indirect effect) was calculated.

### 330 **Potential Indirect Wetland Effects Resulting from Changes in Hydrology Due to** 331 **Drawdown at the Mine Site**

332 An estimate of indirect wetland effects (wetland acres by wetland type, and type of indirect  
333 effect) due to groundwater drawdown from open pit mine dewatering was determined using an  
334 analog model in which the degree of effect was correlated to the distance from the open pit mine  
335 (PolyMet 2011b). The analog approach was based on similar mine settings (e.g., within the  
336 glacial till in the region) and consisted of well data from the Canisteo Pit, which is the only mine  
337 pit within the Mesabi Iron Range that has an associated water balance study with well data that  
338 could be used to assess potential drawdown effects. In addition, two wells near Kinney were also  
339 used for the evaluation. Please refer to Section 5.2.2.3.2 for more information on the analog  
340 approach. The closer a wetland was to the pit where dewatering would occur, the greater the

341 water table drawdown would be and the greater the potential for hydrologic effects on overlying  
342 wetlands. Wetlands were divided into zones based on distance from the open pit. The use of the  
343 impact zones may overestimate indirect effects on wetlands. The analog distances, referenced to  
344 the pit edge, were as follows:

- 345 1. 0 to 1,000 ft;
- 346 2. greater than 1,000 to 2,000 ft;
- 347 3. greater than 2,000 to 3,500 ft; and
- 348 4. greater than 3,500 to 10,000 ft (within Area 1).

349 The following is a discussion of the justification for the use of the analog data based upon  
350 comparisons of the existing regional and site-specific geologic data (e.g., bedrock faults, bedrock  
351 joint systems, bedrock topography, surficial deposits hydraulic conductivities), site-specific  
352 engineering controls (e.g., Category 1 Stockpile surface and groundwater seepage containment  
353 system), and the geologic settings of the analog information sites and the Mine Site (PolyMet  
354 2011b; PolyMet 2015b). Analog data were used instead of a model such as MODFLOW since  
355 MODFLOW could not practically be used to estimate potential indirect wetland effects, due to  
356 complex mixes of bedrock, surficial deposits, and wetland soils at the Mine Site and therefore  
357 could not be used to accurately assess the potential effect of pit dewatering on wetlands  
358 (PolyMet 2015b).

359 The Mine Site contains localized heterogeneous vertical and horizontal hydraulic conductivities  
360 within each soil unit, which also makes the MODFLOW model less effective. Hydraulic  
361 conductivities between the different deposits range from 0.00026 to 31 ft/day (PolyMet 2015b).  
362 Because there is such a wide range in hydraulic conductivity within the natural geologic  
363 formations at the Mine Site, each model layer would contain widely variable hydraulic  
364 conductivities. Thus, it was not feasible to model the expected effects of mine dewatering on  
365 wetlands in a meaningful way. Prior to conducting the analysis to identify indirect wetland  
366 effects resulting from changes in hydrology, bog wetlands within and surrounding the Mine Site  
367 were reclassified as either ombrotrophic or somewhat minerotrophic. This distinction is  
368 important because ombrotrophic bogs would be less likely to be affected by groundwater  
369 drawdowns associated with proposed mining operations, whereas more minerotrophic bogs  
370 would have a higher likelihood of being affected (Eggers 2011a, 2015).

371 A discussion of potential indirect wetland hydrology drawdown effects at the Mine Site,  
372 including conversion to other wetland community types, a change in vegetation without a change  
373 in community type, conversion to uplands, or other effects is provided below in Section  
374 5.2.3.2.2. These effects were categorized by applying the Eggers and Reed (1997, 2014) wetland  
375 classification system to each wetland type based on wetland sensitivity class tables for falling  
376 groundwater tables that were developed for a previously proposed mine project in Wisconsin  
377 (PolyMet 2015b).

### 378 **Potential Indirect Wetland Effects Resulting from Changes in Hydrology at the Plant Site**

379 Potential indirect wetland effects from hydrological changes were evaluated based on estimates  
380 of groundwater upwelling and resulting surface water flow in wetlands and/or groundwater  
381 drawdown near the water containment system that would surround the Plant Site. An estimate of

382 potential indirect wetland effects (wetland acres by wetland type, and type of effect) from  
383 hydrologic changes resulting from the containment system was determined as follows:

- 384 1. The amount of Plant Site groundwater seepage water that would bypass the containment  
385 system and emerge in surface water features, including wetlands, downgradient of the  
386 Tailings Basin was quantified. The quantity of seepage evading the containment system was  
387 confirmed using MODFLOW and incorporated into the GoldSim model as a deterministic  
388 value.
- 389 2. All wetlands (type, acreage) within the surficial aquifer groundwater flowpaths downgradient  
390 of the Plant Site were identified within the boundaries used in the water quality modeling (as  
391 shown in the Groundwater IAP Summary document [MDNR et al. 2011]).
- 392 3. Using the wetlands identified in step 2, wetlands were categorized into minerotrophic  
393 (groundwater-fed) and ombrotrophic (precipitation-fed) wetlands using guidance in the  
394 Corps Memorandum (CEMVP-OP-R) *Distinguishing Between Bogs That Are Entirely*  
395 *Precipitation Driven Versus Those with Some Degree of Mineral Inputs from Groundwater*  
396 *and/or Surface Water Runoff* (Eggers 2011b) and evaluating the potential for indirect effects  
397 resulting from construction of the water containment system.

398 A discussion regarding potential indirect wetland hydrology effects at the Plant Site, including  
399 conversion to other wetland community types, a change in vegetation without a change in  
400 community type, conversion to uplands, or other effects is provided below in Section 5.2.3.2.4.  
401 These effects were categorized by applying the Eggers and Reed (1997, 2014) wetland  
402 classification system to each wetland type based on the wetland sensitivity class tables for rising  
403 groundwater tables that were developed for a previously proposed mine project in Wisconsin  
404 (PolyMet 2015b).

#### 405 **Potential Indirect Effects on Wetlands Abutting the Partridge River and Four Creeks**

406 An estimate of potential indirect wetland effects (wetland acres by wetland type and type of  
407 effect) was determined for wetlands abutting the following:

- 408 • the Partridge River, as a result of changes in river flow resulting from the NorthMet Project  
409 Proposed Action (during operation and post-closure); and
- 410 • the three creeks north and west of the Plant Site (Trimble Creek, Mud Lake Creek, and  
411 Unnamed Creek) and Second Creek south of the Plant Site, as a result of changes in  
412 streamflow resulting from operation of the Plant Site and containment system.

413 Changes in river and creek flow were estimated using mass balance techniques.

#### 414 **Potential Indirect Wetland Effects Resulting from Water Quality Changes**

415 A screening analysis for depositional effects was conducted that estimated potential annual  
416 deposition of dust, metals, and sulfur to wetlands within and adjacent to the Mine Site and Plant  
417 Site from fugitive dust through air dispersion/deposition modeling (AERMOD). Emission rates  
418 and particle size distributions were based on total particulate matter. The estimated deposition  
419 from fugitive dust emissions was used to identify wetlands that have the potential for water  
420 quality changes (e.g., potential for water chemistry changes related to sulfide dust deposition).  
421 The estimated deposition from fugitive dust emissions was used to identify a threshold for a  
422 negative effect on vegetation. The estimated inputs of the dust, metals, and sulfur to wetlands

423 were evaluated for significance to potential changes in water quality. The receptors of interest  
424 were the wetlands that were not identified as directly impacted.

425 Leakage from stockpiles at the Mine Site was evaluated to determine if wetlands would be  
426 impacted. The amount of stockpile leakage water that would potentially discharge to surface  
427 waters and wetlands downgradient of the stockpiles was based on the water quality modeling  
428 (see Section 5.2.2). Wetlands within the surficial aquifer groundwater flowpaths from mine  
429 features were identified and then further characterized into minerotrophic and ombrotrophic  
430 wetlands per Eggers 2011a. Wetlands were then evaluated to determine the potential for indirect  
431 effects based on potential water quality changes from the mine features.

432 Tailings Basin groundwater seepage at the Plant Site was evaluated to determine if wetlands  
433 would be impacted. The chemistry from the Tailings Basin groundwater seepage based on the  
434 water quality modeling (see Section 5.2.2) was determined. Wetlands within the downgradient  
435 zone were identified and then further characterized into minerotrophic and ombrotrophic  
436 wetlands (Eggers 2011a). Wetlands were then evaluated to determine the potential for indirect  
437 effects based on potential water quality changes from the Tailings Basin.

438 Wetlands within and adjacent to the Transportation and Utility Corridor were assessed to  
439 determine if indirect wetland effects would occur to wetlands as a result of water quality  
440 changes. The following was evaluated: the potential release of dust from railcars transporting ore  
441 from the Mine Site to the Plant Site, use of Dunka Road, and product shipping at the Plant Site.

#### 442 **5.2.3.2 NorthMet Project Proposed Action**

443 The NorthMet Project Proposed Action would result in both direct and indirect effects. This  
444 section describes effects within the NorthMet Project area and provides a summary of wetland  
445 effects. Estimates of both direct and indirect wetland effects have changed during the EIS  
446 process as the result of refined analysis and changes in project design. The effects identified in  
447 this FEIS are based on the most current information available and may differ from those  
448 identified in prior reports. Avoidance, minimization, mitigation, and monitoring measures for the  
449 NorthMet Project Proposed Action are discussed in Section 5.2.3.3.

##### 450 **5.2.3.2.1 Mine Site and Transportation and Utility Corridor Direct Wetland Impacts**

451 Direct wetland impacts would result from the following Mine Site and Transportation and Utility  
452 Corridor components: construction and/or installation of the mine pits, Category 1 Stockpile,  
453 Category 2/3 Stockpile, Category 4 Stockpile, Overburden Storage and Laydown Area, haul  
454 roads, rail transfer loadout, WWTF, perimeter dike, culverts, groundwater discharge pipe,  
455 surface and groundwater seepage containment system, stormwater collection ditches and ponds,  
456 CPS, process water pipes and ponds, Treated Water Pipeline, transmission lines, and Dunka  
457 Road upgrades. The Mine Site features would result in 758.2 acres of directly impacted wetlands  
458 (see Figure 5.2.3-1). Table 5.2.3-1 summarizes the directly impacted wetlands within the Mine  
459 Site by community type while Table 5.2.3-2 identifies the activity that causes the impacts  
460 expected at the Mine Site. Three wetland types comprise 89 percent of the expected wetland  
461 impacts in the Mine Site, including 508.3 acres of coniferous bog (67 percent), 97.8 acres of  
462 shrub swamp (13 percent), and 70.3 acres of coniferous swamp (9 percent). Direct impacts  
463 would be caused by fill (10 percent), excavation (12 percent), or a combination of fill and  
464 excavation (78 percent). The majority of the wetlands (99 percent) that would be directly

465 impacted wetlands are rated high quality, while 1 percent are rated as moderate quality (PolyMet  
 466 2015b).

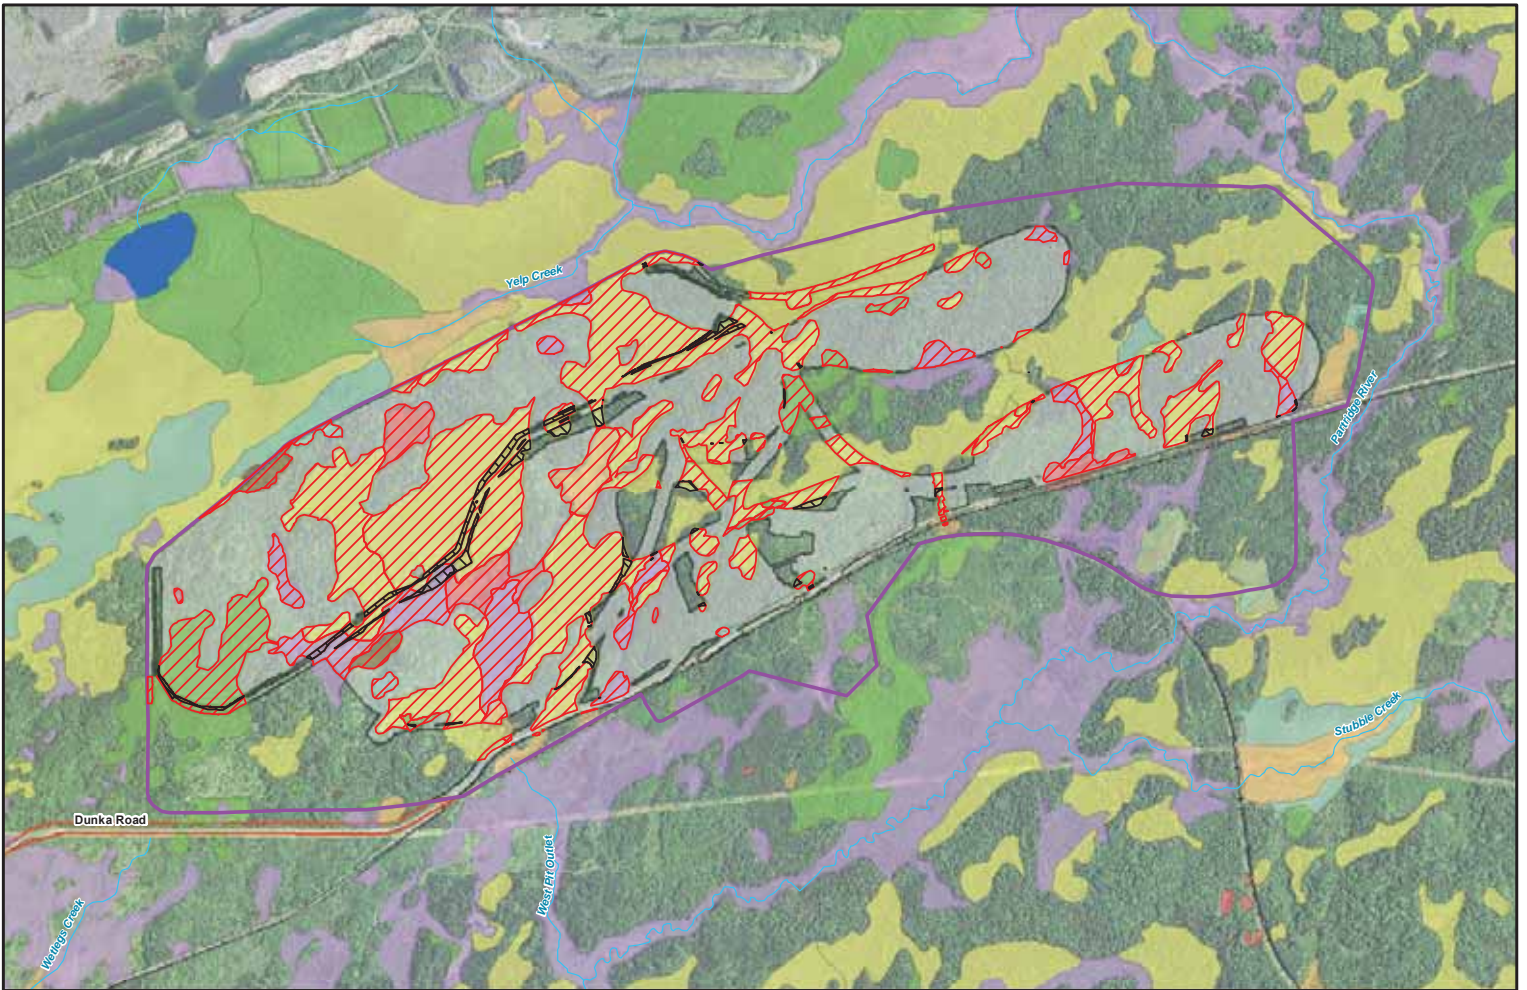

467 **Table 5.2.3-1 Total Projected Direct Wetland Impacts at the Mine Site and the**

475 Source: PolyMet 2015b.

476 PolyMet proposes to minimize wetland impacts by placing waste rock back into the East Pit and  
 477 Central Pit after year 11, thereby reducing the need for additional surface stockpile areas that  
 478 would otherwise affect wetlands. In addition, PolyMet proposes to combine the saturated  
 479 overburden and temporary stockpiles, and leave only unsaturated overburden and peat in the  
 480 Overburden Storage and Laydown Area. By doing so, the footprint of these stockpiles would be  
 481 reduced, resulting in fewer direct wetland impacts.

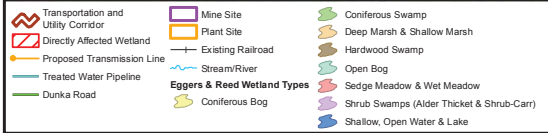

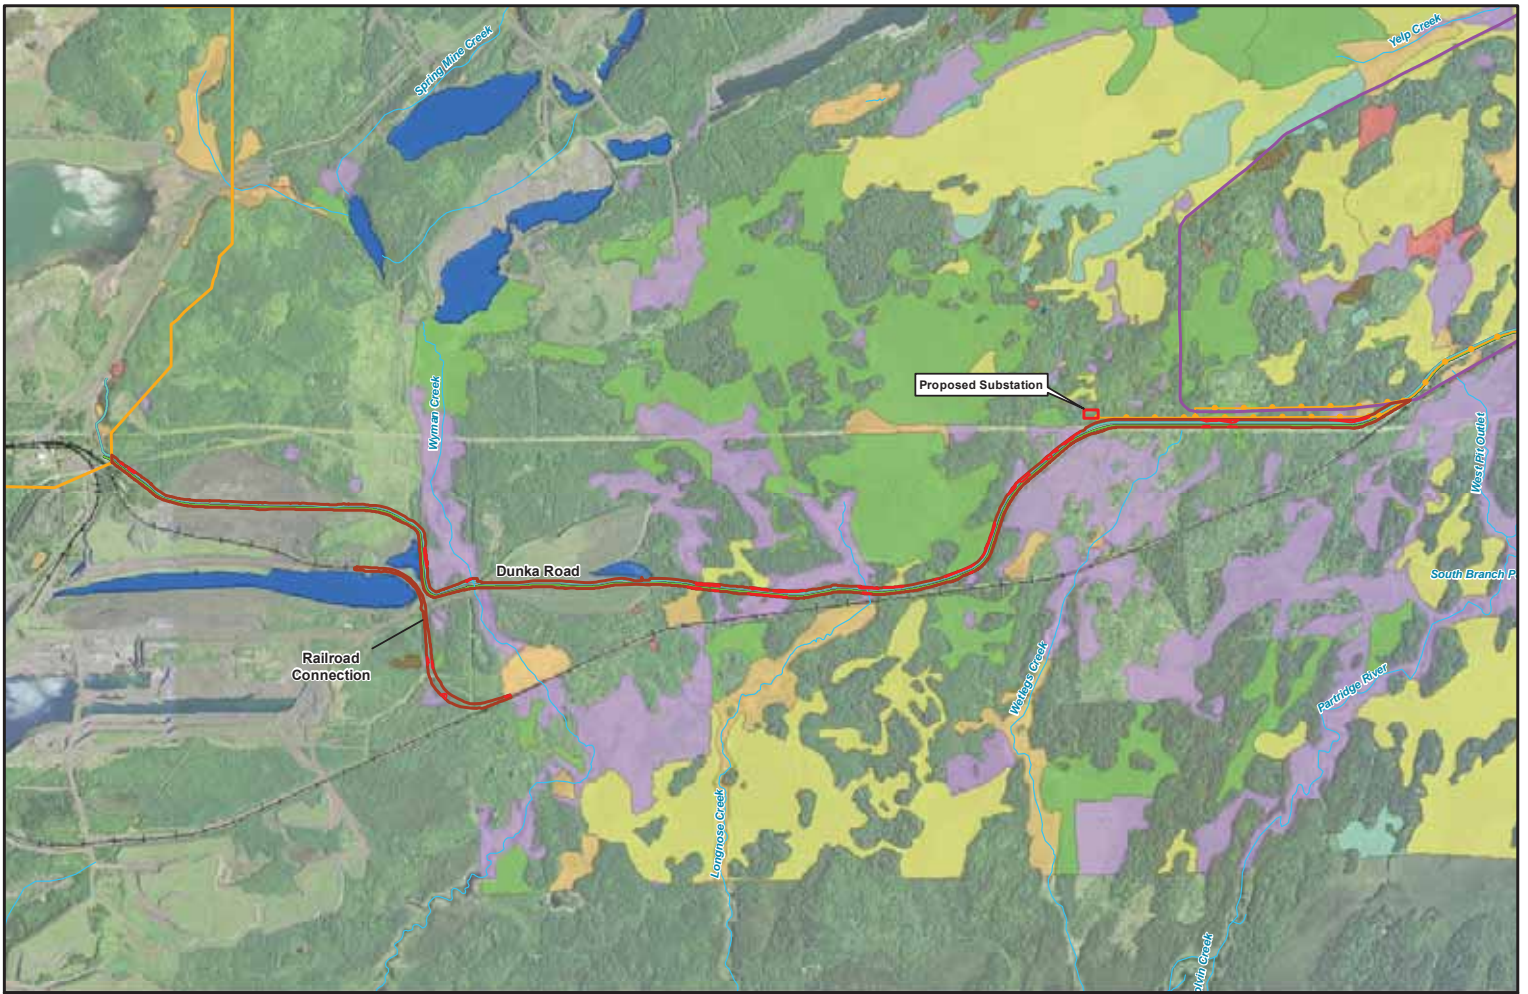

482 In approximately year 52, flooding to the West Pit would be complete. Discharge from the West  
 483 Pit would be pumped to the WWTF for treatment. The WWTF would then be upgraded to  
 484 include RO treatment to achieve a 9 mg/L sulfate effluent, which would then be discharged into  
 485 a wetland and finally through the West Pit Outlet Creek to the Partridge River. The direct  
 486 impacts on this wetland have been included within the wetland effect direct totals in Table  
 487 5.2.3-1.

488 Construction activities within the Transportation and Utility Corridor would affect 7.2 acres of  
 489 wetlands, all of which would be filled. Table 5.2.3-1 summarizes the directly impacted wetlands  
 490 within the Transportation and Utility Corridor by community type while Table 5.2.3-2 identifies  
 491 the activity that causes the impacts expected within the Transportation and Utility Corridor. The  
 492 wetland types that would be directly impacted include shrub swamps (57 percent), coniferous  
 493 swamps (22 percent), coniferous bogs (12 percent), and shallow marshes (8 percent) (see Figure  
 494 5.2.3-2). All of the wetlands to be directly impacted are rated as high quality. The rail spur was  
 495 designed to avoid wetlands to the extent possible within the requirements for rail construction  
 496 based on a portion of the spur being located on an existing rail alignment.

497 **5.2.3.2.2 Mine Site and Transportation and Utility Corridor Indirect Wetland Effects**

498 The potential indirect wetland effects were assessed by identifying wetlands in Area 1 within  
 499 500-ft increments beginning at the edge of the mine pits and extending to a maximum distance of  
 500 10,000 ft (see Figure 5.2.3-3) (PolyMet 2015b). The area of evaluation for the Mine Site  
 501 potential indirect wetlands effects included only wetlands within Area 1 where wetland type  
 502 information had been developed and does not include the directly impacted wetlands.

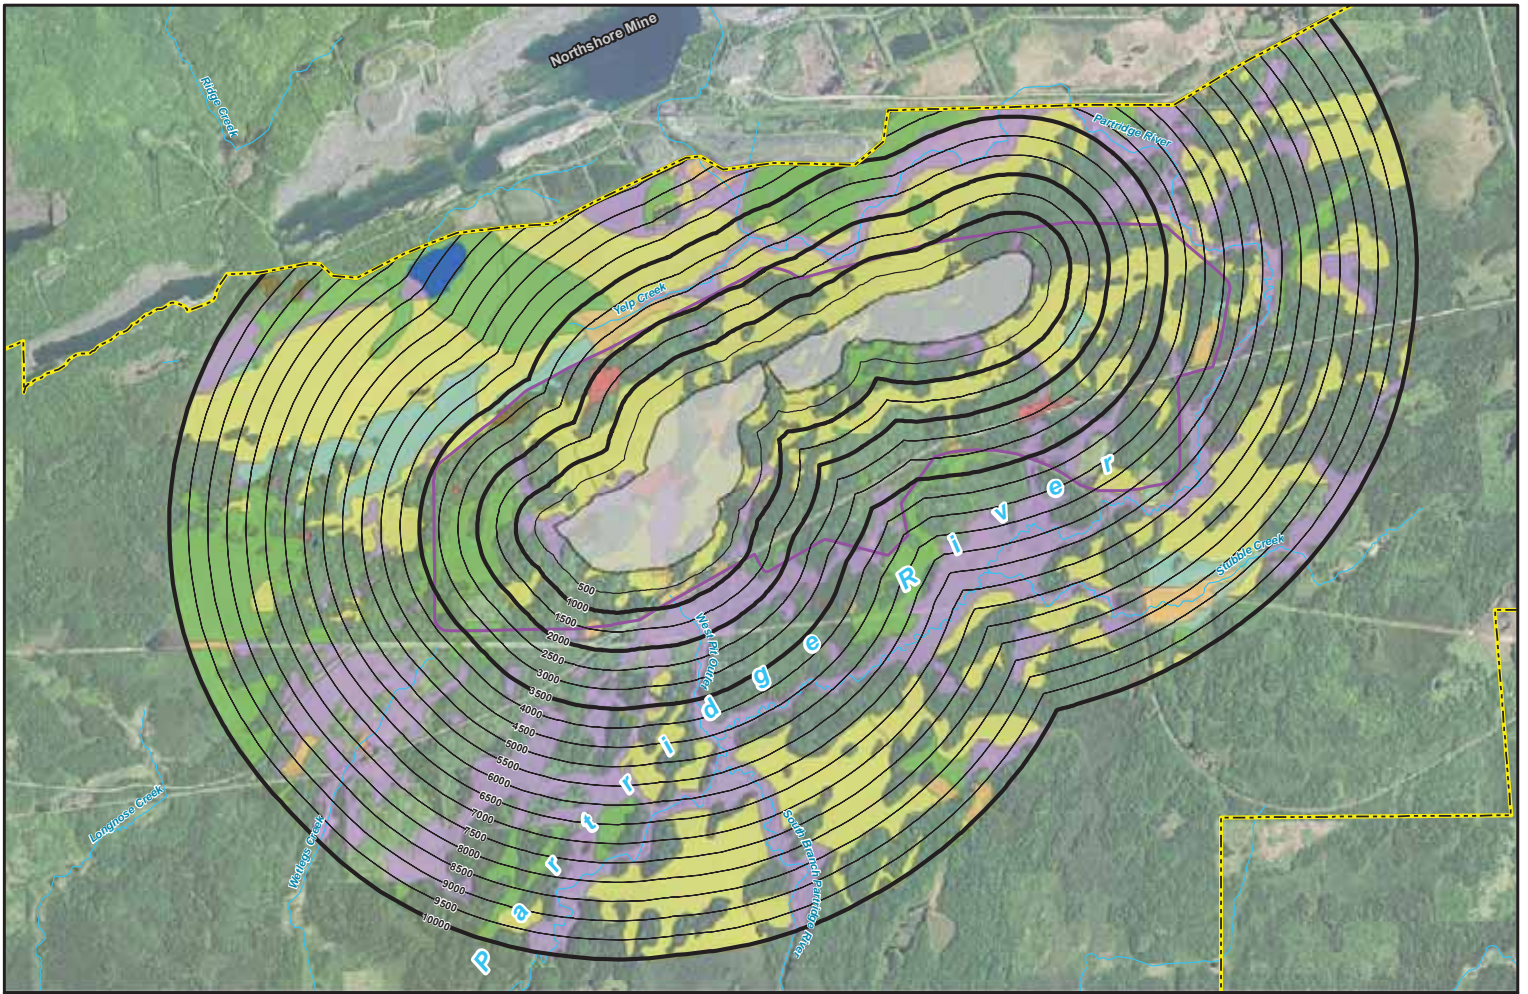

DRAFT

508 **Wetland Fragmentation**

509 Construction of the Mine Site features (e.g., open pits, stockpiles, haul roads, etc.) would result  
510 in 26.4 acres of wetland fragments (see Figure 5.2.3-1). Wetlands were determined to be  
511 fragmented and their associated remaining acreage included as a potential indirect wetland effect  
512 if they were small remnants of a directly impacted wetland located between Mine Site features  
513 (e.g., in the area between the Category 1 Stockpile and the West Pit or along Dunka Road or the  
514 Railroad Connection Corridor) and their functions were lost. The majority of the wetland  
515 fragments in the Mine Site would consist of coniferous bog (79 percent), alder thickets (14  
516 percent), coniferous swamp (7 percent), and sedge/wet meadow (less than 1 percent). In addition,  
517 a 0.01 acre alder thicket would become fragmented just outside of the Transportation and Utility  
518 Corridor near Dunka Road but within Area 1 (PolyMet 2015b). No wetlands would become  
519 fragmented along the Railroad Corridor. The wetland fragments that are expected to maintain  
520 their functions would be included in the wetland hydrology and vegetation monitoring plan that  
521 would be developed and implemented for the NorthMet Project Proposed Action.

522 **Changes in Hydrology Due to Change in Watershed Area**

523 The potential for indirect effects to wetland acreage due to change in watershed area was  
524 assessed by evaluating the change in watershed area per acre of wetland (PolyMet 2015b).  
525 Watersheds were defined for each wetland within the Mine Site boundary, as well as wetlands  
526 outside the Mine Site with a watershed area that may be affected by NorthMet Project area  
527 features. Wetland and watershed areas were determined for the following conditions: existing  
528 conditions, during operations when the maximum amount of watershed has been removed (i.e.,  
529 maximum NorthMet Project Proposed Action extent), and at closure and long-term maintenance.

530 The analysis was completed by first defining the watershed area (i.e., the sum of upland area and  
531 wetland area). For each wetland in the Mine Site, GIS was used to determine the upland area  
532 (acres) and wetland area (acres) within each watershed area (acres). Using these acreages, the  
533 percentage of a wetland within its watershed was calculated. In addition, the tributary acres per  
534 wetland acre were determined as a proportion of the watershed area to wetland area; the  
535 equivalent watershed yield (acre-feet per year) was determined for the existing, maximum  
536 operational extent, and closure and long-term maintenance conditions (the average net  
537 precipitation rate is 11.77 inches per year); and the change in the equivalent yield (inches per  
538 year) estimated over the life of the NorthMet Project Proposed Action was evaluated relative to  
539 existing conditions equivalent yield to calculate the maximum percent change in yield (PolyMet  
540 2011b; PolyMet 2015b).

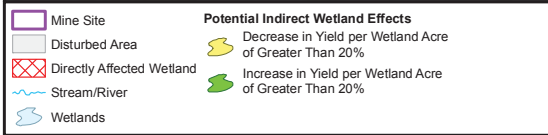

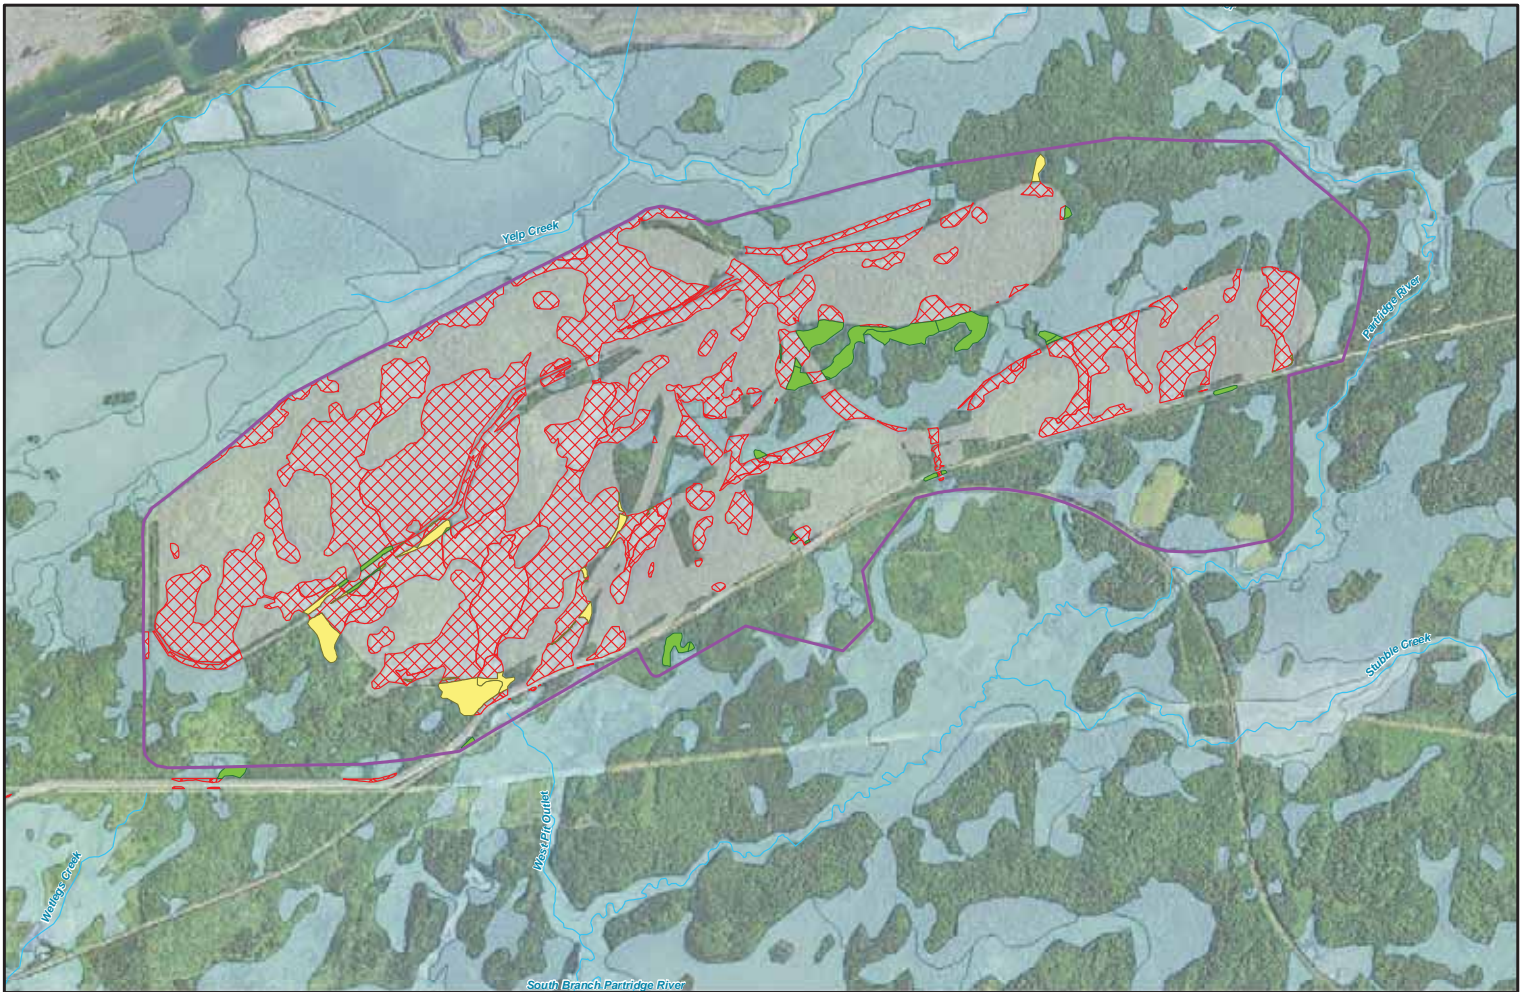

541 The existing conditions include wetlands that represent the existing and relatively undisturbed  
542 conditions at the Mine Site. The analysis included wetlands and associated watersheds that are  
543 partially or completely within the Mine Site boundary. There are a total of 3,325 acres of  
544 wetlands within 6,287 acres of watershed, which results in approximately 53 percent of the  
545 analysis area covered by wetlands (PolyMet 2015b).

546 During operations, some wetlands and watershed areas may be directly impacted by the  
547 NorthMet Project Proposed Action and would no longer be considered as a tributary area to the  
548 wetland. Consequently, the amount of water potentially contributed by the watershed to support  
549 the hydrology of the remaining wetlands may also change.

550 There would be 20 wetlands, potentially indirectly affected, displaying an increase or decrease of  
551 greater than 20 percent equivalent yield. Ombrotrophic coniferous bogs and open bogs were not  
552 included in the total wetland acreage because their hydrology is solely supported by precipitation  
553 and may contain groundwater flowpaths. The hydrology of the ombrotrophic bogs is not  
554 dependent on the size of the watershed. There would be 35 acres (11 wetlands) that would have  
555 the potential to experience an increase in yield per wetland acre of greater than 20 percent, and  
556 15 acres (9 wetlands) that would likely experience a decrease in yield per wetland acre in excess  
557 of 20 percent (see Figure 5.2.3-4). The 49.4 acres of potentially indirectly affected wetland types  
558 include alder thickets (52 percent), coniferous swamp (34 percent), minerotrophic coniferous bog  
559 (8 percent), shallow marsh (6 percent), and sedge/wet meadow (less than 1 percent) (PolyMet  
560 2015b).

561 During reclamation, a portion of the wetlands and wetland watersheds within the Mine Site  
562 would be restored to the existing condition.

565 **Changes in Wetland Hydrology Due to Surficial Aquifer Drawdown**

566 The geologic and hydrogeologic settings of the Mine Site and the analog sites are fairly similar  
567 with a thin veneer of heterogeneous surficial deposits underlain by fractured bedrock. The  
568 hydraulic conductivities of the surficial deposits and bedrock are lower at the Mine Site than at  
569 the analog sites, and so it is expected that the wetland impact zones would likely overestimate  
570 the extent of potential wetland effects. Because of the thin, discontinuous nature of the surficial  
571 deposits at the Mine Site, drawdown effects are expected to be more localized at the Mine Site  
572 than at the analog sites. Additionally, the numerous bedrock outcrops present at the Mine Site are  
573 expected to act as barriers to flow in the unconsolidated aquifer, thereby limiting the area of  
574 influence of the mine pits. Whereas, the analog sites have fewer or no bedrock outcrops  
575 compared to the Mine Site. Last, the presence of the Partridge River approximately 4,000 to  
576 6,000 ft south (downstream) of the mine pits is likely to act as a natural barrier to the expansion  
577 of the cone of depression within the surficial aquifer from 3,500 to 10,000 ft from the pit  
578 (PolyMet 2015b).

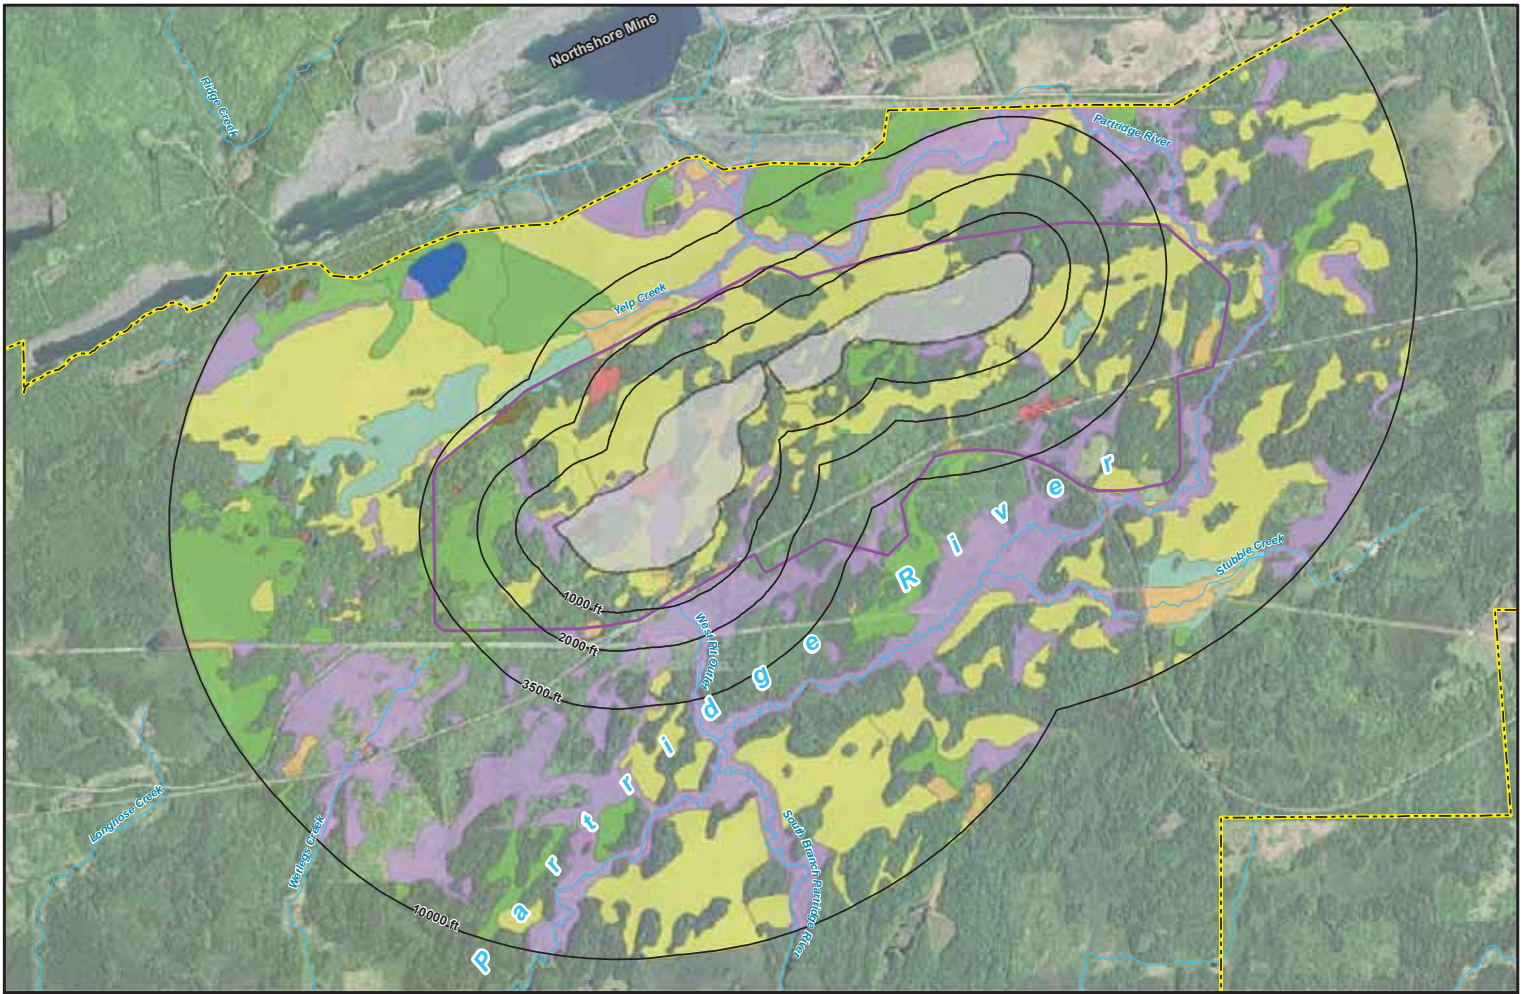

579 Open and coniferous bog wetlands within and surrounding the Mine Site were subcategorized as  
580 either ombrotrophic (hydrology and mineral inputs solely from direct precipitation) or  
581 minerotrophic (some degree of mineral inputs from groundwater and/or surface water runoff) to  
582 determine if the bogs would be affected by groundwater drawdown. Due to the potential  
583 connection to groundwater flowpaths, ombrotrophic bogs would have a low likelihood of being  
584 affected by groundwater drawdowns associated with proposed mining operations. Similarly,  
585 more minerotrophic bogs would have also had a low likelihood of being affected (Eggers 2015a).  
586 Using a conservative approach for the analysis (i.e., one that errs on the side of estimating  
587 greater wetland impacts), all bog communities within 0-1,000 ft from the edge of the mine pits  
588 were categorized as Low Likelihood of wetland hydrology impact (PolyMet 2015b).

589 The potential indirect wetland effect from surficial aquifer drawdown was based on the analog  
590 impact zone with the greater potential drawdown (zone closer to the open pit mine) for wetlands  
591 that lie on both sides of the analog distance boundary. Wetlands were identified within four  
592 analog impact zones (0-1,000 ft, >1,000-2,000 ft, >2,000-3,500 ft, and >3,500-10,000 ft) from  
593 the edge of the mine pits within Area 1 (see Figure 5.2.3-5).

594 The change in wetland hydrology from groundwater drawdown at the Mines Site was assessed  
595 by two different methodologies; therefore, total potential indirect wetland effects were provided  
596 based on both approaches. The two approaches are as follows:

- 597 • **Wetlands Crossing Analog Zones:** Wetlands that were located within multiple analog  
598 impact zones were included in the analog impact zone closest to the edge of the mine pits.  
599 The likelihood of wetland hydrology impact was categorized as High, Medium, Low, and No  
600 Impact for each analog impact zones.
- 601 • **Wetlands within Analog Zones:** Wetlands that were located within multiple analog impact  
602 zones were split along zone edges and acreages were calculated by zone. As a result, the  
603 acreage for wetlands crossing zone edges was split among multiple zones, rather than  
604 included in the analog impact zone that was closest to the edge of the mine pits. The  
605 likelihood of wetland hydrology impact was categorized as High, Medium, Low, and No  
606 Impact for each analog impact zones.

DRAFT

610 Based on the wetlands crossing analog zones analysis approach, there would be 1,328.0 acres of  
 611 wetlands in the 0-1,000 ft zone, 618.6 acres in the >1,000-2,000 ft zone, 1,162.0 acres of  
 612 wetlands in the >2,000-3,500 ft zone, and 2,718.3 acres of wetlands in the >3,500-10,000 ft zone  
 613 beyond the edge of the pits (see Table 5.2.3-3; Figures 5.2.3-6 through 5.2.3-10) (PolyMet  
 614 2015b).

615 **Table 5.2.3-3 Wetlands Crossing Analog Impact Zones Resulting from Potential Changes**  
 616 **in Hydrology**

| Likelihood of Wetland Hydrology Effect Based on Wetland Type for Each Analog Distance | Wetland Area (acres) within each Analog Increment |                |                |                 | Eggers and Reed Wetland Community                                                 |

| No Effect                                                                             | -                                                 | -              | -              | 2,718.3         | All wetland types                                                                 |
| <b>Total Acres of Wetland</b>                                                         | <b>1,328.0</b>                                    | <b>618.6</b>   | <b>1,162.0</b> | <b>2,718.3</b>  |                                                                                   |

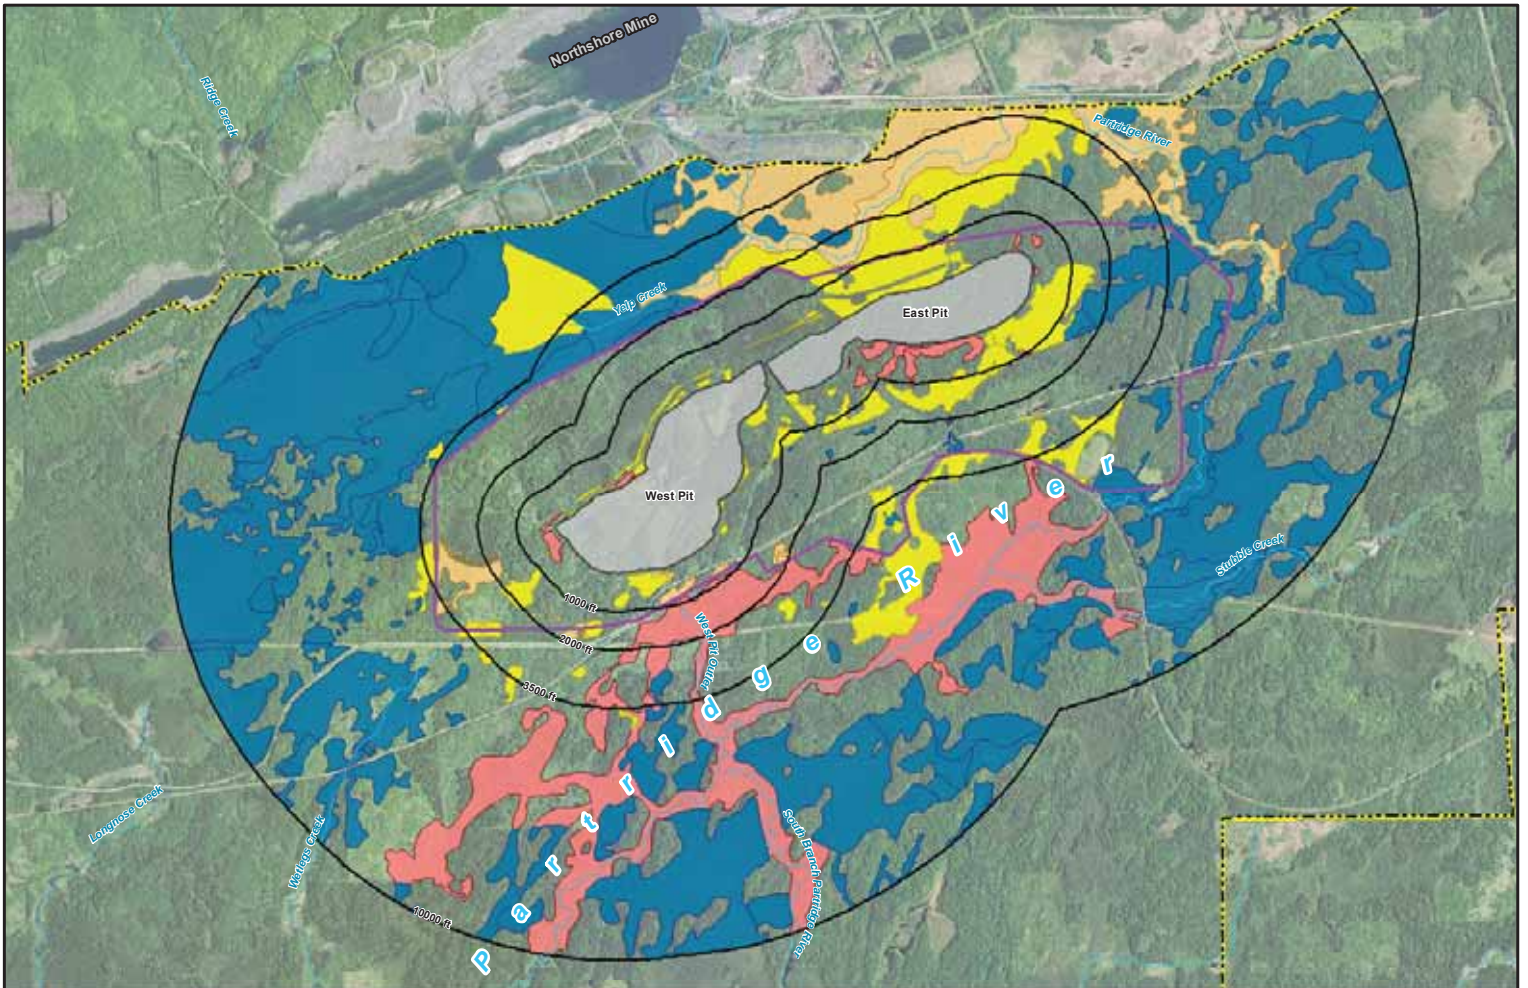

617 Source: PolyMet 2015b

618 Under this methodology approach, the likelihood of wetland hydrology effects would be as  
 619 follows: no effect on 3,679.3 acres of wetlands (63 percent); low likelihood to 750.0 acres of  
 620 wetlands (13 percent); moderate likelihood to 530.7 acres of wetlands (9 percent); and high  
 621 likelihood to 866.9 acres of wetlands (15 percent) (see Table 5.2.3-3). Within 0-10,000 ft from  
 622 the edge of the mine pits, wetland types with a high likelihood of wetland hydrology effects  
 623 include shrub swamps (847.8 acres), coniferous swamp (18.9 acres), and sedge/wet meadow  
 624 (less than 1 acre); with a moderate likelihood include shrub swamp (327.2 acres), coniferous  
 625 swamp (194.9 acres), deep marsh (4.9 acres), shallow marsh (3.4 acres), and hardwood swamp  
 626 (less than 1 acre); and with a low likelihood include coniferous bog (452.8 acres) coniferous  
 627 swamp (222.7 acres), shrub swamps (67.8 acres), shallow marsh (4.1 acres), sedge/wet meadow  
 628 (1.7 acres), and hardwood swamp (less than 1 acre) (PolyMet 2015b).

629 The wetlands categorized as high likelihood are dominated by one alder thicket (823.7 acres) that  
630 has approximately 4 acres (less than 1 percent) within the 0-1,000 ft analog impact zone. The  
631 remainder of this wetland (more than 99 percent) is located more than 1,000 ft away from the  
632 edge of the mine pits and extends out to the edge of Area 1 (see Figure 5.2.3-6).

633 Based on the analog data, hydrologic effects to peat wetlands would only be observed to occur  
634 within 1,000 ft from the edge of the mine pits. Therefore, wetlands were categorized within the  
635 analog impact zones using an alternate method to determine the likelihood of wetland hydrology  
636 effects as described below.

DRAFT

647 For the method approach of wetlands within analog zones, wetlands that were located within  
 648 multiple analog impact zones were split along zone edges, and acreages were calculated by zone.  
 649 The acreage of each wetland type located within these impact zones is summarized in Table  
 650 5.2.3-4 and locations are shown in Figures 5.2.3-11 through 5.2.3-15. Using this analysis  
 651 approach, there would be 233.5 acres of wetlands in the 0-1,000 ft zone, 311.0 acres in the  
 652 >1,000-2,000 ft zone, 718.0 acres of wetlands in the >2,000-3,500 ft zone, and 4,564.4 acres of  
 653 wetlands in the >3,500-10,000 ft zone (PolyMet 2015b).

656 Source: PolyMet 2015b.

657 Under this methodology approach, the likelihood of wetland hydrology effects would be as  
658 follows: no effect on 5,093.5 acres of wetlands (87 percent); low likelihood to 567.9 acres of  
659 wetlands (10 percent); moderate likelihood to 119.1 acres of wetlands (2 percent); and high  
660 likelihood to 46.4 acres of wetlands (less than 1 percent) (see Table 5.2.3-4). Within 0-10,000 ft  
661 from the edge of the mine pits, wetland types with a high likelihood of wetland hydrology effects  
662 include shrub swamps (27.5 acres), coniferous swamp (18.8 acres), and sedge/wet meadows (less  
663 than 1 acre); those with a moderate likelihood include shrub swamp (96.0 acres), coniferous  
664 swamp (14.4 acres), deep marsh (4.9 acres), shallow marsh (3.4 acres), and hardwood swamp  
665 (less than 1 acre); and those with low likelihood include shrub swamp (247.1 acres), coniferous  
666 swamp (135.3 acres), coniferous bog (178.8 acres), shallow marsh (4.1 acres), sedge/wet  
667 meadow (1.7 acres), and hardwood swamp (less than 1 acre) (PolyMet 2015b).

DRAFT

678 The potential indirect wetland hydrology drawdown effects on each wetland type were assessed  
679 based on the wetland sensitivity class tables for falling groundwater tables found in the Crandon  
680 mine project document titled *Wetland Impact Assessment Technical Memorandum – Appendix B*.  
681 The following provides a general discussion regarding potential indirect wetland effects that  
682 could occur based on hypothetical hydrologic drawdown levels using the hydrologic wetland  
683 sensitivity method. The potential indirect wetland effects that could occur include: conversion to  
684 other wetland community types, a change in vegetation without a change in community type,  
685 conversion to uplands, or other effects.

686 Three categories of hydrologic wetland sensitivity, each with associated groundwater drawdown  
687 levels for each wetland community type, were created for the hypothetical hydrologic drawdown  
688 wetland sensitivity assessment (PolyMet 2015b).

- 689 • None-to-Slight: Water level changes in which effect on the community would be slight to  
690 none with the potential for slight changes in abundance of various species but no change in  
691 species present. Monitoring or mitigation not anticipated.
- 692 • Moderate: Water level changes that may have a moderate effect on the wetland community  
693 with the potential for the loss and addition of some species. Monitoring recommended with  
694 mitigation based on monitoring results.
- 695 • Severe: Water level changes expected to result in severe effects on the community with the  
696 potential for considerable loss of characteristic plant species and invasion by other species,  
697 conversion of wetland type or conversion to upland. Monitoring should be conducted and  
698 mitigation may be required. According to the hydrologic wetland sensitivity method,  
699 wetlands in which groundwater is not the principal source of water and in which mitigation  
700 of surface water is planned (e.g., streamflow augmentation) should be excluded from this  
701 category.

702 The hydrologic wetland sensitivity method estimated how wetland communities would respond  
703 to groundwater drawdown by assuming that they would change to drier native plant communities  
704 or variants of the original community. No data or research was utilized from actual wetlands  
705 responding to groundwater drawdown; therefore, this analysis and related data can only be used  
706 as an initial estimate of what changes could be expected should groundwater levels actually fall  
707 as a result of the NorthMet Project Proposed Action. Monitoring of hydrology and vegetation  
708 within potentially affected wetlands represents the best method for documenting actual  
709 community changes resulting from hydrology changes, understanding complex hydrologic  
710 conditions, and identifying potential future indirect effects related from mine features.

711 The preliminary information developed for the hydrologic wetland sensitivity method was  
712 utilized to estimate what type of wetland effects might occur at the Mine Site assuming various,  
713 theoretical groundwater drawdown levels. Table 5.2.3-5 provides a summary of the estimated  
714 wetland community changes using the groundwater drawdown thresholds for each wetland type  
715 based on the hydrologic wetland sensitivity method.

716 **Table 5.2.3-5 Potential Wetland Community Changes Due to Drawdown**

| Impact Sensitivity Category           | None                      |                  | Moderate                  |                                                    | Severe                    |                                                           |
|---------------------------------------|---------------------------|------------------|---------------------------|----------------------------------------------------|---------------------------|-----------------------------------------------------------|
| Community Type                        | Water Level Drawdown (ft) | Potential Effect | Water Level Drawdown (ft) | Potential Effect                                   | Water Level Drawdown (ft) | Potential Effect                                          |
| Ombrotrophic Coniferous and Open bog  | <0.75                     | None             | 0.75-2                    | Minor changes in vegetation; Increased tree growth | >2                        | Possible conversion of wetland type                       |
| Minerotrophic Coniferous and Open bog | <0.5                      | None             | 0.5-2                     | Change in vegetation; Increased tree growth        | >2                        | Possible conversion of wetland type                       |

717 Source: PolyMet 2015b.

718 <sup>1</sup> Shallow marsh, deep marsh, and shallow open water communities were not evaluated in the hydrologic wetland sensitivity  
 719 method as described in the Wetland Work Plan, but were estimated based on best professional judgment (PolyMet 2015b).

720 For minor groundwater drawdown (ranging from 0.5 to 2 ft), no substantial wetland community  
 721 changes were identified. For the moderate sensitivity category (water level changes ranging from  
 722 0.5 to 4 ft), some changes to vegetation would be possible in all wetland communities with  
 723 marshes, open water, and meadows, potentially resulting in conversion of wetland type, and  
 724 there could be increased shrub or tree growth in shrub or forested wetlands. For the severe  
 725 sensitivity category, nearly all wetland community types would be estimated to convert to other  
 726 wetland types with a few wetlands estimated to convert to upland, including sedge/wet meadows

727 and possibly hardwood swamps (PolyMet 2015b). Monitoring to document effects to wetlands  
728 would be recommended for all potential effects in the moderate and severe categories.

729 Groundwater modeling cannot reasonably estimate potential indirect wetland effects; therefore,  
730 analog impact zones can provide a reasonable estimate of the extent of potential indirect wetland  
731 effects resulting from hydrologic effects. In addition, the evaluation of theoretical groundwater  
732 drawdown levels can help estimate what types of potential indirect wetland effects might occur.  
733 However, wetland hydrology is a complex mix of precipitation, surface runoff, and in some  
734 cases, groundwater. The response of complex natural systems to human disturbances can only be  
735 estimated. Therefore, monitoring of wetland hydrology and vegetation communities would occur  
736 to document the extent and magnitude of wetland responses (potential indirect effects) to human  
737 disturbances. The monitoring plan, developed as part of the federal and state permitting process,  
738 would be based on those wetlands that have a high likelihood of indirect effects as a result of  
739 groundwater drawdown. The requirements of the monitoring plan would be determined during  
740 the permitting process. Permit conditions would likely include an adaptive management plan to  
741 account for any additional effects that may be identified in the annual monitoring and reporting.

#### 742 **Wetlands Abutting the Partridge River**

743 There are 1,478.5 acres of wetlands abutting the Partridge River within Area 1 (see Figure  
744 4.2.3-2) are presented in Table 5.2.3-6.

745 **Table 5.2.3-6 Wetlands Abutting the Partridge River**

| <b>Eggers and Reed Class<sup>1</sup></b>            | <b>Wetland Size<br/>(acres)</b> | <b>Wetland Size<br/>(percent)</b> |
|-----------------------------------------------------|---------------------------------|-----------------------------------|
| Coniferous bog                                      | 193.0                           | 13                                |
| Shallow marsh                                       | 12.1                            | 1                                 |
| Shrub swamp (including alder thicket or shrub-carr) | 1,273.5                         | 86                                |
| Total Acres of Wetlands                             | 1,478.5                         | 100                               |

746 Source: PolyMet 2015b.

747 <sup>1</sup> Eggers and Reed 1997.

748 The XP-SWMM model identified that the changes in average annual flow (and therefore stage)  
749 of the Partridge River would be within the naturally occurring annual variation for the Partridge  
750 River. Thus, no potential indirect wetland effects were identified for the wetlands abutting the  
751 Partridge River (PolyMet 2015b).

#### 752 **Water Quality Changes**

753 The screening analysis for depositional effects conducted to estimate potential annual deposition  
754 of dust, metals, and sulfur to wetlands within and adjacent to the Mine Site was performed using  
755 AERMOD. The estimated deposition from fugitive dust emissions was used to identify wetlands  
756 that have the potential for water quality changes. The estimated deposition from fugitive dust  
757 emissions was used to identify a threshold for a negative effect on vegetation. Below is a  
758 summary of the assessment from the *NorthMet Project Wetlands Data Package* (PolyMet  
759 2015b).

760 ***Receptors***

761 The receptors of interest for this analysis were the wetlands that were not directly affected. The  
762 respective initial receptor grids for the Mine Site were set up with near-field receptor spacing of  
763 250 meters (within the ambient air boundary and out to 1,000 meters beyond the ambient air  
764 boundary) and far-field receptor spacing of 1,000 meters (from 1 km out to 5 km from the  
765 ambient air boundary).

766 ***Dust Deposition and Speciation to Individual Metals and Sulfur***

767 For the dust emission sources identified for assessing potential metals and sulfur deposition at  
768 the Mine Site, the highest estimated dust deposition rate for each receptor node was then  
769 speciated to the respective metal and sulfur deposition rates based on the contribution of the  
770 sources to a receptor node and the metal and sulfur composition identified for each contributing  
771 source (e.g., ore and waste rock at the Mine Site). The estimated metal or sulfur deposition for  
772 each contributing dust source at a receptor node was then summed to provide a “total” deposition  
773 rate for each respective metal and for sulfur at that receptor location. Dust deposition rates were  
774 speciated for arsenic, cadmium, chromium, lead, manganese, nickel, and selenium. Copper and  
775 vanadium were also included. For each receptor node, the post-processing of the dust deposition  
776 rate by source contribution was then summed to provide a “total” metal deposition rate and a  
777 “total” sulfur deposition rate.

778 Sulfur associated with fugitive dust is part of the mineral matrix of the rock particles (sulfide).  
779 Therefore, weathering of the particles must occur before any of the sulfur would be released to  
780 soil, soil water, or surface water. Mercury was not considered as part of the evaluation of dust  
781 deposition at the Mine Site because the concentration of mercury in the rock to be mined is very  
782 low and would not be considered environmentally significant in this medium (PolyMet 2015b).  
783 Potential mercury air emissions from ore processing (i.e., potential emissions from the autoclave)  
784 were evaluated for potential local deposition impacts (see Section 5.2.7).

785 ***Estimates of Rural Background Deposition***

786 For dust, an annual effects-level deposition rate of 365 grams per square meter per year (g/m<sup>2</sup>/yr)  
787 was compared to modeled annual dust deposition rates. This deposition rate is a potential effects  
788 threshold for photosynthesis (i.e., potential for reduced photosynthesis due to “dusting” of the  
789 plant surface). However, for this analysis, the vegetative surface area of the wetlands was not  
790 calculated or included in the analysis. The modeled dust deposition rate was assumed to be  
791 applied to the land surface area which is a smaller area than the vegetative surface area.  
792 Vegetative surface area can be up to 13 times greater than the land surface area. By only  
793 assessing dust deposition to the land surface area instead of the vegetative surface area, it is  
794 likely the ratio of modeled deposition rate to the effects level was being overestimated. In other  
795 words, the modeled deposition rate is not being spread over the larger surface area of the  
796 vegetation, which would reduce the effective deposition rate. Because this application did not  
797 include the deposition of dust to the vegetative surface area, it is likely that the areas identified to  
798 exceed the effects threshold of 365 g/m<sup>2</sup>/yr have been overestimated.

799 For metals, background deposition is based on the data from *Atmospheric Deposition of Trace*  
800 *Metals at Three sites near the Great Lakes* (Sweet et al. 1997), which indicated that precipitation  
801 was under-collected by 45 to 70 percent when sample volumes were compared to corresponding

802 rain gage amounts. Because wet deposition was considered to be underestimated, the wet  
803 deposition component was adjusted upward by a factor of 1.6.

804 Total background sulfur deposition included both wet and dry deposition, which was calculated  
805 to be 0.16 g/m<sup>2</sup>/yr. The estimated background deposition used in the analysis for metals and  
806 sulfur was from data collected at sites characterized as open areas in rural settings that were  
807 reasonably distant from industrial sources and population centers. For forested areas, dry  
808 deposition may be underestimated. Vegetation can effectively scavenge fine particles and  
809 aerosols from the atmosphere and this interception can result in dry deposition being 50 percent  
810 or more of the total deposition. A monitoring site in Ely (Fernberg Road), dry deposition was  
811 assumed to be 22 percent of total deposition. Therefore, it is likely that the background sulfur  
812 deposition estimated for this analysis may be low due to an underestimation of dry deposition;  
813 however, no adjustments were made to the background sulfur deposition estimated for this  
814 analysis.

### 815 ***Significance Levels for Estimating the Potential Effects for Identifying Future Monitoring***

816 For dust, metals, and sulfur, the following general categories were used for assessing the  
817 significance of a modeled deposition rate at a receptor node:

- 818 • Less than 100 percent of background: no potential for effects expected.
- 819 • Greater than 100 percent of the background value: potential for effects, include in future  
820 wetland monitoring.

821 These are general categories of potential for effects. Since this was a screening analysis to  
822 identify wetlands for potential inclusion in the monitoring program, there was some flexibility in  
823 identifying a potential level of deposition that suggested a potential for effect and would then  
824 trigger a requirement for monitoring. Another consideration for selecting a deposition rate that  
825 was a high percent of the background rates was the likely overestimation of modeled deposition  
826 and the underestimation of background deposition.

827 Adding to the conservatism in the modeling of particulate metals, this screening analysis used a  
828 maximum dust deposition from a range of possible modeled values and a high-end metal or  
829 sulfur concentration for each source contributing to that receptor node to derive a maximum  
830 potential metal or sulfur deposition for a receptor node.

831 Using a maximum concentration for each contributing emission source to speciate a metal or  
832 sulfur deposition from a maximum modeled dust deposition rate for each receptor node  
833 overestimates individual metal or sulfur deposition. Also adding to the conservatism of this  
834 analysis is the underestimation of background deposition because the ratio of the NorthMet  
835 Project Proposed Action-related deposition is compared to the background deposition. If  
836 background deposition is underestimated, that would indicate that estimated NorthMet Project  
837 Proposed Action-related deposition at more receptor nodes would be higher than background and  
838 further increase the area for potential future monitoring. The underestimation of background  
839 metal deposition (i.e., wet deposition due to under-collection of precipitation) was identified by  
840 Sweet et al. (1997). In addition to the underestimation of background metal deposition,  
841 background wet sulfate deposition may be underestimated, as well, because the National  
842 Atmospheric Deposition Program data for the Fernberg Road monitoring site indicated rainfall in  
843 the last 3 years was about 22 percent below the annual average. If sulfate deposition from 2007

844 and 2008 was used (both years approximately normal for precipitation amount), a background  
845 sulfur deposition rate of 0.23 g/m<sup>2</sup>/yr was calculated—about 44 percent higher than the  
846 background deposition used in the screening analysis. If the higher estimate of background sulfur  
847 deposition was used in the screening analysis, a smaller number of receptor nodes would have  
848 been identified to have modeled sulfur deposition that was more than 100 percent of background  
849 deposition and the area for potential monitoring would be smaller than that identified. Also, it  
850 was found that for forested areas, dry deposition may be systematically underestimated due to  
851 sample collection and analysis methodology. It is possible that the background sulfur deposition  
852 estimated for this analysis may be low due to an underestimate of dry deposition.

853 Given the potential for overestimation of modeled deposition and underestimation of background  
854 deposition, and balancing the conservatism when their respective results are combined in this  
855 analysis, it seems reasonable to select the wetlands estimated to receive greater than 100 percent  
856 of background deposition (a potential doubling of the background deposition) for consideration  
857 in potential future monitoring (PolyMet 2015b).

### 858 ***Fugitive Dust/Metals and Sulfide Dust Emissions***

859 At the Mine Site, dust deposition was concentrated relatively close to the ore loading area near  
860 the southern portion of the ambient air boundary. All receptors have model-estimated dust  
861 deposition of 25 percent or less of the effects-level background of 365 g/m<sup>2</sup>/yr (see Figure  
862 5.2.3-16). The model-estimated dust deposition is largely constrained to within the ambient air  
863 boundary at the Mine Site, and the model-estimated dust deposition would be 50 percent or less  
864 of the effects-level background dust deposition.

865 The highest model-estimated metal and sulfur depositions at the Mine Site were in two defined  
866 areas, which include the ore loading area and at the east end of the Category 2/3 Stockpile (see  
867 Figure 5.2.3-17). All of the receptor nodes with the highest model-estimated deposition rates  
868 (deposition rates greater than 100 percent background) were located within the ambient air  
869 boundary.

870 Of the 19,914 acres of wetlands identified within the Mine Site receptor grid, deposition  
871 modeling results indicated that 234 acres of wetlands could be potentially indirectly affected  
872 (modeled metal deposition rates greater than 100 percent of background). Of the 234 acres of  
873 wetlands, 228 acres (97 percent) would be located within the Mine Site ambient air boundary  
874 (PolyMet 2015b). The 234 acres of wetlands would be included in any future monitoring to be  
875 conducted for the NorthMet Project Proposed Action.

876 The deposition modeling results for dust, metals, and sulfur would likely not have an adverse  
877 effect on wetlands; however, the modeling only indicated those areas that had deposition rates  
878 greater than 100 percent of background deposition. These specific wetlands areas would be  
879 identified for consideration in any future monitoring to be conducted for the NorthMet Project  
880 Proposed Action.

881 The initial assessment provided a discussion on conservatism, including a discussion that the  
882 estimated sulfur deposition was as particle-bound sulfur, with the sulfur being inherent to the  
883 mineral matrix of the dust and not readily available for dissolution in soils or surface waters. A  
884 supplemental assessment has been conducted to provide for a worst-case scenario in that all of  
885 the sulfur in fugitive dust converts to sulfate and would mix with surface water in a wetland

886 (Barr 2015f). A summary of the supplemental assessment evaluation of sulfur from stack  
887 emissions is included in Section 5.2.7.2.6, while the fugitive dust evaluation is presented herein.

888 Based on a conservative assumption that all sulfur in fugitive dust converts to sulfate and mixes  
889 with surface water in wetlands, a potential incremental increase in sulfate was calculated as 4.2  
890 mg/L. When the potential incremental sulfate concentration is mixed with annual precipitation,  
891 the sulfate value was calculated as 1.7 mg/L. Because the sulfur is inherent to the mineral matrix  
892 of the dust particles, it is likely that less than 100 percent of the sulfur would be weathered from  
893 the particles and be available to go into solution if deposited to soils or water. While this  
894 potential incremental change may warrant future monitoring, it would not be expected to have an  
895 effect on methylmercury concentrations in surface water based on available data that indicate a  
896 relative insensitivity of wetlands to additional sulfate (Barr 2015f).

897 Although the actual potential for deposition of fugitive dust to wetlands, and the potential release  
898 of sulfur in that dust, is uncertain, any adverse effects on wetlands are unlikely. The fugitive dust  
899 control plan for both the Mine Site and the Plant Site (including the Tailings Basin) would  
900 minimize such deposition, and the sulfur from any rock dust particles that would be deposited  
901 may not be released or only released slowly through weathering. Using a conservative  
902 assumption that all sulfur in the deposited dust is both released and transformed to sulfate, no  
903 significant increase in methylmercury concentrations would be expected (Barr 2015f).  
904 Additional information relating to mercury methylation is provided in Section 5.2.2.3.4. A  
905 discussion of mercury deposition and bioaccumulation in fish and the assessment of the  
906 cumulative effects is provided in Section 6.2.6.3.3.

#### 907 ***Mine to Plant Site Railroad Corridor - Ore Spillage***

908 The potential release of dust from railcars transporting ore from the Mine Site to the Plant Site  
909 was addressed in the May 6, 2011, Air IAP Summary Memo (PolyMet 2015b):

910         The air IAP group concluded that there would be minimal air impacts from any dust  
911         generated from ore hauled in the railcars due to the coarse nature of the ore.

912 Based on this conclusion, air modeling of potential release of dust from railcars was not  
913 performed because the potential wetland effects would not be significant.

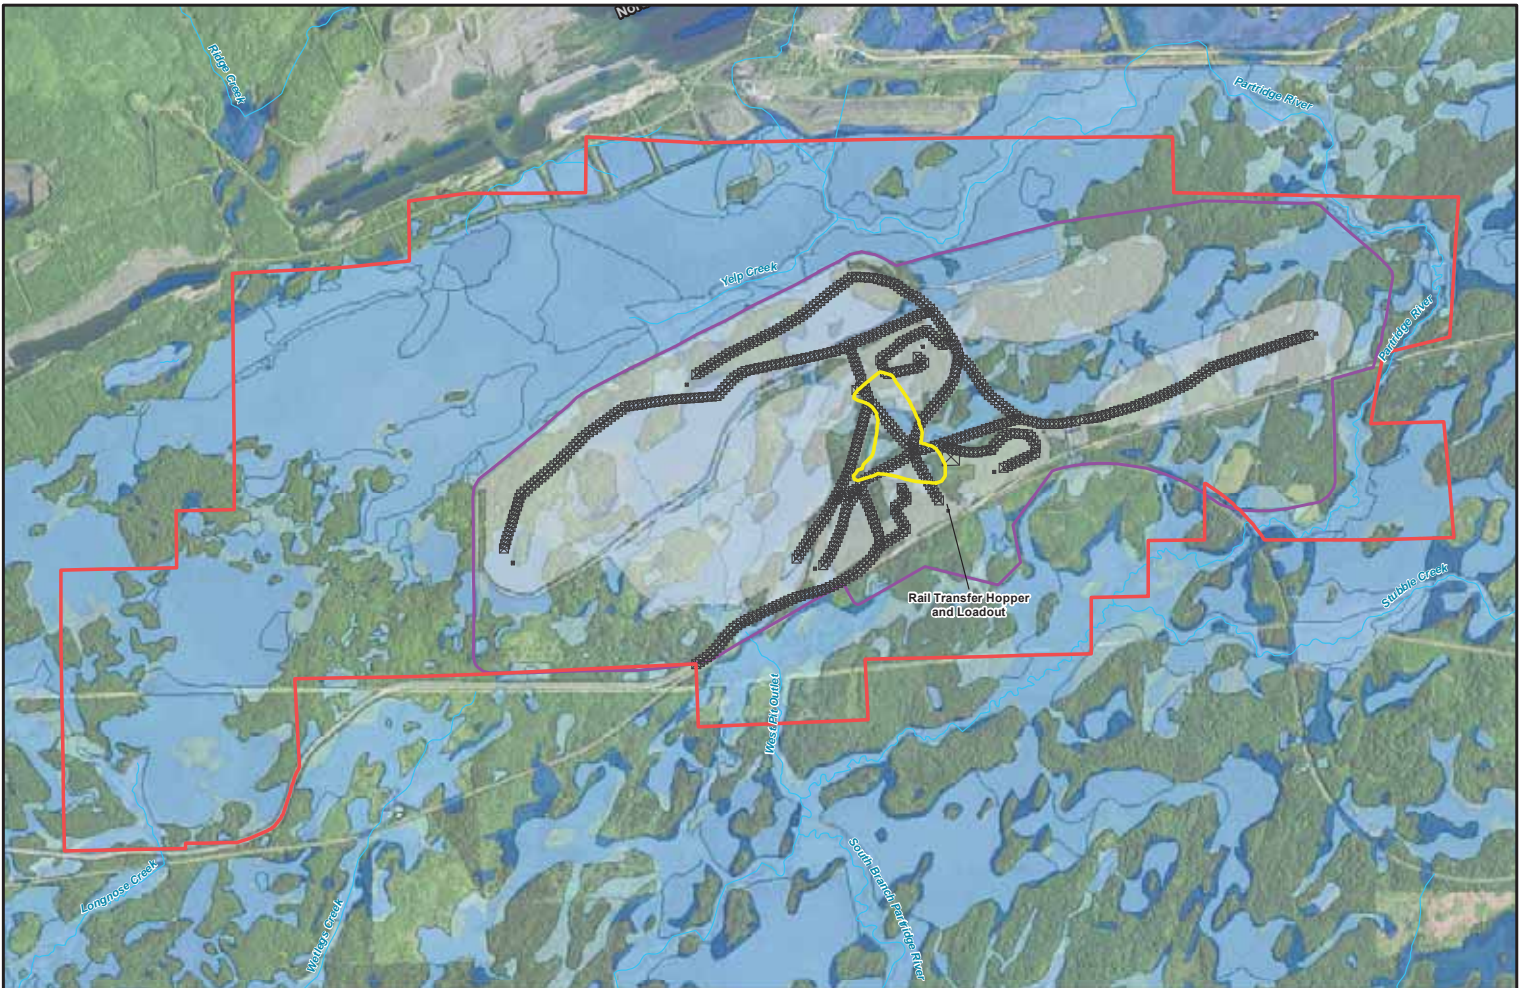

914 The air IAP group concluded that any dust generated from ore hauled in railcars would be coarse  
915 in nature (i.e., relatively large particles). These larger particles would tend to deposit near the  
916 railcar and not be dispersed to any great extent. An estimate of the spillage of ore fines along the  
917 rail corridor is provided in Section 8.4.3 of the Waste Characterization Data Package (PolyMet  
918 2015q). Assuming that all spillage of the coarse material would occur in a 2-meter-wide strip on  
919 both sides of the centerline of the railway (total width equals 4 meters) over the entire haul  
920 distance after loading (approximately 8 miles or 13,000 meters), results in approximately 0.11  
921 kilograms per square meter (kg/m<sup>2</sup>) of ore fines annually or 2.14 kg/m<sup>2</sup> for the 20-year NorthMet  
922 Project Proposed Action. This equates to 0.002 inch of depth annually or 0.05 inches for the  
923 20-year NorthMet Project Proposed Action. However, as described in Section 3.2.2.2.4, PolyMet  
924 has committed to refurbish the rail cars to minimize the gaps along hinges and joint areas to  
925 reduce potential ore spillage. Based upon the rail car modification evaluation performed by  
926 PolyMet (2014a), the ore spillage may be reduced by up to 97 percent which would  
927 proportionally reduce the dilution needed to meet surface water standards (PolyMet 2015b).

928 For most contaminant constituents, the contact water leaving the spillage strip has been estimated  
929 to have a greater than 90 percent likelihood of complying with surface water standards at all  
930 times. Constituents that have the potential to exceed surface water standards at the edge of the 2-  
931 meter spillage strip include aluminum, cobalt, copper, and nickel. Aluminum concentrations are  
932 often above the surface water standard in the background runoff, and it is not possible to achieve  
933 a less than 10 percent likelihood of exceeding the standard in the mixed water (PolyMet 2015b).  
934 For cobalt, copper, and nickel the estimated area (square meters per meter of railroad track on  
935 each side) necessary to provide sufficient dilution for 90 percent probability of compliance is 2.5,  
936 675, and 30 square meters per meter of railroad track on each side, respectively. Therefore, the  
937 limiting area required to provide sufficient dilution water for all constituents has been estimated  
938 at 675 square meters per meter of track (one-sided). Please refer to 5.2.2.3.2 for more  
939 information on ore spillage. Approximately 542.7 acres of wetlands along the railroad corridor  
940 could be potentially indirectly affected by the NorthMet Project Proposed Action.

941 Wetlands that have contributing watersheds that include no segments of the railway (e.g., many  
942 of the wetlands uphill to the north of the rail corridor) were identified as having no potential  
943 indirect effects from rail spillage. Wetlands immediately abutting the railway and whose  
944 watersheds included the rail centerline were identified as potentially being affected, although the  
945 effects may not extend to the full area of the wetland. Wetlands that have contributing  
946 watersheds, which include natural areas that are larger than 675 square meters per meter of track  
947 (one-sided) in the contributing watershed, were identified as having no potential indirect effects.

952 ***Leakage from Stockpiles/Mine Features and Seepage from Mine Pits***

953 The stockpiles, mine pits, and other mine features (e.g., WWTF) are located within the Partridge  
954 River Watershed. Water containing constituents generated in the waste rock stockpiles and mine  
955 pits has the potential to enter the shallow groundwater system via potential leakage through the  
956 liners (e.g., stockpiles and WWTF equalization basins) or seepage from the pits. The leakage or  
957 seepage that enters groundwater would then be transported toward the Partridge River along  
958 groundwater flowpaths. There are five groundwater flowpaths connecting the mine features to  
959 the Partridge River, which include: East Pit – Category 2/3 flowpath, Ore Surge Pile flowpath,  
960 WWTF flowpath, Overburden Storage and Laydown Area flowpath, and West Pit flowpath.  
961 Because the water quality within these flowpaths has the potential to change as a result of the  
962 NorthMet Project Proposed Action, these same flowpaths were considered in the assessment of  
963 potential indirect wetland effects associated with leakage or seepage from mine features  
964 (PolyMet 2015b).

965 Wetlands were identified within the groundwater flowpaths, and the bog wetlands within and  
966 surrounding the Mine Site were subcategorized as either ombrotrophic or minerotrophic  
967 consistent with the November 2011, USACE Memorandum (Eggers 2011a). There are 515.8  
968 acres of wetland resources within the groundwater flowpaths. Other wetlands were classified as  
969 dominated by groundwater, although all wetlands receive precipitation and virtually all water  
970 movement in peat wetlands occurs horizontally in the upper layers of peat. Approximately 66  
971 percent of the wetlands within the flowpaths are classified as dominantly minerotrophic  
972 (groundwater-fed) while 34 percent of the wetlands are supported only by precipitation  
973 (ombrotrophic) (see Table 5.2.3-7).

974 Water quality modeling results indicate groundwater quality along each flowpath would likely  
975 change from existing conditions. It was conservatively assumed that these changes may cause  
976 potential indirect effects to the character, function, and quality of minerotrophic wetlands;  
977 therefore, it was also assumed that all downgradient minerotrophic wetlands located within the  
978 five Mine Site surficial aquifer flowpaths may have potential indirect wetland effects related to  
979 water quality changes as a result of leakage/seepage from mine features (PolyMet 2015b). This  
980 analysis indicates areas that can be conservatively assumed to have potential indirect effects due  
981 to changes in groundwater quality. These specific wetland areas are identified for consideration  
982 in the proposed wetland monitoring plan.

984 Source: PolyMet 2015b.

985 <sup>1</sup> Eggers and Reed 1997, 2014.

986 The Partridge River currently represents the primary discharge location for shallow groundwater  
 987 at the Mine Site. During operations, reclamation, and closure and long-term maintenance,  
 988 groundwater in areas south of the mine pits would continue to discharge to the Partridge River  
 989 while groundwater in areas north of the mine pits would discharge to the mine pits. The amount  
 990 of groundwater emerge in surface water and wetlands between the mine features and the  
 991 Partridge River would be expected to be minimal relative to the amount of groundwater emerge  
 992 in the Partridge River itself. Significant quantities of groundwater are not expected to discharge  
 993 to the wetlands because of the very low hydraulic conductivities of the underlying peat layers  
 994 (PolyMet 2015b). The water quality model assumed that the leakage/seepage from mine features  
 995 releases directly to the Partridge River; therefore, it is assumed that groundwater would not  
 996 emerge in surface water or wetlands along intermediate portions of the flow paths (PolyMet  
 997 2015m). The water quality model cannot be used to quantify the amount of leakage/seepage from  
 998 mine features that discharges directly to individual wetlands. However, the water quality model  
 999 was used to provide a conservative estimate of the potential indirect wetlands effects caused by  
 1000 water quality changes due to leakage/seepage from mine features (PolyMet 2015b).

1001 The leakage/seepage analysis could not indicate or suggest that an effect or adverse effect would  
 1002 occur on wetlands; however, the analysis only indicated those areas that could be conservatively  
 1003 assumed to have a potential indirect effect due to changes in groundwater (PolyMet 2015b).

1004 ***Dunka Road Effects***

1005 Loaded mine haul trucks would not travel on the Dunka Road. Empty mine haul trucks would  
 1006 only travel on Dunka Road when they are in need of maintenance at the Area 1 Shop. The total  
 1007 one-way trips per year have been estimated to be 44 trips. Given the low traffic volumes of haul  
 1008 trucks (less than one trip per week) and that the ore trucks would likely be empty; no potential  
 1009 indirect wetland effects were identified for wetlands abutting Dunka Road (PolyMet 2015b). The

1010 additional light vehicles (e.g., pickups and SUVs), field service trucks, and fuel trucks that would  
1011 travel on Dunka Road more regularly would not contribute to wetland effects.

### 1012 **5.2.3.2.3 Plant Site Direct Wetland Impacts**

1013 PolyMet proposes to reuse the former LTVSMC processing plant and Tailings Basin. The  
1014 processing plant is located on uplands with no wetland resources present. The existing  
1015 constructed plant reservoir located east of the concentrator is not regulated as a wetland.  
1016 Therefore, no direct wetland impacts are anticipated in this portion of the Plant Site.

1017 Direct wetland impacts would result from the following Plant Site components: construction of  
1018 the Tailings Basin, pump station, treated water discharge pipelines, flotation tailings pipeline,  
1019 Tailings Basin containment system to manage Tailings Basin seepage, rock buttress for stability  
1020 along the north and east sides of Cell 2E, drainage swale and overflow channel located northeast  
1021 of Cell 2E, and the Hydrometallurgical Residue Facility.

1022 Direct wetland impacts within the Plant Site would total 148.4 acres. These wetlands impacts  
1023 would be caused by fill (12 percent), excavation (31 percent), excavation and fill (less than one  
1024 percent), and the containment system (58 percent), and therefore, these wetlands would be  
1025 permanently lost. Table 5.2.3-8 summarizes the directly impacted wetlands within the Plant Site  
1026 by community type while Table 5.2.3-9 identifies the activity that causes the impacts expected  
1027 within the Plant Site. The majority of the wetlands (94 percent) that would be impacted are rated  
1028 as low quality and 6 percent are rated as moderate quality wetlands.

1029 The rock buttress described in Section 3.2.3 and Section 4.2.13 would abut the existing toe of the  
1030 Tailings Basin. The water containment system would extend approximately 300 ft around the  
1031 northern and western sides, and portions of the eastern sides of the Tailings Basin, encapsulating  
1032 the Tailings Basin, the rock buttresses and wetlands between it and the rock buttresses.  
1033 Construction of the Tailings Basin for the NorthMet Project Proposed Action would also result in  
1034 expansion of the existing eastern footprint onto natural highland. The majority of the impacted  
1035 wetlands are rated as low quality, primarily because the hydrology supporting these wetlands has  
1036 been modified by seepage from the Tailings Basin and other drainage modifications made in the  
1037 area (PolyMet 2015b). These hydrologic modifications have resulted in inundation and changes  
1038 in wetland cover types from forested and scrub shrub wetlands (as evidenced in aerial  
1039 photographs from the 1940s prior to LTVSMC operations) to deep marsh (Barr 2008b).

1040 Wetlands located outside of the Cliffs Erie Permit to Mine Ultimate Tailings Basin boundary  
1041 (this boundary is shown on Figure 5.2.3-18 and Figure 5.2.3-19) but within the  
1042 Hydrometallurgical Residue Facility are included in the direct wetland impact analysis. As  
1043 previously noted, approximately 28.6 acres of wetlands in the Hydrometallurgical Residue  
1044 Facility are not subject to state or federal regulations as they are located within an actively  
1045 permitted waste storage facility. Two wetlands located in the Hydrometallurgical Residue  
1046 Facility are subject to state or federal regulation covering 7.5 acres and would be directly  
1047 impacted by fill. Both wetlands are shallow marsh wetlands (see Figure 5.2.3-19).

1048 There would be no direct wetland impacts along the Colby Lake Water Pipeline Corridor or in  
1049 the Second Creek area as there would be no construction within these two areas.

1050 **Table 5.2.3-8 Total Projected Direct Wetland Impacts for the Plant Site**

1051 Source: PolyMet 2015b.

1052 <sup>1</sup> Eggers and Reed 1997, 2014.

1053 <sup>2</sup> There are 44 unique wetlands directly impacted at the Plant Site, which includes the Tailings Basin and Hydrometallurgical  
 1054 Residue Facility footprint. One wetland (ID 1155) has been split between the Tailings Basin and Hydrometallurgical Residue  
 1055 Facility footprint in the Wetland Data Package for a total of 45 wetlands directly impacted in Wetland Data Package report.

1060 **Table 5.2.3-9 Type of Projected Direct Wetland Impacts at the Plant Site**

| Type of Impact       | Directly Impacted Wetlands at the Plant Site |     |                  |
|----------------------|----------------------------------------------|-----|------------------|
|                      | Acres                                        | %   | No. <sup>1</sup> |
| Fill                 | 17.6                                         | 12  | 17               |
| Excavation           | 45.2                                         | 31  | 1                |
| Fill and Excavation  | 0.2                                          | <1  | 1                |
| Containment System   | 85.4                                         | 58  | 26               |
| Total Direct Impacts | 148.4                                        | 100 | 45               |

1061 Source: PolyMet 2015b.

1062 <sup>1</sup> There are 44 unique wetlands directly impacted at the Plant Site, which includes the Tailings Basin and Hydrometallurgical  
 1063 Residue Facility footprint. One wetland (ID 1155) has been split between the Tailings Basin and Hydrometallurgical Residue  
 1064 Facility footprint in the Wetland Data Package for a total of 45 wetlands directly impacted in Wetland Data Package report.  
 1065 This would result in impacts on wetlands as a result of filling at the Hydrometallurgical Residue Facility and placement of the  
 1066 containment system at the Tailings Basin.

1067 **5.2.3.2.4 Plant Site Indirect Wetland Effects**

1068 The indirect wetland effects were assessed by identifying wetlands in Area 2 within 500-ft  
 1069 increments beginning at the Plant Site and continuing out to a total of 30,000 ft (see Figure  
 1070 5.2.3-20). The area of evaluation for the Plant Site indirect wetlands effects included wetlands  
 1071 within Area 2 where wetland type information had been developed and wetlands within and near  
 1072 Second Creek, and does not include the directly impacted wetlands. No wetlands are located  
 1073 within the former LTVSMC processing plant; therefore, no indirect wetland effects would occur  
 1074 from its reuse. Furthermore, no indirect wetland affects would occur at the Hydrometallurgical  
 1075 Residue Facility as all wetlands would be directly impacted.

1076 The potential indirect wetland effects to the Second Creek area of analysis was assessed based on  
 1077 changes to hydrology due to groundwater flow or seepage, drawdown or surface water quantity,  
 1078 or changes in surface water quality or metals deposition. There are no predicted potential indirect  
 1079 wetland effects due to wetland fragmentation, changes in watershed area, or dust deposition in  
 1080 the Second Creek area of analysis (PolyMet 2015b).

1081 **Wetland Fragmentation**

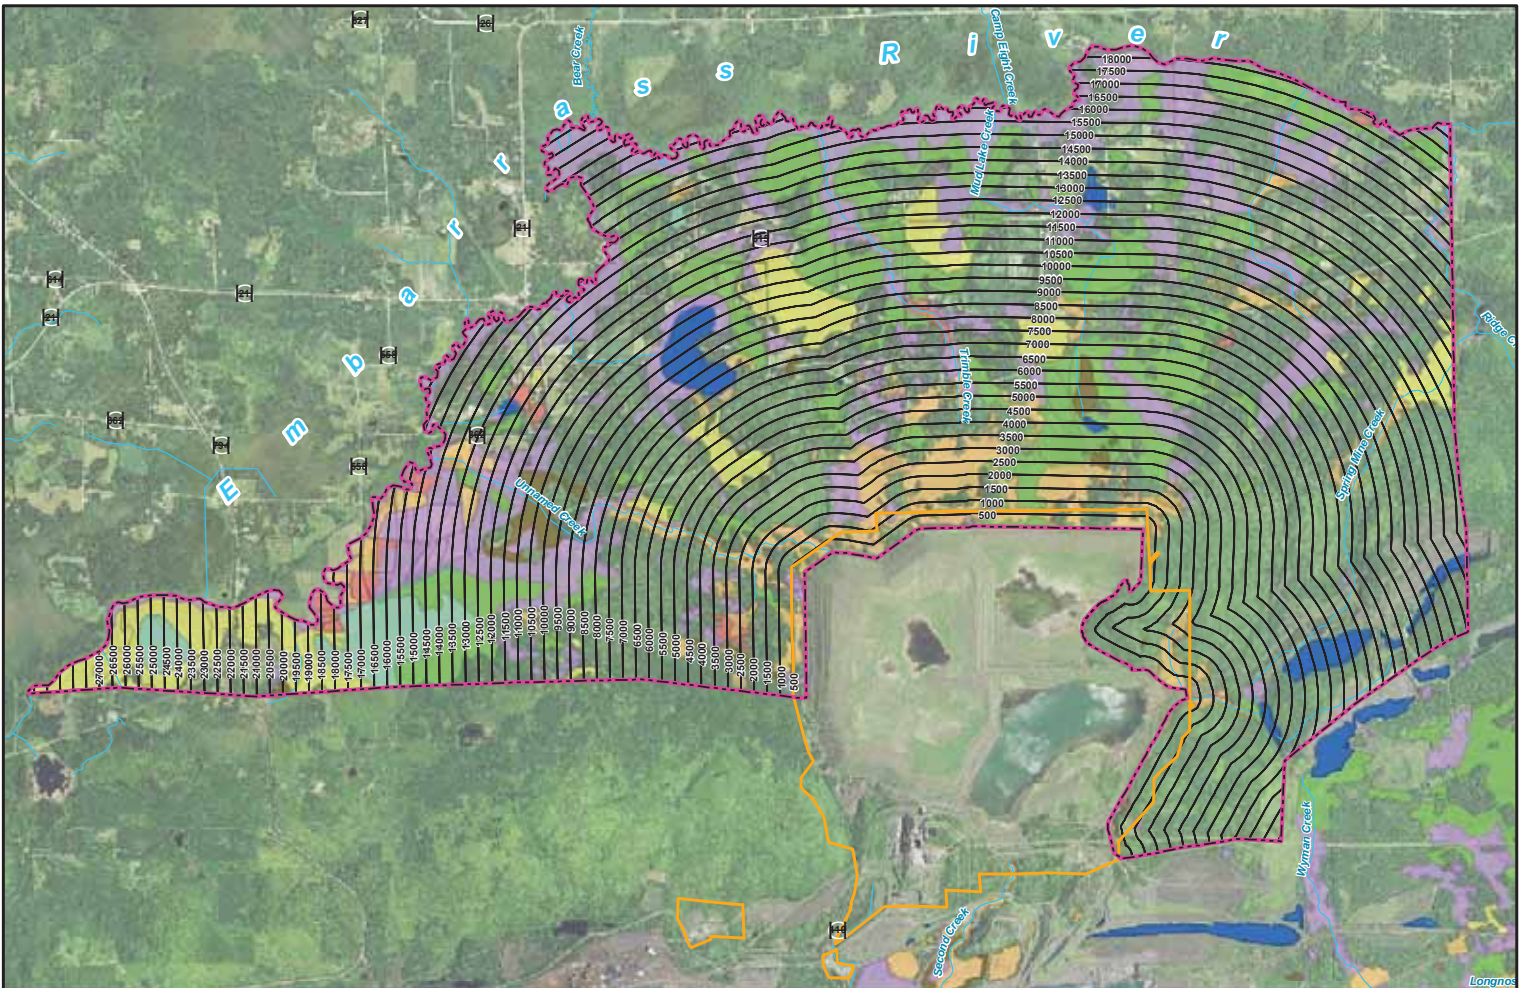

1082 Construction of the Plant Site features (e.g., containment system) would result in 0.5 acre of  
 1083 wetland fragments losing their functions. Wetland fragments would result in the following  
 1084 wetland types: shallow marsh (61 percent), deep marsh (35 percent), coniferous swamp (4  
 1085 percent), and shrub swamps (less than 1 percent). Furthermore, no wetland fragmentation would  
 1086 result from activities to wetlands in Second Creek area of analysis (PolyMet 2015b). The  
 1087 wetland fragments that are expected to maintain their functions would be included in the wetland  
 1088 hydrology and vegetation monitoring plan that would be developed and implemented for the  
 1089 NorthMet Project Proposed Action.

1090 **Changes in Hydrology due to Surficial Groundwater Flow Paths or Seepage from Plant**  
 1091 **Site**

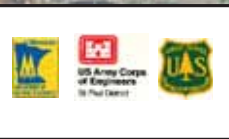

1092 There are three surficial aquifer groundwater flowpaths from the Plant Site (see Figure 5.2.3-21),  
 1093 which include: Unnamed Creek (west flowpath), Trimble Creek (northwest flowpath), and Mud

1094 Lake Creek (north flowpath). Wetland types within the flowpaths that would have potential  
1095 indirect wetland effects resulting from changes in hydrology are presented in Table 5.2.3-10.

1101 Source: PolyMet 2015b.

1102 <sup>1</sup> Eggers and Reed 1997, 2014.

1103 The Tailings Basin containment system, located along the northern, northwestern, and western  
 1104 sides of the Tailings Basin, is modeled to collect at least 90 percent of the Tailings Basin  
 1105 groundwater seepage and 100 percent of the surface water seepage. The uncaptured groundwater  
 1106 seepage would travel within the northern, northwestern, and western groundwater flowpaths (see  
 1107 Section 5.2.2). The Tailings Basin containment system located along a portion of the eastern side  
 1108 of the Tailings Basin would collect 100 percent of groundwater and surface water seepage.

1109 All of the surface flow that currently upwells near the west, northwest, and north toes of the  
 1110 Tailings Basin would be captured and treated by the WWTP and then discharged to the  
 1111 tributaries to prevent significant hydrologic effects due to reduction in flow. To the west, the  
 1112 discharge(s) would be directed to a location near the existing surface discharge SD-006 (see  
 1113 Figure 5.2.3-21). To the northwest and north, the discharge(s) would be spigotted at multiple  
 1114 locations along the downstream side of the Tailings Basin containment system to add flow to the  
 1115 adjacent wetlands (PolyMet 2015b). Flow to Mud Creek would be augmented entirely with off-  
 1116 site runoff diverted toward Mud Lake Creek by a drainage swale constructed northeast of Cell  
 1117 2E. Augmentation would not be necessary at the eastern segment of the Tailings Basin  
 1118 containment system as this area is currently flowing into the Tailings Basin; therefore, the  
 1119 collection of seepage would not have a hydrologic effect to the watershed (PolyMet 2015b). For  
 1120 a detailed discussion of seepage from the Plant Site, refer to Section 5.2.2.

1121 Seepage from the south side of the Plant Site is generally restricted by bedrock outcrops and does  
 1122 not contribute to the groundwater flow south of the Plant Site. All of the seepage from the south  
 1123 side of the Plant Site is surface water, thereby forming the headwaters of Second Creek. There  
 1124 would be no potential indirect effects on wetlands in or abutting Second Creek as a result of  
 1125 changes in groundwater flow (PolyMet 2015b).

1127 **Change in Hydrology due to Drawdown**

1128 The augmentation described above has been designed such that the existing flows within the  
1129 tributaries at the Plant Site are maintained within plus or minus 20 percent, which is within the  
1130 range of annual variability in precipitation as well as streamflow, within the Embarrass River  
1131 Watershed. Therefore, changes to downstream hydrology, including adjacent wetlands, would be  
1132 expected to be within the range of that typically observed due to natural variability (PolyMet  
1133 2015b).

1134 Potential indirect effects on Mud Lake Creek, Trimble Creek, and Unnamed Creek due to  
1135 reduced or increased seepage at the toe of the Tailings Basin are greatest immediately  
1136 downstream of the toe, where seepage and augmentation account for nearly all the water yield.  
1137 Downstream of the toe, the indirect effects on these three creeks would be reduced as the  
1138 watershed area tributary to that location increases, and the portion of total water yield derived  
1139 from runoff increases. Therefore, hydrologic effects diminish as distance from the Tailings Basin  
1140 increases. Wetlands further from the Tailings Basin would likely experience less potential for  
1141 indirect effects due to hydrologic changes (PolyMet 2015b).

1142 Flow augmentation at the southern toe of the Tailings Basin has been designed such that flows to  
1143 Second Creek would be within  $\pm 20$  percent of the pre-Consent Decree condition, which is within  
1144 the range of annual variability in precipitation as well as streamflow, within the Partridge River  
1145 and Embarrass River watersheds. No potential indirect wetland effects would be anticipated for  
1146 the wetlands abutting Second Creek (PolyMet 2015b).

1147 Wetland hydrology is a complex mix of precipitation, surface runoff, and, in some cases,  
1148 groundwater. Despite the use of augmentation to mitigate effects, the response of complex  
1149 natural systems to human disturbances could only be estimated. Therefore, monitoring of  
1150 wetland hydrology and vegetation communities would be the most appropriate way to document  
1151 the extent and magnitude of wetland responses to the NorthMet Project Proposed Action.

1152 Please refer to Section 5.2.3.2.2, Changes in Hydrology Due to Drawdown subsection, for the  
1153 hydrologic wetland sensitivity assessment that was performed to estimate how wetland  
1154 communities would respond to groundwater drawdown by assuming that they would change to  
1155 drier native plant communities or variants of the original community.

1156 **Wetlands Abutting Unnamed Creek, Trimble Creek, Mud Lake Creek, and Second Creek**

1157 There are 2,754.8 acres of wetlands abutting Unnamed Creek, Trimble Creek, and Mud Lake  
1158 Creek within Area 2, and Second Creek, which include shrub swamps, coniferous swamp,  
1159 hardwood swamp, shallow marsh, deep marsh, and sedge/wet meadow (see Figure 4.2.3-5) are  
1160 presented in Table 5.2.3-11.

1163 Sources: PolyMet 2015b

1164 <sup>1</sup> Eggers and Reed 1997, 2014.

1165 Water management at the Plant Site would consist of flow augmentation immediately  
 1166 downstream of the Tailings Basin containment system to minimize hydrologic effects on  
 1167 downstream watercourses (PolyMet 2015b). The hydrologic analysis (see Section 5.2.2)  
 1168 estimated that the changes in average annual flow of Unnamed Creek, Trimble Creek, Mud Lake  
 1169 Creek, and Second Creek would be within the annual variability that naturally occurs within the  
 1170 Partridge River and Embarrass River watersheds. Therefore, no potential indirect wetland effects  
 1171 were identified for the wetlands abutting Unnamed Creek, Trimble Creek, Mud Lake Creek, and  
 1172 Second Creek (PolyMet 2015b).

1173 **Water Quality Changes**

1174 The screening analysis for depositional effects conducted to estimate potential annual deposition  
 1175 of dust, metals, and sulfur to wetlands within and adjacent to the Plant Site was performed using  
 1176 AERMOD. The estimated deposition from fugitive dust emissions was used to identify wetlands  
 1177 that have the potential for water quality changes. The estimated deposition from fugitive dust  
 1178 emissions was used to identify a threshold for a negative effect on vegetation.

1179 Below is a summary of the assessment from the *NorthMet Project Wetlands Data Package*  
 1180 (PolyMet 2015b).

1181 **Receptors**

1182 The receptors of interest for this analysis were the wetlands that were not directly impacted. The  
 1183 respective initial receptor grids for the Plant Site were set up with near-field receptor spacing of  
 1184 250 meters within the ambient air boundary and the far-field receptor spacing was 1,000 meters  
 1185 from the ambient air boundary out to 5 km.

1186 **Dust Deposition and Speciation to Individual Metals and Sulfur**

1187 For the dust emission sources identified for assessing potential metals and sulfur deposition at  
 1188 the Plant Site, the highest estimated dust deposition rate for each receptor node was then  
 1189 speciated to the respective metal and sulfur deposition rates based on the contribution of the  
 1190 sources to a receptor node and the metal and sulfur composition identified for each contributing  
 1191 source (e.g., tailings at the Plant Site). The estimated metal or sulfur deposition for each

1192 contributing dust source at a receptor node was then summed to provide a “total” deposition rate  
1193 for each respective metal and for sulfur at that receptor location. Dust deposition rates were  
1194 speciated for arsenic, cadmium, chromium, lead, manganese, nickel, and selenium. Copper and  
1195 vanadium were also included. For each receptor node, the post-processing of the dust deposition  
1196 rate by source contribution was then summed to provide a “total” metal deposition rate and a  
1197 “total” sulfur deposition rate.

1198 Sulfur associated with fugitive dust is part of the mineral matrix of the rock particles (sulfide).  
1199 Therefore, weathering of the particle must occur before any of the sulfur would be released to  
1200 soil, soil water, or surface water. Because the NorthMet ore is low in mercury, the tailings would  
1201 also be low in mercury, and the pilot study indicated that the mercury preferentially goes to the  
1202 flotation concentrate. The mercury is also expected to be strongly bound within the mineral  
1203 matrix. This would also be true for the LTVSMC tailings that would be used to construct the  
1204 Tailings Basin dams and that may be present on some road surfaces. Therefore, any mercury  
1205 present in dust from the Tailings Basin would not be biologically available (PolyMet 2015b).  
1206 Potential mercury air emissions from ore processing (i.e., potential emissions from the autoclave)  
1207 were evaluated for potential local deposition impacts (see Section 5.2.7).

#### 1208 ***Estimates of Rural Background Deposition***

1209 For dust, an annual effects-level deposition rate of 365 g/m<sup>2</sup>/yr was compared to modeled annual  
1210 dust deposition rates. This deposition rate is a potential effects threshold for photosynthesis (i.e.,  
1211 potential for reduced photosynthesis due to “dusting” of the plant surface). However, for this  
1212 analysis, the vegetative surface area of the wetlands was not calculated or included in the  
1213 analysis. The modeled dust deposition rate was assumed to be applied to the land surface area,  
1214 which is a smaller area than the vegetative surface area. Vegetative surface area can be up to 13  
1215 times greater than the land surface area. By only assessing dust deposition to the land surface  
1216 area instead of the vegetative surface area, it is likely the ratio of modeled deposition rate to the  
1217 effects level was being overestimated. In other words, the modeled deposition rate is not being  
1218 spread over the larger surface area of the vegetation which would reduce the effective deposition  
1219 rate. Because this application did not include the deposition of dust to the vegetative surface  
1220 area, it is likely that the areas identified to exceed the effects threshold of 365 g/m<sup>2</sup>/yr have been  
1221 overestimated.

1222 For metals, background deposition is based on the data from *Atmospheric Deposition of Trace*  
1223 *Metals at Three sites near the Great Lakes* (Sweet et al. 1997), which indicated that precipitation  
1224 was under-collected by 45 to 70 percent when sample volumes were compared to corresponding  
1225 rain gage amounts. Because wet deposition was considered to be underestimated, the wet  
1226 deposition component was adjusted upward by a factor of 1.6.

1227 Total background sulfur deposition included both wet and dry deposition, which was calculated  
1228 to be 0.16 g/m<sup>2</sup>/yr. The estimated background deposition used in the analysis for metals and  
1229 sulfur was from data collected at sites characterized as open areas in rural settings that are  
1230 reasonably distant from industrial sources and population centers. For forested areas, dry  
1231 deposition may be underestimated. Vegetation can effectively scavenge fine particles and  
1232 aerosols from the atmosphere and this interception can result in dry deposition being 50 percent  
1233 or more of the total deposition. A monitoring site in Ely (Fernberg Road), dry deposition was  
1234 assumed to be 22 percent of total deposition. Therefore, it is likely that the background sulfur  
1235 deposition estimated for this analysis may be low due to an underestimation of dry deposition;

1236 however, no adjustments were made to the background sulfur deposition estimated for this  
1237 analysis.

1238 ***Significance Levels for Estimating the Potential Effects for Identifying Future Monitoring***

1239 For dust, metals, and sulfur, the following general categories were used for assessing the  
1240 significance of a modeled deposition rate at a receptor node:

- 1241 • Less than 100 percent of background: no potential for effects expected.
- 1242 • Greater than 100 percent of the background value: potential for effects, include in future  
1243 wetland monitoring.

1244 These are general categories of potential for effects. Since this was a screening analysis to  
1245 identify wetlands for potential inclusion in the monitoring program, there was some flexibility in  
1246 identifying a potential level of deposition that suggested a potential for effect and would then  
1247 trigger a requirement for monitoring. Another consideration for selecting a deposition rate that  
1248 was a high percent of the background rates was the likely overestimation of modeled deposition  
1249 and the underestimation of background deposition.

1250 Adding to the conservatism in the modeling of particulate metals, this screening analysis used a  
1251 maximum dust deposition from a range of possible modeled values and a high-end metal or  
1252 sulfur concentration for each source contributing to that receptor node to derive a maximum  
1253 potential metal or sulfur deposition for a receptor node.

1254 Using a maximum concentration for each contributing emission source to speciate a metal or  
1255 sulfur deposition from a maximum modeled dust deposition rate for each receptor node  
1256 overestimates individual metal or sulfur deposition. Also adding to the conservatism of this  
1257 analysis is the underestimation of background deposition because the ratio of the NorthMet  
1258 Project Proposed Action-related deposition is compared to the background deposition. If  
1259 background deposition is underestimated, that would indicate that estimated NorthMet Project  
1260 Proposed Action-related deposition at more receptor nodes are higher than background and  
1261 further increases the area for potential future monitoring. The underestimation of background  
1262 metal deposition (i.e., wet deposition due to under-collection of precipitation) was identified by  
1263 Sweet et al. (1997). In addition to the underestimation of background metal deposition,  
1264 background wet sulfate deposition may be underestimated, as well, because the National  
1265 Atmospheric Deposition Program data for the Fernberg Road monitoring site indicated rainfall in  
1266 the last three years was about 22 percent below the annual average. If sulfate deposition from  
1267 2007 and 2008 was used (both years approximately normal for precipitation amount), a  
1268 background sulfur deposition rate of 0.23 g/m<sup>2</sup>/yr was calculated—about 44 percent higher than  
1269 the background deposition used in the screening analysis. If the higher estimate of background  
1270 sulfur deposition was used in the screening analysis, a smaller number of receptor nodes would  
1271 have been identified to have modeled sulfur deposition that was more than 100 percent of  
1272 background deposition and the area for potential monitoring would be smaller than that  
1273 identified. Also, it was found that for forested areas, dry deposition may be systematically  
1274 underestimated due to sample collection and analysis methodology. It is possible that the  
1275 background sulfur deposition estimated for this analysis may be low due to an underestimate of  
1276 dry deposition.

1277 Given the potential for overestimation of modeled deposition and underestimation of background  
1278 deposition, and balancing the conservatism when their respective results are combined in this  
1279 analysis, it seems reasonable to select the wetlands estimated to receive greater than 100 percent  
1280 of background deposition (a potential doubling of the background deposition) for consideration  
1281 in potential future monitoring (PolyMet 2015b).

### 1282 ***Fugitive Dust/Metals and Sulfide Dust Emissions***

1283 At the Plant Site, dust deposition was highest in three locations: southwest corner, northwest of  
1284 the Plant Site; southeast corner; and the northeast corner, towards Area 5. All receptors have  
1285 model-estimated dust deposition of 50 percent or less of the effects-level background of 365  
1286 g/m<sup>2</sup>/yr (see Figure 5.2.3-22). The model-estimated dust deposition is largely constrained to  
1287 within the ambient air boundary at the Plant Site, and the model-estimated dust deposition is 50  
1288 percent or less of the effects-level background dust deposition. There would be no potential  
1289 indirect wetland effects due to dust deposition in the Second Creek area of analysis (PolyMet  
1290 2015b).

1291 At the Plant Site, there would be two locations showing model-estimated metal and sulfur  
1292 deposition rates greater than 100 percent of background deposition: 1) approximately the  
1293 southern and western two-thirds of the basin and 2) a small area on the northern and eastern  
1294 portion of the ambient air boundary (see Figure 5.2.3-23). Approximately 90 percent of the  
1295 receptor nodes with the highest model-estimated metal and sulfur deposition rates (rates greater  
1296 than 100 percent of background deposition) were located within the ambient air boundary. The  
1297 remaining 10 percent of the receptor nodes with the highest modeled-estimated metal and sulfur  
1298 deposition are located to the south and east of the Plant Site outside of the ambient air boundary  
1299 (PolyMet 2015b).

1300 Of the 25,846 acres of wetlands identified within the Plant Site receptor grid, deposition  
1301 modeling results indicate that 193.9 acres of wetland could be potentially indirectly affected  
1302 (modeled metal deposition rates greater than 100 percent of background). Of the 193.9 acres,  
1303 58.8 acres would be located within the Plant Site ambient air boundary (PolyMet 2015b). The  
1304 193.9 acres of wetlands should be included in any future monitoring to be conducted for the  
1305 NorthMet Project Proposed Action.

1306 The deposition modeling results identified approximately 44 acres in the Second Creek area of  
1307 analysis that could potentially indirectly affected (modeled metal deposition greater than 100  
1308 percent background). Of the 44 acres, 1 acre is located within the Plant Site ambient air  
1309 boundary. These wetlands are accounted for in the 193.9 acres noted above and would already be  
1310 included in any future monitoring.

1311 The deposition modeling results for dust, metals, and sulfur would likely not have an adverse  
1312 effect on wetlands; however, the modeling only indicated those areas that had deposition rates  
1313 greater than 100 percent of background deposition (PolyMet 2015b). These specific wetlands  
1314 areas would be identified for consideration in any future monitoring to be conducted for the  
1315 NorthMet Project Proposed Action.

1316 The initial assessment provided a discussion on conservatism, including a discussion that the  
1317 estimated sulfur deposition was as particle-bound sulfur, with the sulfur being inherent to the  
1318 mineral matrix of the dust and not readily available for dissolution in soils or surface waters. A  
1319 supplemental assessment has been conducted to provide for a worst-case scenario in that all of

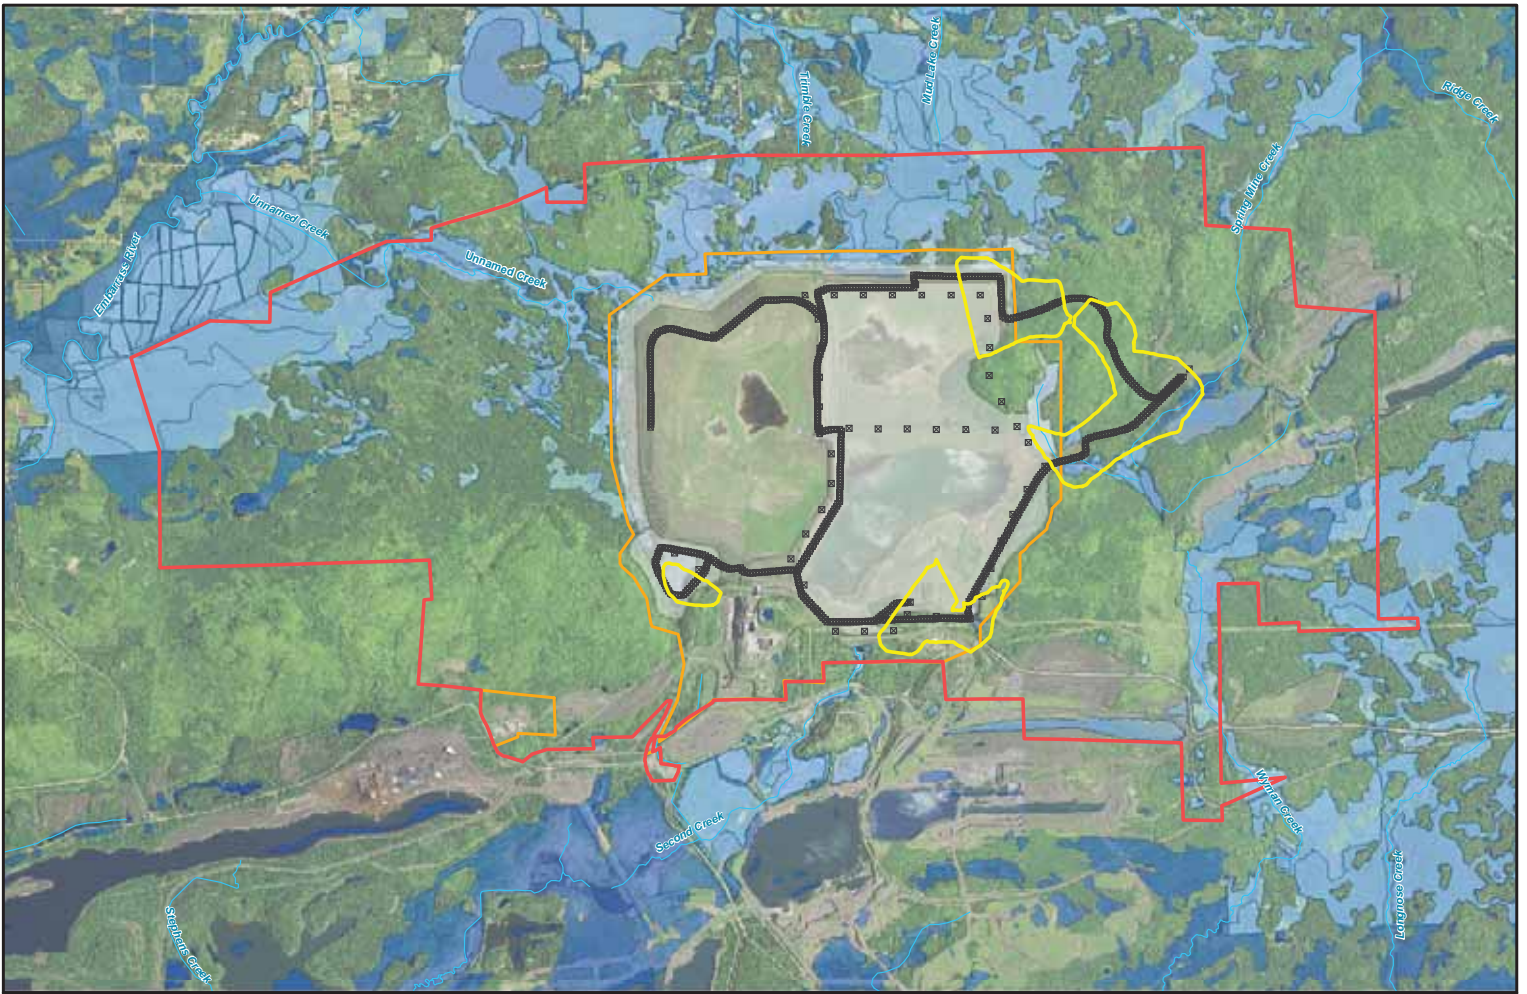

1320 the sulfur in fugitive dust converts to sulfate and would mix with surface water in a wetland  
1321 (Barr 2015f). A summary of the supplemental assessment evaluation of sulfur from stack  
1322 emissions is included in Section 5.2.7.2.6, while the fugitive dust evaluation is presented herein.

1323 Based on a conservative assumption that all sulfur in fugitive dust converts to sulfate and mixes  
1324 with surface water in wetlands, a potential incremental increase in sulfate was calculated as 4.2  
1325 mg/L. When the potential incremental sulfate concentration is mixed with annual precipitation,  
1326 the sulfate value was calculated as 1.7 mg/L. Because the sulfur is inherent to the mineral matrix  
1327 of the dust particles, it is likely that less than 100 percent of the sulfur would be weathered from  
1328 the particles and be available to go into solution if deposited to soils or water. While this  
1329 potential incremental change may warrant future monitoring, it would not be expected to have an  
1330 effect on methylmercury concentrations in surface water based on available data that indicate a  
1331 relative insensitivity of wetlands to additional sulfate (Barr 2015f).

1332 Although the actual potential for deposition of fugitive dust to wetlands, and the potential release  
1333 of sulfur in that dust, is uncertain, any adverse effects on wetlands are unlikely. The fugitive dust  
1334 control plan for both the Mine Site and the Plant Site (including the Tailings Basin) would  
1335 minimize such deposition, and the sulfur from any rock dust particles that would be deposited  
1336 may not be released or only released slowly through weathering. Using a conservative  
1337 assumption that all sulfur in the deposited dust is both released and transformed to sulfate, no  
1338 significant increase in methylmercury concentrations would be expected (Barr 2015f).  
1339 Additional information in regards to mercury methylation is provided in Section 5.2.2.3.4. A  
1340 discussion of mercury deposition and bioaccumulation in fish and the assessment of the  
1341 cumulative effects is provided in Section 6.2.6.3.3.

DRAFT

1347 **Water Quality Changes**

1348 The NorthMet Project Proposed Action could affect water quality downstream of the Tailings  
 1349 Basin and in the Second Creek area by alternating the chemistry and volume of seepage and  
 1350 surface water discharges leaving the Tailings Basin and to the headwaters of Second Creek  
 1351 (PolyMet 2015b; PolyMet 2015j). The NorthMet Project Proposed Action is predicted to meet all  
 1352 water quality evaluation criteria, or not worsen conditions where contamination already exceeds  
 1353 the criteria. The collection of existing seepage by the containment system and augmentation with  
 1354 WWTP effluent water would generally improve downstream water quality relative to current  
 1355 conditions. Effects that would occur on surface water and groundwater quality are discussed in  
 1356 Section 5.2.2. Even if water quality improves, there would be a potential for indirect effects to  
 1357 wetlands due to changes in water quality. Potential indirect wetland effects due to water quality  
 1358 changes that would likely occur at the Plant Site would be a result of changes in groundwater  
 1359 quality, in surface water quality, or in both groundwater and surface water quality and would be  
 1360 limited to the wetlands abutting Second Creek (PolyMet 2015b).

1361 Wetland areas that would be potentially affected by water quality changes are shown in Figure  
 1362 5.2.3-21 and listed in Table 5.2.3-12. Note that within this section, the term groundwater and  
 1363 surface water refer to the path by which NorthMet Project Proposed Action water leaves the  
 1364 Tailings Basin (e.g., potential effects from Tailings Basin groundwater seepage that discharges to  
 1365 surface water at a downstream location are classified as a potential effect due to changes in  
 1366 groundwater quality). Potential indirect effects due to changes in surface water quality are  
 1367 expected to diminish as the distance from the Tailings Basin increases. Upstream of County  
 1368 Road 666, there are approximately 179 acres of wetlands abutting Second Creek that could be  
 1369 potentially indirectly affected by the change in water quality due to stream flow augmentation of  
 1370 Second Creek.

1371 **Table 5.2.3-12 Wetland Areas Potentially Indirectly Affected by Changes in Water Quality**

| Wetland Area Potentially Affected by Changes in Water Quality | Mud Lake Creek (North)<br>Acres | Trimble Creek (Northwest)<br>Acres | Unnamed Creek (West)<br>Acres | Downstream of Groundwater Flowpaths <sup>3</sup><br>Acres | Total<br>Acres |
|---------------------------------------------------------------|---------------------------------|------------------------------------|-------------------------------|-----------------------------------------------------------|----------------|
| Groundwater Quality <sup>1</sup>                              | 296.5                           | 514.0                              | 1,162.1                       | --                                                        | 1,972.7        |
| Surface Water and Groundwater Quality <sup>2</sup>            | 835.8                           | 568.9                              | 690.9                         | 570.2                                                     | 2,665.7        |
| Total                                                         | 1,132.3                         | 1,082.9                            | 1,853.0                       | 570.2                                                     | 4,638.4        |

1372 Source: PolyMet 2015b.

1373 <sup>1</sup> Groundwater refers to water leaving the Tailings Basin within the surficial aquifer. Effects resulting from the discharge of that  
 1374 seepage to surface water have been considered an effect due to groundwater in the analysis.

1375 <sup>2</sup> All areas potentially affected by changes in surface water quality have also been potentially affected by changes in  
 1376 groundwater quality.

1377 <sup>3</sup> Potentially affected wetlands are located along Trimble Creek and Mud Lake Creek, but outside of groundwater flowpaths (see  
 1378 also Footnote (1)).

1379 Potential for indirect effects from changes in groundwater quality may occur anywhere along the  
 1380 modeled groundwater flowpaths previously mentioned. Wetlands abutting the three creeks that  
 1381 may be indirectly affected (4,068.2 acres) by changes in groundwater quality are shown on  
 1382 Figure 5.2.3-21. The effects on groundwater quality diminish as distance from the Tailings Basin  
 1383 increases, as the relative portion of total groundwater that originates from the Tailings Basin

1384 decreases (see Section 5.2.2). It has been determined that the amount of Tailings Basin seepage  
1385 remaining in the surficial aquifer would be small; therefore, the potential for indirect effects as a  
1386 result of changes in groundwater quality are anticipated to be small.

1387 Potential effects from changes in groundwater quality may also occur in wetlands abutting  
1388 tributary streams (all reaches of Unnamed Creek, Trimble Creek, and Mud Lake Creek) into  
1389 which affected groundwater would discharge (see Figure 5.2.3-21). Wetlands abutting these  
1390 streams and outside of the modeled groundwater flowpaths resulted in an additional 570.2 acres  
1391 of potential indirect effects due to changes in groundwater quality (PolyMet 2015b).

1392 Potential indirect effects from changes in surface water quality would also likely occur in  
1393 wetlands within the surface watersheds immediately downstream of the Tailings Basin, which  
1394 includes watersheds upstream of modeling locations UC-1a, TC-1, and MLC-3 (see Figure  
1395 5.2.3-21). The potential indirect effects from changes in surface water quality include 1,158  
1396 acres of wetlands (all of which would also likely be potentially indirectly affected by changes in  
1397 groundwater quality). Downstream of these locations, potential indirect effects due to changes in  
1398 surface water quality are limited to wetlands abutting the tributary streams. These areas include  
1399 an additional 1,505 acres of wetlands (all of which may also be potentially indirectly affected by  
1400 changes in groundwater quality) (PolyMet 2015b).

1401 As with effects from changes in groundwater quality, potential effects as a result of changes in  
1402 surface water quality would be expected to diminish as distance from the Tailings Basin  
1403 increases and flows originating from the NorthMet Project Proposed Action are diluted by  
1404 natural runoff.

1405 The wetland hydrology downstream of the Tailings Basin is too complex to be accurately  
1406 incorporated into the Plant Site probabilistic model detailed in Section 5.2.2. The response of  
1407 such complex natural systems to water quality changes originating at the Tailings Basin can only  
1408 be estimated (PolyMet 2015b). Therefore, monitoring of wetland hydrology and vegetation  
1409 communities would be the best way to document the extent and magnitude of wetland responses  
1410 (potential indirect wetland effects) to the NorthMet Project Proposed Action.

#### 1411 **5.2.3.2.5 Summary of NorthMet Project Proposed Action Direct Impacts and Indirect** 1412 **Wetland Effects**

##### 1413 ***Direct Impacts***

1414 Direct wetland impacts for the NorthMet Project Proposed Action are summarized in Table  
1415 5.2.3-13. Of the 166 wetlands within the NorthMet Project area, 128 wetlands would be directly  
1416 impacted, totaling 913.8 acres of direct wetland impact. The Mine Site would contain the  
1417 majority of the direct wetland impacts. The majority of the direct impacts would occur as a result  
1418 of a combination of filling and excavation (65 percent) (see Table 5.2.3-14).

1419 **Table 5.2.3-13 Total Projected Direct Wetland Impacts for the NorthMet Project Proposed**  
 1420 **Action**

1427 **Potential Indirect Effects**

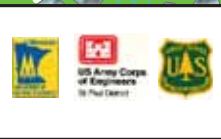

1428 Potential indirect wetland effects from the NorthMet Project Proposed Action would result  
 1429 from one or more of the following six factors: 1) wetland fragmentation; 2) change in wetland  
 1430 hydrology resulting from changes in watershed area; 3) changes in wetland hydrology due to  
 1431 groundwater drawdown resulting from open pit mine dewatering; 4) changes in wetland  
 1432 hydrology from groundwater drawdown resulting from operation of the Plant Site, including  
 1433 groundwater seepage containment; 5) changes in stream flow near the Mine Site and Plant Site,  
 1434 as well as associated effects on wetlands abutting the streams; and 6) changes in wetland water  
 1435 quality related to atmospheric deposition of dust and rail car spillage associated with Mine Site  
 1436 and Plant Site operations. A rating system (scaled from 0 to 6) was developed for the  
 1437 wetlands based on the number of factors that may potentially affect it. Wetlands that were not  
 1438 determined to be potentially indirectly affected were rated as zero and wetlands that were  
 1439 determined to be potentially indirectly affected by all six factors were rated as a six; however, no  
 1440 wetlands were rated as a six (see Figures 5.2.3-24 and 5.2.3-29) (PolyMet 2015b). The NorthMet  
 1441 Project Proposed Action could indirectly affect up to either 7,694.2 acres of wetlands located

1442 within and around the NorthMet Project area, based on the method of wetlands crossing analog  
1443 impact zones, or up to 6,568.8 acres of wetlands located within and around the NorthMet Project  
1444 area, based on the method of wetlands within analog impact zones (PolyMet 2015b). The indirect  
1445 effects analyses performed for the EIS were not performed to characterize impacts but were done  
1446 to inform where monitoring should take place for those areas that were identified as having a  
1447 potential for indirect wetland effects. Potential indirect wetland effects are presented in Table  
1448 5.2.3-15.

| 5                                                      | 0.3                                                                                          | <1  | 0.3                                                                                        | <1  |
| Total Acres of Indirect<br>Wetland Impact <sup>2</sup> | 7,694.2                                                                                      | 100 | 6,568.8                                                                                    | 100 |

1463 Sources: PolyMet 2015b

1464 <sup>1</sup> A wetland may be potentially indirectly affected by none of the six factors or up to a maximum of six, with different  
 1465 combinations of factors possible. A rating was developed for the wetlands based on the number of factors that may potentially  
 1466 affect it – from No Effect (0 factors) to 6 (all six factors potentially indirectly affecting the wetland).

1467 <sup>2</sup> The analyses and assessments were completed using the same set of wetlands that were not directly impacted; therefore, there  
 1468 are wetlands that may be potentially indirectly affected by more than one type of assessed source. The potential indirect  
 1469 wetland affects for each wetland cannot be summed across the analysis as this would likely result in double-counting of  
 1470 wetland acres. The results of the analyses and assessments identify areas to be monitored for potential wetland effects.

1471 As discussed below, wetland mitigation for potential indirect wetland effects would be  
 1472 determined by the agencies during permitting. If the NorthMet Project Proposed Action were to  
 1473 be permitted and it was determined that the NorthMet Project Proposed Action would cause  
 1474 future wetland effects, wetland monitoring would be conducted. Wetland hydrology and  
 1475 vegetation would be monitored, and additional monitoring locations may be considered during  
 1476 permitting. A component of the monitoring plan would be based on those wetlands that would  
 1477 have a high likelihood of indirect effects as a result of groundwater drawdown. The likelihood of  
 1478 potential wetland hydrology effects (low, moderate, and high), based on the method of wetlands  
 1479 crossing analog impact zones, would be 2,147.6 acres, of which 866.9 acres of wetlands  
 1480 (15 percent) would have a high likelihood of wetland hydrology effects. The likelihood of  
 1481 potential wetland hydrology effects (low, moderate, and high), based on the method of wetlands  
 1482 within analog impact zones, would be 733.3 acres, of which 46.4 acres of wetlands (1 percent)  
 1483 would have a high likelihood of wetland hydrology effects. If the monitoring determined that  
 1484 indirect wetland effects had occurred, additional compensation may be required if determined  
 1485 necessary by the permitting agencies.

1486 In the event that the required wetland monitoring identified additional indirect effects, permit  
 1487 conditions would likely include a plan for adaptive management practices to be implemented,  
 1488 such as expanded monitoring and hydrologic controls. Additionally, compensatory mitigation  
 1489 may be required if additional impacts are identified during annual reporting. Permit conditions  
 1490 would likely include an adaptive management plan to account for any additional effects that may  
 1491 be identified in the annual monitoring and reporting.

1492 **5.2.3.3 NorthMet Project Proposed Action Wetland Impact Avoidance,**  
1493 **Minimization, Mitigation, and Monitoring Measures**

1494 This section discusses measures that were taken to avoid and minimize wetland impacts,  
1495 evaluates PolyMet's proposed wetland mitigation for unavoidable impacts, discusses other  
1496 potential mitigation measures that may benefit wetlands, and identifies key elements of a wetland  
1497 monitoring plan. The wetland impact, avoidance, minimization, mitigation and monitoring plan  
1498 presented in the EIS would be reviewed during permitting; therefore, the mitigation and  
1499 proposed monitoring could change during permitting.

1500 **5.2.3.3.1 Wetland Avoidance and Minimization**

1501 Section 404 regulations of the CWA, Minnesota's WCA rules, and Minnesota's water quality  
1502 standards under *Minnesota Rules* 7050.0186 require that impacts to wetlands be avoided and  
1503 minimized to the extent practicable, and if wetland impacts cannot be avoided and/or minimized,  
1504 then compensatory mitigation practices would be necessary.

1505 Final regulations and guidelines associated with Section 404 of the CWA require that project  
1506 proponents eliminate or reduce adverse impacts to waters of the United States by taking certain  
1507 specific steps during project planning. These include: 1) modify the project to avoid adverse  
1508 impacts, 2) incorporate measures to minimize adverse impacts, and 3) compensate for  
1509 unavoidable adverse impacts through restoration, enhancement, creation, or in-lieu fee.

1510 PolyMet proposes to avoid and minimize wetland impacts through a number of measures that are  
1511 incorporated into the proposed mine plan. Direct wetland impacts at the Mine Site have been  
1512 reduced during the development of the NorthMet Project Proposed Action. Modifications to the  
1513 NorthMet Project Proposed Action that have occurred during the development of the EIS have  
1514 resulted in avoidance and minimization of impacts on wetland resources. To date, these  
1515 modifications have reduced the acreage of wetlands impacted from 1,257 to 913.8 acres, a 27  
1516 percent decrease.

1517 At the Mine Site, waste rock would be placed back into the East Pit and Central Pit after year 11,  
1518 thereby reducing the need for additional surface stockpile areas that would otherwise affect  
1519 wetlands. In addition, PolyMet proposes to combine the saturated overburden and temporary  
1520 stockpiles that contain membrane liners, which were separate in the original NorthMet Project  
1521 Proposed Action design. The Overburden Storage and Laydown Area would only store peat and  
1522 unsaturated overburden (PolyMet 2015a). By reducing the footprint of the Overburden Storage  
1523 and Laydown Area and stockpiles, direct wetland impacts were reduced. Similarly, PolyMet  
1524 proposes to construct the Category 4 Stockpile in the footprint of the Central Pit, which would be  
1525 mined later and thus avoid additional direct wetland impacts. Reactive waste rock stockpiles  
1526 would be lined, and stormwater runoff that contacted reactive rock would be contained to help  
1527 prevent water quality-related effects on adjacent wetlands. In addition, hydrologic effects would  
1528 be reduced by the use of seepage control measures, which would be installed at the mine pits to  
1529 restrict shallow groundwater movement through higher permeability areas and help prevent  
1530 drawdown of wetland water levels near mine pits. Haul road construction/layout has been re-  
1531 configured to have fewer haul roads and locations thereby reducing land and wetland disturbance  
1532 and truck distance to be driven. Haul road construction would include placement of large rocks  
1533 as a foundation to allow shallow subsurface groundwater flowpaths in the wetlands to be  
1534 maintained within the active areas of the Mine Site between the pits and stockpiles.

1535 Specifically, utilizing existing Plant Site infrastructure, the existing LTVSMC Tailings Basin,  
1536 and the Transportation and Utility Corridor all serve as avoidance measures since building these  
1537 on undeveloped sites could impact at least hundreds of acres of additional wetlands. Reusing  
1538 existing infrastructure limits wetland impacts from these activities to previously disturbed areas.  
1539 Additionally, cutoff berms/walls, trenches, and sump and pump systems would be used to collect  
1540 current and future surface seepage from around the toe of the Tailings Basin (PolyMet 2011b).  
1541 This surface seepage would ultimately be re-routed to the Tailings Basin, thus avoiding or  
1542 minimizing discharges to surrounding wetlands. Construction of the containment system,  
1543 however, would reduce the amount of seepage flowing to four tributaries of the Embarrass River  
1544 (PolyMet 2015a). Streamflow would be augmented using WWTP effluent so that the target  
1545 annual average flow that supports existing wetland hydrology would be met.

#### 1546 **5.2.3.3.2 Wetland Mitigation**

1547 As previously noted, jurisdictional wetlands are regulated under state and federal laws, including  
1548 the WCA (*Minnesota Rules* Chapter 8420), *Minnesota Rules*, part 7050.0186, and Sections 401  
1549 and 404 of the CWA. In addition, some wetlands are also designated as Minnesota Public Waters  
1550 and subject to the Public Waters Work Permit Rules (*Minnesota Rules* Chapter 6115). However,  
1551 no public water wetlands would be impacted by the NorthMet Project Proposed Action.

1552 Both the state and federal wetland regulations require that a permit, approval, and/or certification  
1553 be issued by the regulatory agency for wetland impacts as defined by the respective regulations.  
1554 The USACE St. Paul District is the permitting authority for the DA permit pursuant to Section  
1555 404 of the CWA; the MDNR Division of Lands and Minerals administers the WCA approval  
1556 process as part of the Permit to Mine (*Minnesota Rules*, part 8420.0200, subpart 1D); and the  
1557 MPCA has authority under Section 401 of the CWA to certify that discharges authorized under  
1558 Section 404 comply with water quality standards.

1559 The wetland mitigation planning process relied on the WCA wetland replacement siting rules  
1560 (*Minnesota Rules* part 8420.0522), compensatory mitigation requirements under state water  
1561 quality standards (*Minnesota Rules* part 7050.0186), and the USACE *St. Paul District Policy for*  
1562 *Wetland Compensatory Mitigation in Minnesota* (2009).

#### 1563 **Sequencing**

1564 The compensatory wetland mitigation site selection for the NorthMet Project Proposed Action  
1565 began in 2005 and has gone through a rigorous site selection evaluation. Prior to the 2008  
1566 Federal Mitigation Rule, the Aitkin and Hinckley sites were selected, initial approvals by the  
1567 regulatory agencies were received, and substantial investments were made by PolyMet, to  
1568 develop both sites for compensatory mitigation. The USACE guidance that was utilized prior to  
1569 the implementation of the 2008 Federal Mitigation Rule was to look for mitigation sites that  
1570 could provide the following: restoration of historical wetlands, high probability of success,  
1571 achieves at least partial in-kind mitigation and sites that had ditched and/or tiled peatlands to  
1572 provide for restoration. When the 2008 Federal Mitigation Rule went into effect, the USACE  
1573 informed PolyMet of the priority for siting any future compensatory mitigation within the St.  
1574 Louis River/Great Lakes Basin. The Zim Site was subsequently proposed as a third site.  
1575 PolyMet, along with, in some cases, state and federal agencies, have conducted and are  
1576 continuing to conduct extensive efforts to find additional suitable sites within in the Great Lakes  
1577 Basin for wetland mitigation.

1578 The 2008 Federal Mitigation Rule and 2009 USACE St. Paul District Policy specifies a  
1579 preferential sequence for compensatory mitigation (i.e., use of mitigation banking credits, use of  
1580 project-specific compensation that is based on a watershed approach, use of project-specific  
1581 compensation that is on-site and in-kind, and use of project-specific compensation that is off-site  
1582 and/or out-of-kind), and aims to select mitigation sites as close as possible to the watershed of  
1583 impact; however, sometimes this cannot be accomplished. The 2009 USACE St. Paul District  
1584 Policy accepts out-of-watershed mitigation; however, the USACE's preference is for the  
1585 mitigation to be within the same watershed as a proposed project. The term "watershed  
1586 approach" is defined in 33 USC § 332.2 as "an analytical process for making compensatory  
1587 mitigation decisions that support the sustainability or improvement of aquatic resources in a  
1588 waters. It involves consideration of watershed needs, and how locations and types of  
1589 compensatory mitigation projects address those needs..."

1590 As such, the compensatory mitigation approach by PolyMet followed the 2009 USACE St. Paul  
1591 District Policy in effect at the time the proposed compensation sites were selected. Further, the  
1592 Zim Site was developed in accordance with a watershed approach. In combination, the proposed  
1593 compensatory mitigation is appropriate for the siting and scale of the impacts that would result  
1594 from the NorthMet Project Proposed Action. As noted above for the project-specific  
1595 compensation, the following compensatory mitigation siting sequence is required: on-site, in the  
1596 same 10-digit HUC watershed, in the same 8-digit HUC watershed, in the same modified 6-digit  
1597 watershed, in the same 4-digit HUC watershed, and then statewide.

1598 While on-site replacement of wetlands is listed first in the sequencing, on-site conditions may  
1599 not be the most suitable for successful wetland mitigation. In fact, 33 USC § 332.3(b) states that  
1600 compensatory mitigation should be located where it is most likely to successfully replace lost  
1601 functions and services within the watershed, not specifically on-site. Moreover, the preferred  
1602 mitigation methodology stated under the 2008 Federal Mitigation Rule begins with the utilization  
1603 of mitigation banks and in-lieu fee programs within appropriate service areas prior to permittee-  
1604 responsible mitigation (33 USC § 332.3(b)(2)-(3)). Following the use of mitigation banks and in-  
1605 lieu fee programs, the 2008 Federal Mitigation Rule states that permittee-responsible mitigation  
1606 following a watershed approach (i.e., providing for mitigation in the best suitable location within  
1607 the proposed impact watershed) should be used (33 USC § 332.3(b)(4)). Only after mitigation  
1608 banks, in-lieu fee programs (where available), and permittee-responsible mitigation under a  
1609 watershed approach have been exhausted or are infeasible should permittee-responsible  
1610 mitigation through on-site and in-kind mitigation be considered (33 USC § 332.3(b)(5)).

1611 Compensatory mitigation is defined as restoration (reestablishment or rehabilitation),  
1612 establishment (creation), enhancement, and/or, in certain circumstances, preservation of aquatic  
1613 resources for the purposes of offsetting unavoidable adverse impacts that remain after all  
1614 appropriate and practicable avoidance and minimization has been achieved (33 CFR § 332.2).  
1615 When comparing the alternatives, restoration is the best approach for replacing lost functions;  
1616 preservation does not replace the lost functions and creation is both slow to replace the functions  
1617 and has a lower degree of success. Restoration should generally be the first option considered  
1618 because the likelihood of success is greater and the impacts to potentially ecologically important  
1619 uplands are reduced compared to establishment. Also, the potential gains in terms of aquatic  
1620 resource functions are greater, compared to enhancement and preservation (33 CFR § 332.3(a)(2)  
1621 and 40 CFR § 230.93(a)(2)). Furthermore, the 2009 USACE St. Paul District Policy guidance  
1622 states that restoration is the preferred compensatory mitigation technique. Restoration sites

1623 historically supported wetlands and frequently retain some wetland components (e.g., hydric  
1624 soils) even after man-made disturbances such as drainage and cropping. Restoration also applies  
1625 to increasing the functional level of existing, degraded wetlands. Restoration through re-  
1626 establishment involves techniques for returning wetland functions to a location where no wetland  
1627 currently exists. This technique results in a gain in both wetland acres and wetland functions.

1628 The primary goal of wetland mitigation is to restore high-quality wetland communities of the  
1629 same type, quality, and function as those to be impacted to the extent practicable. To achieve that  
1630 goal, state and federal guidelines were followed during the wetland mitigation planning process,  
1631 with a preference placed on restoring drained wetlands over creating wetlands. The five main  
1632 categories of mitigation methods considered appropriate in northern Minnesota by state and  
1633 federal agencies were 1) restoration of former or degraded wetlands, 2) enhancement of existing  
1634 wetlands, 3) wetland preservation, 4) wetland creation, and 5) upland buffers.

### 1635 **USACE Mitigation Ratios and Financial Assurance**

1636 The 2009 USACE St. Paul District Policy applies three factors to determine compensation ratios:  
1637 in-place versus out-of-place, in-kind versus out-of-kind, and in-advance versus not in-advance.  
1638 These factors are defined as follows:

- 1639 • In-place mitigation means the replacement of the impacted aquatic site would take place in  
1640 the same 8-digit Hydrologic Unit Code (HUC) watershed as the proposed impacted resource.  
1641 The USACE St. Paul District Policy uses the term “in-place” to include on-site, which is  
1642 defined as an area located on the same parcel of land as the impact site, or on a parcel of land  
1643 contiguous to the impact site.
- 1644 • Out-of-place mitigation means the replacement of the impacted aquatic site would take place  
1645 in a different 8-digit HUC watershed as the proposed impacted resource.
- 1646 • In-kind mitigation means the replacement of the impacted aquatic site with a resource of a  
1647 similar structural and functional type to the impacted resource (same species composition).
- 1648 • Out-of-kind mitigation means the replacement of an impacted aquatic site with a resource of  
1649 a different structural and functional type from the impacted resource (different species  
1650 composition).
- 1651 • In-advance mitigation is a form of mitigation that is designed, permitted, and constructed in  
1652 advance of a permitted impact.

1653 The temporal loss issue is addressed by the in-advance versus not-in-advance factor. The 2008  
1654 Federal Mitigation Rule states that compensation ratios of greater than 1:1 can be applied to  
1655 account for factors including temporal loss and the difficulty of restoring or establishing certain  
1656 wetlands/aquatic resources (33 CFR 332.3 (f)).

1657 The 2008 Federal Mitigation Rule also states that “difficult-to-replace” wetlands/aquatic  
1658 resources include bogs and forested wetlands (33 CFR 332.3(e)(3) and Preamble, page 19633).  
1659 The majority of wetlands that would be impacted by the NorthMet Project Proposed Action  
1660 would be “difficult-to-replace” (coniferous bog, open bog, coniferous swamp, and hardwood  
1661 swamp) (USACE 2013). The 2008 Federal Mitigation Rule includes a provision for a case-by-  
1662 case determination of mitigation ratios higher than the minimum 1:1 where necessary to account  
1663 for the difficulty of restoring or establishing the desired aquatic resource type and functions.

1664 USACE St. Paul District Policy (2009) states that compensation ratios can be raised on a case-  
1665 by-case basis if the impacted wetland/aquatic resource provides rare or exceptional functions,  
1666 including plant communities that rate “exceptional” using MnRAM, or have a high rating using a  
1667 Floristic Quality Assessment. Most of the wetlands that would be impacted by the NorthMet  
1668 Project Proposed Action would generate high Floristic Quality Assessment scores for those plant  
1669 community types in Minnesota (Milburn et al. 2007). Therefore, per the 2009 USACE St. Paul  
1670 District Policy, the District Engineer may determine that a higher compensation ratio would be  
1671 required to offset losses of wetlands that would be difficult to replace and/or provide an  
1672 exceptional or high functional level/condition.

1673 The 2009 USACE St. Paul District Policy states a base compensation ratio of 1.5:1 (1.5 credits  
1674 of compensatory mitigation for every 1 acre of wetland loss), and a minimum of 1:1, with a  
1675 provision for a case-by-case determination of higher ratios to account for factors including  
1676 difficult-to-replace, rare, and/or exceptional wetlands/aquatic resources. For low- to moderate-  
1677 quality wetlands, the 1.5:1 base ratio would apply in accordance with District Policy. For  
1678 impacts to wetlands that have exceptional or high functional levels/conditions, are difficult-to-  
1679 replace, and/or where there is a considerable temporal loss in replacing functions (e.g., forested  
1680 wetlands), the USACE may require additional compensation in accordance with District Policy.  
1681 The 1.5:1 ratio can be reduced by qualifying for the following incentives, but can be no less than  
1682 a minimum 1:1 ratio:

- 1683 • In-place incentive: the project-specific mitigation site is located on site or within the same  
1684 8-digit HUC watershed as the authorized wetland impacts or bank credits are purchased  
1685 within the same bank service area—reduce ratio by 0.25.
- 1686 • In-kind incentive: the mitigation wetlands are of the same type (same wetland plant  
1687 community) as the wetlands authorized to be impacted—reduce ratio by 0.25.
- 1688 • In-advance incentive: 1) a project-specific mitigation site must have wetland hydrology and  
1689 initial hydrophytic vegetation established at least one full growing season in advance of the  
1690 authorized wetland impacts provided initial performance standards are met, or 2) USACE-  
1691 approved bank credits are purchased—reduce ratio by 0.25.

1692 If none of these incentives are met, the minimum mitigation ratio required is 1.5:1. If one of the  
1693 three incentives is met, the minimum required mitigation ratio is 1.25:1; if two or three are met,  
1694 the ratio is 1:1. According to USACE St. Paul District’s compensatory wetland mitigation policy  
1695 (USACE 2009), requirements for mitigation can exceed the 1.5:1 mitigation ratio if the impacted  
1696 wetlands provide rare or exceptional functions.

1697 District guidance on compensatory mitigation emphasizes the consideration of a functional  
1698 approach to offset proposed project impacts. While bogs and forested wetlands are characterized  
1699 as difficult-to-replace, the proposed compensation sites for the NorthMet Project Proposed  
1700 Action (discussed below) would be likely to achieve in-kind compensation to offset functional  
1701 losses. The proposed mitigation sites were selected based on availability and the high likelihood  
1702 of meeting performance criteria.

1703 The proposed wetland restoration and enhancement performance criteria place a strong emphasis  
1704 on ensuring that the proposed mitigation strategy provides for the adequate replacement of lost  
1705 functions. For purposes of compensatory mitigation, the focus is on functions. The 2008 Federal  
1706 Mitigation Rule specifically eliminated use of the term “values.” An abbreviated MnRAM

1707 functional assessment, which was agreed upon by the USACE, was utilized to assess wetland  
1708 functions for the Mine Site, Transportation and Utility Corridor, and Plant Site. Both the USACE  
1709 and WCA require functions to be replaced; however, both agencies use a set of defined ratio  
1710 requirements to determine the number of acres required to replace functions lost as there is  
1711 currently no suitable quantitative functional assessment method in Minnesota. Based on the  
1712 findings and where impacts occur (e.g., types of wetlands), the mitigation ratios and credits have  
1713 been increased to take into account the functions lost due to the NorthMet Project Proposed  
1714 Action. For example, additional compensatory mitigation (i.e., higher replacement ratios) is  
1715 proposed to offset loss of bog wetlands, which is a difficult-to-replace wetland type. All of the  
1716 wetland mitigation proposed would be restoration with a minimal component of wetland  
1717 preservation; no creation of wetlands would be part of the off-site mitigation.

1718 The USACE St. Paul District has not made a final determination of the compensation ratios that  
1719 would be required. A decision on whether proposed compensation would qualify for the 0.25  
1720 incentive for in-advance requires additional information including: 1) development of  
1721 performance standards that would specify the hydrology and initial vegetation to be established,  
1722 and 2) number of growing seasons that wetland compensation sites would be established in  
1723 advance of authorized impacts. Final determination of compensation ratios and use of incentives  
1724 would be determined during permitting.

1725 The compensatory mitigation ratios proposed in the FEIS for the NorthMet Project Proposed  
1726 Action are based on recommended USACE St. Paul District guidance. They assume successful  
1727 outcomes for the proposed compensatory mitigation sites. Base compensation ratios, as  
1728 presented in the FEIS, for impacts on high-quality, difficult-to-replace bog and forested wetlands  
1729 have been increased to 2:1 (USACE 2013). For impacts on low- and moderate-quality wetlands,  
1730 a base ratio of 1.5:1 would be applied (USACE 2013). In-kind, in-place, and in-advance  
1731 incentives to reduce the recommended base ratios would be considered at the time of permitting.  
1732 USACE St. Paul District guidance on recommended compensation ratios takes these incentives  
1733 into account. The final decision on compensatory mitigation ratios and the use of incentives  
1734 would be determined at the time of the CWA Section 404 permit decision based on current  
1735 District guidance.

1736 USACE compensatory wetland mitigation is regulated by 33 CFR 332.3(n), which describes the  
1737 use of financial assurances. The District Engineer may determine that financial assurances are  
1738 unnecessary for a compensatory mitigation project if alternate mechanisms are available to  
1739 ensure a high level of confidence that the mitigation would be provided and maintained.

1740 The CWA Section 404 permit and the Permit to Mine (see below) both have financial assurance  
1741 mechanisms to ensure successful completion of the 1) compensatory mitigation (in the case of  
1742 the CWA Section 404) and 2) NorthMet Project Proposed Action (in the case of the Permit to  
1743 Mine). Financial assurance can be a condition of a permit under CWA Section 404, and the  
1744 MDNR has authority to require a performance bond or other instrument that meets criteria in rule  
1745 for compliance with the conditions of the Permit to Mine. Section 3.2.2.4 provides a discussion  
1746 of the financial assurance for the NorthMet Project Proposed Action.

1747 The USACE generally requires compensatory mitigation for adverse impacts to aquatic  
1748 resources under 33 CFR 332.3(n). This regulation establishes standards and criteria for the  
1749 general compensatory mitigation requirements of the Section 404 permit. Specifically, 33 CFR  
1750 332.3(n)(1) addresses financial assurance stating:

1751           The district engineer shall require sufficient financial assurances to ensure a high level of  
1752           confidence that the compensatory mitigation project will be successfully completed, in  
1753           accordance with applicable performance standards.

1754           Financial assurance for the direct wetland impact mitigation would be required until success of  
1755           the mitigation sites can be assured. While this wetland mitigation would be expected to be  
1756           approved and constructed in advance of any authorized wetland impacts, it is unclear whether  
1757           these sites would be well-enough established for financial assurance to be waived. The USACE  
1758           would also consider the application of financial assurances for potential indirect wetland effects  
1759           and monitoring. The USACE would require consideration of financial assurances during the  
1760           permitting process.

1761           **State Mitigation Ratios and Financial Assurance**

1762           *Minnesota Rules*, part 7050.0186, requires compensatory mitigation to be sufficient to ensure  
1763           replacement of the diminished or lost designated uses of the wetland that was physically altered.  
1764           To the extent prudent and feasible, the same types of wetlands impacted are to be replaced in the  
1765           same watershed, before or concurrent with the actual alteration of the wetland. In addition, the  
1766           WCA states that for wetlands in counties where 80 percent or more of pre-settlement wetlands  
1767           exist, including St. Louis County, minimum replacement ratio requirements are as determined by  
1768           mitigation location and type (see Table 5.2.3-16). Based on the WCA wetland replacement  
1769           standards (*Minnesota Rules* 8420.0522, Subpart 4), the required replacement ratio would be  
1770           either 1:1 or 1.5:1. For those wetlands that would be replaced in the watershed with the same  
1771           wetland type, the base replacement ratio that would likely be required is 1:1, and for those  
1772           wetlands that would be replaced outside of the watershed, the ratio would be increased to 1.5:1.  
1773           The actual replacement ratios required in permitting may be more than the minimums shown in  
1774           Table 5.2.3-16, subject to the evaluation of wetland functions.

1775

1776 **Table 5.2.3-16 Summary of Wetland Mitigation Ratios**

| Regulation                                          | Location of Impacts | Replacement                            | Minimum Replacement Ratio |
|-----------------------------------------------------|---------------------|----------------------------------------|---------------------------|
| Minnesota Administrative Rules                      |                     |                                        |                           |
| <i>Minimum Replacement Ratios: Wetland Banking</i>  |                     |                                        |                           |
| >80% area or agricultural land                      |                     | Outside bank service area              | 1.5:1                     |
|                                                     |                     | Within bank service area               | 1:1                       |
| <i>Minimum Replacement Ratios: Project-Specific</i> |                     |                                        |                           |
| >80% area or agricultural land                      |                     | Outside major watershed or out-of-kind | 1.5:1                     |
|                                                     |                     | Within major watershed and in-kind     | 1:1                       |
| USACE                                               |                     |                                        |                           |
| >80% area                                           |                     | Not in-place, in-kind nor in-advance   | 1.5:1                     |
|                                                     |                     | In-place, in-kind and in-advance       | 1:1                       |

1777 Sources: Wetland Conservation Act (MDNR 1991); USACE 2009.

1778 *Minnesota Rules* 8420.0522 outlines the replacement standards for wetlands as regulated under  
 1779 WCA. *Minnesota Rules* 8420.0522, subparts 9(A) and (B) discuss financial assurance  
 1780 requirements for compensatory wetland mitigation stating:

1781 (A) For wetland replacement that is not in advance, a financial assurance acceptable to  
 1782 the local government unit must be submitted to, and approved by, the local government  
 1783 unit to ensure successful replacement. The local government unit may waive this  
 1784 requirement if it determines the financial assurance is not necessary to ensure successful  
 1785 replacement. The local government unit may incorporate this requirement into any  
 1786 financial assurance required by the local government unit for other aspects of the project.  
 1787 (B) The financial assurance may be used to cover costs of actions necessary to bring the  
 1788 project into compliance with the approved replacement plan specifications and  
 1789 monitoring requirements.

1790 Financial assurance could be waived by the approval authority if it is determined that financial  
 1791 assurance is not necessary to ensure wetland replacement. Additionally, the MDNR has the  
 1792 authority through the Permit to Mine process to require a performance bond or other instrument  
 1793 that meets criteria in rule as means to ensure compliance with *Minnesota Rules*, part 6130, which  
 1794 includes successful completion of reclamation and closure activities. Please refer to Section  
 1795 3.2.2.4 for more information on financial assurance.

1796 The financial assurance requirements would be part of the WCA permitting process for the  
 1797 NorthMet Project Proposed Action. Wetland replacement for the NorthMet Project Proposed  
 1798 Action is anticipated to be approved and constructed in advance of any authorized wetland  
 1799 impacts (under WCA approval) and, therefore, would not require financial assurance.

1800 Section 401 of the CWA requires the MPCA to certify that all projects that receive a federal  
 1801 license or permit are in compliance with state and federal water quality guidelines. Therefore, as  
 1802 part of their review, the MPCA conducts a separate review for compliance with water quality

1803 standards and policies and guidelines, which includes mitigation for wetland impacts and  
1804 approval of the wetland replacement ratios. This review process must be completed before the  
1805 DA permit pursuant to Section 404 of the CWA can be issued.

1806 **Summary of Mitigation Requirements**

1807 PolyMet would ultimately need to satisfy both the federal and state mitigation requirements. The  
1808 number of mitigation credits to be earned by replacement wetlands would be determined during  
1809 permitting by the appropriate agencies reviewing the wetland mitigation plan. This would be  
1810 based on the extent to which the sites meet the target goals established during permitting. These  
1811 include, among other things, restoration of wetland appropriate hydrology and the establishment  
1812 of a target plant community or type. The NorthMet Project Proposed Action is estimated to  
1813 directly impact 913.8 acres. Depending on the location, type, and timing of compensatory  
1814 mitigation, the minimum required amount of replacement wetlands for direct impacts, based  
1815 upon USEPA recommendations, could potentially range from 913.8 acres up to 1,827.6 acres  
1816 (i.e., 1:1 up to 2:1 compensation ratios).

1817 The USACE has concluded that the mitigation sites selected and the wetland credits generated at  
1818 the three mitigation sites would be acceptable for use in compensating for direct wetland losses.  
1819 The USACE has not made a final decision on the mitigation ratios that would be required to  
1820 compensate for direct wetland impacts; if fully successful, it is likely these three mitigation sites  
1821 would generate sufficient credits to compensate for the 940.7 acres of wetlands directly  
1822 impacted. In the event that not all of the credits generated by these sites are utilized to  
1823 compensate for direct wetland impacts, any excess credits could be used to compensate for  
1824 indirect losses (USACE 2015a). The current proposed mitigation presented below shows that  
1825 PolyMet could have an excess of mitigation credits from the three mitigation sites if the  
1826 mitigation sites are successful and meet the performance standards. However, it is understood  
1827 that mitigation sites sometimes are not fully successful; contingency plans (discussed below)  
1828 would be developed for the NorthMet Project Proposed Action and approved during permitting.  
1829 The USACE encourages the development of mitigation for foreseeable indirect effects, which  
1830 the current proposed mitigation plan appears to achieve.

1831 Financial assurance for the direct wetland impact mitigation would be required until success of  
1832 the mitigation sites can be assured. While this wetland mitigation is expected to be approved and  
1833 constructed in advance of any authorized wetland impacts, it is unclear whether these sites would  
1834 be well enough established for financial assurances to be waived. The USACE would also  
1835 consider the application of financial assurances for potential indirect wetland effects and  
1836 monitoring. Both the USACE and state would require consideration of financial assurances  
1837 during the permitting process.

1838 Wetland mitigation for potential indirect wetland effects would be determined by the agencies  
1839 during permitting. If the NorthMet Project Proposed Action were to be permitted and  
1840 constructed, wetland monitoring would be conducted to determine if the NorthMet Project  
1841 Proposed Action caused future indirect wetland effects. Wetlands hydrology and vegetation  
1842 would be monitored, and additional monitoring locations may be considered during permitting.  
1843 A component of the monitoring plan would be based on those wetlands that have a high  
1844 likelihood of indirect effects as a result of groundwater drawdown. If the monitoring determined  
1845 that indirect wetland effects had occurred, additional compensation may be required if  
1846 determined necessary based on the monitoring results. In the event that the required wetland

1847 monitoring identified additional indirect effects, permit conditions would likely include a plan  
1848 for adaptive management practices to be implemented, such as expanded monitoring and  
1849 hydrologic controls. Additionally, compensatory mitigation may be required if additional  
1850 impacts are identified during annual reporting.

1851 **Wetland Mitigation Study Limits**

1852 The NorthMet Project area lies in St. Louis County in the St. Louis River Watershed (#3) within  
1853 the Lake Superior basin (wetland mitigation Bank Service Area #1). Locations for wetland  
1854 mitigation projects were evaluated in the following priority order:

- 1855 • on-site;
- 1856 • off-site in the St. Louis River Watershed (same 8-digit HUC);
- 1857 • off-site in the Great Lakes Basin (same 4-digit HUC); and
- 1858 • off-site in an adjacent 4-digit HUC, selecting an 8-digit HUC as close as possible to the  
1859 impacted site.

1860 Each of these potential locations areas is described below.

1861 **On-site Mitigation**

1862 In accordance with the USACE's St. Paul District Compensatory Wetland Mitigation Policy  
1863 (USACE 2009) and state guidelines, the potential for creating wetlands on-site was considered  
1864 first. The Wetland Management Plan (PolyMet 2015c) identified the potential for on-site  
1865 restoration during reclamation. On-site wetland restoration (101.8 acres) is planned in the  
1866 following areas: temporary Category 2/3 Stockpile, Overburden Storage and Laydown Area,  
1867 some haul roads and adjacent ditches, and WWTF ponds and process water ponds. Establishment  
1868 of on-site wetlands is expected to occur during reclamation. Of the 101.8 acres of planned on-site  
1869 wetland restoration, 72 acres of wetlands may be created at the temporary mine stockpile areas  
1870 after removal of the Category 2/3 Stockpile and the Overburden Storage and Laydown Area. The  
1871 remaining acres of wetland restoration would be within the other above mentioned Project areas.  
1872 Design of wetland restoration areas would be further evaluated in the detailed reclamation design  
1873 and would include the preservation of upland buffer around the perimeter of the wetland  
1874 restoration areas. The establishment of the estimated 101.8 acres of on-site wetland restoration is  
1875 not included in the mitigation credits. The generation of wetland credits in these areas has the  
1876 potential to be used on a contingency basis, but compensatory credit would not be considered at  
1877 this time for a variety of reasons, including the fact that any restoration efforts would not occur  
1878 for many years.

1879 **Off-site Mitigation**

1880 The initial wetland mitigation study scope focused on the areas containing greater than 80  
1881 percent of their historic wetland resources as defined in the WCA. This area was selected as the  
1882 initial study area to comprehensively cover the priority mitigation areas, with the understanding  
1883 that suitable opportunities may not be available within each priority area.

1884 Available wetland mitigation banking credits that were available for purchase by PolyMet were  
1885 evaluated in portions of bank service areas 1 through 6 and found to be insufficient to satisfy the  
1886 compensatory mitigation requirements for the NorthMet Project Proposed Action. Subsequently,

1887 a GIS analysis was performed to identify potential wetland mitigation sites within the defined  
1888 study area. The primary goal of the analysis was to identify large, potentially drained wetlands  
1889 located primarily on private or tax-forfeit land within the study area to provide preliminary data  
1890 for more detailed ground investigations to proceed. To achieve the goal of the mitigation plan,  
1891 which is to replace lost wetland functions using compensatory wetland types in-kind to the  
1892 degree practicable, areas where drained wetlands could be restored were preferable over areas  
1893 where wetlands could be created (Barr 2008m). Other siting criteria used in the GIS analysis  
1894 included potential wetland enhancement areas, potential wetland preservation areas, and  
1895 potential wetland creation areas (Barr 2008m). Sites were identified by overlaying and  
1896 evaluating numerous existing spatial data sources to locate those sites with the greatest  
1897 mitigation potential. Some of the data sources utilized included the following:

- 1898 • geomorphology/soil types (Loesch 1997);
- 1899 • land ownership (separated by county/state/federal and private ownership) (MLMIC 1983);
- 1900 • land slope/Digital Elevation Model (MLMIC 1999);
- 1901 • streams/ditches (MDNR 1980);
- 1902 • major watersheds; and
- 1903 • land cover (Loesch 1998).

1904 The analysis was conducted by establishing specific filtering criteria to identify potential wetland  
1905 mitigation sites. The general filtering criteria included the following:

- 1906 • land slopes of less than or equal to 1 percent slope;
- 1907 • areas mapped as peat or lacustrine geomorphology;
- 1908 • private or county tax-forfeit property;
- 1909 • areas within 1.1 miles of a ditch; and
- 1910 • areas meeting all of the above criteria with at least 100 contiguous acres.

1911 The analysis was limited to sites with more than 100 acres of wetland mitigation potential due to  
1912 the anticipated difficulties in planning numerous, small wetland mitigation projects, and the  
1913 desire to identify opportunities that were feasible. In addition, the NorthMet Project Proposed  
1914 Action represented an opportunity to restore large wetland systems and provide greater public  
1915 and ecological benefit that are typically not available with smaller projects.

1916 This GIS analysis resulted in the development of a polygon data layer, which contained nearly  
1917 900 areas with potential for mitigation in the study area. This analysis resulted in several  
1918 findings.

1919 First, a large proportion of the study area was in state and federal ownership. Discussions with  
1920 the various state and federal entities regarding wetland mitigation on their respective properties  
1921 resulted in the following conclusions:

- 1922 • The USFS was unable to provide assurances that they would be able to protect restored  
1923 wetlands on federal lands in perpetuity as required by wetland regulations.

1924 • The State of Minnesota provided general criteria for restoring wetlands on state lands. The  
1925 criteria required either a justification for how revenue production (i.e., peat mining, forest  
1926 harvest) would not be affected or provide land in exchange that had a comparable value.  
1927 PolyMet determined that these were not acceptable criteria and the state provided no  
1928 certainty that the NorthMet Project Proposed Action would be viable if PolyMet expended 1  
1929 to 2 years of effort to meet the imposed criteria. This conclusion was supported in part by an  
1930 effort to restore wetlands on Site 8362, a partially state-owned site, as discussed below.

1931 • The Board of Water and Soil Resources has oversight regarding the administration of the  
1932 Minnesota WCA. The Board of Water and Soil Resources provides guidance and  
1933 interpretation of the WCA rules and has the most extensive experience with application of  
1934 the rules. The Board of Water and Soil Resources' experience with wetland restoration on  
1935 tribal lands found that impressing permanent conservation easements granted to the state was  
1936 not possible to protect the restored wetlands.

1937 • PolyMet had a signed agreement with St. Louis County near Floodwood to restore wetlands  
1938 as mitigation (see discussion on Site 8362 below) for the NorthMet Project Proposed Action.  
1939 The agreement was nullified by the state courts. In addition, legal proceedings through the  
1940 state legislature and state court would have been required for ditch abandonment and for  
1941 placement of a conservation easement on the land.

1942 Therefore, it was determined that, because of these uncertainties and risks, mitigation on state  
1943 and federal lands represented a minimal potential for a private enterprise to conduct  
1944 compensatory wetland mitigation on these lands.

1945 Second, many of the wetland systems within the study area have not been affected by historic  
1946 drainage or other significant alteration. In areas lacking significant alterations, wetland  
1947 preservation and establishment of upland buffers constitute the primary methods to generate  
1948 wetland compensation credits within the study area. Wetlands that meet the criteria for wetland  
1949 restoration credits include completely drained wetlands, partially drained wetlands, and wetlands  
1950 with at least a 20-year history of agricultural production (Barr 2008m).

1951 Third, much of the study area was characterized by surface geology that is not indicative of large  
1952 wetland systems prone to easy drainage. The majority of the Arrowhead region, including Cook,  
1953 Lake, and much of St. Louis counties, is mapped with surface geology typified by steep, igneous  
1954 bedrock terrains; rolling surficial deposit plains; and rolling to undulating areas of supraglacial  
1955 drift (Loesch 1997). These geomorphological associations are also typically associated with  
1956 steeper land slopes containing few drained or sufficiently altered wetlands.

1957 Opportunities exist for accomplishing the preferred method of wetland compensation—  
1958 restoration—within the St. Louis River Watershed and northeastern Minnesota in general. Tens  
1959 of thousands of acres of peatlands are adversely affected by ditch systems. Specific to the St.  
1960 Louis River Watershed, hundreds of acres of ditched, hydric soils in agricultural use exist in the  
1961 central portion of the watershed. A determination by the USACE as to the practicality of wetland  
1962 restoration within one or more of these sites has not been completed. The wetland mitigation  
1963 opportunities were determined to not be feasible or prudent for one or more of the following  
1964 different factors: private property, public roads, and active gravel operations that could be  
1965 hydrologically impacted by wetland restoration; insufficient wetland drainage; insufficient  
1966 agricultural history existing public ditches that could not be abandoned; potentially contaminated  
1967 soils; unwilling landowners; considerable existing upstream drainage through the site; active

1968 pursuit of the properties by others; and/or presence of severed mineral rights on many of the  
1969 lands (Barr 2008m).

1970 ***St. Louis River Watershed (Same 8-digit HUC)***

1971 Approximately 101 potential wetland mitigation areas were identified within the St. Louis River  
1972 Watershed and other watersheds tributary to Lake Superior. The specific areas identified as  
1973 having potential for wetland restoration were evaluated in more detail by reviewing NWI maps,  
1974 plat maps, recent aerial photographs, and USGS topography to find the sites with the highest  
1975 potential.

1976 The sites with the highest potential were further evaluated by conducting site visits and meetings  
1977 with various regulatory agencies. The majority of these potential mitigation sites, however, were  
1978 eliminated from further consideration due to issues that included: lack of wetland drainage or  
1979 altered land uses that would qualify as wetland restoration or enhancement (e.g., unaltered sites  
1980 can qualify for regulatory compensation credits such as wetland preservation and upland  
1981 buffers); infeasibility of planning numerous small projects; potential flooding of private property,  
1982 roads, or other infrastructure; upstream ditch drainage through the potential wetland restoration  
1983 areas that would have to be maintained; potential soil contamination; regulatory applicability;  
1984 complex land ownership; existing peat mining operations; and legal considerations.

1985 For purposes of the CWA regulatory program, the term *highest potential* is not the applicable  
1986 standard for evaluating compensatory mitigation. Rather, *practicable* is the standard used in  
1987 conjunction with the fundamental goal of compensatory mitigation: replace lost wetland  
1988 functions, in-kind and in-place, to the extent practicable. Potential compensation sites are not  
1989 limited to those that are least difficult and/or least expensive. Sites that have some greater  
1990 difficulty and/or cost may be practicable, particularly if they are the only sites that would meet  
1991 the fundamental goal of compensatory mitigation.

1992 The area around Meadowlands and Floodwood appeared to have the most suitable  
1993 characteristics. Two contiguous areas in this region, covering approximately 270 square miles,  
1994 were mapped as level peat. The one site found to be initially feasible was designated as Site  
1995 8362. Site 8362 was located within the same watershed as the NorthMet Project area, had the  
1996 greatest potential for wetland restoration with limited peripheral issues, and contained the  
1997 potential to restore bog wetlands similar to those proposed for effect. Thus, Site 8362 was  
1998 initially selected for further study and PolyMet signed an agreement with St. Louis County.  
1999 Approximately 640 acres of the site are owned by the State of Minnesota with the remainder  
2000 designated as tax-forfeit land. Further pursuit of wetland restoration activities at Site 8362 was  
2001 halted for a number of reasons that rendered the site impracticable, including the following:

- 2002 • The district court nullified PolyMet's agreement with St. Louis County in April 2007,  
2003 thereby not allowing any further study of the site.
- 2004 • There was a lack of local support, and there was, in fact, broad opposition from local  
2005 residents.
- 2006 • Extensive hydrologic monitoring and evaluation was required to document the degree of  
2007 drainage at the site to support the proposed mitigation credits. This would have required  
2008 long-term monitoring to adequately demonstrate the drainage and there was uncertainty

2009 regarding the outcome of such monitoring. Such monitoring activities were no longer  
2010 allowed after April 2007 due to the district court action.

2011 • Preservation credits would only be allowed where there was a demonstrable threat that could  
2012 be eliminated (i.e., peat mining, tree-topping, or all-terrain vehicle activity). There are only  
2013 about 400 acres of documented minable peat and the County had indicated they were  
2014 unlikely to agree to limit tree-topping activities. Therefore, the ability to show a  
2015 demonstrable threat that would meet regulatory criteria appeared unlikely.

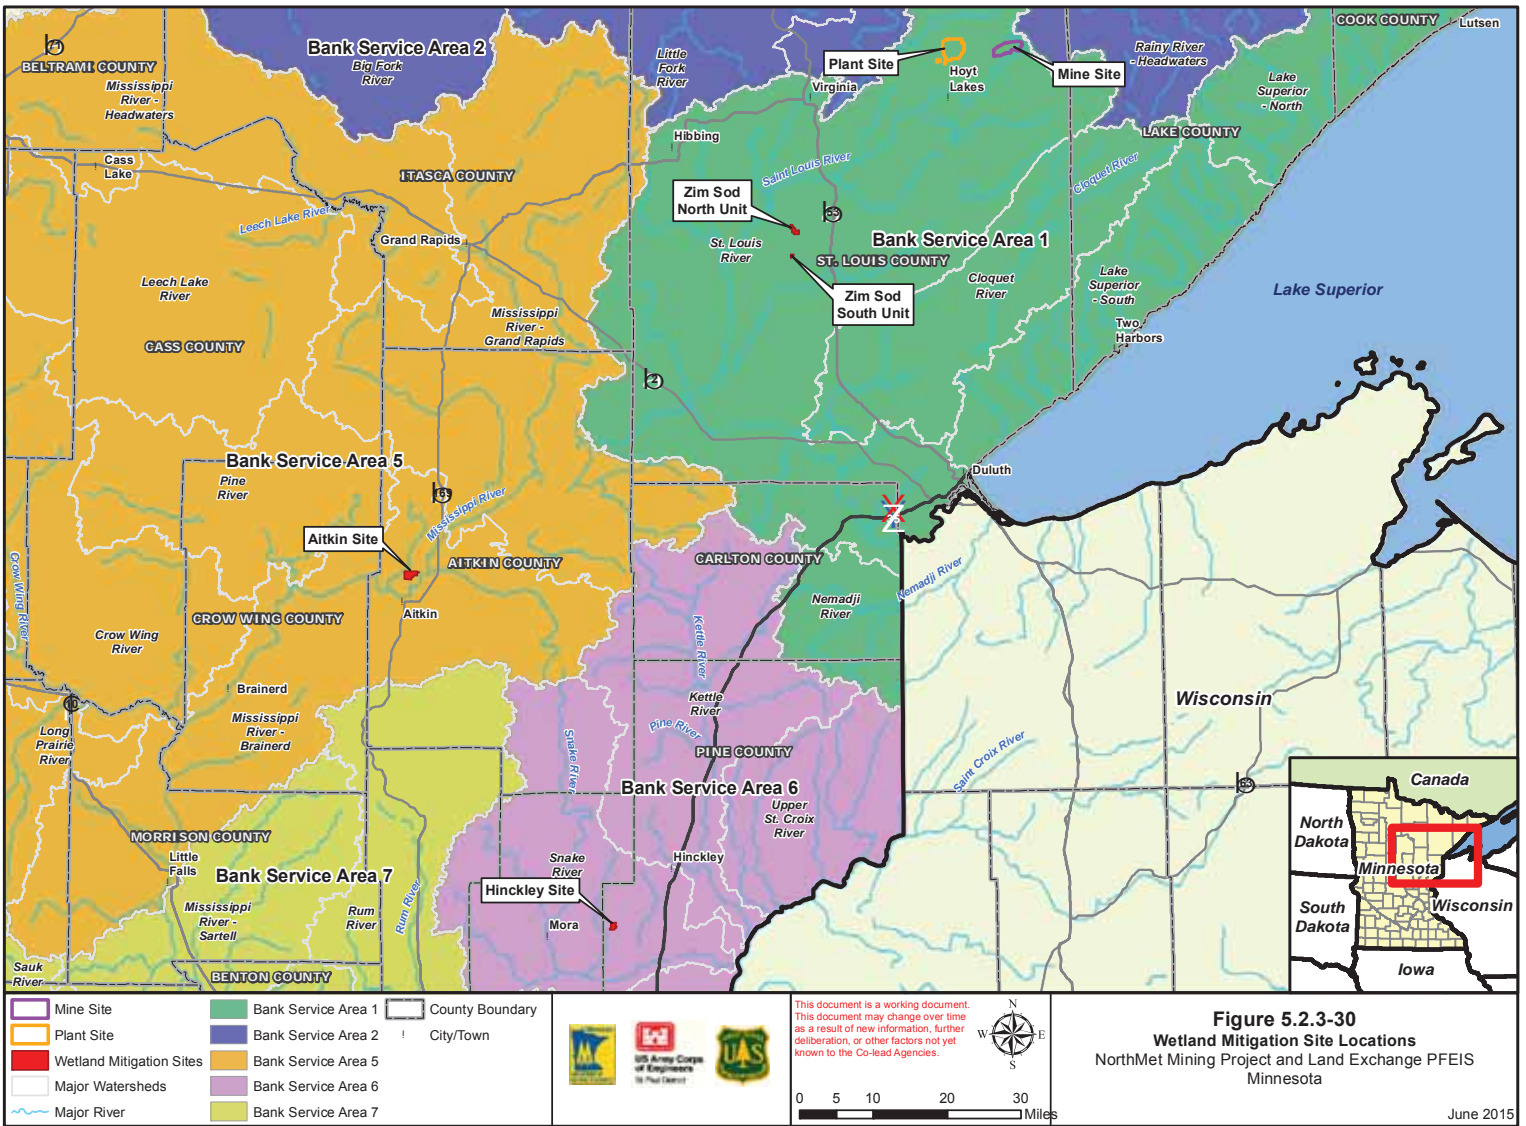

2016 • Even if the agreement with the county was reestablished, that agreement would have required  
2017 ditch-abandonment proceedings in district court with public hearings that would have likely  
2018 been opposed by local residents.

2019 • The agreement with the County (if it were to be reinstated) would have also required  
2020 receiving legislative authorization to place a permanent conservation easement over the  
2021 restoration area. The likelihood of that was uncertain.

2022 One additional wetland restoration area has been further identified since the DEIS within the  
2023 NorthMet Project area watershed. The Zim Sod (Zim) wetland mitigation site is located in St.  
2024 Louis County in the St. Louis River major watershed (#3), within the Lake Superior basin (bank  
2025 service area #1) (see Figure 5.2.3-30).

DRAFT

DRAFT

DRAFT

2029 ***Great Lakes Basin (Same 4-digit HUC)***

2030 With Site 8362 no longer a feasible mitigation option, pursuit of the high-priority sites identified  
2031 in watersheds adjacent to the St. Louis River Watershed was initiated along with the continued  
2032 search for existing bank credits, wetland banks in various stages of planning, and various other  
2033 potential wetland mitigation opportunities located in central and northwestern parts of  
2034 Minnesota.

2035 Fifteen sites were determined to have high potential for wetland mitigation in watersheds located  
2036 adjacent to the St. Louis River Watershed. Of these, 10 sites were evaluated in the Mississippi  
2037 River-Grand Rapids Watershed, three sites were evaluated in the Kettle River Watershed, and  
2038 two sites were evaluated in the Nemadji River Watershed. After further study, these sites were  
2039 eliminated from further consideration due to issues that included: lack of wetland drainage or  
2040 altered land uses that would fit the regulatory requirements for restoration credit; potential  
2041 flooding of roads or other infrastructure; upstream ditch drainage through the wetland that would  
2042 have to be maintained; complex land ownership; existing peat mining operations; and legal  
2043 considerations.

2044 ***Adjacent 4-digit HUC, Selecting an 8-digit HUC as Close as Possible to the Impacted Site***

2045 Ten potential wetland mitigation sites, initially determined to have some potential, were located  
2046 in watersheds neighboring the watersheds adjacent to the St. Louis River. These sites were  
2047 evaluated to determine the relative potential for mitigation, the level of risk and uncertainty, and  
2048 the likely costs. These sites were primarily located in Aitkin County.

2049 Eight of these 10 sites were eliminated from further consideration due to issues that included  
2050 unwilling landowners, significant private properties that would be hydrologically affected by  
2051 wetland restoration, insufficient agricultural history, insufficient wetland drainage to qualify for  
2052 restoration credit, considerable existing upstream drainage through the site, or active pursuit of  
2053 the properties by others. Two priority properties were identified with willing landowners that had  
2054 the potential to accomplish compensatory wetland mitigation for nearly the entire NorthMet  
2055 Project area. These sites are located in watersheds neighboring those adjacent to the St. Louis  
2056 River and outside the 1854 Ceded Territory. These two sites included the Aitkin mitigation site  
2057 (Aitkin) and the Hinckley mitigation site (Hinckley). The Aitkin and Hinckley sites are located  
2058 within the Mississippi River Basin (4-digit HUC) and 8-digit HUC watersheds of Elk-Nokasippi  
2059 #10 and Snake River #36, respectively (see Figure 5.2.3-30). The Aitkin Site is located in Aitkin  
2060 County in bank service area #5 and the Hinckley Site is located in Pine County in bank service  
2061 area #6 (see Figure 5.2.3-30). USACE St. Paul wetland compensatory mitigation replacement  
2062 ratios are based on three factors: in-place versus out-of-place, in-kind versus out-of-kind, and in-  
2063 advance versus not in-advance (see Table 5.2.3-16). As previously stated, the USACE St. Paul  
2064 District and the state have not made a final determination of the compensation ratios that would  
2065 be required for the NorthMet Project Proposed Action. Base compensation ratios for USACE  
2066 would be either 2:1 or 1.5:1 and for the state 1.5:1 or 1:1 depending on the location, quality of  
2067 the wetland, wetland type, and timeframe of the compensation. The final decision on  
2068 compensatory mitigation ratios would be determined during permitting.

2069 ***Off-site Wetland Restoration Projects***

2070 The off-site wetland restoration projects, as defined in the Wetland Management Plan (PolyMet  
2071 2015c), that would provide required mitigation for the NorthMet Project Proposed Action  
2072 wetland impacts include Hinckley, Aitkin, and the Zim wetland mitigation sites (see Figure  
2073 5.2.3-30). As previously noted, the Zim site is located within the NorthMet Project area 8-digit  
2074 HUC watershed, whereas Aitkin and Hinckley are located outside the 8-digit HUC watershed  
2075 area. The mitigation would be considered in advance if the initial phases of restoration on all of  
2076 the proposed off-site wetland mitigation sites would be completed at least one full growing  
2077 season in advance of the authorized wetland impacts provided initial performance standards are  
2078 met for which the mitigation would compensate.

2079 The proposed mitigation is expected to compensate for all the direct wetland impacts, as well as  
2080 the indirect fragmentation impacts—a total of 940.7 acres (see Tables 5.2.3-18 and 5.2.3-19).  
2081 The majority of the credits would be in-kind mitigation and nearly one-third of the credits would  
2082 be from within the NorthMet Project area watershed (see Tables 5.2.3-17, 5.2.3-18, 5.2.3-19).  
2083 Based on PolyMet's current mitigation proposal and assuming the mitigation efforts are fully  
2084 successful and target communities are established, 83 percent of the impacts to coniferous bogs  
2085 would be mitigated by in-kind and in-place credits, or 439.9 coniferous bog credits; the  
2086 remaining 17 percent would be replaced out-of-kind. Out-of-kind credits would be used to  
2087 mitigate impacts on wet meadow, shallow marsh, deep marsh, open bog, and coniferous bog  
2088 communities; these would not be replaced in-kind because of hydrological and ecological  
2089 constraints at the proposed mitigation sites. Forty-seven percent of the wetland impacts are  
2090 currently proposed to be replaced in-kind, in-place, and before the impacts occur on site. An  
2091 additional 29 percent of the proposed impacts are proposed to be replaced in-kind and before the  
2092 impacts occur on site. Most of the additional mitigation credits that are proposed outside of the  
2093 watershed would fulfill mitigation requirements above the minimum 1:1 ratio.

2094 Mitigation credits assumed for calculations include 100 percent credit for restoration of  
2095 drained/farmed wetlands, 75 percent credit for creation of on-site wetlands, 50 percent credit for  
2096 partially drained wetlands and ditches, 25 percent credit for upland buffer, and 12.5 percent  
2097 credit for preservation. The final mitigation credits required to offset the impacts of the proposed  
2098 NorthMet Project Proposed Action would be determined by the agencies during wetland  
2099 permitting. The amount of credit generated by the mitigation sites would ultimately be  
2100 determined by the permitting agencies. This would be based on the extent to which the sites meet  
2101 the target goals established during permitting. These include, among other things, restoration of  
2102 wetland appropriate hydrology and the establishment of a target plant community or type.

2103 **Aitkin Site**

2104 The Aitkin Site is currently an active sod farm that has been drained by ditches and subsurface  
2105 drain tiles. The overall objective of the restoration plan is to restore the hydrology by removal of  
2106 the internal drainage system and the construction of outlets that regulate the required  
2107 hydrological conditions (Barr 2008m). The site has also been used for sod, wheat, soybeans,  
2108 sunflowers, and wild rice production. The 1,070-acre site is located north of the city of Aitkin,  
2109 Minnesota, in Aitkin County. The site is in the Elk-Nokasippi major watershed within bank  
2110 service area #5, adjacent to bank service area #1 where the NorthMet Project area would be  
2111 located.

2112 The site is located outside of the NorthMet Project area watershed. The proposed wetland  
2113 mitigation area includes 808.3 acres of wetland restoration and 83.2 acres of upland buffer  
2114 preservation. Restoration methods on the site are designed to restore the following wetland types:  
2115 Type 3 (shallow marsh), Type 6 (shrub-carr), Type 7 (hardwood swamp), and Type 7 (coniferous  
2116 swamp).

2117 Hydrology monitoring at the Aitkin Site began in 2012, as well as at a reference wetland site, to  
2118 characterize the pre-restoration hydrology, and continued in 2013 and 2014 (PolyMet 2015c).  
2119 Based on the 2 years of monitoring data at the Aitkin Site, monitoring indicates that the majority  
2120 of the site no longer has wetland hydrology. Results of 2014 monitoring will be submitted to the  
2121 USACE and the MDNR in 2015. Concurrence of the monitoring results will be conducted by  
2122 permitting agencies during the permitting process (PolyMet 2015c). The state and federal  
2123 agencies have not yet made a determination on the drainage status of the mitigation site (i.e.,  
2124 drained, partially drained, etc.); this determination will be made during permitting, including  
2125 credit ratios.

2126 The minimum replacement ratio that would be allowed by the USACE is 1:1 (USACE 2009) for  
2127 those wetlands that would be replaced with the same wetland type, and at least one full growing  
2128 season in advance of the authorized wetland impacts provided initial performance standards are  
2129 met; however, base compensation ratios for impacts on high-quality, difficult-to-replace bog and  
2130 forested wetlands would be increased to 2:1 (USACE 2013). For impacts on low- and moderate-  
2131 quality wetlands, a base ratio of 1.5:1 would be applied (USACE 2013). In-kind, in-place, and  
2132 in-advance incentives to reduce the recommended base ratios would be considered at the time of  
2133 permitting (see Tables 5.2.3-17 and 5.2.3-18). Compensation proposed at the Aitkin Site would  
2134 be expected to meet in-kind compensation, resulting in a compensation ratio for high-quality  
2135 wetland impacts of 1.75:1, and if in advance, the ratio would be reduced to 1.5:1. For low- to  
2136 moderate-quality wetlands, the recommended base ratio of 1.5:1 would be required and could be  
2137 reduced to 1.25:1 if in-kind and 1:1 if also in-advance. Under the Minnesota WCA, the  
2138 replacement ratio that would likely be required is 1.5:1, because the Aitkin Site wetlands are out  
2139 of the NorthMet Project area watershed (see Tables 5.2.3-17 and 5.2.3-19).

2140 The site-specific mitigation design proposed by PolyMet includes the following methods of  
2141 restoration to receive wetland mitigation credits, which would be reviewed and approval  
2142 determined during permitting:

- 2143 • Restoration of effectively drained wetland (restoration via reestablishment) on 758.3 acres  
2144 for 100 percent mitigation credit or 758.3 credits;
- 2145 • Hydrologic restoration of 50.1 acres of partially drained wetland (restoration via  
2146 rehabilitation) to receive 50 percent credit or 25.0 credits; and
- 2147 • Restoration of native vegetation on 83.2 acres of uplands and filled ditches, for 20.8 credits  
2148 based on the 25 percent credit calculation for upland buffer.

2149 The vegetation and hydrology would likely be restored to the site over a 1- to 2-year construction  
2150 period, followed by up to 20 years of management, or more if warranted. The restoration work is  
2151 expected to begin on the site after permit approval such that the initial phases of the restoration  
2152 would be completed more than one full growing season before the impacts from the NorthMet  
2153 Project Proposed Action would occur (PolyMet 2013o). Performance standards have been  
2154 developed for the mitigation site to guide the restoration activities and to monitor whether

2155 vegetation and hydrology are meeting the design goals. To protect the site, a permanent  
2156 conservation easement or deed recording would be prepared and recorded at approval of permit  
2157 or prior to impact, as required by the permitting agency. The wetland restoration area would be  
2158 monitored for up to 20 years beginning in the first full growing season after completing  
2159 hydrologic restoration and ending upon certification by the USACE and MDNR that the  
2160 wetlands have met performance standards (PolyMet 2013o; PolyMet 2015c).

2161 The objective of the wetland restoration is to restore hydrology within the site by removing the  
2162 internal drainage system and constructing outlets to establish specific hydrologic conditions that  
2163 would meet the goals and performance standards established for the site and approved by the  
2164 appropriate agencies. The hydrology would be restored utilizing broad, rock-lined weirs, and  
2165 eliminating culverts with the exception of the culverts in a couple of locations. Once hydrology  
2166 restoration has been achieved, an adaptive management program is proposed to guide  
2167 development of the restored wetlands to achieve the targeted conditions. The vegetative  
2168 restoration of the herbaceous layer in each wetland community would be conducted to promote  
2169 the establishment of characteristic native species that are present in the seed bank or that may be  
2170 transported to the area from adjacent wetlands. The goal of the restoration is to provide a setting  
2171 and conditions in which the restoration areas would be restored to naturally self-sustaining and  
2172 functioning wetlands to the extent feasible. The proposed wetland communities have been  
2173 planned in areas that appear to match the natural hydrologic characteristics of each community  
2174 type. However, during the restoration process, it is expected that the defined areas and wetland  
2175 communities may change to some degree and the plan would allow for adaptation to the  
2176 conditions. The overall plan for the Aitkin Site includes the following components: general site  
2177 preparation, natural regeneration in all proposed communities, seeding/planting of shallow marsh  
2178 and shrub-carr communities, planting hardwood swamp community, seeding/planting of  
2179 coniferous swamp communities, and upland area establishment. General site preparation would  
2180 be prior to or concurrent with hydrological restoration activities. Existing, non-native, and  
2181 invasive vegetation would be removed through mechanical means or herbicide application.  
2182 Diverse, native wetland vegetation is expected to develop in the restoration wetlands from the  
2183 existing seed bank and from the wetland vegetation that surrounds the wetland restoration site  
2184 through vegetative propagation and seed dispersal mechanisms. At the end of the second  
2185 growing season these areas would be assessed to determine if additional seeding is required.  
2186 These areas include shallow marsh, emergent fringes, and shrub-carr.

2187 Hardwood swamp communities would require planting of trees in the spring of the second or  
2188 third year after construction, depending on the success of herbaceous species establishment, the  
2189 presence of invasive species, and the stability of the hydrology. Coniferous swamp communities  
2190 would be established initially by direct-seeding tamarack in the spring.

2191 Vegetation in the existing upland areas would be managed to promote natural succession of the  
2192 existing plant communities. The primary maintenance activity would be control of non-native  
2193 invasive species and seeding to develop diverse, native communities.

#### 2194 Hinckley Site

2195 The Hinckley Site currently has about 375 acres under agricultural production and has been  
2196 drained by ditches and sub-surface drain tiles. This 511-acre site is located southwest of the city  
2197 of Hinckley, Minnesota at the intersection of Sod Road and Highway 107. The mitigation site is  
2198 located in Pine County in the Snake River major watershed (#36) within bank service area #6,

2199 adjacent to bank service area #1 where the NorthMet Project area is located. The overall  
2200 objective of the Hinckley restoration plan is to restore the hydrologic connection between  
2201 upstream watersheds and the restoration site and to disable the internal drainage system on-site.  
2202 The restoration process would start with activities to restore site hydrology (Barr 2008m).

2203 The site is located outside of the NorthMet Project area watershed. The proposed wetland  
2204 mitigation area includes 286.2 acres of wetland restoration and 91.2 acres of upland buffer  
2205 preservation. Restoration methods on the site are designed to restore the following wetland types:  
2206 Type 2 (fresh wet meadow), Type 2 (sedge meadow), Type 6 (shrub-carr), Type 6 (alder thicket),  
2207 and Type 7 (hardwood swamp).

2208 Hydrology monitoring at the Hinckley Site began in 2014, as well as at two reference wetland  
2209 sites, to characterize the pre-restoration hydrology (PolyMet 2015c). Results of 2014 monitoring  
2210 will be submitted to the USACE and the MDNR in 2015. Concurrence of the monitoring results  
2211 will be conducted by permitting agencies during the permitting process (PolyMet 2015c). The  
2212 state and federal agencies have not yet made a determination on the drainage status of the  
2213 mitigation site (i.e., drained, partially drained, etc.); this determination will be made during  
2214 permitting, including credit ratios.

2215 The minimum replacement ratio that would be allowed by the USACE is 1:1 (USACE 2009) for  
2216 those wetlands that are replaced with the same wetland type, and at least one full growing season  
2217 in advance of the authorized wetland impacts provided initial performance standards are met;  
2218 however, base compensation ratios for impacts on high-quality, difficult-to-replace bog and  
2219 forested wetlands would be increased to 2:1 (USACE 2013). For impacts on low- and moderate-  
2220 quality wetlands, a base ratio of 1.5:1 would be applied (USACE 2013). In-kind, in-place, and  
2221 in-advance incentives to reduce the recommended base ratios would be considered at the time of  
2222 permitting (see Table 5.2.3-17 and Table 5.2.3-18). Compensation proposed at the Hinckley Site  
2223 would be expected to meet the in-kind incentive, resulting in a compensation ratio for high-  
2224 quality wetland impacts of 1.75:1, and if in-advance, the ratio would be reduced to 1.5:1. For  
2225 low- to moderate-quality wetlands, the recommended base ratio of 1.5:1 would be required and  
2226 could be reduced to 1.25:1 if in-kind and 1:1 if also in-advance. Under the Minnesota WCA, the  
2227 replacement ratio that would likely be required is 1.5:1, because the Hinckley Site wetlands are  
2228 out of the NorthMet Project area watershed (see Tables 5.2.3-17 and 5.2.3-19).

2229 The site-specific mitigation design proposed by PolyMet includes the following methods of  
2230 restoration to receive wetland mitigation credits, which would be reviewed and approval  
2231 determined during permitting:

- 2232 • Restoration of effectively drained wetlands (restoration via reestablishment) on 277.4 acres  
2233 for 100 percent mitigation credit or 277.4 credits;
- 2234 • Hydrologic restoration of 8.7 acres of partially drained wetlands (restoration via  
2235 rehabilitation) to receive 50 percent credit or 4.4 credits; and
- 2236 • Restoration of native vegetation on 91.2 acres of uplands and filled ditches, for 22.8 credits  
2237 based on the 25 percent credit calculation for upland buffer.

2238 The vegetation and hydrology would likely be restored to the site over a 1- to 2-year construction  
2239 period, followed by up to 20 years of management or more, if warranted. The restoration work is  
2240 expected to begin on the site after permit approval such that the initial phases of the restoration  
2241 would be completed more than one full growing season before the impacts of the NorthMet

2242 Project Proposed Action would occur (PolyMet 2013o). Performance standards have been  
2243 developed for the mitigation site to guide the restoration activities and to monitor whether  
2244 vegetation and hydrology are meeting the design goals. To protect the site, a permanent  
2245 conservation easement or deed recording would be prepared and recorded at the time of permit  
2246 approval or prior to impact, as required by the permitting agency. The wetland restoration area  
2247 would be monitored for up to 20 years beginning in the first full growing season after completing  
2248 hydrologic restoration and ending upon certification by the USACE and MDNR that the  
2249 wetlands have met performance standards (PolyMet 2013o; PolyMet 2015c).

2250 The objective of the wetland restoration is to restore the hydrologic connection between the  
2251 upstream watersheds and the site and disable the internal drainage system within the site. The  
2252 hydrology would be restored by filling ditches and utilizing broad, rock-lined overflow weirs,  
2253 and eliminating culverts where possible to establish specific hydrologic conditions that would  
2254 meet the goals and performance standards established for the site and approved by the  
2255 appropriate agencies. Once hydrology restoration has been achieved, an adaptive management  
2256 program is proposed to guide development of the restored wetlands to achieve the targeted  
2257 conditions.

2258 The vegetative restoration of the herbaceous layer in each wetland community would be  
2259 conducted to promote the establishment of characteristic native species that are present in the  
2260 seed bank or that may be transported to the area from adjacent wetlands. The goal of the  
2261 restoration is to provide a setting and conditions in which the restoration areas would be restored  
2262 to naturally self-sustaining and functioning wetlands, to the extent feasible. The proposed  
2263 wetland communities have been planned in areas that appear to match the natural hydrologic  
2264 characteristics of each community type. However, during the restoration process, it is expected  
2265 that the defined areas and wetland communities may change to some degree and the plan would  
2266 allow for adaptation to the conditions.

2267 The overall plan for the Hinckley Site includes the following components: general site  
2268 preparation, natural regeneration in all proposed communities, seeding/planting of sedge/wet  
2269 meadow and shrub-carr/alder-thicket communities, management of the existing hardwood  
2270 swamp community, and upland area management. General site preparation would be prior to or  
2271 concurrent with hydrological restoration activities. Existing, non-native, and invasive vegetation  
2272 would be removed through mechanical means or herbicide application. Diverse, native wetland  
2273 vegetation is expected to develop in the restoration wetlands from the existing seed bank and  
2274 from the wetland vegetation that surrounds the wetland restoration site through vegetative  
2275 propagation and seed dispersal mechanisms. At the end of the second growing season, these  
2276 areas would be assessed to determine if additional seeding is required. These areas include sedge  
2277 and wet meadows and shrub-carr/alder thickets.

2278 The existing hardwood swamp would be managed to minimize the prevalence of non-native,  
2279 invasive species; however, it is not anticipated that active seeding and planting would be  
2280 required.

2281 Vegetation in the existing upland areas would be managed to promote natural succession of the  
2282 existing plant communities. The primary maintenance activity would be control of non-native  
2283 invasive species such as buckthorn, honeysuckle, reed canary grass, and garlic mustard.

2284 Zim Site

2285 The Zim Site is currently an active sod farm that has been drained by ditches and sub-surface  
2286 drain tiles. This site is located in two separate units (north and south) on approximately 569 acres  
2287 of land located southwest of the city of Eveleth, Minnesota. The site is located in St. Louis  
2288 County in the St. Louis River major watershed (#3), within the Lake Superior basin (bank  
2289 service area #1). The overall objective of the Zim restoration plan is to restore a native wetland  
2290 plant community.

2291 The site is located within the NorthMet Project area watershed. The proposed wetland mitigation  
2292 area includes 508.2 acres of wetland restoration and preservation, and 22.7 acres of upland buffer  
2293 preservation. Restoration methods on the site would be designed to restore a (Type 8) coniferous  
2294 bog community; however, developing a bog community is highly dependent on soil and  
2295 groundwater parameters that are difficult to control. Therefore, a coniferous swamp community  
2296 would be the contingent community if the soil and groundwater conditions are not adequate for  
2297 bog regeneration. Coniferous bog or swamp is the target for the whole site; however, where trees  
2298 do not successfully establish, the target community would be a shallow, open water wetland. If  
2299 the target community changes, the credit ratios would be recalculated and would be determined  
2300 during the permitting process.

2301 Hydrology monitoring at the Zim Site, as well as at a reference wetland site, began in 2012 to  
2302 characterize the pre-restoration hydrology, and continued in 2013 and 2014 (PolyMet 2015c).  
2303 Based on 2 years of monitoring data at the Zim Site, the majority of the sod fields on the site no  
2304 longer have wetland hydrology. The forested locations on the Zim Site exhibit hydrology  
2305 representative of partially drained wetlands. Results of 2014 monitoring will be submitted to the  
2306 USACE and the MDNR in 2015. Concurrence of the monitoring results will be conducted by  
2307 permitting agencies during the permitting process (PolyMet 2015c). The state and federal  
2308 agencies have not yet made a determination on the drainage status of the mitigation site (i.e.,  
2309 drained, partially drained, etc.); this determination, including the determination of credit ratios,  
2310 will be made during permitting.

2311 The minimum replacement ratio that would be allowed by the USACE is 1:1 (USACE 2009) for  
2312 those wetlands that are replaced with either the same wetland type, or at least one full growing  
2313 season in advance of the authorized wetland impacts provided initial performance standards are  
2314 met; however, base compensation ratios for impacts on high-quality, difficult-to-replace bog and  
2315 forested wetlands would be increased to 2:1 (USACE 2013). For impacts on low- and moderate-  
2316 quality wetlands, a base ratio of 1.5:1 would be applied (USACE 2013). In-kind, in-place, and  
2317 in-advance incentives to reduce the recommended base ratios would be considered at the time of  
2318 permitting (see Tables 5.2.3-17 and 5.2.3-18). Compensation proposed at the Zim Site would be  
2319 expected to meet both in-kind and in-place incentives, thereby reducing the compensation ratio  
2320 for high-quality wetland impacts from 2:1 to 1.5:1. If in-advance, the ratio would be further  
2321 reduced to 1.25:1. For low- to moderate-quality wetlands, the recommended base ratio of 1.5:1  
2322 would be required and could be reduced to 1.25:1 if in-place and 1:1 if also in-advance or in-  
2323 kind. Under the Minnesota WCA, the replacement ratio that would likely be required is 1:1 for  
2324 those wetlands that are replaced with the same wetland type and in the same watershed (see  
2325 Tables 5.2.3-17 and 5.2.3-19).

2326 The site-specific mitigation design proposed by PolyMet includes the following methods of  
2327 restoration to receive wetland mitigation credits, which would be reviewed and approval  
2328 determined during permitting:

- 2329 • Restoration of effectively drained wetlands on 401.5 acres for 100 percent mitigation credit  
2330 or 401.5 credits;
- 2331 • Restoration of 8.3 acres of excavated ponds for 100 percent mitigation credit or 8.3 credits;
- 2332 • Hydrologic restoration of 48.1 acres of partially drained wooded wetlands to receive 50  
2333 percent credit or 24.1 credits;
- 2334 • Restoration of natural surface grade and wetland conditions in 21.5 acres of ditches, which  
2335 would be filled to receive 50 percent credit or 10.7 credits;
- 2336 • Restoration of native vegetation on 22.7 acres of upland buffers within drained fields and  
2337 filled ditches, each of which would remain drained due to open ditches that cannot be filled,  
2338 for 5.7 credits based on the 25 percent credit calculation for upland buffer; and
- 2339 • Easement protection of 28.8 acres of native coniferous bog communities at 12.5 percent  
2340 credit for a total of 3.6 credits for preservation.

2341 The vegetation and hydrology would be restored to the site over a 1- to 2-year construction  
2342 period, followed by up to 20 years of management or more, if warranted. The restoration work is  
2343 expected to begin on the site after permit approval such that the initial phases of the restoration  
2344 would be completed more than one full growing season before the impacts of the NorthMet  
2345 Project Proposed Action would occur (PolyMet 2013o). Performance standards have been  
2346 developed for the mitigation site to guide the restoration activities and to monitor whether  
2347 vegetation and hydrology are meeting the design goals (Barr 2011k). To protect the site, a  
2348 permanent conservation easement or deed recording would be prepared and recorded at approval  
2349 of permit or prior to impact, as required by the permitting agency. The wetland restoration area  
2350 would be monitored for up to 20 years beginning in the first full growing season after completing  
2351 hydrologic restoration and ending upon certification by the USACE and MDNR that the  
2352 wetlands have met performance standards (PolyMet 2013o; PolyMet 2015c).

2353 The objective of the wetland restoration is to restore hydrology within the site by filling the  
2354 interior ditches, leveling the raised berms, and disabling drain tiles to establish specific  
2355 hydrologic conditions that would meet the goals and performance standards established for the  
2356 site and approved by the appropriate agencies. Once hydrology restoration has been achieved, an  
2357 adaptive management program is proposed to guide development of the restored wetlands to  
2358 achieve the targeted conditions. Coniferous bog or swamp communities would be determined  
2359 using established and approved bog restoration methods. Native, harvested bog material would  
2360 be spread throughout the site to facilitate the re-introduction of sphagnum mosses and other bog  
2361 species that cannot be easily re-introduced by seed. Natural regeneration of the herbaceous  
2362 ground cover, in combination with the addition of bog harvest materials, would be supported by  
2363 intensive weed management. Tree and shrub seedlings would be installed by hand throughout the  
2364 site. The site would be carefully monitored and managed, and supplemental plantings and  
2365 seeding may be used to encourage development until performance standards are met. The overall  
2366 plan for the Zim Site includes the following components: general site preparation, site grading  
2367 and hydrology restoration, bog restoration methods, tree and shrub installation, natural  
2368 regeneration and bog establishment, and supplemental planting and seeding.

2369 **Table 5.2.3-17 Summary of Proposed Wetland Mitigation Credits**

| Community/Credit Type                                                             | Wetland Mitigation Within Project Watershed <sup>1</sup> |               | Wetland Mitigation Outside Project Watershed <sup>1</sup> |                  |                | Total Wetland Mitigation Acres <sup>1</sup> | Total Wetland Mitigation Credits <sup>1,6</sup> |
|-----------------------------------------------------------------------------------|----------------------------------------------------------|---------------|-----------------------------------------------------------|------------------|----------------|---------------------------------------------|-------------------------------------------------|
|                                                                                   | Zim Sod (acres)                                          | Total Credits | Aitkin (acres)                                            | Hinckley (acres) | Total Credits  |                                             |                                                 |
| <b>Off-site Restoration of Effectively Drained Wetlands<sup>2</sup></b>           |                                                          |               |                                                           |                  |                |                                             |                                                 |
| Type 2 Fresh (Wet) Meadow                                                         | 0.0                                                      | 0.0           | 0.0                                                       | 0.0              | 0.0            | 0.0                                         | 0.0                                             |
| Type 2 Sedge Meadow                                                               | 0.0                                                      | 0.0           | 0.0                                                       | 51.0             | 51.0           | 51.0                                        | 51.0                                            |

2371 <sup>1</sup> Totals may not add exactly due to rounding.

2372 <sup>2</sup> Credits for restoration of completely drained wetlands are worth 100 percent of the acreage restored based on USACE St. Paul District Policy (Restoration via re-establishment) and the Minnesota WCA Chapter 8420.0526, Subpart 3.

2373 <sup>3</sup> Credits for restoration of partially drained wetlands are worth 50 percent of the acreage restored based on USACE St. Paul District Policy (Restoration via rehabilitation) and the Minnesota WCA Chapter 8420.0526, Subpart 4.

2374

2375

- 2376 <sup>4</sup> Credits for wetland preservation are worth 12.5 percent of the acreage protected under a conservation easement based on USACE St. Paul District Policy (Preservation) and the  
2377 Minnesota WCA Chapter 8420.0526, Subpart 9 (per *Minnesota Statute* 103G.2251 modified August 1, 2011).  
2378 <sup>5</sup> Credits for upland buffers are worth 25 percent of the acreage of native, non-invasive vegetation established or maintained adjacent to the wetland based on USACE St. Paul  
2379 District Policy (Preservation) and the Minnesota WCA Chapter 8420.0526, Subpart 1.  
2380 <sup>6</sup> The determination of final mitigation credits required to offset the impacts of the proposed NorthMet Project Proposed Action would be determined by the agencies during  
2381 wetland permitting. This would be based on the extent to which the sites meet the target goals established during permitting. These include, among other things, restoration of  
2382 wetland appropriate hydrology and the establishment of a target plant community or type.

DRAFT

2383 **Table 5.2.3-18 Summary of Proposed Wetland Mitigation for Direct Impacts Utilizing USACE Credits**

| Wetland or Credit Type                                                                                                                                  | Mitigation Credits Available <sup>1</sup> |              |              |                                    | NorthMet Project Proposed Action Direct Wetland Impacts in Acres <sup>1,2</sup>          |                                                                        |                    | Total Credits Required for Mitigation at Base Ratio <sup>1,9</sup> | No More Than 2 Apply <sup>9</sup>     |                                        |                                                       | Total Applied Mitigation Credits <sup>1,6,7,9</sup> | Applied Mitigation Ratio <sup>8,9</sup> |  |

2384 Source: PolyMet 2015c.

2385 <sup>1</sup> Totals may not add exactly due to rounding.

2386 <sup>2</sup> The total includes fragmentation of wetlands that would occur at the Mine Site and Plant Site (26.9 acres).

2387 <sup>3</sup> Base ratio 1.5:1 per USACE St. Paul District Policy (USACE 2009) for wetlands that are not considered high-quality or difficult-to-replace, which includes forested wetland and bog communities.

2388 <sup>4</sup> Base ratio 2:1 per USACE May 29, 2013 Draft Memorandum (USACE 2013) for wetlands that are high quality or difficult-to-replace, which includes forested wetland and bog communities.

2389 <sup>5</sup> Based on USACE May 29, 2013 Draft Memorandum (USACE 2013) for in-advance qualification assuming all mitigation would be constructed one full growing season before wetland impacts were to occur.

2390 <sup>6</sup> Total Applied Mitigation Credits = Total Credits Required for Mitigation minus Incentive Credits.

2391 <sup>7</sup> Credits applied may include surplus credits from different wetland types.

2392 <sup>8</sup> The ratio of credits applied to NorthMet Project Proposed Action impacts (not including the surplus credits).

2393 <sup>9</sup> The determination of final mitigation credits required to offset the impacts of the proposed NorthMet Project Proposed Action would be determined by the agencies during wetland permitting. This would be based on the extent to which the sites meet the target goals established during permitting.

2394 <sup>10</sup> These include, among other things, restoration of wetland appropriate hydrology and the establishment of a target plant community or type.

2395 <sup>10</sup> Includes 0.5 credit of upland buffer, applied from totals listed above.

2400 Source: PolyMet 2015c

2401 <sup>1</sup> Totals may not add exactly due to rounding.

2402 <sup>2</sup> The total includes fragmentation of wetlands that would occur at the Mine Site and Plant Site (26.9 acres).

2403 <sup>3</sup> Additional mitigation required for mitigation out of the watershed at Aitkin and Hinckley sites. Determined by multiplying 0.5 by Total Impact Area.

2404 <sup>4</sup> Assume 1:1 replacement for 439.9 acres compensated in-kind and in the watershed and 1.5:1 for the remaining 90.1 acres replaced out of the watershed.

2405  
2406  
2407  
2408

- <sup>5</sup> The ratio of credits applied to NorthMet Project Proposed Action impacts (not including the surplus credits).
- <sup>6</sup> The determination of final mitigation credits required to offset impacts of the proposed NorthMet Project Proposed Action would be determined by the agencies during wetland permitting. This would be based on the extent to which the sites meet the target goals established during permitting. These include, among other things, restoration of wetland appropriate hydrology and the establishment of a target plant community or type.

DRAFT

### 2409 **5.2.3.3.3 Mitigation Summary**

2410 Compensatory mitigation is required for the 913.8 acres of wetlands that would be directly  
2411 impacted. In addition, compensatory mitigation for the 26.9 acres of wetland fragmentation  
2412 would be provided up front. The overall wetland mitigation strategy for the NorthMet Project  
2413 Proposed Action is to compensate for unavoidable wetland impacts in-place, in-kind where  
2414 possible and in-advance of impacts when feasible in order to replace lost wetland functions. Due  
2415 to both on- and off-site limitations and technical feasibility, it is not practicable to replace all  
2416 impacted wetland types with an equivalent area of in-kind wetlands. Off-site wetland mitigation  
2417 projects would be implemented to fulfill the requirements for compensatory mitigation.  
2418 PolyMet's current off-site mitigation proposal includes the:

- 2419 • Aitkin Site – 808.3 acres of wetland restoration and 83.2 acres of upland buffer;
- 2420 • Hinckley Site – 286.2 acres of wetland restoration and 91.2 acres of upland buffer; and
- 2421 • Zim Site – 508.2 acres of wetland restoration and 22.7 acres of upland buffer.

2422 Off-site wetland compensation of 1,602.7 acres could provide 1,513.3 wetland mitigation credits.  
2423 In addition, a total of 197.1 acres of upland buffer areas are proposed to be established with  
2424 native vegetation around the wetland restoration areas. In accordance with USACE guidelines,  
2425 credit for the upland buffer areas would be at a 4:1 ratio, resulting in an additional 49.3 credits.  
2426 The total off-site mitigation could provide 1,562.5 wetland mitigation credits. Tables 5.2.3-17,  
2427 5.2.3-18, and 5.2.3-19 provide a summary of wetland mitigation. Compensatory mitigation ratios  
2428 determined in permitting may vary from these assumptions.

2429 Finally, establishment of approximately 101.8 acres of wetland would likely occur during  
2430 reclamation of the Mine Site; this establishment is not included in the mitigation credits  
2431 discussed above as credit is not being requested at this time.

2432 In accordance with the 2008 Federal Mitigation Rule, USACE policy, and overall requirements  
2433 of the CWA, the primary focus of compensatory mitigation is to replace lost wetland functions  
2434 within the same 8-digit HUC watershed as the impact site—in this case, the St. Louis River  
2435 Watershed/Great Lakes Basin. Initially, no practicable compensation sites were found in the St.  
2436 Louis River watershed, but subsequently, the Zim Site was found and incorporated as part of the  
2437 compensatory mitigation plan. The permanent functional loss of wetlands within the St. Louis  
2438 River Watershed/Great Lakes Basin would be considered during permitting. This is particularly  
2439 critical in that 8-digit HUC watersheds adjacent to the Great Lakes—including the St. Louis  
2440 River Watershed—have been identified as coastal watersheds for purposes of the 2008 Federal  
2441 Mitigation Rule.

2442 The majority of the credits would be in-kind mitigation, and nearly one-third of the credits would  
2443 be from within the NorthMet Project area watershed (see Tables 5.2.3-17, 5.2.3-18, 5.2.3-19).  
2444 Based on PolyMet's current mitigation proposal and assuming the mitigation efforts are fully  
2445 successful and target communities are established, 83 percent of the impacts to coniferous bogs  
2446 would be mitigated by in-kind and in-place credits, or 439.9 coniferous bog credits; the  
2447 remaining 17 percent would be replaced out-of-kind. Out-of-kind credits would be used to  
2448 mitigate impacts on wet meadow, shallow marsh, deep marsh, open bog, and coniferous bog  
2449 communities; these would not be replaced in-kind because of hydrological and ecological  
2450 constraints at the proposed mitigation sites. Forty-seven percent of the wetland impacts are

2451 currently proposed to be replaced in-kind, in-place, and before the impacts occur on site. An  
2452 additional 29 percent of the proposed impacts are proposed to be replaced in-kind and before the  
2453 impacts occur on site. Most of the additional mitigation credits that are proposed outside of the  
2454 watershed would fulfill mitigation requirements above the minimum 1:1 ratio. The preferred  
2455 location of siting any additional compensatory mitigation that may be required for the NorthMet  
2456 Project Proposed Action would be within the St. Louis River/Great Lakes Basin.

2457 The USACE requires a detailed compensatory mitigation plan for anticipated wetland impacts  
2458 that would occur during the first 5 years of the NorthMet Project Proposed Action. A detailed  
2459 mitigation plan must be submitted for each subsequent 5-year increment of wetland impacts to  
2460 the USACE for approval. The anticipated wetland types to be restored off-site include a  
2461 combination of the same and different types as the impacted wetlands. Some off-site wetlands  
2462 would be restored in advance of impacts, while other wetlands would be restored after the  
2463 impacts.

2464 The change in wetland hydrology from groundwater drawdown at the Mine Site was assessed by  
2465 two different methodologies; therefore, total indirect wetland effects were provided based on  
2466 both approaches. The NorthMet Project Proposed Action could indirectly affect up to either  
2467 7,694.2 acres of wetlands located within and around the NorthMet Project area, based on the  
2468 method of wetlands crossing analog impact zones, or up to 6,568.8 acres of wetlands located  
2469 within and around the NorthMet Project area, based on the method of wetlands within analog  
2470 impact zones (PolyMet 2015b). Regardless of the method used, wetland mitigation for indirect  
2471 wetland effects would be determined by the agencies during permitting. If the NorthMet Project  
2472 Proposed Action were to be permitted and constructed, wetland monitoring would be conducted  
2473 to determine if the NorthMet Project Proposed Action causes future indirect wetland effects.  
2474 Wetlands and vegetation would be monitored; additional monitoring locations may be  
2475 considered during permitting. A component of the monitoring plan would be based on those  
2476 wetlands that have a high likelihood of indirect effects as a result of groundwater drawdown. If  
2477 the monitoring determined that indirect wetland effects had occurred, additional compensation  
2478 may be required if determined necessary by the permitting agencies. In the event that the  
2479 required wetland monitoring identified additional indirect effects, permit conditions would likely  
2480 include a plan for adaptive management practices to be implemented, such as expanded  
2481 monitoring and hydrologic controls. Additionally, compensatory mitigation may be required if  
2482 additional impacts are identified during annual reporting. Permit conditions would likely include  
2483 an adaptive management plan to account for any additional impacts that may be identified in the  
2484 annual monitoring and reporting.

#### 2485 **5.2.3.3.4 Monitoring Plan for Mitigation Sites**

2486 Wetland hydrology monitoring has begun at the mitigation sites to assess hydrological conditions  
2487 prior to the determination about the NorthMet Project Proposed Action and would continue after  
2488 hydrology restoration is complete to determine whether or not the restored wetland areas are in  
2489 conformance with performance standards and would determine whether continued monitoring  
2490 would be required.

2491 The wetland restoration area monitoring would begin during the first full growing season after  
2492 completing hydrologic restoration. In addition to monitoring of the restored wetlands, one  
2493 reference wetland of each restoration community type would be monitored within the general  
2494 area of each restoration site in areas with relatively natural hydrologic conditions similar to that

2495 of the proposed target communities. A monitoring plan would be submitted to the appropriate  
2496 state and federal agencies for review and approval that would include proposed locations of  
2497 reference wetlands prior to implementing the monitoring program (PolyMet 2013o; PolyMet  
2498 2015c).

2499 Vegetative monitoring would entail conducting a detailed vegetation survey at least once per  
2500 year (typically July to August) in each wetland mitigation community, as well as the reference  
2501 wetland communities, to evaluate the success of the restoration during the appropriate  
2502 monitoring period for each community type.

2503 Hydrologic monitoring would involve the installation and periodic monitoring of shallow  
2504 recording wells at multiple locations sufficient to characterize hydrology. Continuous recording  
2505 wells that record water table elevations multiple times each day would be utilized to the extent  
2506 feasible and would be placed throughout the sites sufficient to characterize hydrology.  
2507 Hydrologic monitoring would be used to measure the success of hydrologic restoration relative  
2508 to the established performance standards for each community type and to assess the extent of  
2509 wetlands on each site (PolyMet 2015c; PolyMet 2013o). Water elevations would be recorded at  
2510 least once per week from May through mid-July and monthly thereafter until the end of the  
2511 growing season (PolyMet 2015c).

2512 The duration of monitoring would depend on the target wetland communities at each site and the  
2513 success of establishment of those communities. Bogs and forested wetlands would be monitored  
2514 for up to 20 years, or more if warranted. Monitoring of emergent and shrub-carr wetland  
2515 communities would continue for up to 10 years, or more if warranted. Certain components of the  
2516 monitoring may be discontinued sooner if performance standards were met and approval was  
2517 provided by the USACE and MDNR (PolyMet 2015c; PolyMet 2013o).

2518 After restoration, the monitoring design may be altered to better characterize restored conditions  
2519 (PolyMet 2013o). Water levels would be recorded several times each day in the stilling wells for  
2520 the duration of the growing season; staff gauges would be checked weekly for the first 10 weeks  
2521 of the growing season and twice monthly thereafter. Hydrology monitoring in saturated soil  
2522 communities would be completed using shallow water table monitoring wells within each  
2523 community recorded several times each day for the duration of the growing season (PolyMet  
2524 2013o). Hydrologic parameters for Hinckley and Aitkin would be evaluated in the mitigation  
2525 areas more intensively during the first 2 years and then would be performed at a level appropriate  
2526 to the hydrologic characteristics of each area thereafter (PolyMet 2014h; PolyMet 2014i;  
2527 PolyMet 2014j). Reference wells would be established for each community type and monitoring  
2528 with those wells would continue for the duration of site hydrology monitoring (PolyMet 2013o).

2529 Hydrologic monitoring at the three mitigation sites would generally occur for at least 5 years;  
2530 however, certain wetland types may be monitored longer. In shrub communities, monitoring  
2531 would generally be for 8 years, and in forested communities, it would generally be 20 years.  
2532 Monitoring would begin in the first full growing season after beginning hydrologic restoration to  
2533 document the progress and condition of the wetland communities at the mitigation site.  
2534 Monitoring reports would be prepared and submitted to the appropriate agencies, and the  
2535 frequencies of the reports would be based on permit conditions. The monitoring report completed  
2536 after the final growing season would assess whether or not the restored wetlands are in  
2537 conformance with performance standards (PolyMet 2014h; PolyMet 2014i; PolyMet 2014j).

2538 Reports would describe the status of the wetland mitigation, summarize the results of the  
2539 vegetative and hydrologic monitoring, discuss management activities and corrective actions  
2540 conducted during the previous period, and discuss activities planned for the following period.  
2541 The reports would be submitted to the USACE and MDNR by December 31 of each year.  
2542 Monitoring requirements would be determined during the permitting process.

2543 **Contingencies for Unsuccessful Mitigation**

2544 If the restored wetland communities at any of the mitigation sites did not meet performance  
2545 standards, remedial or corrective actions and possibly additional mitigation credits may be  
2546 required and would be determined by the USACE and state during the permitting process. For  
2547 example, PolyMet could characterize site conditions relative to the performance standards in  
2548 each monitoring report and, if the standards were not met, remedial actions would be proposed to  
2549 meet the standard(s). The following contingencies have been proposed by PolyMet (PolyMet  
2550 2013o) and would be finalized and approved during permitting:

- 2551 • Performance standards within any planned community type not met for 3 consecutive years  
2552 would be analyzed to determine the effects on the approved wetland mitigation credits and  
2553 propose an alteration to the plan, which could include a modification of wetland community  
2554 type, changes to the proposed credit ratios, and additional wetland mitigation.
- 2555 • If any wetland community has not developed as planned and as defined in the performance  
2556 standards after the fifth full growing season after restoration, PolyMet would work with the  
2557 USACE and MDNR on appropriate alternative plans, including alternative mitigation or  
2558 revisions to the overall mitigation ratio based on changes to wetland community types.
- 2559 • Any plan revisions would be submitted to the USACE and MDNR for review and approval  
2560 prior to implementation.

2561 If it is determined that additional wetland mitigation would be required due to unsuccessful  
2562 mitigation restoration, PolyMet would first utilize the excess credits (see Tables 5.2.3-18 and  
2563 5.2.3-19) and then would identify and pursue wetland mitigation opportunities, including  
2564 wetland preservation options, within the watershed of the NorthMet Project area. PolyMet would  
2565 use available information from BWSR and other relevant entities that is available at the time it is  
2566 determined additional potential wetland mitigation is needed. Information on the wetland  
2567 mitigation opportunities identified and pursued would be coordinated with and submitted to the  
2568 USACE and state for review and approval prior to making final decisions on additional  
2569 mitigation (PolyMet 2013o).

2570 **5.2.3.3.5 Monitoring Plan for Mine Site and Plant Site Wetland for Potential Indirect**  
2571 **Effects**

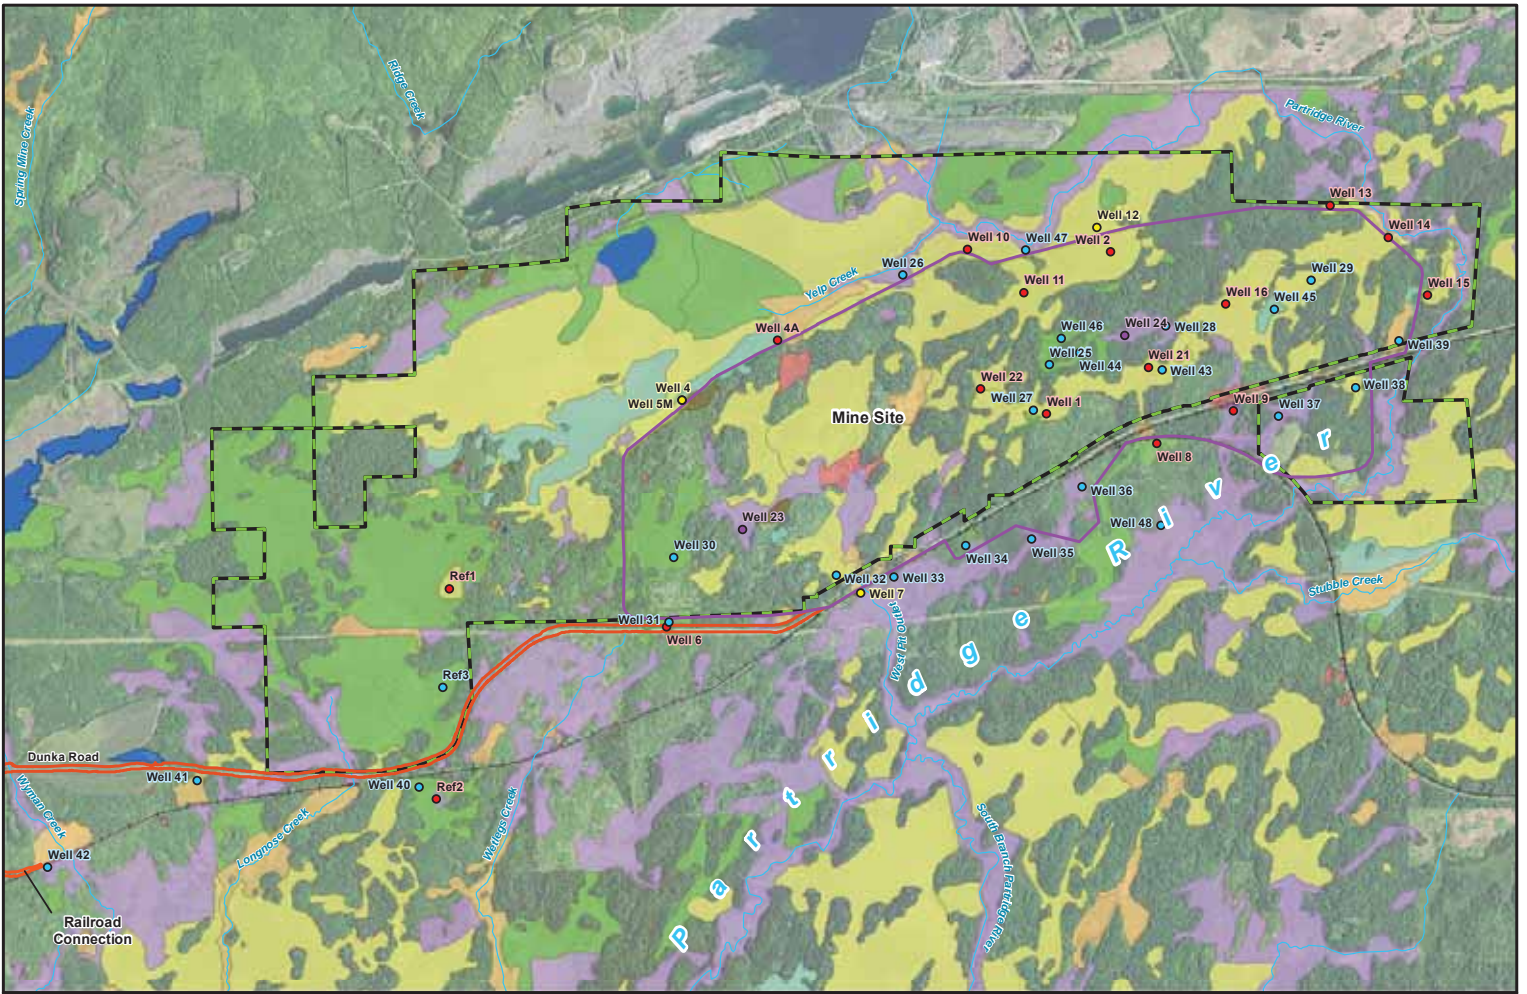

2572 Wetland monitoring would occur in and around the Mine Site and Plant Site prior to and during  
2573 construction and operation of the NorthMet Project Proposed Action, if permitted, and would be  
2574 used to assess whether or not potential indirect effects on wetlands were occurring. If monitoring  
2575 of wetlands for potential indirect effects did determine effects were occurring, additional  
2576 compensation may be required, if determined necessary, based on monitoring results. Monitoring  
2577 is proposed within all wetlands containing a potential indirect wetland impact factor rating of 3  
2578 to 5 and a sampling of those wetlands with factor ratings of 1 or 2 (see Figures 5.3.2-31 and  
2579 5.2.3-32) (PolyMet 2013o). A component of the monitoring plan would be based on those

2580 wetlands that would have a high likelihood of indirect effects as a result of groundwater  
2581 drawdown. If indirect wetland effects were to occur, PolyMet would be required to work with  
2582 the USACE and state to respond, which may include the option to provide compensatory  
2583 mitigation for any documented indirect effects. The monitoring plan would be updated annually  
2584 based on results from the previous year. A total of 56 monitoring wells and four reference wells  
2585 are proposed to document potential indirect wetland effects.

2586 The criteria for determining if potential indirect wetland effects are occurring is provided below.  
2587 In addition, permit conditions would include an adaptive management plan, summarized below,  
2588 to account for any additional effects that may be identified in the annual monitoring and  
2589 reporting. To determine if indirect effects occur, hydrology, vegetation, and wetland boundaries  
2590 would be monitored, documented, and compared with baseline monitoring and reference  
2591 wetlands.

DRAFT

2597 **Pre-Project Wetland Hydrology Monitoring Sites**

2598 In 2005, 20 shallow manual wells and four recording wells were initially installed at 19 locations  
2599 around the Mine Site. A total of 11 monitoring locations were situated around the perimeter of  
2600 the Mine Site and are not expected to be affected by the NorthMet Project Proposed Action. The  
2601 remaining eight monitoring locations are located within the Mine Site and have the potential to  
2602 be affected by the NorthMet Project Proposed Action. In 2008, two wells were removed because  
2603 they were within future stockpile locations, two new wells were added at the Mine Site, one well  
2604 was relocated out of the direct effect area, and two wells were installed in reference wetlands  
2605 located west of the Mine Site (PolyMet 2015c). Furthermore, in 2008, all monitoring locations  
2606 were instrumented with recording wells so water levels could be recorded every 2 to 4 hours. In  
2607 2010, two wells were relocated because they were determined to be in areas that would be  
2608 directly impacted by the NorthMet Project Proposed Action. During 2008 through 2010, there  
2609 were 21 locations monitored at the Mine Site. In 2014, wetland monitoring locations were  
2610 installed at 25 additional locations at the Mine Site and Transportation and Utility Corridor. In  
2611 addition, in 2014 another reference wetland was selected, for a total of three reference wetlands  
2612 to monitor (see Figure 5.2.3-31) (PolyMet 2015c). Pre-project monitoring did not include  
2613 collection of vegetation or wetland boundaries other than what was completed during the wetland  
2614 delineation and baseline wetland type evaluation (PolyMet 2015c; PolyMet 2013o).

2615 Shallow monitoring wells were installed at eight locations around the Plant Site in 2010. One of  
2616 the eight wells was installed in a reference wetland located north of the Plant Site that would not  
2617 be affected by the NorthMet Project Proposed Action. Two monitoring wells were placed west of  
2618 the Plant Site along Unnamed Creek; two wells were placed north of the Plant Site, adjacent to a  
2619 large deep marsh wetland complex; and three wells were placed along the flowpath of Trimble  
2620 Creek. The monitoring wells were typically placed to a depth of 2 to 5 ft bgs. In 2014, shallow  
2621 monitoring wells were installed at seven additional locations in the Plant Site area and a second  
2622 reference wetland was selected (see Figure 5.2.3-32).

2623 The monitoring protocol would continue for the life of the NorthMet Project Proposed Action, if  
2624 approved, though portions of the monitoring design could be altered to improve the design or to  
2625 eliminate unnecessary data collection, which would be done in coordination with the appropriate  
2626 agencies. Pre-project hydrology monitoring of wetlands and groundwater within and surrounding  
2627 the Mine Site started in 2005 and in 2010 at the Plant Site at well locations approved by the  
2628 USACE and MDNR, and would continue throughout the NorthMet Project Proposed Action in  
2629 accordance with the planned study (PolyMet 2015c). The primary objectives of the Mine Site  
2630 and Plant Site wetland hydrology monitoring studies include the following:

- 2631 1. Gain a better understanding of the wetland hydrology at the Mine Site and Plant Site (i.e.,  
2632 defining whether specific wetlands are recharging the surficial deposits aquifer or are  
2633 discharging to surface waters).
- 2634 2. Collect baseline hydrology data at the Mine Site and Plant Site that could be used to assess  
2635 the effect of the NorthMet Project Proposed Action on wetland hydrology.
- 2636 3. Review the data collected at the Mine Site in the hydrogeologic study along with the wetland  
2637 hydrology data to determine whether specific wetlands within the Mine Site area have  
2638 perched water tables or are in direct hydrologic connection with the surficial deposits aquifer.

2639 4. Determine the potential for indirect wetland effects at the Mine Site and Plant Site resulting  
2640 from the NorthMet Project Proposed Action.

2641 The majority of the pre-project monitoring locations would be utilized for future monitoring  
2642 during mining activities. The monitoring of the well locations would be expanded to include  
2643 vegetation sampling and wetland boundaries, and additional monitoring locations may be  
2644 considered during permitting. .

#### 2645 **Project Wetland Hydrology Monitoring Sites**

2646 Wetland hydrology monitoring would be conducted during operation of the NorthMet Project  
2647 Proposed Action to document indirect wetland effects. Prior to the start of the NorthMet Project  
2648 Proposed Action, monitoring would be established based on permit conditions, which would  
2649 describe the purpose, methods, and criteria to be implemented to document indirect wetland  
2650 effects. As previously stated, the monitoring wells were planned within all wetlands with effect  
2651 factor ratings of 3 and within a sampling of wetlands with effect factor ratings of 1 and 2 located  
2652 throughout the areas of potential indirect wetland effects.

2653 As noted in the Section 404 permit application, PolyMet proposes to install shallow water table  
2654 monitoring wells at each of the proposed wetland monitoring locations shown in Figures  
2655 5.2.3-31 and 5.2.3-32. Each monitoring location would have one recording well and one manual  
2656 well; if any wells were to become damaged, PolyMet would replace the wells as soon as  
2657 practical to maintain data continuity. Monitoring would continue in all of the existing wells, with  
2658 the exception of wells #1 and #6. These two wells would be moved outside of areas that would  
2659 be directly impacted (see Figures 5.2.3-31 and 5.2.3-32). Hydrologic monitoring would continue  
2660 at the existing and proposed monitoring locations and at reference wetland locations every year  
2661 throughout the growing season for the life of the mine operation. PolyMet would review the  
2662 monitoring information and, if it were determined that certain wells were not providing useful  
2663 information, the monitoring plan could be modified with the concurrence of the USACE and  
2664 MDNR.

#### 2665 **Reference Wetland Hydrology Monitoring Sites**

2666 Pre-project monitoring locations would include three reference wetlands, one within each of the  
2667 three major project areas (see Figures 5.2.3-31 and 5.2.3-32), approved by the USACE and  
2668 MDNR to document the natural hydrologic fluctuations in wetlands that would not be affected  
2669 by the NorthMet Project Proposed Action and would facilitate interpretation of the NorthMet  
2670 Project Proposed Action hydrologic data.

#### 2671 **Wetland Vegetation and Boundary Monitoring**

2672 In addition to hydrology monitoring, wetland vegetation monitoring would be conducted during  
2673 the operation of the NorthMet Project Proposed Action. Baseline conditions for wetland  
2674 vegetation would be established during the first growing season after permit issuance and at 5-  
2675 year intervals throughout the life of the mine. Data would be used to document potential shifts in  
2676 vegetation that are inconsistent with changes documented in the reference wetlands. Baseline  
2677 data already available from existing plots, wetland delineation, monitoring, and other on-site  
2678 studies may also be used to document baseline conditions if these data may help to determine the  
2679 cause of changes in vegetation characteristics or to demonstrate natural variability within the  
2680 wetlands (PolyMet 2013o).

2681 PolyMet has also proposed that portions of the monitored wetlands be reviewed every 5 years,  
2682 concurrent with the vegetation monitoring, to evaluate wetland boundaries. Wetland boundaries  
2683 would be field-delineated and located using a GPS with sub-foot horizontal accuracy. The field-  
2684 based delineation would map at least 25 percent of the wetland boundary at each of the wetlands  
2685 with monitoring locations. The boundaries would be mapped on a rotating basis to include 25  
2686 percent of the wetland boundary every 5 years, including some overlap every 10 years. A  
2687 transect composed of at least two wetland delineation sample points would be completed along a  
2688 sections of the boundary reviewed in each of the monitored wetlands (PolyMet 2013o).

2689 The delineation data would be compiled to map the boundary of each of the wetlands with  
2690 monitoring locations. Based on the portion of the wetland that is delineated, the whole wetland  
2691 boundary would be mapped using desktop review of current aerial photography, topography  
2692 (LIDAR or site-specific data), and hydrology monitoring data. The results would be reported to  
2693 the USACE and MDNR at the end of each year of monitoring (PolyMet 2013o).

#### 2694 **Criteria Impacts Threshold Levels**

2695 The hydrology, vegetation, and wetland boundary monitoring data collected as part of the  
2696 proposed monitoring program by PolyMet would be evaluated to determine if adverse, indirect  
2697 wetland effects occur as a result of the NorthMet Project Proposed Action. PolyMet has  
2698 proposed the following criteria threshold levels for indicating if an adverse, potential indirect  
2699 wetland effects are occurring (PolyMet 2013o):

- 2700 • A 50 percent reduction of the baseline wetland hydrology hydroperiod. Antecedent  
2701 precipitation and reference wetland hydrology would be considered in the evaluation of  
2702 wetland hydrology hydroperiod. The hydroperiod of a wetland is equal to the length of time  
2703 and portion of the year the wetland holds ponded water or saturation within 12 inches of the  
2704 soil surface. This period of time generally varies from year to year based on climatic  
2705 conditions. Therefore, the judgment of surpassing this threshold would be evaluated  
2706 considering the monitoring for each wetland conducted during the pre-project time period  
2707 and data from reference wetlands of similar community types or hydrologic regime.
- 2708 • A change in vegetation species composition of 25 percent or greater in one or more strata that  
2709 is inconsistent with vegetation changes in the reference wetlands. For instance, if stinging  
2710 nettles (*Urtica dioica*) cover changed from 5 to 30 percent, it may indicate changes in  
2711 wetland hydrology and would be reviewed carefully relative to the hydrology data. Other  
2712 factors may contribute to changes in vegetation (disturbances or species introductions) that  
2713 may be unrelated to changes in wetland hydrology or the nearby NorthMet Project area; such  
2714 factors would be considered as appropriate.
- 2715 • Loss of wetland area (as defined by the wetland boundary determination) that is inconsistent  
2716 with wetland area loss at reference wetlands.

2717 The above criteria have been proposed by PolyMet as part of its Section 404 permit application,  
2718 and permit conditions would indicate the final criteria thresholds if the NorthMet Project  
2719 Proposed Action were approved. The criteria would also be considered and need to be approved  
2720 during the WCA permitting process and Section 401 certification process. These criteria or those  
2721 that are approved during permitting would be evaluated by PolyMet with consideration of the  
2722 NorthMet Project Proposed Action activities and likelihood that such activities are responsible  
2723 for the changes. Should adverse, indirect wetland effects be identified during the monitoring

2724 program, an estimation of such effects would be included in the monitoring report in the year  
2725 that they are first detected. The data for hydrology, vegetation, and wetland boundary monitoring  
2726 would be compiled in a report, including methods, results, and evaluation of potential adverse  
2727 indirect wetland effects; this report would be submitted to the USACE and MDNR by the end of  
2728 each monitoring year.

### 2729 **Indirect Effects Mitigation**

2730 If it is determined that indirect wetland effects occurred based on the criteria effects threshold  
2731 levels, PolyMet would work with the appropriate agencies to respond, which could require  
2732 PolyMet to provide compensatory mitigation for any documented indirect effects. If indirectly  
2733 affected wetlands require compensatory mitigation, the acreage would be calculated by  
2734 community type and provided in annual monitoring reports to the appropriate agencies.  
2735 Compensatory mitigation would be based on WCA requirements and the USACE St. Paul  
2736 District Policy for wetland mitigation, as well as that identified below.

2737 The excess wetland mitigation credits proposed are expected to be available to compensate for  
2738 potential indirect wetland effects. PolyMet would follow, if necessary, the general planning  
2739 approach described above and below for contingencies for unsuccessful mitigation to identify,  
2740 plan, and receive the USACE and state approval of mitigation plans to develop additional  
2741 mitigation credits. If additional mitigation credits were needed, site selection would be consistent  
2742 with USACE and WCA guidance. PolyMet is proposing to mitigate the compensatory loss of  
2743 wetland areas as a result of potential indirect effects in accordance with the mitigation ratios that  
2744 were utilized for direct wetland impacts. In addition, PolyMet has proposed in the Section 404  
2745 permit application that partial drainage or other changes to the wetlands that do not result in the  
2746 wetland loss, but exceed the threshold levels identified above, could be mitigated at a lower ratio  
2747 depending on the extent and degree of the changes to wetland function. The minimum ratio of  
2748 mitigation credit PolyMet is proposing to use would be 0.25:1.

### 2749 **Wetlands Adaptive Monitoring Plan**

2750 PolyMet has, in their Section 404 permit application, proposed utilizing an adaptive monitoring  
2751 plan approach to evaluate the most effective monitoring strategy for potential indirect effects.  
2752 Their proposed wetland adaptive monitoring plan outlined below needs to be reviewed and  
2753 approved prior to permitting:

- 2754 • The monitoring plan would be updated annually based on results from the previous year.
- 2755 • Monitoring plan criteria would be included in the Wetland Management Plan, which would  
2756 contain all criteria and permit conditions.
- 2757 • If indirect impacts were observed, additional monitoring may be developed to focus in those  
2758 areas and/or to focus on a specific impact factor.
- 2759 • Additional monitoring may include new monitoring locations in other wetlands and more  
2760 detailed delineation and vegetation data collection.

2761 PolyMet's current proposed adaptive monitoring plan includes two phases. Phase I would be  
2762 broad-based monitoring to identify changes to wetlands or changes that may affect wetlands or  
2763 surface waters; Phase II monitoring may be implemented to provide a more detailed assessment  
2764 in a given area to analyze a potential impact factor. If necessary, the Phase II monitoring would

2765 be designed and implemented as needed to address the changes identified during Phase I  
2766 monitoring. Phase II would be used to determine the need for additional mitigation or to develop  
2767 a plan to control the changes identified during Phase I and minimize future effects on wetlands.  
2768 The adaptive monitoring plan would be reviewed and approved during permitting.

#### 2769 **5.2.3.3.6 Reporting**

2770 Reports would be compiled to document pre-project hydrology conditions and restoration  
2771 outcomes from the three mitigation sites as well as for the hydrology monitoring at the NorthMet  
2772 Project areas, which would be implemented to fulfill the requirements for compensatory  
2773 mitigation.

#### 2774 **Off-site Monitoring Reports for Wetland Restoration**

2775 Reports have been prepared to document the activities that would be conducted at the off-site  
2776 wetland mitigation sites, which include information regarding existing conditions at the site,  
2777 construction activities, management activities, wetland restoration goals, performance standards,  
2778 schedules, and monitoring plans (PolyMet 2014h; PolyMet 2014i; PolyMet 2014j). These plans  
2779 were developed to comply with WCA rules (*Minnesota Rules*, chapter 8420), Section 404 of the  
2780 CWA as administered by the USACE, and *Minnesota Rules*, part 7050.0186 (wetland mitigation)  
2781 as administered by the MPCA.

2782 Project-specific wetland mitigation plans for three mitigation sites were prepared that describes  
2783 the compensatory wetland mitigation that would be used to replace unavoidable wetland impacts  
2784 associated with the NorthMet Project Proposed Action. The wetland mitigation plans were  
2785 updated and submitted to the USACE in May 2014 for the three sites.

2786 PolyMet would submit progress monitoring reports for the wetland mitigation sites as  
2787 determined during permitting to document restoration outcomes. Wetland restoration  
2788 construction progress would be tracked along with compliance with permit conditions. The  
2789 reports would describe the status of the wetland mitigation, summarize the results of the  
2790 vegetation and hydrology monitoring, discuss management activities and corrective actions  
2791 conducted during the previous year, and discuss activities planned for the following year. The  
2792 monitoring report completed after the tenth growing season would assess whether or not the  
2793 restoration were sufficiently complete and if additional monitoring and reporting were warranted  
2794 (PolyMet 2015c).

#### 2795 **Reporting on Mine Site and Plant Site Wetland Hydrology for Potential Indirect Effects**

2796 Pre-project wetland hydrology monitoring reports, generated to meet reporting requirements,  
2797 have been compiled and document 5 years of pre-project planning and monitoring at the Mine  
2798 Site (2005 to 2009). PolyMet has continued to conduct wetland hydrology monitoring since 2009  
2799 at the Mine Site. Pre-project wetland hydrology monitoring at the Plant Site has also been  
2800 conducted in 2010, 2011, and 2012 at the Plant Site and is ongoing. Future project wetland  
2801 hydrology monitoring reports would be submitted in accordance with any permit issued.

2802 Monitoring data would be submitted to the USACE and MDNR annually for the life of the mine.  
2803 Hydrology data would be presented every year to show monitoring locations, hydrographs, and  
2804 analysis of wetland hydrologic conditions in the context of precipitation conditions. Vegetation  
2805 and wetland boundary data would be presented every 5 years and would be used to determine the

2806 acreage of impacts and potential indirect effects that were not evident based on hydrologic data.  
2807 Indirect effects would be assessed in the annual reports to the extent possible. Acreage of indirect  
2808 effects, if any, would be determined and would be used to determine the requirements for  
2809 wetland mitigation credits, if such credits were needed. If compensatory mitigation were  
2810 necessary, credits would be proposed in the annual report as described above (PolyMet 2013o).

DRAFT

## 1 **5.2.4 Vegetation**

2 This section describes the environmental consequences of the NorthMet Project Proposed Action  
3 to vegetation, which include direct effects on land cover types, native plant community types,  
4 MBS Sites of Biodiversity Significance, and rare or sensitive plant species, as well as effects  
5 from existing or introduced invasive non-native species.

### 6 **Summary**

7 The NorthMet Project Proposed Action would disturb 1,718.6 acres of the Mine Site and have  
8 the greatest effect on upland conifer forest land cover types. Approximately 2,189.7 acres of the  
9 Plant Site would be disturbed by the NorthMet Project Proposed Action, with most effects  
10 occurring in already disturbed areas and tailings ponds. All land within the Transportation and  
11 Utility Corridor would be affected (120.2 acres), the majority of which is already disturbed.

12 The NorthMet Project Proposed Action would affect approximately 1,719 acres that are mapped  
13 by the MDNR as MBS Sites of High Biodiversity Significance. Within these Sites of High  
14 Biodiversity Significance, several native plant communities are mapped that would be affected  
15 by the NorthMet Project Proposed Action, including 698.2 acres with a conservation status rank  
16 of “imperiled-vulnerable” (conservation status rank S2 or S3) or “vulnerable” (conservation  
17 status rank S3), 92.6 acres with a conservation status rank of “apparently secure” (conservation  
18 status rank S4), and 178.9 acres with a conservation status rank of “widespread and secure”  
19 (conservation status rank S5).

20 Disturbed areas would be reclaimed during operations and at closure. Reclamation objectives  
21 would include rapidly establishing a self-sustaining plant community, controlling air emissions,  
22 controlling soil erosion, providing wildlife habitat, and minimizing the need for maintenance.  
23 Seed mixes and methodologies would be designed to minimize the introduction of invasive  
24 species. Reclamation seed mixes would be approved during permitting.

25 There are no federally listed plant species at the NorthMet Project area. There are 10 state-listed  
26 plant species, all at the Mine Site; 8 species would be directly affected and two would potentially  
27 be indirectly affected by the NorthMet Project Proposed Action.

28 Indirect effects from the NorthMet Project Proposed Action could include dust deposition on  
29 vegetation, hydrology changes, ore spillage along the Transportation and Utility Corridor, and  
30 erosion on the Tailings Basin. Mitigation measures would be in place for each of these potential  
31 effects.

### 32 **5.2.4.1 Methodology and Evaluation Criteria**

33 This section compares the types of data presented in Section 4.2.4 for the NorthMet Project area.  
34 Specifically, GIS data were obtained from the MDNR regarding GAP land cover types, native  
35 plant communities, MBS Sites of Biodiversity Significance, and listed ETSC plant species within  
36 the NHIS. Data were obtained from the USFS regarding MIH types, forest stand age classes,  
37 RFSS, invasive non-native species, and landscape ecosystems. Separate NorthMet Project area-  
38 specific listed species survey reports were also utilized to supplement MDNR NHIS data and  
39 estimate effects on populations.

40 GIS analysis was used to calculate effects on the data layers mentioned above. The effects were  
41 calculated for habitat types, classifications, and species where they overlap the NorthMet Project  
42 area footprints.

43 Direct effects on natural features (e.g., vegetative cover types, plant communities, MBS Sites of  
44 Biodiversity Significance, and rare species) occur through clearing, filling, and other  
45 construction activities. A direct effect on an ETSC plant species occurs when the action results in  
46 the removal or loss (i.e., taking) of an individual plant or entire plant population. Direct effects  
47 are those that are a result of the NorthMet Project Proposed Action, that are immediate, and that  
48 often last for years.

49 An indirect effect occurs when a cover type, plant community, Site of Biodiversity Significance,  
50 or rare species experiences a change in vegetative composition. Indirect effects can occur over  
51 time or after the action is completed and can occur on- or off-site. Indirect effects on vegetation  
52 may include changes in hydrology, deposition of particulate matter (dust), changes in  
53 successional stage, alteration of microclimate (e.g., tree removal resulting in drier soil  
54 conditions), loss of pollinators or loss of fungal associates in the rooting zone, erosion and  
55 sedimentation, and invasion of non-native species. Indirect effects were estimated by comparing  
56 the proximity of the NorthMet Project area infrastructure footprints to existing natural features  
57 (e.g., habitat types, plant species present). Typically, indirect effects are more likely to occur  
58 and/or are more likely to be evident in vegetation communities that are closer to NorthMet  
59 Project components and other infrastructure (e.g., roads). Indirect effects tend to diminish with  
60 increasing distance from NorthMet Project components and other infrastructure.

#### 61 **5.2.4.2 NorthMet Project Proposed Action**

62 This section describes the effects of NorthMet Project Proposed Action construction, operation,  
63 and closure on vegetation cover types and plant species. Potential effects from invasive non-  
64 native species are discussed separately.

##### 65 **5.2.4.2.1 Mine Site**

##### 66 ***Effects on Cover Types***

##### 67 ***Habitat Types***

68 Construction and operation of the NorthMet Project Proposed Action at the Mine Site would  
69 directly affect 1,718.6 acres (57 percent of the Mine Site) of land with various MDNR GAP land  
70 cover designations as a result of excavating the mine pits and creating overburden and waste  
71 rock stockpiles and associated internal haul roads and drainage ditches. As shown in Table  
72 5.2.4-1, these effects would include 62 percent (741.9 acres) of the upland conifer forest at the  
73 Mine Site. Other high-acreage directly-affected cover types include lowland coniferous forest  
74 (437.2 acres) and upland deciduous forest (354.7 acres). Approximately 1,295.9 acres, or about  
75 43 percent of the Mine Site, would not be disturbed. The wetland field assessment indicated a  
76 high level of wetland quality. Section 5.2.3 provides a more detailed discussion of wetland  
77 effects.

78 **Table 5.2.4-1 Direct Effects on Cover Types at the Mine Site**

| Cover Types                           | Affected Acres | Non-affected Acres <sup>1</sup> | Total Cover Type Acres | Percent of Cover Type Affected |
|---------------------------------------|----------------|---------------------------------|------------------------|--------------------------------|
| Upland coniferous forest              | 741.9          | 453.6                           | 1,195.5                | 62                             |
| Lowland coniferous forest             | 437.2          | 344.0                           | 781.2                  | 56                             |
| Upland deciduous forest               | 354.7          | 293.3                           | 648.0                  | 55                             |
| Shrubland                             | 133.0          | 108.7                           | 241.7                  | 55                             |
| Disturbed                             | 44.0           | 84.0                            | 128.0                  | 34                             |
| Aquatic environments                  | 6.0            | 6.7                             | 12.7                   | 47                             |
| Upland conifer-deciduous mixed forest | 1.5            | 0.9                             | 2.4                    | 63                             |
| Cropland/grassland                    | 0.2            | 4.7                             | 4.9                    | 4                              |
| Lowland deciduous forest              | 0.0            | 0.1                             | 0.1                    | 0                              |
| Total <sup>2</sup>                    | 1,718.6        | 1,295.9                         | 3,014.5                | 57                             |

79 Source: MDNR 2006b.

80 Notes:

81 <sup>1</sup> Areas of cover types not directly affected by mine pits, stockpiles, roads, or other infrastructure.

82 <sup>2</sup> Total acres may be more or less than presented due to rounding.

83 **Minnesota Biological Survey**

84 Approximately 353.6 acres of the One Hundred Mile Swamp MBS Site of High Biodiversity  
 85 Significance and 1,364.9 acres of the Upper Partridge River MBS Site of High Biodiversity  
 86 Significance would be affected by the NorthMet Project Proposed Action. The portions of these  
 87 two MBS sites that are within the Mine Site area represent a small portion of the mapped Sites of  
 88 High Biodiversity Significance in St. Louis County (2 percent) and the State of Minnesota (less  
 89 than 1 percent). Habitat effects associated with the NorthMet Project Proposed Action would not  
 90 result in a large percentage decline in statewide areas ranked as high by the MBS (MDNR  
 91 2008a).

92 Approximately 698.2 acres of the “imperiled-vulnerable” or “vulnerable” native plant  
 93 communities—the black spruce-Jack pine woodlands (FDn32c; 495.5 acres; 20 percent of  
 94 community within Laurentian Uplands subsection) and rich black spruce swamp (FPn62a; 202.7  
 95 acres; 1 percent of community within Laurentian Uplands subsection)—would also be affected.  
 96 Approximately 92.6 acres of the “apparently secure” native plant communities—i.e., black  
 97 spruce bog: treed subtype (APn80a1; 77.7 acres; 4 percent of community within Laurentian  
 98 Uplands subsection) and poor tamarack-black spruce swamp (APn81b; 14.9 acres; less than 1  
 99 percent of community within Laurentian Uplands subsection)—would be affected.  
 100 Approximately 178.9 acres of “widespread and secure” native plant communities would also be  
 101 affected, including alder (maple-loosestrife) swamp (FPn73a; 42.5 acres; 3 percent of  
 102 community within Laurentian Uplands subsection), aspen-birch forest: balsam fir subtype  
 103 (FDn43b1; 101.1 acres; less than 1 percent of community within Laurentian Uplands  
 104 subsection), and poor black spruce swamp (APn81a; 35.3 acres; less than 1 percent of  
 105 community within Laurentian Uplands subsection).

106 Some of the native plant communities identified at the NorthMet Project area are wetlands.  
 107 WCA rules (including those parts applicable to mining projects under Minnesota Rules  
 108 8420.0930) include a special consideration for wetlands that are rare natural communities  
 109 (Minnesota Rules 8420.0515, subp 3). Guidance developed by MDNR and BWSR on rare  
 110 natural communities (MDNR and BWSR 2011) identifies that rare natural communities are

111 native plant communities having a conservation status rank of S1, S2, or S3, or any native plant  
112 community that is contained within an area mapped or determined by MBS to be eligible for  
113 mapping as an area of outstanding or high biodiversity significance ranking. Figure 4.2.4-2  
114 depicts these Sites of Biodiversity Significance.

115 The Permit to Mine would address special consideration of wetlands that include rare natural  
116 communities. Additional information on rare natural communities would be included in the  
117 wetland permit application as part of the Permit to Mine process for further refinement of site-  
118 specific conditions.

### 119 ***Culturally Important Plants***

120 Potential effects on wild rice as a result of the NorthMet Project Proposed Action would vary by  
121 location. The CEC modeling scenario concentrations exceed the sulfate evaluation criterion at  
122 PM-13. However, under project conditions, the project would not cause or contribute to an  
123 exceedance of the 10-mg/L sulfate evaluation criterion for the Embarrass River at PM-13, since  
124 the Tailings Basin containment and seepage collection system would capture seepage presently  
125 going to the Embarrass River tributaries. Sulfate concentrations currently exceed 10 mg/L in the  
126 Partridge River at SW-005. GoldSim results predict that for all situations where a theoretical  
127 impact could be attributed to the NorthMet Project Proposed Action, the expected increase in  
128 sulfate concentration at SW-005 (and SW-006) would be less than or equal to 0.1 mg/L, and this  
129 would be superimposed on typical annual fluctuations of several mg/L. A practical consequence  
130 of this result is that the effects of the NorthMet Project Proposed Action would not be  
131 identifiable by even the most robust field monitoring program. Effects, as well as water quality  
132 standards, are discussed more thoroughly in Section 5.2.2.

133 While a distinct list of plant species important to the Bands is not available, Sections 4.2.9.3.3  
134 and 5.2.9.2.2 discuss more broadly the effects on the ecological subsections, large landscapes,  
135 and connected ecosystems.

### 136 ***Indirect Effects***

137 In addition to the direct effects mentioned above, potential indirect effects on remaining  
138 vegetative cover types at the Mine Site could be associated with dust from road traffic and  
139 mining operations and with changes in hydrology. Dust on leaves can affect the rates of  
140 photosynthesis and respiration, which both influence plant growth. If sulfide-containing dust is  
141 deposited on leaves, it could react with oxygen in the air and water from precipitation to create  
142 sulfates over a period of weeks to months. This residual build-up in the soil could inhibit growth  
143 by slowly acidifying the soil conditions. The distance dust travels depends on wind speed,  
144 antecedent weather conditions, dust particle size, and vegetation density near the source. Section  
145 5.2.7.2.6 states that the NorthMet Project Proposed Action is not expected to have a significant  
146 effect on sulfate deposition in the state, and so no threat to sensitive vegetation is expected.  
147 PolyMet proposes to implement various dust-control measures such as stabilizing disturbed soils  
148 by temporarily establishing vegetation and water spraying during dry periods (consistent with  
149 *Minnesota Rules*, part 6132.2800). As Section 5.2.7 further describes, fugitive dust control  
150 measures would result in 90 percent control at the Mine Site. These measures, which are  
151 standard practice for existing taconite mines on the Mesabi Iron Range, have proven to be  
152 adequate to minimize potential indirect effects from fugitive dust. The Mine Site AERA did not  
153 assess potential local mercury deposition because potential emissions are less than 1.0 lb/yr (Barr

154 2011g). However, the mercury deposition on terrestrial environments would be expected to be  
155 not significant when compared to variability in background mercury concentrations.

156 As Section 5.2.3 explains, vegetation located within zones with a high likelihood of hydrology  
157 effects would be more likely to have community changes than those with no or low likelihood of  
158 effect.

### 159 ***Reclamation***

160 Reclamation activities help to offset a portion of the effects of a project. Reclamation and  
161 revegetation at the Mine Site would promote cover development and initiate vegetative  
162 succession on stockpiles, the combined East Central Pit, and Mine Site infrastructure footprints.  
163 Fertilizer would be applied at rates recommended for each group of species planted, and would  
164 be worked into the soil to a depth of 8 inches on the level and 4 inches on all slopes  
165 (PolyMet2015g, Attachment A). Soil testing would be completed, as needed, to evaluate  
166 fertilizer requirements. On areas to be mulched after seeding, no more seed would be sown than  
167 could be mulched the same day. Seed would be sown via mechanical Truax native seed drills or  
168 hydrospreading at specified rates of application, unless inaccessible or wet areas dictate the use  
169 of hand-operated spreaders. Seedbeds would be firmed using cultipackers, or seeds would be  
170 covered before mulching. Six different types of mulch could be applied, depending on the  
171 situation. As nutrients and organic matter are returned to the soil, the conditions on the reclaimed  
172 areas would become more suitable for migration of nearby native herbaceous and woody species.

173 The Category 1 Stockpile would be incrementally and progressively reclaimed throughout the  
174 life of the mine, starting in year 14, to minimize erosion of the outer slopes, promote post-closure  
175 land use, and minimize the need for active site care and maintenance during the post-closure  
176 period. Prior to construction of the cover system, the stockpile surfaces would be graded for  
177 long-term stability, to promote vegetation growth and erosion control, and to develop a surface  
178 drainage network over the stockpile (PolyMet 2015h). After grading, an engineered  
179 geomembrane system would be constructed. The geomembrane system would consist of, from  
180 top to bottom: 18 inches of rooting zone soil consisting of on-site unsaturated overburden mixed  
181 with peat, as needed, to provide organic matter; 12 inches of granular drainage material with  
182 drain pipes to facilitate lateral drainage of infiltrating precipitation and snowmelt off the  
183 stockpile cover; a 40 mil geomembrane barrier layer; and a 6-inch soil bedding layer below the  
184 geomembrane (PolyMet 2015a). The stockpile would then be locally contoured to provide some  
185 topographic variety to the surface. Finally, the stockpile would be seeded with a certain selection  
186 of grasses/forbs at the top and bench flats and a potentially different group of species for the  
187 slopes, depending on the availability and suitability of the species (PolyMet 2015g, Attachment  
188 A). The three groups of species designated for the top and benches would include a native, slow-  
189 growth mix; a non-native, rapid-growth mix; and a mix of both native and non-native species.  
190 The species mix for the stockpile slopes would contain the same native species as the stockpile  
191 bench and flats, and a slightly modified group of non-native species. The cover would store  
192 precipitation within the loose layer during the period when vegetation is dormant. The trapped  
193 water would then be removed from the cover system by transpiration of the plants during the  
194 growing season and evaporation. Vegetation would also aid in stabilizing the cover from wind  
195 and rain erosion (Polymet 2015h).

196 Both the Category 2/3 Stockpile and the Category 4 Stockpile would be temporary and would be  
197 removed at closure. Temporary stockpile reclamation would begin during operations. The

198 material in these stockpiles would be relocated to the East Pit starting in year 11 (PolyMet  
 199 2014b). After removal of the material, the footprint of the Category 2/3 Stockpile and portions of  
 200 the Category 4 Stockpile that do not become the Central Pit would be reclaimed by subsequent  
 201 seeding and planting of grass and forb species similar to those planted for the Category 1  
 202 Stockpile top and benches (PolyMet 2015g, Attachment A). Depressions in both temporary  
 203 stockpile footprints with sufficient hydrology and soil conditions would be seeded with a  
 204 different group of native grasses (e.g., fringed brome, bluejoint, Virginia wild rye, tall manna  
 205 grass, fowl bluegrass, tussock sedge, pointed broom sedge, dark green bulrush, and woolgrass)  
 206 and forbs (e.g., Canada anemone, marsh milkweed, flat-topped aster, common boneset, grass-  
 207 leaved goldenrod, spotted Joe Pye weed, blue monkey flower, giant goldenrod, and Eastern  
 208 panicked aster) suitable for wet soils. The West Pit would become open water, while the  
 209 combined East Central Pit would be partially filled with material from the Category 2/3  
 210 Stockpile and Category 4 Stockpile to support wetland vegetation with species discussed above  
 211 for the removed stockpile depressions (see Table 5.2.4-2). The pit wall overburden slopes would  
 212 be planted with the same mix mentioned for stockpile slopes above (PolyMet 2015g, Attachment  
 213 A). The acres reclaimed (see Table 5.2.4-2) do not equal the acres disturbed as some haul roads  
 214 and buildings would remain after cessation of operations.

215 Following demolition of Mine Site buildings and parking areas, suitable overburden would be  
 216 placed over the footprint, to a depth of 2 ft., and revegetated (PolyMet 2015g). Mine Site roads  
 217 deemed unnecessary for future access by the MDNR would be scarified and revegetated, as well.  
 218 Disturbed areas, building sites, and reclaimed roads would all be seeded with a similar mix of  
 219 grass and forb species as that planted on the Category 1 Stockpile top and benches (PolyMet  
 220 2015g, Attachment A).

221 **Table 5.2.4-2 Proposed Vegetation Types and Acreages for Reclaimed Stockpiles and Pits at**  
 222 **the Mine Site**

| Type                                          | Proposed Reclamation Vegetation | Acres |
|-----------------------------------------------|---------------------------------|-------|
| Category 1 Stockpile                          | Grassland/herbaceous            | 526   |
| Category 2/3 Stockpile (Removed)              | Wetland; Grassland/herbaceous   | 180   |
| Category 4 Stockpile (Removed)                | Wetland; Grassland/herbaceous   | 57*   |
| Ore Surge Pile (Removed)                      | Wetland; Grassland/herbaceous   | 31    |
| Overburden Storage and Laydown Area (Removed) | Wetland; Grassland/herbaceous   | 41    |
| Combined East Central Pit                     | Wetland                         | 207*  |
| West Pit                                      | Open pit lake                   | 321   |
| Roads, Parking Areas, Buildings               | Grassland/herbaceous            | 88    |

223 Sources: PolyMet 2015g, Attachment A; PolyMet 2014b; PolyMet 2015h; PolyMet 2014q; Kearney, Barr Engineering, Pers.  
 224 Comm., February 6, 2013.

225 \*The Central Pit would be mined at the location of the temporary Category 4 Stockpile after it is removed. The reclamation acres  
 226 for the Category 4 Stockpile and the Combined East Central Pit overlap.

### 227 ***Effects of Invasive Non-native Plants***

228 Disturbances associated with the construction of the Mine Site would result in exposed soil  
 229 surfaces that would have the potential for colonization by invasive species. PolyMet proposes to  
 230 temporarily vegetate and stabilize disturbed areas during operation and permanently reclaim  
 231 during closure by spreading seeds. Species proposed for revegetation on most disturbed areas  
 232 and the Category 1 Stockpile top and benches include native and non-native species. There are

233 native grass species (e.g., fringed brome, switchgrass, Canada wild rye, bluejoint, poverty  
234 oatgrass, slender wheatgrass, fowl bluegrass, and false melic) and native forb species (e.g.,  
235 common yarrow, pearly everlasting, flat-topped aster, tall cinquefoil, large-leaved aster, stiff  
236 goldenrod, smooth wild rose, black-eyed susan, gray goldenrod, upland white aster, Lindley's  
237 aster, smooth aster, and American vetch). According to the PolyMet Reclamation Seeding and  
238 Mulching procedure (PolyMet 2015g, Attachment A), preference would be given to establishing  
239 native plant communities, and the introduction of invasive plant species would be avoided to the  
240 extent practicable. Reclamation objectives include rapidly establishing a self-sustaining plant  
241 community, controlling air emissions, controlling soil erosion, providing wildlife habitat, and  
242 minimizing the need for maintenance.

243 Non-native species that could be planted include: oats, winter wheat, alfalfa, timothy, redtop,  
244 alsike clover, white clover, Canada bluegrass, intermediate wheatgrass, cicer milkvetch,  
245 birdsfoot trefoil, perennial ryegrass, smooth brome grass, meadow brome, and red fescue. These  
246 species are known to establish quickly and form a nearly complete groundcover, which can help  
247 prevent erosion, maintain water quality, and increase soil stability on more susceptible areas. The  
248 legume species listed would also fix atmospheric nitrogen into the soil to help re-establish soil  
249 nutrients. Generally, these species would be planted as temporary cover crops until the native  
250 species developed and could out-compete them. However, some of the proposed species are  
251 considered invasive (e.g., birdsfoot trefoil, redtop, smooth brome grass, Canada bluegrass).  
252 Section 5.2.4.2.4 discusses suggested mitigation measures for non-native or invasive species.

253 The proposed Type 1 mulch (hay, straw, and agricultural grass/legume cuttings) would be  
254 relatively free of seed-bearing stalks or propagules of noxious weed species, as defined by the  
255 rules and regulations of the Minnesota Department of Agriculture (PolyMet 2015g, Attachment  
256 A).

257 The introduction of invasive non-native species would be more detrimental to the relatively high-  
258 quality vegetation communities at the Mine Site than to those at the Plant Site, which is already  
259 heavily disturbed. Introduction of invasive non-native species could result in decreased diversity  
260 of plant species and habitats available to wildlife species. Several ETSC plant species at the  
261 Mine Site may be susceptible to increased competition from invasive non-native species. There  
262 are already a few occurrences of yellow sweetclover and bladder campion at the Mine Site,  
263 which may invade future disturbed areas.

264 Minnesota's noxious weed law (*Minnesota Statutes* § 18.75-18.91) contains procedures for  
265 controlling and eradicating noxious weeds on all lands within the state. None of the species  
266 proposed to be potentially planted are considered state-prohibited noxious weeds. The MDNR  
267 has made recommendations for non-invasive species for the seed mix and the final seed mix  
268 would be approved during permitting.

### 269 **Effects on Threatened and Endangered Plant Species**

270 The MDNR NHIS and separate rare species surveys were utilized to map known ETSC species  
271 locations using GIS data. Updated MDNR Element Occurrence attribute data were used to  
272 estimate the NorthMet Project area and statewide population numbers of a species, per MDNR  
273 guidance (Joyal, MDNR, Pers. Comm., February 13, 2012). An individual is defined here as a  
274 single plant of a species. A colony (observation) is a group of individual plants of one species in  
275 a distinct geographic location. A population is a group of individuals or colonies of one species

276 that may be separated geographically, but are close enough geographically to interbreed and  
277 persist over time.

278 No federally listed threatened or endangered plant species occur at the Mine Site. However, the  
279 NorthMet Project Proposed Action would have both direct (8 species) and potential indirect (two  
280 species) effects on state-listed ETSC plant species at the Mine Site, affecting 1 percent of the  
281 known statewide populations for these 10 species. Table 5.2.4-3 summarizes the direct and  
282 indirect NorthMet Project Proposed Action effects on each of the ETSC plant species that are  
283 located in the vicinity of the Mine Site, which includes some of the Transportation and Utility  
284 Corridor. These numbers may overestimate the actual effects as a proportion of the number of  
285 actual populations in the state. Intensive surveys, such as those performed at the Mine Site, have  
286 not been performed throughout the state; therefore, the actual number of statewide populations  
287 may be larger than that identified in the MDNR NHIS.

288 Rulemaking was conducted with the intent to update the list of ETSC species (*Minnesota Rules*,  
289 parts 6134.0100 to 6134.0400), with new listings becoming effective on August 19, 2013  
290 (MDNR 2013h). This FEIS considers any new listings, or changes in the previous listings,  
291 associated with the updated list.

DRAFT

295 Notes:

- 296 <sup>1</sup> The state status is E – Endangered; T – Threatened; and SC – Species of Special Concern. The global ranks range from G1 to G5. A lower global ranking (e.g., G3) indicates a  
297 species at higher global risk than higher ranking (e.g., G5) (NatureServe 2014).
- 298 <sup>2</sup> Populations are interpreted from MDNR NHIS data using Element Occurrence, which differs from the DEIS, which used colonies as the population estimate.
- 299 <sup>3</sup> Direct effects are expected for those populations that would be removed or buried by mine activities. Effects are calculated for populations rather than individuals because of the  
300 large variation and inaccuracies in the estimates of number of individuals per population.
- 301 <sup>4</sup> Indirect effects may occur to those populations within or near the Mine Site. These populations may be affected by changes in hydrology, water quality, dust, or inadvertent  
302 activities. As above, effects are given for populations rather than individuals.
- 303 <sup>5</sup> Statewide population data provided by Lisa Joyal (MDNR) on March 26, 2013.
- 304 <sup>6</sup> Population estimates are approximate and used for comparative purposes only. The number of individuals is based upon populations for which data exist.
- 305 <sup>7</sup> Data included here were provided by the Division of Ecological Resources, MDNR, and were current as of August 5, 2014. These data are not based on an exhaustive inventory  
306 of the state. The lack of data for any geographic area shall not be construed to mean that no significant features are present

DRAFT

307 The NorthMet Project Proposed Action would directly affect 8 of the 10 state-listed ETSC plant  
308 species found at or in the immediate vicinity of the Mine Site (see Table 5.2.4-3). Most of the  
309 direct effects would involve the complete loss of colonies within a population as a result of  
310 excavation of the mine pits, burial under stockpiles, or disturbance during infrastructure  
311 construction.

312 The NorthMet Project Proposed Action would potentially indirectly affect 2 of the 10 state-listed  
313 ETSC plant species found at or in the immediate vicinity of the Mine Site (see Table 5.2.4-3).  
314 The NorthMet Project Proposed Action may also result in indirect effects on some colonies of  
315 the directly affected state-listed ETSC plant species at the Mine Site. These indirect effects may  
316 occur as a result of changes in hydrology or water quality, deposition of particulate matter (dust),  
317 application of road salts, or weed incursion. Individual species appear to differ in their response  
318 to these indirect effects. For example, several of the ETSC plant species typically occur along or  
319 in old tailings ponds or along roadsides where disturbance and dust are frequent. To a certain  
320 extent, each species' sensitivity to disturbance can be inferred from currently occupied habitats.  
321 Habitats were considered "disturbed" if they consisted of tailings ponds, gravel pits, landing  
322 pads, logging roads, ditches, or roadsides. Several species may not actually be disturbance-  
323 tolerant, as much as they are able to colonize previously disturbed sites. Repeated soil  
324 disturbance near these species may have an effect on such populations in the short term. Overall,  
325 less than 1 percent of the known statewide populations for these state-listed ETSC species would  
326 potentially be indirectly affected by the NorthMet Project Proposed Action. In some cases,  
327 potential indirect effects on ETSC plant species that would be near, but outside, the footprint of  
328 these facilities could be avoided or reduced by fencing or flagging ETSC populations to prevent  
329 disturbance.

330 Minnesota's endangered species law (*Minnesota Statute*, § 84.0895) and associated rules  
331 (*Minnesota Rules*, parts 6212.1800–6212.2300 and 6134) impose a variety of restrictions,  
332 permits, and exemptions pertaining to ETSC species. "The law and rules prohibit taking,  
333 purchasing, importing, possessing, transporting, or selling" endangered or threatened plants,  
334 including their parts or seeds, without a permit (MDNR 2011m). "Taking," as it relates to plants  
335 includes picking, digging, or destroying. There is the potential that PolyMet would need to seek a  
336 Take Permit from the MDNR for state-listed ETSC plant species. If it is determined by the  
337 MDNR that there are no feasible alternatives to taking, the applicant must pursue compensatory  
338 mitigation. Transplantation is generally not considered by the MDNR to be acceptable mitigation  
339 for taking of endangered or threatened species (MDNR 2011m). The MDNR suggests that  
340 typical compensatory mitigation for taking endangered or threatened species in Minnesota  
341 include the following:

- 342 • Funding state acquisition of another site where the species occurs that is currently  
343 unprotected and vulnerable to destruction,
- 344 • Funding additional survey work to locate other sites, and/or
- 345 • Funding research to improve our understanding of the habitat requirements or protection  
346 needs of the species (MDNR 2011k).

347 A discussion of the effects on each individual ETSC species is provided below.

348 Prairie moonwort populations are commonly observed on sparsely vegetated mineral soil from  
349 sediments of iron mine tailings ponds and grassy railroad embankments (NatureServe 2014). Of

350 the 69 known populations statewide, one colony of one population within the Mine Site area,  
351 along Dunka Road, could be directly affected by pipeline construction and road  
352 improvements/maintenance as part of the NorthMet Project Proposed Action (1 percent affected)  
353 (see Table 5.2.4-3). This species is less tolerant of disturbance than other *Botrychium* species;  
354 however, since it prefers sparsely vegetated areas, it may actually expand into disturbed areas  
355 along Dunka Road in the future. At the Mine Site, grassland areas would not be affected, but  
356 around 34 percent of previously disturbed areas would be affected, resulting in potentially  
357 reduced on-site habitat for this species (see Table 5.2.4-1).

358 *Botrychium pallidum* (pale moonwort) populations are most commonly observed on mine  
359 tailings basins and along roadsides. Of the 99 known populations statewide, three colonies of one  
360 population within the Mine Site, along Dunka Road, could be directly affected by pipeline  
361 construction and road improvements/maintenance as part of the NorthMet Project Proposed  
362 Action (1 percent affected) (see Table 5.2.4-3). One separate colony is located near the railroad  
363 track and may be indirectly affected. This species, however, appears to be semi-tolerant of  
364 disturbance since sites that are kept open by regular disturbance are particularly suitable  
365 (NatureServe 2014). Colonies may actually expand into newly disturbed areas along Dunka  
366 Road and at the Mine Site. Grassland areas at the Mine Site would not be affected, but around 34  
367 percent of previously disturbed areas would be affected, resulting in reduced on-site habitat for  
368 this species (see Table 5.2.4-1).

369 *Botrychium rugulosum* (ternate, or St. Lawrence, grapefern) often occurs on tailings basins,  
370 along roadsides, and in shaded wetland forests. Of the 72 known extant populations in  
371 Minnesota, one population (with four individuals) occurs along Dunka Road at the Mine Site  
372 (1 percent affected) (see Table 5.2.4-3). This population may be directly affected by vehicle  
373 operation or road improvements and maintenance as part of the NorthMet Project Proposed  
374 Action. This species appears to be semi-tolerant of disturbance and populations. At the Mine  
375 Site, around 62 percent of upland conifer forests and around 55 percent of upland deciduous  
376 forests would be affected, resulting in much less on-site habitat for this species (see Table  
377 5.2.4-1).

378 *Botrychium simplex* (least moonwort) frequently occurs in shrublands, forests, tailings basins,  
379 and along roadsides. Of the 210 known populations statewide, three occur at the Mine Site, all of  
380 which are expected to be directly affected (see Table 5.2.4-3). Of these populations, 21 colonies  
381 are expected to be directly affected—seven from stockpiles and mine pits, and another 14 from  
382 construction of the haul roads, water pipeline, ditches, railroad track, or transmission line  
383 (1 percent affected). The colonies affected by stockpiles and mine pits would be removed, while  
384 the colonies affected by construction of pipelines or ditches may be reduced in the short term.  
385 Depending on proximity to construction activities, some of these colonies would likely recover  
386 by expanding along Dunka Road and at the Mine Site post-closure, as this species appears to be  
387 semi-tolerant of disturbance. At the Mine Site, around 34 percent of disturbed areas and around  
388 55 percent of shrublands would be directly affected, resulting in less on-site habitat for this  
389 species (see Table 5.2.4-1).

390 *Caltha natans* (floating marsh-marigold) is found primarily in relatively undisturbed habitats and  
391 is not likely to be tolerant of disturbance. Of the 15 known populations statewide, one population,  
392 which consists of 13 colonies, occurs at the Mine Site (see Table 5.2.4-3). One colony is  
393 expected to be directly affected by stockpile development. Two other colonies are located close  
394 to Dunka Road and could be potentially indirectly affected by road construction or

395 improvements. Ten other colonies are located in the vicinity of, but outside, the Mine Site,  
396 several of which occur along the Partridge River. Since water from the West Pit would be  
397 discharged downstream of these colonies, it is unlikely there would be indirect effects on them.  
398 Effects would not occur to all thirteen colonies of the Mine Site population as indicated in Table  
399 5.2.4-3 because direct and indirect effects due to the NorthMet Project Proposed Action would  
400 be limited to three of the thirteen colonies. All known Minnesota populations occur in St. Louis  
401 County; one in the northern third of the county, two in the southern third, and twelve in the  
402 central third. A few of the statewide populations contain many more individuals (thousands) than  
403 the population at the Mine Site. Since the known statewide population for this species is smaller  
404 than the other species present, the effect on its population in Minnesota would be  
405 correspondingly larger (seven percent affected). As mentioned, however, due to the size of other  
406 statewide populations, and since three out of thirteen colonies of the Mine Site population could  
407 be affected, the actual percent affected would be smaller than seven percent (using available  
408 data, approximately less than one percent). The mitigation measures mentioned above,  
409 particularly the purchase of an unprotected site with a population of the species, should be  
410 assessed. At the Mine Site, around 47 percent of aquatic environments would be directly  
411 affected, resulting in reduced on-site habitat for this species (see Table 5.2.4-1).

412 *Eleocharis nitida* (neat spike-rush) at the Mine Site is primarily observed in roadside ditches  
413 along Dunka Road with gravel or sandy substrates. Of the 49 known populations in the state, one  
414 occurs on the Mine Site (2 percent affected) (see Table 5.2.4-3). Of this population, eight  
415 colonies are found along Dunka Road, and three colonies are located along the railroad tracks.  
416 All of the eight Dunka Road colonies are likely to be directly affected by ditch construction. The  
417 other three colonies may be potentially indirectly affected by changes in hydrology or water  
418 quality. This species seems to be semi-tolerant of disturbance since it has inhabited roadside  
419 ditches. At the Mine Site, around 47 percent of aquatic environments and 34 percent of disturbed  
420 areas would be directly affected, resulting in less on-site habitat for this species  
421 (see Table 5.2.4-1).

422 *Juncus stygius* var. *americanus* (bog rush) has 30 known populations in the state, none of which  
423 occur at the Mine Site; however, one population is located upgradient of the Mine Site within the  
424 One Hundred Mile Swamp (see Table 5.2.4-3). This population would not be directly affected,  
425 but it may be potentially indirectly affected by changes in hydrology (3 percent affected).  
426 However, Section 5.2.3 indicates there would likely be no wetland hydrology effects in this area.  
427 At the Mine Site, around 56 percent of lowland coniferous forests would be directly affected,  
428 resulting in reduced habitat nearby for this species (see Table 5.2.4-1).

429 *Platanthera clavellata* (club-spur orchid) has 123 known populations in the state, none of which  
430 occur at the Mine Site; however, one population is located upgradient of the Mine Site within the  
431 One Hundred Mile Swamp (see Table 5.2.4-3). This population would not be directly affected,  
432 but three colonies may be potentially indirectly affected by changes in hydrology, since the  
433 species is sensitive to this type of change (1 percent affected). However, Section 5.2.3 indicates  
434 there would likely be no wetland hydrology effects in this area. At the Mine Site, around 56  
435 percent of lowland coniferous forests would be directly affected, resulting in reduced habitat  
436 nearby for this species (see Table 5.2.4-1).

437 *Ranunculus lapponicus* (lapland buttercup) is found in conifer/sphagnum bogs on the Mine Site.  
438 Of the 83 known populations statewide, one population occurs at the Mine Site (1 percent  
439 affected) (see Table 5.2.4-3). Of this population, three colonies are expected to be directly

440 affected by construction of a waste rock stockpile. The other four colonies may be potentially  
441 indirectly affected by changes in hydrology, water chemistry, or dust. This species may face  
442 short- and long-term effects at the Mine Site since it is most likely intolerant of disturbance. At  
443 the Mine Site, around 56 percent of lowland coniferous forests would be directly affected,  
444 resulting in much less on-site habitat for this species (see Table 5.2.4-1).

445 *Sparganium glomeratum* (clustered bur-reed) has been observed along roadsides and in lowland  
446 forests. Of the 158 known populations statewide, one population occurs at the Mine Site  
447 (1 percent affected) (see Table 5.2.4-3). Of this population, eight colonies would be directly  
448 affected—three colonies by construction of the mine pits and stockpiles, and five colonies along  
449 Dunka Road by construction of the water pipeline, railroad track, or transmission line. The  
450 remaining five colonies may be indirectly affected by changes in hydrology, water quality, or  
451 dust. This species may be slightly tolerant of some disturbance, since it can be found along  
452 disturbed wetland edges; however, short-term effects may be more pronounced than long-term  
453 effects. At the Mine Site, around 47 percent of aquatic environments and 56 percent of lowland  
454 coniferous forests would be directly affected, resulting in much less on-site habitat for this  
455 species (see Table 5.2.4-1).

456 *Torreyochloa pallida* (Torrey's manna-grass) is often seen along roadsides and may be semi-  
457 tolerant of disturbance. Of the 74 known populations statewide, one occurs at the Mine Site  
458 (1 percent affected) (see Table 5.2.4-3). Of this population, one colony along Dunka Road may  
459 be directly affected by construction of a transmission line. The remaining three colonies are  
460 located away from any proposed construction and may be sufficiently removed from potential  
461 direct and indirect effects of the NorthMet Project Proposed Action. At the Mine Site, around 47  
462 percent of aquatic environments and 56 percent of lowland coniferous forests would be directly  
463 affected, resulting in less on-site habitat for this species (see Table 5.2.4-1).

#### 464 ***Regional Foresters Sensitive Species***

465 The USFS RFSS data layer indicates there are no known RFSS plants on the federal lands, which  
466 include the majority of the Mine Site. However, several state-listed ETSC plant species known to  
467 exist on the Mine Site are also listed as RFSS plants in the Superior National Forest. Six of these  
468 species would be affected by the NorthMet Project Proposed Action, including *Botrychium*  
469 *pallidum*, *Botrychium rugulosum*, *Botrychium simplex*, *Caltha natans*, *Eleocharis nitida*, and  
470 *Juncus stygius* var. *americanus*.

471 MIH types are not fully mapped for the Mine Site since not all of it consists of federal land, but  
472 MIH types are mapped for the federal lands located within the Mine Site. On this portion of the  
473 Mine Site, upland forest (MIH 1; approximately 531 acres affected) would be affected the most  
474 of all MIH types, which means RFSS plant species listed under the upland forest category (see  
475 Table 4.2.4-5) could be most affected by the NorthMet Project Proposed Action. However, since  
476 there are suitable habitats for each RFSS species within each MIH type, a direct correlation  
477 between loss of MIH and loss of RFSS plants cannot be made. Upland conifer forest (MIH 5;  
478 approximately 505 acres affected) lands would be the next group most affected, though there is  
479 overlap of this category with upland forest since upland conifer forest occurs within upland  
480 forest types. Some RFSS species that occupy upland forest may also be affected by this category.  
481 Lowland black spruce-tamarack forest (MIH 9; approximately 483 acres affected) would be  
482 subject to effects comparable to upland conifer forest, and some of the RFSS species listed in  
483 this category would be affected similarly. The lowland emergent wetland type would be affected

484 (approximately 11 acres affected), but likely only one of the five RFSS plant species listed for  
485 that type may be minimally affected. Aquatic habitat (MIH 14) is not mapped at the Mine Site;  
486 however, there are some aquatic habitats on the parcel that would be affected and, thus, some of  
487 the RFSS species listed in this category may be affected. Section 5.2.6 provides further  
488 discussion of effects on aquatic habitats and species.

489 The one RFSS plant not listed as an ETSC species but that is known to occur on the Mine Site,  
490 according to MDNR NHIS data, is *Botrychium michiganense*, which is very closely related to  
491 *Botrychium hesperium*. *B. hesperium* typically occurs in western states, while *B. michiganense*  
492 typically occurs around the Great Lakes states. One population is known to occur on the Mine  
493 Site, of which five colonies would be affected by stockpile development, haul road placement, or  
494 the Transportation and Utility Corridor immediately adjacent to the Mine Site (MDNR 2014d). It  
495 often occurs in grassy roadsides and fields, and requires at least somewhat open habitat created  
496 by natural disturbance events. While anthropogenically disturbed areas have been observed to  
497 harbor reasonably large numbers of individuals, habitat created in this way has not been proven  
498 to support long-term viable populations (NatureServe 2013). At the Mine Site, grassland areas  
499 would not be affected, but around 34 percent of previously disturbed areas would be affected,  
500 resulting in potentially reduced on-site habitat for this species (see Table 5.2.4-1).

501 The USFS determined that the NorthMet Project Proposed Action would not affect 20 RFSS  
502 plants on the Superior National Forest. These 20 species include: alpine milkvetch,  
503 *Arctoparmelia centrifuga*, *Arctoparmelia subcentrifuga*, Braun's holly fern, creeping rush,  
504 Chilean sweet-cicely, Douglas' hawthorn, white mountain saxifrage, largeleaf sandwort, little  
505 goblin moonwort, Northern arnica, maidenhair spleenwort, muskroot, nodding saxifrage, Oakes'  
506 pondweed, Scotch false asphodel, short sedge, smooth woodsia, triangle grapefern, and Wain's  
507 cup lichen. In addition, the NorthMet Project Proposed Action may affect individuals, but are not  
508 likely to cause a trend to federal listing or loss of viability for the remaining 38 RFSS plants on  
509 the Superior National Forest. Please see the Biological Evaluation listed on the USFS website  
510 (<http://www.fs.usda.gov/goto/superior/northmet>) for more information about effects on RFSS  
511 plants.

#### 512 **5.2.4.2.2 Transportation and Utility Corridor**

##### 513 **Effects on Cover Types**

##### 514 ***Habitat Types***

515 Construction and transportation activities within the Transportation and Utility Corridor, as part  
516 of the NorthMet Project Proposed Action, would affect all 120.2 acres of the MDNR GAP land  
517 cover designations (see Table 5.2.4-4). The majority of effects would be on formerly disturbed  
518 (94.4 acres) and grassland areas (9.8 acres).

519 **Table 5.2.4-4 Direct Effects on Cover Types along the Transportation and Utility Corridor**

| Cover Types                           | Affected Acres | Non-affected Acres | Total Cover Type Acres | Percent of Cover Type Affected |
|---------------------------------------|----------------|--------------------|------------------------|--------------------------------|
| Disturbed                             | 94.4           | 0                  | 94.4                   | 100                            |
| Cropland/grassland                    | 9.8            | 0                  | 9.8                    | 100                            |
| Shrubland                             | 7.7            | 0                  | 7.7                    | 100                            |
| Aquatic environments                  | 2.7            | 0                  | 2.7                    | 100                            |

520 Source: MDNR 2006b.

521 Note:

522 <sup>1</sup> Total acres may be more or less than presented due to rounding.

523 **Minnesota Biological Survey**

524 The NorthMet Project Proposed Action would affect 22.5 acres of MBS Sites of High  
 525 Biodiversity Significance (2.9 acres of the One Hundred Mile Swamp and 19.6 acres of the  
 526 Upper Partridge River) within the Transportation and Utility Corridor. Similar to the Mine Site,  
 527 this 22.5-acre area represents a very small portion of the mapped Sites of High Biodiversity  
 528 Significance in St. Louis County (less than 1 percent) and the State of Minnesota (less than  
 529 1 percent). Habitat effects associated with the NorthMet Project Proposed Action would not  
 530 result in a large percentage decline in those areas ranked as high by the MBS.

531 NorthMet Project Proposed Action activities within the corridor would also affect approximately  
 532 2 acres of “widespread and secure” native plant communities, including 2 acres of the aspen-  
 533 birch forest: balsam fir subtype (FDn43b1; less than 1 percent of community within Laurentian  
 534 Uplands subsection), and less than 0.1 acre of the low shrub poor fen (APn91a; less than  
 535 1 percent of community within Laurentian Uplands subsection).

536 **Indirect Effects**

537 Potential indirect effects on vegetative cover types remaining along the Transportation and  
 538 Utility Corridor could include those caused by dust from road traffic or spillage from rail cars.  
 539 Section 5.2.4.2.1 provides further discussion on the effects of dust. PolyMet plans to use the  
 540 existing but currently decommissioned fleet of LTVSMC side-dump rail ore cars. These cars are  
 541 a different design than the bottom-dump rail pellet cars that are used across the Iron Range and  
 542 during past LTVSMC operations. Prior to the start of operations, PolyMet would refurbish these  
 543 ore cars, which would include tightening or replacement of the couplings and linkages to  
 544 minimize gaps along the hinges and joint areas where spillage could occur. Refurbishment of  
 545 these cars would largely reduce the potential for spillage along the Transportation and Utility  
 546 Corridor (PolyMet 2014a). Larger pieces of ore that are spilled from the cars would be  
 547 recovered during routine maintenance of the track, thus minimizing indirect effects. As Section  
 548 5.2.7 further describes, no significant reactive airborne fugitive dust from the rail transport is  
 549 expected. Smaller effects in already-disturbed areas could occur along Dunka Road near the

550 Mine Site. A water pipeline for treated water and a transmission line would be constructed along  
551 Dunka Road on previously disturbed land. Construction of the pipeline and transmission line  
552 would expose soil during construction and could bury vegetation under rock fill.

### 553 ***Reclamation***

554 Dunka Road would not be reclaimed after the NorthMet Project area is closed, since it is an  
555 existing private road. Railroad track and ties that are not used by common carriers would be  
556 removed and recycled (PolyMet 2015a). The Treated Water Pipeline between the Mine Site and  
557 Plant Site would be removed (PolyMet 2015g).

### 558 ***Effects of Invasive Non-native Plants***

559 The Transportation and Utility Corridor is already disturbed, and contains several non-native  
560 and/or invasive species. Disturbance associated with the widening of Dunka Road and  
561 installation of the water pipeline, transmission line, and rail line would result in exposed soil  
562 surfaces that would have the potential for colonization of invasive species. Therefore, the general  
563 effects of invasive non-native plant species along the Transportation and Utility Corridor would  
564 be the same as the Mine Site or Plant Site.

### 565 ***Effects on Threatened and Endangered Plant Species***

566 No federally listed threatened or endangered plant species occur within the .Transportation and  
567 Utility Corridor. The NorthMet Project Proposed Action would have both direct and potential  
568 indirect effects on the same state-listed ETSC plant species as those found at the Mine Site.  
569 Since some of the populations occur along Dunka Road near or overlapping the Mine Site, they  
570 are discussed in Section 5.2.4.2.1 along with the effects on plant populations at the Mine Site.  
571 Table 5.2.4-3 summarizes the direct and indirect effects of the NorthMet Project Proposed  
572 Action on each of those ETSC plant species. For the ETSC species located within the  
573 Transportation and Utility Corridor not adjacent to the Mine Site (*Botrychium pallidum*), effects  
574 are discussed below (see Table 5.2.4-5). As mentioned for the Mine Site, these numbers may  
575 overestimate the actual effects as a proportion of the number of actual populations in the state.

576 Rulemaking was conducted with the intent to update the list of ETSC species (*Minnesota Rules*,  
577 parts 6134.0100 to 6134.0400), with new listings becoming effective on August 19, 2013  
578 (MDNR 2013h). This FEIS considers any new listings, or changes in the previous listings,  
579 associated with the updated list.

580 **Table 5.2.4-5 Effects on Known State-listed ETSC Plant Populations in the Transportation and Utility Corridor**

| Plant Species<br>(state status/<br>global status <sup>1</sup> ) | Known Mine Site Populations |                      |                                                 |                                      |                           | Known Statewide Populations             |                                                          |                                                  |                                                    |                                               |

|                                                                 | Total<br>Populations        | Total<br>Individuals | Direct<br>Effects <sup>2</sup><br>(Populations) | Indirect<br>Effects<br>(Populations) | Unaffected<br>Populations | Total Known<br>Populations <sup>3</sup> | Average<br>Individuals<br>per<br>Population <sup>4</sup> | Percent<br>Directly<br>Affected<br>(Populations) | Percent<br>Indirectly<br>Affected<br>(Populations) | Total<br>Percent<br>Affected<br>(Populations) |
| <i>Botrychium<br/>pallidum</i> (SC/G3)                          | 3                           | 16                   | 3                                               | 0                                    | 0                         | 99                                      | 15                                                       | 3                                                | 0                                                  | 3                                             |
| Total                                                           | 3                           | 16                   | 3                                               | 0                                    | 0                         | 99                                      | NA                                                       | NA                                               | NA                                                 | NA                                            |

581 Source: Barr 2012n.

582 Notes:

583 <sup>1</sup> The state status is E – Endangered. The global ranks range from G1 to G5. A lower global ranking (e.g., G3) indicates a species at higher global risk than higher ranking (e.g.,  
 584 G5) (NatureServe 2014).

585 <sup>2</sup> Direct effects are expected for those populations that would be removed or buried by road improvement activities. Effects are calculated for populations rather than individuals  
 586 because of the large variation and inaccuracies in the estimates of number of individuals per population.

587 <sup>3</sup> Statewide population data provided by Lisa Joyal (MDNR) on March 26, 2013. Statewide population data does not include the three populations of *B. pallidum* found during  
 588 NorthMet Project Proposed Action-specific survey (Barr 2012w), as these were not included in NHIS data, thus inflating effects on statewide population.

589 <sup>4</sup> Population estimates are approximate and used for comparative purposes only. The number of individuals is based upon populations for which data exist.

590 The NorthMet Project Proposed Action would directly affect the one state-listed ETSC plant  
591 species (*Botrychium pallidum*) found within the Transportation and Utility Corridor not adjacent  
592 to the Mine Site (see Table 5.2.4-5). The direct effects would involve the complete loss of  
593 populations as a result of disturbance during road construction and improvement activities.  
594 Section 5.2.4.2.1 above discusses Minnesota's endangered species law, as well as permits and  
595 mitigation for ETSC species.

596 *Botrychium pallidum* (pale moonwort) populations are most commonly observed on mine  
597 tailings basins and along roadsides. Of the 99 known NHIS populations statewide, six colonies of  
598 three populations along Dunka Road could be directly affected by road improvements or  
599 maintenance as part of the NorthMet Project Proposed Action (3 percent affected) (see Table  
600 5.2.4-5). These populations were found during a separate species survey and are not included in  
601 the NHIS data. In addition, without the NHIS element occurrence attribute, it was estimated that  
602 there are three distinct populations by virtue of three separate locations of the six colonies. Thus,  
603 the effects on statewide populations are slightly inflated. All of the grassland and previously  
604 disturbed areas along the Transportation and Utility Corridor would be affected, resulting in  
605 reduced on-site habitat for this species (see Table 5.2.4-4).

#### 606 **5.2.4.2.3 Plant Site**

##### 607 **Effects on Cover Types**

##### 608 ***Habitat Types***

609 Construction, operation, and closure of the NorthMet Project area at the Plant Site would have  
610 fewer effects on native vegetation than at the Mine Site because much of the Plant Site  
611 (61 percent) has already been heavily disturbed or is barren (see Table 4.2.4-8). Most of the  
612 effects of the NorthMet Project Proposed Action are on disturbed areas or tailings ponds, but  
613 other affected areas include isolated stands of forest or shrublands (see Table 5.2.4-6). Other  
614 effects on MDNR GAP land cover types at the Plant Site are smaller. Approximately 2,189.7  
615 acres (48 percent) of the Plant Site would be affected by NorthMet Project Proposed Action  
616 activities. A description of the potential effects on wetlands north of the Tailings Basin is  
617 presented in Section 5.2.3.

618 **Table 5.2.4-6 Direct Effects on Cover Types at the Plant Site<sup>1</sup>**

| Cover Types                           | Affected Acres | Non-affected Acres <sup>2</sup> | Total Cover Type Acres | Percent of Cover Type Affected |
|---------------------------------------|----------------|---------------------------------|------------------------|--------------------------------|
| Disturbed                             | 1,104.0        | 1,651.5                         | 2,755.5                | 40                             |
| Aquatic environments                  | 573.0          | 63.8                            | 636.8                  | 90                             |
| Upland deciduous forest               | 295.1          | 352.5                           | 647.6                  | 46                             |
| Shrubland                             | 144.9          | 188.9                           | 333.8                  | 43                             |
| Upland coniferous forest              | 52.0           | 47.8                            | 99.8                   | 52                             |
| Lowland coniferous forest             | 20.7           | 21.2                            | 41.9                   | 49                             |
| Cropland/grassland                    | 0.0            | 0.0                             | 0.0                    | 0                              |
| Lowland deciduous forest              | 0.0            | 0.0                             | 0.0                    | 0                              |
| Upland conifer-deciduous mixed forest | 0.0            | 0.0                             | 0.0                    | 0                              |
| Total                                 | 2,189.7        | 2,325.8                         | 4,515.4                | 48                             |

619 Source: MDNR 2006b.

620 Notes:

621 <sup>1</sup> This table reflects only those effects on plant communities occurring within the boundaries of the Plant Site. The table does not  
 622 include the potential indirect effects on the wetlands north of the Tailings Basin due to hydrology changes.

623 <sup>2</sup> Areas of cover types not within a 50-ft buffer of buildings, Tailings Basin/spillway reclamation area, or railroad connection.

624 **Minnesota Biological Survey**

625 There are no MBS Sites of Biodiversity Significance or native plant communities identified at  
 626 the Plant Site.

627 **Indirect Effects**

628 In addition to the direct effects mentioned above, potential indirect effects on vegetation at and  
 629 surrounding the Plant Site could include dust or erosion. Vegetation would be established on  
 630 tailings dams during construction to minimize erosion and fugitive dust (PolyMet 2015n). Water  
 631 level would be managed in the Tailings Basin to limit the amount of exposed beach, which  
 632 would minimize dust. Additionally, other fugitive dust control measures (e.g., mulching,  
 633 temporary seeding, and dust suppressants) would be applied to inactive beaches. As Section  
 634 5.2.7 further describes, fugitive dust control measures would result in an 80 percent reduction of  
 635 emissions at the Plant Site. Section 5.2.7.2.6 states that the NorthMet Project Proposed Action is  
 636 not expected to have a significant effect on sulfate deposition in the state, and so no threat to  
 637 sensitive vegetation is expected. Potential mercury emissions at the Plant Site are expected to be  
 638 4.6 lb/yr. Overall, about 95 percent of the mercury originating in the ore is expected to remain  
 639 within—or be adsorbed to—the tailings and the hydrometallurgical residue, where it would  
 640 remain isolated from further transport to the environment. The mercury deposition on terrestrial  
 641 environments would be expected to be not significant when compared to variability in  
 642 background mercury concentrations. In the event erosion occurs on the Tailings Basin, it would  
 643 be corrected and re-vegetated; if necessary for repetitive or excessive erosion, channels or outfall  
 644 structures would be designed to address the issue.

645 **Reclamation**

646 At closure, the buildings and other infrastructure at the Plant Site would be removed, and  
 647 foundations would be razed and buried to a minimum depth of 2 ft. with overburden material  
 648 suitable for vegetation. Plant Site roads that are not deemed necessary for access by the MDNR

649 would be scarified and vegetated, and asphalt from paved surfaces would be removed and  
650 recycled. These disturbed areas would be seeded with the same potential three mixes (native,  
651 non-native, or mixed) as those mentioned for disturbed areas in Section 5.2.4.2.1 (PolyMet  
652 2015g, Attachment A).

653 The Tailings Basin would be incrementally reclaimed by a qualified professional pursuant to  
654 *Minnesota Rules*, part 6132.2700. As dams are constructed, exterior slopes would be stabilized  
655 and vegetated in accordance with requirements in the Fugitive Emissions Control Plan (PolyMet  
656 2015l). Inactive interior beach areas would be temporarily vegetated as necessary for fugitive  
657 dust control, using oats, winter wheat, annual ryegrass, white clover, redtop, and alsike clover, or  
658 some combination of these species for various times of the year (PolyMet 2015g, Attachment A).  
659 The exterior dam faces would be permanently vegetated by a qualified reclamation contractor  
660 according to requirements of the Reclamation Seeding Plan. Upland areas would be planted with  
661 permanent vegetation and mulched to control potential fugitive dust in accordance with  
662 requirements in the Fugitive Emissions Control Plan. Upland beach areas would be planted with  
663 the same potential three mixes (native, non-native, or mixed) as that mentioned for disturbed  
664 areas in Section 5.2.4.2.1, while the dam slopes and benches would be planted with the same mix  
665 as that mentioned for the slopes of the Category 1 Stockpile (PolyMet 2015g, Attachment A).  
666 Interior portions would be graded to provide a gently sloping surface that effectively routes  
667 storm water runoff to the interior of the Tailings Basin and promotes wetlands creation between  
668 the beach and pond areas. Exposed beach areas would be amended with bentonite to limit  
669 oxygen infiltration into the tailings. The cover layer of tailings would be replaced and vegetated  
670 in accordance with requirements of the Reclamation Seeding Plan (PolyMet 2013l). Wet soils  
671 near the Tailings Basin pond would be planted with the same mix as that mentioned for the East  
672 Pit backfill and depressions in the temporary stockpile footprints (see Section 5.2.4.2.1)  
673 (PolyMet 2015g, Attachment A). Establishment of dense vegetative cover and root mass is  
674 among the most effective methods to minimize erosion, so the quality and density of the  
675 vegetation would be periodically reviewed after final reclamation construction is complete.  
676 Areas where vegetation does not become well established would receive additional seeding  
677 and/or fertilizer and other amendments in accordance with requirements of the Reclamation  
678 Seeding Plan. Reclamation areas would be inspected in spring and fall to repair erosion areas and  
679 failed seeding areas, until MDNR determines that the areas are stable and self-sustaining.

680 Reclamation of the Hydrometallurgical Residue Facility would include removal of ponded water  
681 from the cell surface, removal of pore water from the residue, construction of the cell cover  
682 system, and establishment of vegetation and surface water runoff controls. The exterior slopes of  
683 the Hydrometallurgical Residue Facility dams would be incrementally reclaimed throughout the  
684 life of the mine. This would include stabilization and vegetation in accordance with *Minnesota*  
685 *Rules*, part 6132.3200. Final reclamation would generally consist of grading the cell area into a  
686 gently sloping surface. The cover would consist of a layer of LTVSMC tailings immediately  
687 above the drained residue. This would be topped, if necessary, with a non-woven needle-punched  
688 geotextile fabric. Next, a geosynthetic clay barrier layer and a 40 mm LDPE or similar MPCA-  
689 approved geomembrane barrier layer would be placed (PolyMet 2015a). Additional LTVSMC  
690 coarse tailings and/or common borrow and cover soils would be placed on top of the barrier layer  
691 to create a surface capable of sustaining a vegetated cover (PolyMet 2012e). The  
692 Hydrometallurgical Residue Facility dam slopes and benches would be planted with the same  
693 mix as that mentioned for the Category 1 Stockpile slopes in Section 5.2.4.2.1 (PolyMet 2015g,  
694 Attachment A). Turf and final cover would be inspected and maintained by mowing once per

695 year or as needed, fertilizing when visual inspection indicates poor vegetation growth, and  
696 implementing repairs.

697 The Colby Lake Water Pipeline Corridor would not be subject to any additional disturbance or  
698 effects as a result of the NorthMet Project Proposed Action. Maintenance activities would likely  
699 continue to occur on the pipeline.

#### 700 **Effects of Invasive Non-native Plants**

701 The revegetation plan following closure at the Plant Site is similar to what is planned at the Mine  
702 Site as described above. Use of the proposed seed mix could introduce invasive non-native  
703 species, depending on which species are included in the mix, to an area of primarily native  
704 vegetation that surrounds the Plant Site. However, the existing LTVSMC Tailings Basin and  
705 most of the Plant Site are already heavily disturbed, and several invasive non-native species  
706 currently inhabit these areas (e.g., smooth brome grass, reed-canary grass, yellow sweetclover).  
707 These species, once introduced, are difficult to remove and could spread to and colonize  
708 susceptible areas following future disturbance (e.g., blowdown, logging, fire). These species may  
709 reduce diversity, out-compete native vegetation, and provide lower quality habitat for some  
710 specialist animal species. Generally, dominance by invasive non-native species would reduce the  
711 quality of native cover types and habitat remaining at the Plant Site. The MDNR has made  
712 recommendations for non-invasive species for the seed mix and the final seed mix would be  
713 approved during permitting.

#### 714 **Effects on Threatened and Endangered Plant Species**

715 The NorthMet Project Proposed Action would likely have no effect on federal or state ETSC  
716 plant species at the Plant Site or Colby Lake Water Pipeline Corridor because none are known to  
717 occur within the boundaries of these areas, according to MDNR NHIS data. However, no site-  
718 specific studies have been conducted at the Plant Site and so potential species not reported in the  
719 NHIS data may not be represented.

### 720 **5.2.4.2.4 Potential Mitigation Measures**

#### 721 **Mine Site Mitigation Measures**

722 A preferred mitigation measure would be to reseed with the native species, provided they can  
723 perform as effectively as the non-native species. In some areas where erosion control would be  
724 critical to prevent slope failures, non-native species may be needed. Temporary stabilization  
725 efforts using non-native species should use non-invasive plant species to minimize the long-term  
726 risk to surrounding plant communities. In the event invasive non-native species are introduced,  
727 an additional mitigation measure would be to implement a monitoring and control program for  
728 invasive species (including noxious weeds) to ensure these species do not overtake surrounding  
729 native communities. Additionally, the purchase of an unprotected site with a population of  
730 *Caltha natans* should be assessed as mitigation, since the statewide population is lower than the  
731 other ETSC species affected.

#### 732 **Plant Site Mitigation Measures**

733 The measures outlined in the Mine Site Mitigation Measures section above should be applied to  
734 the Plant Site as well. Another recommended mitigation measure may also benefit vegetation at

735 the Plant Site specifically. The addition of organic amendments (peat) to the top foot of the  
736 Tailings Basin would improve soil and water quality and promote the development of shoreline  
737 and near-shore wetland vegetation.

### 738 **5.2.4.3 NorthMet Project No Action Alternative**

#### 739 **5.2.4.3.1 Effects on Cover Types**

740 Under the NorthMet Project No Action Alternative, the Mine Site would not be developed, the  
741 Transportation and Utility Corridor would not be disturbed beyond routine maintenance, and the  
742 Plant Site would have no additional tailings added to the existing LTVSMC Tailings Basin.  
743 Forest-harvesting would continue to occur on the federal land portions of the Mine Site under the  
744 Forest Plan. While timber harvests would result in the immediate loss of some habitat types,  
745 permanent changes are not expected. The Forest Plan calls for an increase in older-age stands,  
746 which would likely come at the expense of younger-age stands in the long term. The majority of  
747 the federal lands are designated as General Forest – Longer Rotation Management Area, which  
748 correlates with the increase in older-age stands overall. The former LTVSMC processing plant  
749 would be reclaimed and revegetated in accordance with its separate closure plan sooner than  
750 under the NorthMet Project Proposed Action. Direct and indirect effects of the NorthMet Project  
751 No Action Alternative on cover types are considered minimal, as the Mine Site and portions of  
752 federal lands would continue to be managed in the same way they have been, and the  
753 Transportation and Utility Corridor and Plant Site have been disturbed in the past.

#### 754 **5.2.4.3.2 Effects of Invasive Non-native Plants**

755 Invasive or non-native species may still invade the Mine Site as a result of logging, mineral  
756 exploration, vehicle traffic, and natural disturbances, but are likely to do so much more slowly  
757 than under the NorthMet Project Proposed Action. Invasive non-native species already exist  
758 along the Transportation and Utility Corridor and Plant Site, but they would likely spread more  
759 slowly under the NorthMet Project No Action Alternative than under the NorthMet Project  
760 Proposed Action due to less disturbance.

#### 761 **5.2.4.3.3 Effects on Threatened and Endangered Plant Species**

762 Under the NorthMet Project No Action Alternative, colonies of state-listed ETSC plant species  
763 would not be affected. Timber harvests are expected to continue to occur on the federal land  
764 portions of the Mine Site. The NorthMet Project area has historically been logged and the state-  
765 listed ETSC plant species present on site have persisted. It is unlikely that continued logging,  
766 which now is more likely to employ best management practices to minimize detrimental effects,  
767 would affect the species in the long term. Potential indirect effects under the NorthMet Project  
768 No Action Alternative could come from increased competition as succession proceeds to older-  
769 age forest stands or with invasive non-native species. Effects of increased competition could  
770 include reduced spore production and consequently reduced population size in the early  
771 successional plant species (e.g., *Botrychium* spp.). Continued maintenance would likely occur  
772 along Dunka Road and the railroad where several of the *Botrychium* populations occur. Long-  
773 term succession at these locations is unlikely due to this maintenance, and these populations  
774 could persist given available habitats. The Transportation and Utility Corridor and Plant Site  
775 contain no occurrences of state-listed ETSC plant species and so the NorthMet Project No Action  
776 Alternative is not expected to have any effects.

777 The USFS determined that the NorthMet Project No Action Alternative would have no effect on  
778 all 58 RFSS plants on the Superior National Forest. A Biological Evaluation has been prepared  
779 that contains further information about RFSS. The Biological Evaluation is included in  
780 Appendix D and is posted on the USFS website ([http://www.fs.usda.gov/goto/superior/](http://www.fs.usda.gov/goto/superior/northmet)  
781 [northmet](http://www.fs.usda.gov/goto/superior/northmet)).  
782

DRAFT

## 1 **5.2.5 Wildlife**

2 This section describes the environmental consequences of the NorthMet Project Proposed Action  
3 to wildlife including direct effects such as the loss of individuals/ populations of affected species  
4 or a decrease in habitat, as well as indirect effects such as displacement, competition, or changes  
5 in the greater regional area.

### 6 **Summary**

7 The NorthMet Project Proposed Action is expected to affect three federally listed species, the  
8 Canada lynx, gray wolf, and northern long-eared bat. The Canada lynx would likely be affected  
9 through localized direct decrease and fragmentation of designated critical habitat and the  
10 increased potential (albeit low) for incidental take resulting from vehicular collisions due to  
11 increased NorthMet Project Proposed Action-related traffic. Restoration of disturbed areas as  
12 part of mine closure would potentially create lynx habitat, although this successional process  
13 could take decades. The gray wolf would likely be affected through loss of habitat and the  
14 increased potential (albeit low) for incidental take resulting from vehicular collisions due to  
15 increased NorthMet Project Proposed Action-related traffic. The northern long-eared bat would  
16 likely be affected through loss of potential summer roost habitat and foraging areas. The  
17 NorthMet Project Proposed Action is not likely to affect the bald eagle, which is also protected  
18 under federal law (although not a federally listed endangered or threatened species). Eight  
19 additional state-listed and special concern species, which include eastern heather vole, moose,  
20 little brown bat, eastern pipistrelle, northern goshawk, boreal owl, wood turtle, and yellow rail,  
21 may be affected by the NorthMet Project Proposed Action. It is expected that the Laurentian  
22 tiger beetle, taiga alpine butterfly, Freija's grizzled skipper butterfly, Nabokov's blue butterfly,  
23 and Quebec emerald dragonfly would not be affected. SGCN, RFSS, and other wildlife species,  
24 including those considered tribally or culturally significant, may be affected by human activity,  
25 noise and vibration, rail and vehicle traffic, and decrease of habitat.

### 26 **5.2.5.1 Methodology and Evaluation Criteria**

27 This section uses data presented in Section 4.2.5 to analyze effects on wildlife. Specifically,  
28 survey reports and GIS data were obtained regarding land cover and habitat types, forest stand  
29 age classes, listed ETSC, SGCN, RFSS, and other wildlife species. GIS analysis was used to  
30 calculate direct and indirect effects on these resources.

31 The analysis of direct effects included the potential of a take of federally or state-listed species.  
32 Pursuant to the federal ESA, *take* is defined as "to harass, harm, pursue, hunt, shoot, wound, kill,  
33 trap, capture, or collect, or to attempt to engage in any such conduct." Take of an individual or  
34 population could occur for various reasons such as traffic collisions, habitat destruction, or  
35 change in an individual or population's habitat use due to noise, other disturbance, or  
36 contamination of food or water sources. Take of a listed species would be considered a  
37 significant effect. The USFWS can issue a permit for the incidental take of a federally listed  
38 wildlife species consistent with the goal of conservation of the species. Permit applicants must  
39 design, implement, and demonstrate availability of funding for a conservation plan that  
40 minimizes and mitigates harm to the affected species during the proposed project. Without a  
41 permit, the take of a federally listed protected species is punishable by fines or imprisonment.  
42 Permitting for taking of a state-listed species is regulated by the MDNR.

43 Analysis was also conducted for potential indirect effects on federally or state-listed species,  
44 such as increased competition for resources or habitat due to displacement of individuals from  
45 the affected area into the territory of other animals, or other indirect effects that cause mortality  
46 or reduced breeding and recruitment in the future population.

47 In addition to listed species, analysis was completed of potential direct and indirect effects on  
48 habitat types that affect population size and long-term viability for other species potentially at  
49 risk (SGCN, RFSS, and species of cultural concern). Direct effects could include vegetation  
50 removal by clearing, burial, or other destructive activity. Indirect effects could include changes  
51 within larger ecological units (e.g., the Laurentian Uplands or Partridge River Watershed), but  
52 not necessarily at the Mine Site or Plant Site, that could occur at a later point in time, such as a  
53 change in long-term vegetation composition or dominance, habitat conversion due to hydrologic  
54 changes, invasion by non-native species, or disruption of natural disturbance regimes (e.g., the  
55 annual natural hydrological cycle). Depending on the magnitude of the effect, direct effects may  
56 require mitigation.

### 57 **5.2.5.2 NorthMet Project Proposed Action**

58 This section describes the effects on wildlife due to construction and operation activities.

#### 59 **5.2.5.2.1 Federally Listed Species**

60 As required under Section 7 of the ESA, the USACE and the USFS have initiated consultation  
61 with the USFWS regarding potential effects on federally listed species to ensure that actions they  
62 authorize or permit would not jeopardize listed species or designated critical habitats.  
63 Consultation is currently ongoing and will continue throughout the EIS process.

64 A Biological Assessment has been prepared that contains further information about federally  
65 listed species. The Biological Assessment is included in Appendix D and is posted on the USFS  
66 website (<http://www.fs.usda.gov/goto/superior/northmet>). The Biological Assessment analyzes  
67 effects on the Canada lynx, gray wolf, and northern long-eared bat. The organization of the  
68 methodologies and discussion in the Biological Assessment may be different from the FEIS. The  
69 Biological Assessment also contains a determination of effects for the three species.

70 The Co-lead Agencies met with the USFWS several times during informal consultation. The  
71 USACE, USFS, and USFWS initiated informal consultation on February 26, 2010, when the  
72 agencies met to discuss the NorthMet Project. The USACE subsequently met with the USFWS  
73 on May 3, 2011, September 1, 2011, and February 28, 2013 to discuss it further. The USACE,  
74 USFS, and USFWS met on July 9, 2014 to identify tasks to be accomplished in the development  
75 of the Biological Assessment. Specifically, the northern long-eared bat and habitat were  
76 discussed, which led to further USFS bat survey work being proposed. The USACE, USFS, and  
77 USFWS met on October 29, 2014 to discuss comments received on the draft Biological  
78 Assessment and potential mitigation measures.

#### 79 **Canada Lynx**

80 In 2009, it was estimated that there were likely fewer than 200 lynx in Minnesota (Moen 2009).  
81 However, individuals can travel well beyond their home range, specifically when prey is scarce,  
82 at times more than 1,000 km (Moen 2010). Three individual lynx have been harvested in  
83 Ontario, approximately 400 road miles from their known locations in Minnesota. Of the 55

84 incidental take records the USFWS has documented from 2001 through 2013, two of the records  
85 involved lynx killed by trains, and seven of the records involved lynx struck by vehicle traffic  
86 along roads (USFWS 2013).

87 The NorthMet Project area is currently within the 8,065 square mile designated critical habitat  
88 for the Canada lynx (USFWS 2009), which includes much of St. Louis, Lake, and Cook  
89 counties. Surveys identified at least 20 different individual lynx were identified within 18 miles  
90 (ENSR 2006), and lynx sign was observed on the Mine Site in 2010. A collared and studied lynx,  
91 L11, was identified adjacent to the NorthMet Project area, south of Dunka Road. This animal  
92 may have been using the NorthMet Project area for forage and travel as part of her home range  
93 between when she was collared in early 2004 and when she was trapped in Ontario, Canada in  
94 2006. Lynx tracks were observed at the Mine Site in 2010, and there have been multiple  
95 observations of lynx sign within 5 miles of the federal lands (USFS 2013).

96 Site clearing and mining activities associated with the NorthMet Project Proposed Action would  
97 potentially affect lynx by reducing available habitat and increasing habitat fragmentation. The  
98 total effect from increased activity is not known, as lynx have been known to habituate to  
99 increased human activity (Sunde et al. 1998). The NorthMet Project Proposed Action mining  
100 activities would disturb approximately 2 square miles (1,454.0 acres) of suitable lynx habitat,  
101 currently a mix of upland forest and lowland forest and bog. Restoration of disturbed areas as  
102 part of mine closure would eventually create potential lynx habitat, although this successional  
103 process could take decades. Potential lynx habitat would be lost for the duration of mine  
104 operations (over 20 years) and an additional 20 years or more after closure before suitable lynx  
105 habitat would again occur at the Mine Site (ENSR 2006).

106 Assuming that the territory of a resident lynx is 58 square miles for males and 28 square miles  
107 for females, the reduction of habitat at the Mine Site corresponds to a reduction of three to seven  
108 percent of an individual's territory (ENSR 2006). Territory size expands in response to periods  
109 of reduced snowshoe hare density, and the related lynx and snowshoe hare populations tend to  
110 loosely follow a 10-year cycle, though other factors contribute to lynx population shifts. ENSR  
111 2006 surveys for the NorthMet Project Proposed Action were done during a low point in the  
112 lynx/snowshoe hare density cycle.

113 Though no lynx were identified during the ENSR 2006 surveys, those that may currently be  
114 using the Mine Site could expand their territory into surrounding areas. Surveys conducted in  
115 2006 by Moen et al. found evidence of at least 20 individuals within 18 miles of the NorthMet  
116 Project area, and lynx sign has been observed on the Mine Site by the USFS. Lynx density in the  
117 vicinity is considered low relative to the rest of the Minnesota lynx range (ENSR 2006).  
118 Individuals displaced from the Mine Site may be affected by increased stress and potential  
119 mortality due to utilization of unfamiliar territory and competition with other lynx or predator  
120 species. Although the NorthMet Project Proposed Action would result in a reduction and  
121 fragmentation of lynx habitat at the Mine Site, little to no effect on statewide lynx populations  
122 would occur as it is unlikely that an individual lynx or pair of lynx would be affected by the  
123 habitat decrease.

124 According to the USFS, LAUs are land areas identified for purposes of analysis and  
125 development of conservation measures for lynx (USFS 2004b). They range in size from just  
126 under 17,000 acres up to more than 91,000 acres. As discussed in Section 4.2.5.2.1, the federal  
127 lands (including the Mine Site) are located within LAU 12.

128 The USFS determined that approximately 2,737 acres, or 4.0 percent of LAU 12 is currently  
 129 unsuitable for lynx use (USFS 2013). As noted above, the NorthMet Project Proposed Action  
 130 would disturb 1,454 acres of lynx habitat, making them unsuitable for lynx. The percent of LAU  
 131 12 unsuitable for lynx would increase to 6.1 percent. This percentage is well within the Forest  
 132 Plan guideline (G-WL-3) that unsuitable habitat is not exceed 30 percent of the LAU.

133 The increased vehicle traffic associated with the NorthMet Project Proposed Action mining  
 134 activities could affect species such as the lynx. An average of 2,066 miles per day of vehicular  
 135 traffic is expected within the Mine Site, primarily to haul ore to the rail siding and waste rock to  
 136 the stockpiles (see Table 5.2.5-1).

137 **Table 5.2.5-1 Vehicle Traffic within the Mine Site Only**

| Vehicle type                          | Vehicle Weight (Tons) | Speed (Average MPH) | Total Road Miles in Mine Site | Annual Vehicle Miles Traveled (Estimated) | Estimated Average Total Miles Per Day (Estimated) |
|---------------------------------------|-----------------------|---------------------|-------------------------------|-------------------------------------------|---------------------------------------------------|
| Haul Trucks and Construction Vehicles | 81.5-425              | 12-14               | 15.3                          | 61,400-979,000                            | 2,066.0                                           |

138 Source: Barr 2012g.

139 Although there is the potential for incidental take as a result of vehicle collisions with lynx, haul  
 140 traffic at the Mine Site would likely have little direct effect on lynx. Current lynx use of the Mine  
 141 Site appears to be very low; in the future, the area would be heavily affected by mining  
 142 operations and not likely to be used by lynx.

143 The NorthMet Project area is currently within designated critical habitat for the Canada lynx  
 144 (USFS 2008a). Lynx may be affected by increased vehicle and train traffic. Lynx are highly  
 145 mobile and lynx habitat can be found immediately adjacent to the corridor. The increased vehicle  
 146 traffic associated with the NorthMet Project Proposed Action, including train and small vehicle  
 147 traffic between the Mine Site and Plant Site, could potentially result in vehicle collisions with  
 148 lynx (see Table 5.2.5-2). The NorthMet Project Proposed Action would generate 1,734.9 miles of  
 149 vehicle traffic between the Mine Site and Plant Site each day. This traffic would consist  
 150 primarily of light trucks and maintenance vehicles traveling 30 to 45 mph and a few large fuel  
 151 trucks, waste/supply trucks, and trains traveling 15 to 40 mph.

152 **Table 5.2.5-2 Vehicular and Train Traffic Volume along the Transportation and Utility**  
 153 **Corridor**

| Vehicle Type                                                       | Vehicle Weight (Tons) | Speed (Min – Max MPH) | Total Miles (Per Day) |
|--------------------------------------------------------------------|-----------------------|-----------------------|-----------------------|
| Light Cars, Trucks, and Vans – primarily Mine Site to Area 2 Shops | 2                     | 30-45                 | 961.1                 |
| Fuel Trucks, Supply and Waste Trucks                               | 40                    | 25-40                 | 346.7                 |
| Haul Trucks                                                        | 81.5 – 240            | 35                    | 9.1                   |
| Trains                                                             | 3,000                 | 15-25                 | 418.0                 |
| <b>Total</b>                                                       |                       |                       | <b>1,734.9</b>        |

154 Source: Barr 2012g.

155 Though vehicle traffic increases the chance of incidental lynx mortality, this species does not  
 156 rely strictly upon roads for long-distance travel, though they use less energy doing so (Moens  
 157 2010). Straight-line movement of collared lynx through the roadless BWCAW suggests that

158 when roads are not available, lynx will still travel in a line where possible. As such, while lynx  
159 may be affected by vehicle traffic along the Transportation and Utility Corridor, the flat terrain  
160 near the NorthMet Project area would allow lynx to travel through the area.

161 Evidence of lynx was not found during surveys of the Plant Site. Approximately 76 percent of  
162 the Plant Site cover/habitat type is disturbed or aquatic, which is considered unsuitable lynx  
163 habitat. Lynx are unlikely to utilize the Plant Site, but may forage in the surrounding area. As  
164 such, activities at the Plant Site are unlikely to affect the Canada lynx.

165 State and federal forest lands near the Mine Site or Plant Site would continue to provide refuge  
166 for lynx, and it is likely lynx would favor these areas over those affected by mining for the  
167 duration of mine operations. Overall, the effects on the Canada lynx described above would  
168 result in the localized direct decrease and fragmentation of habitat, including designated critical  
169 habitat, and the increased potential (albeit low) for incidental take resulting from vehicular  
170 collisions; however, these effects are not anticipated to threaten the overall species population  
171 level and abundance in Minnesota. The Biological Assessment concludes that the NorthMet  
172 Project Proposed Action would be likely to adversely affect the Canada lynx and may affect but  
173 is not likely to adversely affect Canada lynx critical habitat.

#### 174 **Gray Wolf**

175 As noted in Section 4.2.5, the Mine Site and Plant Site are likely part of a territory occupied by a  
176 single pack of wolves. The footprint of the Mine Site would remove approximately two square  
177 miles (1,454 acres) of habitat, or one percent to a maximum of ten percent of a single wolf pack  
178 territory. This reduction in available habitat is small and is not expected to affect the highly  
179 mobile wolf population in the region, which is considered healthy by the MDNR. After closure,  
180 this area would again be available and suitable as wolf habitat, but, as described above for the  
181 lynx, this would not occur for 40 to 45 years.

182 Vehicle collisions are a cause of wolf mortality (Fuller and Harrison 2005). The increased  
183 vehicular activity associated with the NorthMet Project Proposed Action could potentially result  
184 in vehicle collisions with wolves. The haul road network would increase the road density (linear  
185 miles of road per square mile of habitat) at the Mine Site; however, mining operations would  
186 disturb the Mine Site such that it would reduce habitat availability for the gray wolf. Therefore,  
187 the haul road network itself would not influence the overall effects of the NorthMet Project  
188 Proposed Action on the gray wolf.

189 State and federal forest lands near the Mine Site or Plant Site would continue to provide refuge  
190 for wolves, and it is likely wolves would favor these areas over those affected by mining for the  
191 duration of mine operations. The gray wolf population in Minnesota (estimated at 2,922,423 gray  
192 wolves) is considered fully recovered by the MDNR as it has surpassed the federal delisting goal  
193 of 1,251 to 1,400 wolves. However, the gray wolf was re-listed as federally threatened by the  
194 U.S. District Court on December 19, 2014.

195 Overall the effects described above would result in the direct decrease and fragmentation of  
196 habitat suitable for the gray wolf, the increased potential for incidental take from vehicular  
197 collisions, and indirect decline in prey species due to habitat decrease. Together these factors are  
198 not anticipated to threaten the overall species population level and abundance in Minnesota. The  
199 Biological Assessment concludes that the NorthMet Project Proposed Action would be likely to  
200 adversely affect the gray wolf but is not likely to jeopardize the continued existence of gray

201 wolves. It also concluded that the NorthMet Project Proposed Action and may affect but is not  
202 likely to adversely affect gray wolf critical habitat.

203 **Northern Long-Eared Bat**

204 Northern long-eared bats were detected in surveys throughout much of northeastern Minnesota  
205 (USFS 2014; Grandmaison et al. 2013; USFS 2014c). The most prominent threat to the northern  
206 long-eared bat is white-nose syndrome. The fungus known to cause white-nose syndrome,  
207 *Pseudogymnoascus destructans*, has been observed in the Tower/Soudan Mine, a hibernacula for  
208 several bat species located about 15 miles northwest of the NorthMet Project area. White-nose  
209 syndrome has advanced geographically from New York in 2006, causing 99 percent decreases in  
210 population numbers in the northeast United States (USFWS 2013b).

211 Bats may forage along the forest edge habitat along the Transportation and Utility Corridor, but  
212 there are no caves or mine shafts present that may be used for hibernation. Abel (2011) generally  
213 found that bat foraging activity is highest near aquatic features. Forest edges along utility  
214 corridors are also used for bat foraging, and they may forage along these features more  
215 frequently than in interior forest habitat. Generally, the West Pit, water treatment ponds, and  
216 Tailings Basin pond would not offer suitable habitat for emerging insects. Bats would be more  
217 likely to forage above natural wetlands that support more insect activity. Bats have been  
218 observed in Plant Site buildings, but do not hibernate or roost in great numbers at the Plant Site.  
219 Approximately eight percent of the Plant Site also contains possible tree roosting habitat that  
220 would be affected.

221 At the Mine Site, 1,718.6 acres would be disturbed due to the NorthMet Project Proposed  
222 Action, of which approximately 90 percent would be upland or lowland deciduous/coniferous  
223 forests and aquatic areas that could be utilized by the northern long-eared bat. Forest clearing  
224 activities at the Mine Site are likely to affect northern long-eared bat individuals as there would  
225 be a loss of potential summer roost habitat and foraging areas. The interim 4(d) rule (50 CFR  
226 Part 17, April 2, 2015) specifies that forest clearing activities may not occur within the summer  
227 maternity roosting season within one quarter mile of known occupied roost trees. Tree removal  
228 outside of the summer maternity roosting season (June 1 through July 31) would help mitigate  
229 and reduce lethal take of northern long-eared bat individuals.

230 Resuming operations at the Plant Site buildings would likely disrupt the bat's use of them for  
231 roosting. The NorthMet Project Proposed Action is not expected to affect bat hibernacula, as  
232 none have been observed on the Mine Site, Transportation and Utility Corridor, or Plant Site, but  
233 would reduce potential roosting and foraging habitat. The Biological Assessment concludes that  
234 the NorthMet Project Proposed Action may affect but is not likely to adversely affect the  
235 northern long-eared bat. The Biological Assessment contains additional details on effects to the  
236 northern long-eared bat.

237 **5.2.5.2.2 State-listed Species**

238 Rulemaking was conducted with the intent to update the list of ETSC species (*Minnesota Rules*,  
239 part 6134.0100 to 6134.0400), with new listings becoming effective on August 19, 2013 (MDNR  
240 2013h). This FEIS considers any new listings, or changes in the previous listings, associated with  
241 the updated list.

242

243 **Moose**

244 There is habitat available for the moose on the Mine Site, and individuals and their sign (e.g.,  
245 tracks, droppings, browsing evidence, etc.) have been observed on it. This is in close proximity  
246 to the Transportation and Utility Corridor and Plant Site. Due to the primarily disturbed nature of  
247 these latter areas, it is likely that moose occur but unlikely that they utilize the areas often.  
248 Habitat fragmentation and loss, climate change, disease, and predation are all potential factors in  
249 moose population decline (MDNR 2013d). The key habitat types considered moose habitat  
250 include mature forest, grassland/brushland, and aquatic environments. A total of 2,785.9 acres of  
251 these key habitat types would be directly affected by the NorthMet Project Proposed Action (see  
252 Table 5.2.5-3). As such, the NorthMet Project Proposed Action would likely affect moose  
253 individuals in the vicinity through habitat loss and fragmentation, though not likely at a  
254 population level.

255 **Little Brown Bat**

256 The little brown bat is known to occur at the Mine Site, Transportation and Utility Corridor, and  
257 Plant Site. As a habitat generalist, it has suitable foraging and potential roosting habitat in these  
258 three areas. Of the bats observed in the NorthMet Project area and in northeastern Minnesota, the  
259 majority are little brown bat (USFS 2014; Grandmaison et al. 2013; USFS 2014c). The most  
260 prominent threat to the little brown bat is white-nose syndrome. The fungus known to cause  
261 white-nose syndrome, *Pseudogymnoascus destructans*, which has been observed in the  
262 Tower/Soudan Mine, a hibernacula for several bat species located about 15 miles northwest of  
263 the NorthMet Project area. As discussed above in Section 5.2.5.2.1 for the northern long-eared  
264 bat, white-nose syndrome has caused 99 percent decreases in bat populations throughout the  
265 northeast U.S. where it originated (USFWS 2013b). No known hibernacula sites would be  
266 disturbed as a result of the NorthMet Project Proposed Action. It is expected that the reduction of  
267 foraging and potential summer roosting habitat would affect individuals, but likely not at a  
268 population level.

269 **Eastern Pipistrelle**

270 Potential summer roosting habitat is available for the eastern pipistrelle at the Mine Site,  
271 Transportation and Utility Corridor, and Plant Site. However, no individuals have been observed  
272 or detected within any of these areas during field surveys. USFS surveys from the Kawishiwi  
273 District in 2013 and St. Louis/Lake counties in 2014 did not detect eastern pipistrelle  
274 (Grandmaison et al. 2013; USFS 2014c). As with the bats discussed above, the most prominent  
275 threat to the eastern pipistrelle is white-nose syndrome. It is unlikely that the species would be  
276 affected by the NorthMet Project Proposed Action, as none are known to occur in the area, and  
277 no known hibernacula sites would be disturbed.

278 **Northern Goshawk**

279 The northern goshawk may occasionally be present at the Mine Site, since nest sites have been  
280 identified by the USFS approximately 0.75 mile west of the Mine Site and near the proposed  
281 East Pit and Central Pit areas. Two northern goshawk territories have been identified at or near  
282 the Mine Site, as they have nested on the Mine Site and adjacent federal lands in 2000, 2009,  
283 2011, and 2013 (USFS 2013). The One Hundred Mile Swamp northern goshawk territory, which  
284 is within the Mine Site, is no longer considered active. The Wetlegs Creek northern goshawk

285 territory, located on the federal lands adjacent to the Mine Site, is still considered active and is  
286 being monitored. The NorthMet Project Proposed Action would directly affect one of the two  
287 known nest site areas. The northern goshawk may be occasionally present along the  
288 Transportation and Utility Corridor, due to the proximity of the active northern goshawk  
289 territory. No nests are known to occur at the Plant Site. Because the northern goshawk has nested  
290 in the NorthMet Project area and was identified during calling surveys, activities at the Mine Site  
291 may affect the northern goshawk due to loss of habitat.

292 **Boreal Owl**

293 There is suitable habitat available for the boreal owl at the Mine Site and along the  
294 Transportation and Utility Corridor. An individual was heard along Dunka Road in 1988 to 1989,  
295 but none were observed in subsequent surveys. Since the Minnesota NHIS does not contain any  
296 occurrences within 10 miles of the NorthMet Project area, and they have not been observed since  
297 1988 to 1989, it is unlikely that boreal owls utilize the Mine Site, Transportation and Utility  
298 Corridor, or Plant Site often. The NorthMet Project area is located at the southern edge of its  
299 range. The removal of mixed forest habitats at the Mine Site and along the Transportation and  
300 Utility Corridor is unlikely to jeopardize the boreal owl's presence in Minnesota.

301 **Wood Turtle**

302 There is no habitat suitable for wood turtles at the Mine Site and no individuals are known to  
303 occur. Individuals could potentially use the southern riparian fringe of the Mine Site though no  
304 wood turtles are currently known to occur in the fringe areas that would be affected by the  
305 project. The fringe areas would also not be affected by activities at the Transportation and Utility  
306 Corridor. There is no suitable habitat for wood turtles at the Plant Site and no individuals are  
307 known to occur.

308 The predicted small decrease in Upper Partridge River flow during active mining is not likely to  
309 negatively affect the wood turtle. The most likely effect of a decrease in water level would be to  
310 expose additional nesting areas. Over the long term, the exposed soil on the lower bank would be  
311 overtaken by vegetation from the upper bank and become less suitable habitat for the wood  
312 turtle.

313 Wood turtles are not likely to be affected by project activities because there would be no direct  
314 loss of individuals, populations, or suitable habitat and the NorthMet Project Proposed Action  
315 would have no indirect effects on downstream habitat.

316 **Eastern Heather Vole**

317 The eastern heather vole has not been observed within 10 miles of the Mine Site nor has it been  
318 found in small mammal surveys in the region (Christian 1993; Jannett 1998). The NorthMet  
319 Project area is at the southern edge of its range. Approximately 1,445 acres of potentially  
320 suitable habitat exist at the Mine Site (see Table 4.2.4-1), and there is potentially suitable habitat  
321 for the species along the Transportation and Utility Corridor. Additionally, there is potentially  
322 suitable habitat for the eastern heather vole at the Plant Site, 45 percent of which may be affected  
323 by the NorthMet Project Proposed Action (see Table 5.2.4-6). The eastern heather vole could be  
324 present at the NorthMet Project area, but, if so, it is likely to be in very small numbers. Given the  
325 lack of known occurrences of eastern heather vole in the area, the habitat effects are unlikely to  
326 jeopardize the presence of eastern heather vole in Minnesota.

327 **Yellow Rail**

328 The yellow rail was not found during PolyMet's surveys at the Mine Site and was not reported in  
329 the NHIS database within 10 miles of the NorthMet Project area. Small, scattered areas of its  
330 preferred habitat, sedge/wet meadow, are present at the Mine Site, but the minimum nesting  
331 patch size used by rails (54 acres) (Goldade et al. 2002) exceeds the total amount of suitable  
332 habitat available (39.5 acres at the Mine Site and 1.5 acres at the Plant Site; refer to Section  
333 4.2.3). Since the yellow rail was not detected in surveys and patches of its preferred habitat are  
334 smaller than the reported minimum patch size for nesting, it is not expected that the NorthMet  
335 Project Proposed Action would affect the yellow rail.

336 **Laurentian Tiger Beetle**

337 The lack of suitable habitat and any NHIS recorded observations in the NorthMet Project area  
338 for the tiger beetle suggest that the species does not occur at the Mine Site, Plant Site, or  
339 Transportation and Utility Corridor. Therefore, the NorthMet Project Proposed Action should  
340 have no effect on the tiger beetle.

341 **Taiga Alpine**

342 The taiga alpine butterfly was not observed during surveys and the NHIS has no records of one  
343 occurring within 10 miles of the NorthMet Project area. The preferred habitat types (black spruce  
344 bogs and swamps) do occur on the Mine Site and in proximity to the Transportation and Utility  
345 Corridor and Plant Site. The NorthMet Project Proposed Action may affect individuals but would  
346 not likely have any effect on the species at a population level.

347 **Freija's Grizzled Skipper**

348 The Freija's grizzled skipper butterfly was not observed during surveys and the NHIS has no  
349 records of the species occurring within 10 miles of the NorthMet Project area. The only known  
350 Minnesota occurrence is in Lake County. The preferred habitat types (forest openings bordered  
351 by black spruce and tamarack swamps) do occur on the Mine Site and in proximity to the  
352 Transportation and Utility Corridor and Plant Site. The NorthMet Project Proposed Action may  
353 affect individuals but would not likely have any effect on the species at a population level.

354 **Nabokov's Blue**

355 The Nabokov's blue butterfly was not observed during surveys and the NHIS has no records of  
356 one occurring within 10 miles of the NorthMet Project area. The preferred habitat type for the  
357 larval butterfly (open woodlands with abundant dwarf bilberry) potentially occurs on the Mine  
358 Site, Transportation and Utility Corridor, or Plant Site. The NorthMet Project Proposed Action  
359 may affect individuals but would not likely have any effect on the species at a population level.

360 **Quebec Emerald**

361 The Quebec emerald dragonfly inhabits poor fens, a wetland type not identified at the Mine Site  
362 but similar to the sedge/wet meadow that is present. Approximately 38.2 of the existing 39.5  
363 acres of wet meadow/sedge meadow at the Mine Site would be affected by mining activities.  
364 There are no poor fens found along the Transportation and Utility Corridor or Plant Site, though  
365 approximately 1.5 acres of sedge/wet meadow are present at the Plant Site, and 1.4 acres would  
366 be affected by activities. There has only been one documented occurrence of this species in

367 Minnesota (Lake County in 2006, more than 20 miles east of the NorthMet Project area)  
368 (Minnesota Odonata Survey Project 2012); therefore, the likelihood of observing Quebec  
369 emerald dragonfly individuals or populations within the vicinity of the NorthMet Project area is  
370 low. As such, this species is not expected to be affected.

### 371 **5.2.5.2.3 Species of Greatest Conservation Need**

372 Along with federally and state-listed species, the NorthMet Project Proposed Action would affect  
373 SGCN at the Mine Site as a result of increased human activity and noise, collisions with  
374 vehicular and rail traffic, and decrease of habitat. Due to the number of SGCN species identified  
375 (see Table 4.2.5-1) effects are classified below by the type of disturbance.

#### 376 **Increased Human Activity**

377 SGCN would be directly affected through increased human activity due to mining activities.  
378 Factors such as noise, dust, light, and vehicle traffic may frighten some species and discourage  
379 their use of otherwise suitable habitat. In general, suitable habitat is available in the area adjacent  
380 to the NorthMet Project area and most mobile wildlife species would be displaced. Following  
381 migration to new areas, displaced individuals could increase the competition for resources in  
382 their new habitat. Displaced species could also suffer increased mortality due to foraging in new  
383 areas. Less mobile species, such as herptiles (e.g., frogs, turtles), would likely incur relatively  
384 high mortality rates since they cannot quickly migrate from the area and would be more  
385 susceptible to changing habitat conditions. During the winter, a combination of plowing and  
386 sand, gravel, or salt (magnesium chloride) applications would be used to keep roadways  
387 passable. The potential exists for sand and salts to accumulate in the trenches adjacent to the  
388 roadways and affect less mobile species. These areas are not considered high quality habitat and  
389 are not likely to affect wildlife.

390 Effects on wildlife due to trapping and hunting are minimal because public access would be  
391 restricted. Through the Land Exchange Proposed Action, NorthMet Project area lands would  
392 enter into private ownership and would not be accessible for public use. As discussed in Section  
393 5.2.11.2.1, public access is limited and would remain limited during mining operations and  
394 following mine closure. As such, wildlife species are not likely to be affected by changes in  
395 hunting and trapping activity.

396 Ground-nesting bird species and some raptor species have been known to utilize cliff areas for  
397 nesting and foraging. The SGCN include the northern goshawk, common nighthawk, and  
398 northern harrier. These birds could be affected by disturbance if they were to nest along the cliffs  
399 created by the pit rims.

#### 400 **Noise Effects**

401 The Biological Assessment concludes that noise effects on wildlife are largely unknown and the  
402 assessment of effects is subjective. However, noise associated with mining activities, including  
403 noise from vehicle and rail traffic, would likely affect wildlife. Mammals can be sensitive to  
404 sound levels below the range of human hearing, which is 20-16,000 hertz. The sensitivity  
405 thresholds for animals are generally lower, some below 20 hertz (US FHWA 2011). Effects due  
406 to acute noise (such as blasting) are not well studied, but would likely cause animals to startle  
407 and would interrupt forage or nesting activities (Larkin 1994). Noise does not appear to seriously  
408 affect invertebrates or fish, but does result in some disturbance to mammals (such as startling,

409 forage interruption, and avoidance of the area of potential effect [Larkin 1994]). Bird  
410 communication would be masked by noise if the vocalizations are less than 18-20 dB above  
411 noise levels in the environment (US FHWA 2011). Changes in communication have been known  
412 to result in decreased reproduction and anomalies in learned vocalizations (Larkin 1994).  
413 Songbird populations have been shown to decrease with noise levels as low as 35 dB (Forman  
414 and Alexander 1998). Section 5.2.8 provides further discussion on the noise modeling  
415 predictions for the NorthMet Project area. Though wildlife species are likely to be sensitive to  
416 changes in noise levels, there are no local, national, or international standards or limits that are  
417 applicable to the NorthMet Project Proposed Action. Wildlife species may be affected by noise  
418 in the NorthMet Project area, though adjacent habitat is available.

#### 419 **Vehicular and Rail Traffic Effects**

420 Wildlife mortality generally increases with increasing traffic volumes and vehicle speed. In  
421 general, highly mobile species and habitat generalists (species that utilize a wide variety of  
422 habitats) are known to have higher road mortalities.

423 As discussed above, vehicular traffic would average 2,066 miles per day within the Mine Site  
424 (see Table 5.2.5-1). Traffic effects from collisions with wildlife depend upon factors such as  
425 traffic volume, traffic speed, and the species involved. The potential for road effects increases if  
426 the roads are bordered by high-quality habitat or are crossed by wildlife travel corridors. The  
427 high density of affected wetlands at the Mine Site bordering the haul roads may result in a  
428 relatively high rate of amphibian and reptile effects. Shrubs and trees near roadsides can increase  
429 road crossings by deer and birds. The barrier effect of roads is greater for small mammals,  
430 amphibians, and reptiles than for birds and large mammals (Kaselloo 2004). Species that utilize  
431 the small preserved forest island remnants between haul roads at the Mine Site would be most  
432 affected. Indirect effects from vehicle activities are expected locally at the Mine Site for SGCN  
433 species but would not be measurable at the scale of the Nashwauk and Laurentian Uplands or the  
434 Partridge River Watershed.

435 Effects at the Transportation and Utility Corridor are primarily related to vehicle and rail traffic.  
436 Travel between the Mine Site and Plant Site is expected to average 1,735 miles per day with  
437 travel speeds averaging between 15 and 45 mph, with trains, fuel, and waste/supply trucks  
438 traveling somewhat slower (see Table 5.2.5-2). SGCN may be affected by noise and light  
439 associated with vehicle and rail traffic, and by collisions with vehicles or trains.

440 Transportation effects at the Plant Site are primarily related to vehicle traffic associated with  
441 construction of the NorthMet Project Proposed Action. Typical daily operations at the Plant Site  
442 would generate approximately 828 miles of vehicle traffic, primarily light trucks. Though noise  
443 and light may affect SGCN at the Plant Site, the disturbed nature of the area would mean that  
444 effects would be negligible.

#### 445 **Wildlife Habitat Effects**

446 The direct effect on wildlife habitat (and by inference on SGCN species) was assessed by  
447 evaluating the acres of habitat types that would be lost under the NorthMet Project Proposed  
448 Action (see Figure 4.2.4-3). The changes in cover type are summarized in Table 5.2.5-3.

449 **Table 5.2.5-3 Direct Effects on Key Habitat Types**

| <b>Key Habitat Types</b>                                         | <b>Total Acres<sup>1</sup> of Cover Type Present at Mine Site (Total Acres<sup>1</sup> of Cover Type Directly Affected)</b> | <b>Total Acres<sup>1</sup> of Cover Type Present at Transportation and Utility Corridor (Total Acres<sup>1</sup> of Cover Type Directly Affected)</b> | <b>Total Acres<sup>1</sup> of Cover Type Present at Plant Site (Total Acres<sup>1</sup> of Cover Type Directly Affected)</b> |
|------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------|
| Mature Upland Forest, Continuous Upland/Lowland Forest (MIH1-13) | 2,627.2 (1,535.3)                                                                                                           | 5.5 (5.5)                                                                                                                                             | 789.3 (367.8)                                                                                                                |
| Open Ground, Bare Soils (no MIH)                                 | 128.0 (44.0)                                                                                                                | 94.4 (94.4)                                                                                                                                           | 2,755.5 (1,104.0)                                                                                                            |
| Grassland and Brushland, Early Successional Forest (no MIH)      | 246.6 (133.2)                                                                                                               | 17.5 (17.5)                                                                                                                                           | 333.8 (144.9)                                                                                                                |
| Aquatic Environments (MIH 14)                                    | 12.7 (6.0)                                                                                                                  | 2.7 (2.7)                                                                                                                                             | 636.8 (573.0)                                                                                                                |
| <b>Total</b>                                                     | <b>3,014.5 (1,718.6)</b>                                                                                                    | <b>120.1 (120.1)</b>                                                                                                                                  | <b>4,515.4 (2,189.7)</b>                                                                                                     |

450 Data from Tables 5.2.4-1, 5.2.4-4, and 5.2.4-6.

451 Note:

452 <sup>1</sup> Total acres may be more or less than presented due to rounding.

453 **Mature Upland/Lowland Forest**

454 At the Mine Site, approximately 1,535 acres (58 percent) of the mature forest would be lost as a  
 455 result of the NorthMet Project Proposed Action. All of the SGCN found in this mature upland  
 456 forest habitat are birds (see Table 4.2.5-1), which would be displaced, but likely not injured or  
 457 killed, during mine construction and operation. Nesting birds could be affected during the  
 458 breeding season, especially during brooding and until fledglings become independent.  
 459 Reclamation of the Mine Site would include revegetating nearly all disturbed ground according  
 460 to *Minnesota Rules*, part 6132.2700.

461 Of the 5.5 acres of mature upland/lowland forest along the Transportation and Utility Corridor,  
 462 all 5.5 acres would be affected. As such, activities would affect SGCN in mature upland/lowland  
 463 forest habitat along the Transportation and Utility Corridor, though effects would be narrow and  
 464 primarily located along the corridor.

465 Most of the Plant Site is developed or disturbed with only approximately 17 percent (789 acres)  
 466 consisting of forest habitat (see Table 5.2.5-3). Approximately 368 acres of this forest habitat at  
 467 the Plant Site would be disturbed, most of which is in small or isolated patches of aspen-birch  
 468 forest that are in poor to fair condition (MDNR 2013a). Therefore, activities at the Plant Site  
 469 would not have an effect on SGCN using mature upland/lowland forest habitat.

470 Reclamation and revegetation of the NorthMet Project area would initiate vegetative succession  
 471 on stockpiles, the East Pit and Central Pit, and Mine Site infrastructure (PolyMet 2015h). The  
 472 Category 1 Stockpile would be incrementally and progressively reclaimed throughout the life of  
 473 the mine through contouring the stockpile to provide topographic variety, covering with a layer  
 474 of evapotranspiration soil, and finally seeding of grasses and forbs.

475 Reclamation and re-vegetation of the NorthMet Project area would improve wildlife habitat  
476 relative to conditions during mine operations; however, the quality of habitat for SGCN is likely  
477 to remain degraded for some decades after closure relative to pre-mining operations due to  
478 conversion of high-quality habitat to lower-quality habitat.

479 **Open Ground/Bare Soils**

480 The likelihood of SGCN using open ground or bare soils at the Mine Site, Transportation and  
481 Utility Corridor, or Plant Site is small. These areas were the result of past mining activity, are  
482 generally of low-quality, and are expected to decrease after mine closure as a result of  
483 reclamation.

484 Therefore, NorthMet Project Proposed Action effects on open ground/bare ground habitat should  
485 result in little effect on wildlife.

486 **Brush/Grassland**

487 Approximately 133 of the 247 total acres (54 percent) of brush/grassland at the Mine Site would  
488 be directly affected by the NorthMet Project Proposed Action. Brush and grassland (including  
489 early successional forest) at the Mine Site and Plant Site consist of small vegetative patches that  
490 are generally not suitable for SGCN. Young trees (less than 4 inches dbh) make up most of this  
491 habitat type (ENSR 2005). One SGCN associated with this habitat type, the American  
492 woodcock, was observed by USFS personnel at the Mine Site. The least weasel may occur as  
493 well. Most of the other SGCN (see Table 4.2.5-1) are associated with large patches of grassland  
494 and savanna habitats, which are not present at the Mine Site.

495 Stands of brush/grassland (including early successional forest) along the Transportation and  
496 Utility Corridor consist of small vegetative patches that are generally not suitable to SGCN.  
497 Young trees (less than 4 inches dbh) make up most of this habitat type (ENSR 2005). Most of the  
498 other SGCN (see Table 4.2.5-1) are associated with large patches of grassland and savanna  
499 habitats. Though all 17.5 acres of brush/grassland along the Transportation and Utility Corridor  
500 would be directly affected, activities along the Transportation and Utility Corridor would not  
501 affect grassland/brush SGCN based on the fragmented nature of this habitat.

502 Similar to the Mine Site, brush/grassland (including early successional forest) at the Plant Site  
503 consists of small vegetative patches that are generally not suitable to SGCN. Young trees (less  
504 than 4 inches dbh) make up most of this habitat type (ENSR 2005). Most of the other SGCN (see  
505 Table 4.2.5-1) are associated with large patches of grassland and savanna habitats.  
506 Approximately 145 of the 334 acres of brush/grassland at the Plant Site would be directly  
507 affected by the activities at the Plant Site. The reclaimed Plant Site, specifically the Tailings  
508 Basin, would be revegetated with grassland vegetation species. Overall, the NorthMet Project  
509 Proposed Action would have no adverse effects on grassland/brush SGCN.

510 During reclamation, PolyMet would remove or cover portions of the existing road, railroad, and  
511 ditch and dike systems and restore them. Reclamation of these areas, which currently constitute  
512 poor wildlife habitat, would ultimately enhance wildlife habitat when compared to current  
513 conditions. Some SGCN, such as the eastern meadowlark, northern harrier, and common  
514 nighthawk would most likely use the grasslands until they are replaced by early successional  
515 forest about 20 to 50 years after closure. Early successional forests are likely to support the two  
516 following SGCN: white-throated sparrow and American woodcock.

517 **Open Water**

518 SGCN such as the black duck, American bittern, and swamp sparrow utilize open water habitats.  
519 The NorthMet Project Proposed Action would create approximately 321 acres of open water at  
520 the Mine Site by eventually flooding the West Pit, which is estimated to fill between year 40 and  
521 45. The West Pit would be fenced as a deterrent to wildlife species even though this habitat is not  
522 likely to provide high quality foraging habitat for waterfowl because of a lack of emergent or  
523 submerged vegetation along the pit fringes. Ponds at the wastewater treatment facilities would  
524 also be fenced to prevent wildlife from using the water. At the Plant Site, open water habitat  
525 primarily occurs in the existing LTVSMC Tailings Basin. None of the SGCN targeted during a  
526 2005 survey were observed on open water during the survey (ENSR 2005); however, common  
527 waterfowl and water birds were observed at the Tailings Basin during migration, in particular  
528 Canada goose and ducks. Existing open water habitat would be maintained during operations,  
529 though the acreage of open water would fluctuate according to processing needs.

530 Wildlife, specifically aquatic birds, may utilize open water habitat created by the NorthMet  
531 Project Proposed Action. Wildlife species have been observed utilizing the existing LTVSMC  
532 Tailings Basin, as well as other Mesabi Iron Range tailings basins, specifically during migration.  
533 Unlike arid states such as Nevada, pit lakes and tailings basins are not the only readily available  
534 source of open water for wildlife use. Minnesota has over 13 million acres of lakes and wetlands,  
535 and the NorthMet Project Proposed Action would result in less than one hundredth of a percent  
536 increase in habitat. Though adjacent habitat is readily available, wildlife species may still utilize  
537 the Tailings Basin.

538 Some wildlife species, specifically those that feed on aquatic prey, may be susceptible to  
539 mercury exposure (USEPA 1997) directly from open water sources such as the pit lake and  
540 Tailings Basin pond, and indirectly at the Partridge River and Embarrass River. Effects to  
541 aquatic species are discussed in Section 5.2.6.2. Specific species such as loons, osprey, mink,  
542 and otter may be affected. As discussed in Section 5.2.5.2.2, eagles may be less likely to be  
543 affected by mercury. While wildlife use of open water created by the NorthMet Project Proposed  
544 Action may be limited due to fencing and available habitat, wildlife species may be affected.

545 Surface water quality standards do not apply to the pit lake or Tailings Basin. Any discharge  
546 water, such as the pit lake overtopping, would be treated in order to meet water quality standards  
547 and, as such, would not likely affect wildlife species.

548 **Wetlands**

549 Of the wetland-related SGCN, the marbled godwit and olive-sided flycatcher were surveyed for,  
550 but not found (ENSR 2005). The bog copper butterfly also was not found during surveys and  
551 there are no known NHIS records of any sightings within 12 miles of the Mine Site. As discussed  
552 above, the black duck, American bittern, and swamp sparrow are not likely to be present because  
553 they require open water and non-forested wetlands, which are relatively scarce at the Mine Site.  
554 The red-backed salamander is primarily an upland species, but may be present along the edges of  
555 mixed hardwood swamps. The taiga alpine butterfly may inhabit the black spruce bogs of the  
556 Mine Site and is historically known to occur in the Laurentian and Nashwauk Uplands (MDNR  
557 2006d).

558 Based on the site-specific wetland delineation, the NorthMet Project Proposed Action would  
559 directly affect 758.2 acres of wetlands at the Mine Site, primarily coniferous bog (508.3 acres

560 directly affected), shrub swamp (97.8 acres directly affected), and coniferous swamp (70.3 acres  
561 directly affected). These wetland types are common in the Partridge River Watershed.  
562 Consequently, the decrease of this habitat at the Mine Site is expected to displace wildlife into  
563 surrounding similar habitat, which would be large enough to absorb the displaced wildlife.

564 There are 7.2 acres of wetlands/open water along the Transportation and Utility Corridor, and  
565 those 7.2 acres would be affected by activities along the corridor. There are 148.4 acres of  
566 affected wetland at the Plant Site. On-site wetland use by the SGCN described above may be  
567 limited, and these wetlands are generally considered to be of low quality.

568 Wetland mitigation is proposed off-site at three mitigation sites (see Section 5.2.3). Off-site  
569 mitigation would consist of 1,602.7 acres of wetland restoration and preservation and 197.1 acres  
570 of upland buffer areas of various habitat types at the three sites. In addition, approximately 101.8  
571 acres of wetland may be restored on-site; however, this would not result in mitigation credits at  
572 this time.

### 573 **Multiple Habitats**

574 Species using multiple habitats and known to occur on or near the NorthMet Project area (e.g.,  
575 gray wolf, Canada lynx, least flycatcher, Connecticut warbler) are discussed above. Most  
576 multiple-habitat SGCN use mature/continuous and early successional forest. NorthMet Project  
577 Proposed Action effects are therefore largely limited to the mature/continuous forest habitats  
578 described above.

### 579 **Wildlife Corridors**

580 There is one wildlife corridor located approximately 0.5 mile northwest of the Mine Site (see  
581 Figure 6.2.5-2). Mine Site operations, which provide a source of disturbance from noise and  
582 mining activity, would indirectly affect the corridor by reducing the effective, undisturbed size of  
583 the large habitat block southeast of the corridor. These activities would limit access to the  
584 corridor in the vicinity of the Mine Site; however, the corridor would continue to be accessible  
585 north of the Mine Site and from south and southwest of the corridor. Vegetative restoration of  
586 the stockpiles and disturbed areas, as proposed during closure, would mitigate some of the  
587 effects of habitat loss in this large habitat block in the long term. Not all of the Mine Site would  
588 be available for habitat restoration due to fencing around the mine pits and the open water in the  
589 West Pit.

590 Rail and vehicular traffic between the Mine Site and Plant Site would increase as a result of the  
591 NorthMet Project Proposed Action. While the Transportation and Utility Corridor is outside of  
592 wildlife corridors, they run parallel and perpendicular to the wildlife corridors and would  
593 potentially affect wildlife use. Tepper (2011) demonstrates the importance of road ecology,  
594 which studies the barrier effect of roads on plant and animal ecology. Tepper cites several  
595 examples of road underpasses or overpasses to provide corridors for plant and wildlife  
596 movement without having to cross the roadways. However, these wildlife crossings generally  
597 require a large financial cost to construct. Leete and Alcott (2011) stated that Minnesota's  
598 relatively flat topography would not be suitable for large wildlife crossings, and suggested  
599 instead utilizing multiple low cost wildlife-friendly mitigation designs rather than one large  
600 crossing. Mitigation measures for wildlife species would be considered during the Endangered  
601 Species Act Section 7 consultation process.

602 Additionally, there is one wildlife corridor located approximately 1 mile southeast of the existing  
603 Plant Site. The existing LTVSMC Tailings Basin provides poor habitat, is not likely to be  
604 heavily used by wildlife, and currently obstructs animal movement. Because current use is  
605 already limited, increased activity at the Tailings Basin would likely have minimal effect on  
606 wildlife movement through the corridor. The proposed vegetative restoration of the Tailings  
607 Basin and adjacent processing plant at closure may increase the value of the corridor by  
608 improving habitat to the northwest. The mining features surrounding this corridor would not be  
609 complete barriers to wildlife movement (Barr 2009a).

#### 610 **5.2.5.2.4 Regional Forester Sensitive Species**

611 A Biological Evaluation has been prepared that contains further information about RFSS. The  
612 Biological Evaluation is included in Appendix D and is posted on the USFS website  
613 (<http://www.fs.usda.gov/goto/superior/northmet>). Similar to the Biological Assessment, the  
614 organization of the methodologies and discussion in the Biological Evaluation may be different  
615 from the FEIS. The Biological Evaluation also contains determinations of effect for RFSS  
616 species.

617 The USFS determined that the NorthMet Project Proposed Action may affect individuals but is  
618 not likely to cause a trend to federal listing or loss of viability for 18 RFSS terrestrial wildlife  
619 species on the Superior National Forest.

620 Of the 18 terrestrial RFSS on the 2011 list for the Superior National Forest, 12 of these are also  
621 federally- or state-listed ETSC species (gray wolf, eastern heather vole, northern long-eared bat,  
622 little brown bat, eastern pipistrelle, northern goshawk, boreal owl, wood turtle, taiga alpine  
623 butterfly, Freija's grizzled skipper butterfly, Nabokov's blue butterfly, and Quebec emerald) and  
624 are discussed above. Three other RFSS (the olive-sided flycatcher, bay-breasted warbler,  
625 Connecticut warbler) are on the SGCN list and are discussed by habitat type or disturbance type  
626 in Section 5.2.5.2.3 above. Three other species, including the bald eagle, great gray owl, and  
627 three-toed woodpecker are discussed below.

#### 628 **Bald Eagle**

629 Bald eagles typically nest in large trees within 500 ft of lakes or rivers (Guinn 2004). There are  
630 no large lakes or rivers at the Mine Site that would provide optimal nesting/ foraging habitat,  
631 though the Partridge River (approximately 0.5 mile south of the Mine Site) would provide some,  
632 though less-than-optimal, habitat. The Partridge River is 4.9 miles south of the Plant Site, and the  
633 Embarrass River is 2.5 miles north and west. The USFWS National Bald Eagle Management  
634 Guidelines (USFWS 2007) suggest that human activity within 0.25 mile to 2 miles can be seen  
635 or heard by eagles and, depending on the level of screening and habituation of individual eagles,  
636 may cause them to abandon a nest. Generally, the closer the activity is, the greater the effect. If  
637 eagles were to nest on the portion of the Partridge River or the Embarrass River near the  
638 NorthMet Project area, they could be within the 2-mile disturbance range. The nearest recorded  
639 bald eagle nest to the Mine Site is approximately 6.5 miles to the southeast (MDNR 2013a).

640 Bald eagle nesting territories in Minnesota generally have a 10-mile radius that varies with  
641 habitat quality (Guinn 2004). Bald eagle nests near the NorthMet Project area are on average 5.7  
642 miles apart (3.8 to 9.4 mile range), which is less than the average territory radius. This suggests  
643 that the area is densely populated with bald eagle nesting territories and that no new eagles are  
644 likely to move into the area (MDNR 2014d). As eagles become more numerous, any eagles

645 seeking to establish new territories in the area would need to select lower quality habitat and/or  
646 move into closer proximity to human activity.

647 Surface water contaminants (e.g., mercury) that are absorbed by prey species such as waterfowl  
648 via dietary exposure (e.g., through the consumption of fish) could lead to ingestion of  
649 contamination by eagles (Marr 2008). However, bald eagles are relatively insensitive to the toxic  
650 effect of mercury exposure through their food (Judd 2013). In addition, waterfowl and some  
651 birds of prey demethylate mercury, which reduces their potential exposure.

652 In summary, the NorthMet Project Proposed Action is not likely to affect bald eagles because the  
653 known nesting sites are more than 2 miles from the NorthMet Project area; optimal habitat for  
654 nesting and foraging bald eagles is not present at the Mine Site, Plant Site, or Transportation and  
655 Utility Corridor; and bald eagles are not sensitive to mercury exposure.

#### 656 **Great Gray Owl**

657 During owl surveys (AECOM 2009a), one great gray owl was observed foraging along the  
658 Transportation and Utility Corridor near the Mine Site. A great gray owl had used a historic  
659 goshawk nest at the Mine Site. Great gray owls nested in the NorthMet Project area in 2006  
660 (AECOM 2009a), 2010, and 2011 (USFS 2013). Owls are sensitive to disturbance, so  
661 populations would be unlikely to use the NorthMet Project area during mine operations, though  
662 the species may be affected by the NorthMet Project Proposed Action as it has been observed  
663 and has nested in the area.

#### 664 **Three-Toed Woodpecker**

665 Systematic survey data for three-toed woodpeckers are lacking; however, one bird was observed  
666 during overall field surveys (ENSR 2000) and by USFS personnel in 2007. Generally, the young  
667 age of the forest habitat at the Mine Site is not suitable for three-toed woodpeckers, and  
668 populations or individuals in the area are not likely to occur. Woodpeckers are sensitive to  
669 disturbance and would not be expected to use the Mine Site during mining operations. Though  
670 not surveyed, the Transportation and Utility Corridor and Plant Site lack the old-growth forest or  
671 recent burn habitat preferred by the three-toed woodpecker. Woodpeckers are sensitive to  
672 disturbance and would not be expected to use the Transportation and Utility Corridor or Plant  
673 Site. Though existing populations are estimated to be low, and prime habitat is not available, the  
674 three-toed woodpecker may be affected by loss of overall forest habitat in the NorthMet Project  
675 area.

#### 676 **5.2.5.2.5 Other Wildlife Species**

677 Other wildlife species in the NorthMet Project area, including common and/or game species  
678 (such as white-tailed deer, bear, fox, porcupine, etc.) would likely be affected in ways similar to  
679 special status species. Mobile individuals would avoid direct effects but may be indirectly  
680 affected by a decrease of habitat. Given the adjacent habitat available to these species, local  
681 effects are expected due to competition from migrating individuals, but these would not threaten  
682 overall populations. Effects on wildlife species important to the Bands are discussed in Section  
683 5.2.9 on a connected ecosystems level.

684 Due to the relative stability in population and harvest levels for white-tailed deer and bear  
685 (MDNR 2013b, MDNR 2013c), along with the limited hunting access at the NorthMet Project

686 area and available adjacent habitat, the NorthMet Project Proposed Action is not likely to  
687 threaten deer or bear populations or hunting opportunities. Model estimates show that changes in  
688 the average annual flow of the Partridge and Embarrass rivers would be within naturally  
689 occurring annual variations. As a result, effects to amphibians or sensitive wildlife species due to  
690 hydrologic changes in these systems would be limited.

### 691 **5.2.5.3 NorthMet Project No Action Alternative**

#### 692 **5.2.5.3.1 Mine Site**

693 Under the NorthMet Project No Action Alternative, mining would not occur. As described in  
694 Section 5.2.4.3.1, forest harvesting would continue to occur in portions of the federal lands,  
695 including the Mine Site. While timber harvests would result in the immediate decrease of some  
696 habitat types, permanent changes are not expected and conversion from one habitat type to  
697 another would benefit some species. Direct and indirect effects of the NorthMet Project No  
698 Action Alternative on wildlife and their habitat types are not expected, as the federal lands would  
699 continue to be managed as they currently are. Species individuals may still be affected due to  
700 existing land use (timber harvest, exploration, vehicle traffic, etc.) but effects are less than those  
701 expected under the NorthMet Project Proposed Action. The use of privately owned land at the  
702 Mine Site would also determine effects on wildlife under the NorthMet Project No Action  
703 Alternative.

#### 704 **5.2.5.3.2 Plant Site and Transportation and Utility Corridor**

705 Under the NorthMet Project No Action Alternative, the former LTVSMC processing plant would  
706 be reclaimed and areas revegetated in accordance with the Reclamation Plan (PolyMet 2015g)  
707 much sooner than under the NorthMet Project Proposed Action. Revegetation would restore  
708 habitat for some species. Species individuals may still be affected due to disturbances related to  
709 reclamation, but effects are less than those expected under the NorthMet Project Proposed  
710 Action. The Transportation and Utility Corridor would remain in private ownership and would  
711 likely continue to be used in a similar manner as under existing conditions. Wildlife could be  
712 affected along the Transportation and Utility Corridor by noise and light associated with vehicle  
713 traffic, and by collisions with vehicles. However, impacts would be fewer than under the  
714 NorthMet Project Proposed Action due to a lower frequency of vehicle activity along these  
715 routes.

## 1 **5.2.6 Aquatic Species**

2 This section describes the potential effects of the NorthMet Project Proposed Action on fish and  
3 aquatic macroinvertebrate communities, especially special status species, associated with  
4 waterbodies found in the NorthMet Project area. These potential effects include changes in  
5 physical habitat (including flow), riparian and aquatic connectivity, and water quality.

### 6 **Summary**

7 The NorthMet Project Proposed Action could affect aquatic physical habitat via changes in flow,  
8 affect riparian and aquatic connectivity via construction activities within the riparian zone, affect  
9 water quality by increasing solute concentrations above Class 2B standards, and, as a result of  
10 these changes, potentially affect aquatic species including special status species (i.e., federally or  
11 state-listed threatened and endangered species, RFSS, and MDNR SGCN).

12 The NorthMet Project Proposed Action would reduce flow in the Partridge River by a maximum  
13 of about 8 percent (Section 5.2.2.3.2) and reduce flow in the Embarrass River by a maximum of  
14 about 3 percent (Section 5.2.2.3.3), and generally change flows in several tributary streams  
15 draining to the Partridge and Embarrass rivers by a maximum of about plus or minus 20 percent,  
16 which would fall into the range of annual natural variability in terms of precipitation (Section  
17 5.2.2.3). These reduced flows are not anticipated to result in any measurable effect on available  
18 aquatic habitat in any streams in the NorthMet Project area, as long as seasonal flow variation is  
19 also maintained. Studies conducted by the USGS in streams and rivers indicated that the severity  
20 of flow alteration had a direct correlation on the community alteration of fish and  
21 macroinvertebrates (Carlisle et al. 2013).

22 The NorthMet Project Proposed Action activities would not occur within the riparian buffer of  
23 any streams; therefore the NorthMet Project Proposed Action would not affect the extent of  
24 natural vegetative cover along riparian areas and would not result in a decrease in the RCI. The  
25 NorthMet Project Proposed Action would also not result in any new dams, bridges, or culverts  
26 within perennial or intermittent streams; therefore, the NorthMet Project Proposed Action would  
27 not affect the hydrologic connectivity along streams and would not result in a decrease in the  
28 ACI. In the general vicinity of the NorthMet Project area, there are numerous case histories of  
29 dewatered mine pits in wetland areas. The historical information clearly indicates that there has  
30 not been extensive loss (i.e., drying up) of wetlands next to these pits except perhaps within 100  
31 ft or so of the pit rim. This may be explained by the hydrogeology, which typically consists of a  
32 thin and moderately permeable surficial unit overlying low-permeability bedrock. Even when the  
33 pit water level is well below the top of bedrock, the low-permeability bedrock limits the amount  
34 of surficial groundwater that can drain downward into the pit and there is sufficient recharge to  
35 the surficial unit to maintain wetland conditions. It is anticipated that riparian zones (wetlands)  
36 adjacent to the Partridge River would not experience any measurable groundwater drawdown,  
37 particularly coupled with minimal surface water flow change due to the NorthMet Project  
38 Proposed Action.

39 Water quality modeling (see Section 5.2.2) predicts that the NorthMet Project Proposed Action  
40 would meet all Class 2B (aquatic life) water quality standards with the possible exception of  
41 aluminum in Embarrass River tributaries draining the Tailings Basin. For aluminum, ambient  
42 water quality, at times, already exceeds the Class 2B standard in both the Partridge River and  
43 Embarrass River. In the Partridge River, the NorthMet Project Proposed Action would not

44 measurably increase aluminum concentrations relative to the CEC Scenario results (Section  
45 5.2.2.3.2). In the Embarrass River, the increase in concentration relative to the CEC Scenario  
46 would not be the result of increased aluminum loadings from the NorthMet Project Proposed  
47 Action, but rather the result of mass loading from surface runoff and the loading from other  
48 minor sources (Section 5.2.2.3.3). Although all other solutes are predicted to meet evaluation  
49 criteria or not cause or contribute to exceedances of evaluation criteria, the aggregate of these  
50 solutes, primarily metals, has the potential to affect aquatic biota.

51 In terms of special status species, there are no federal or state-listed threatened or endangered  
52 fish or macroinvertebrate species known to occur in the NorthMet Project area (USFWS 2011).  
53 There are four special status aquatic species (i.e., RFSS and SGCN) that have not been found in  
54 the NorthMet Project area, but suitable habitat is likely to occur and the species could be present.

55 The NorthMet Project area encompasses several waterbodies within both the Partridge and  
56 Embarrass River watersheds that provide a variety of habitats for aquatic biota. Predicted effects  
57 on aquatic biota from the NorthMet Project Proposed Action are possible due to changes in water  
58 chemistry, including increases in heavy metals. Effects on the success of fish spawning in  
59 tributary streams would be addressed by maintenance of seasonal, bankfull flows over the life of  
60 the NorthMet Project Proposed Action, especially when stream-related flow augmentation occurs  
61 within the Embarrass River Watershed.

#### 62 **5.2.6.1 Methodology and Evaluation Criteria**

63 The operation, reclamation, and closure of the NorthMet Project Proposed Action may result in  
64 changes in the physical aquatic habitat or water quality that would result in effects on fish and  
65 aquatic species. To assess these effects, predicted changes in water quality and flow, as presented  
66 in Section 5.2.2, were used in combination with data on existing aquatic biota conditions, as  
67 discussed in Section 4.2.6, to determine potential effects on aquatic biota in surface waterbodies  
68 located in the NorthMet Project area.

69 The following criteria were considered in this evaluation:

- 70 • Physical alteration of stream conditions and the effect on fish and macroinvertebrate  
71 assemblages;
- 72 • Numeric water quality standards established for the protection of aquatic life in affected  
73 waterbodies;
- 74 • The structure or function of the aquatic species assemblages in affected stream segments; and
- 75 • Effects on one or more protected aquatic species or their habitat.

76 With respect to mercury, the criteria is an increase in the body burden of mercury in aquatic biota  
77 since this is the primary mechanism through which mercury affects aquatic life.

#### 78 **5.2.6.2 NorthMet Project Proposed Action**

##### 79 **5.2.6.2.1 Partridge River**

80 This section describes the potential effects of the NorthMet Project Proposed Action on aquatic  
81 resources in the Partridge River Watershed, including effects on physical habitat, riparian and  
82 aquatic connectivity, and water quality.

83 ***Physical Habitat Effects***

84 Hydrologic changes often have effects on fish and aquatic macroinvertebrates. While many  
85 aspects of the hydrologic regime can be important to the maintenance of fish and  
86 macroinvertebrate assemblages, reduction in baseflow (the portion of streamflow from  
87 groundwater) is particularly relevant because it represents a loss of habitat.

88 In the Partridge River, results of the water modeling (described in Section 4.2.2)—as predicted at  
89 monitoring stations SW-002, SW-004, and SW-004a—were used to describe predicted flow for  
90 the upper Partridge River Watershed within the vicinity of the Mine Site. These monitoring  
91 stations were selected due to their geographical location (see Figure 5.2.6-1), and likely represent  
92 the area that would best describe potential maximum effects along the Partridge River.

93 At SW-002, SW-004, and SW-004a, baseflow (i.e., average 30-day annual low flow) gradually  
94 decreases during the first 11 years of mining, but in the worst case only represents a 4 to 5  
95 percent reduction and a 0.3 to 1.6 cfs reduction in absolute flow (year 11). In terms of long-term  
96 closure, the average annual 30-day minimum flow is estimated to decrease from 0.41 cfs  
97 (existing conditions) to 0.40 cfs at SW-002 and from 0.92 cfs (existing conditions) to 0.89 cfs at  
98 SW-004. At SW-004a, the average annual 30-day minimum flow is estimated to increase from  
99 2.44 cfs (existing conditions) to 2.98 cfs (see Table 5.2.6-1). The annual daily mean flow would  
100 follow similar trends as the 30-day annual low flow, with a maximum decrease of 5 percent at  
101 year 11 and remain approximately the same as existing conditions for long-term closure  
102 (PolyMet 2015m, Attachment J). Most of these changes in flow are too small to be measurable  
103 and, therefore, hydrologic alteration is not expected to degrade physical aquatic habitat by  
104 destabilizing the stream channel.

105 The effects from the NorthMet Project Proposed Action on seasonal flow would be negligible  
106 and, therefore, no adverse effects on aquatic habitat or species are anticipated.

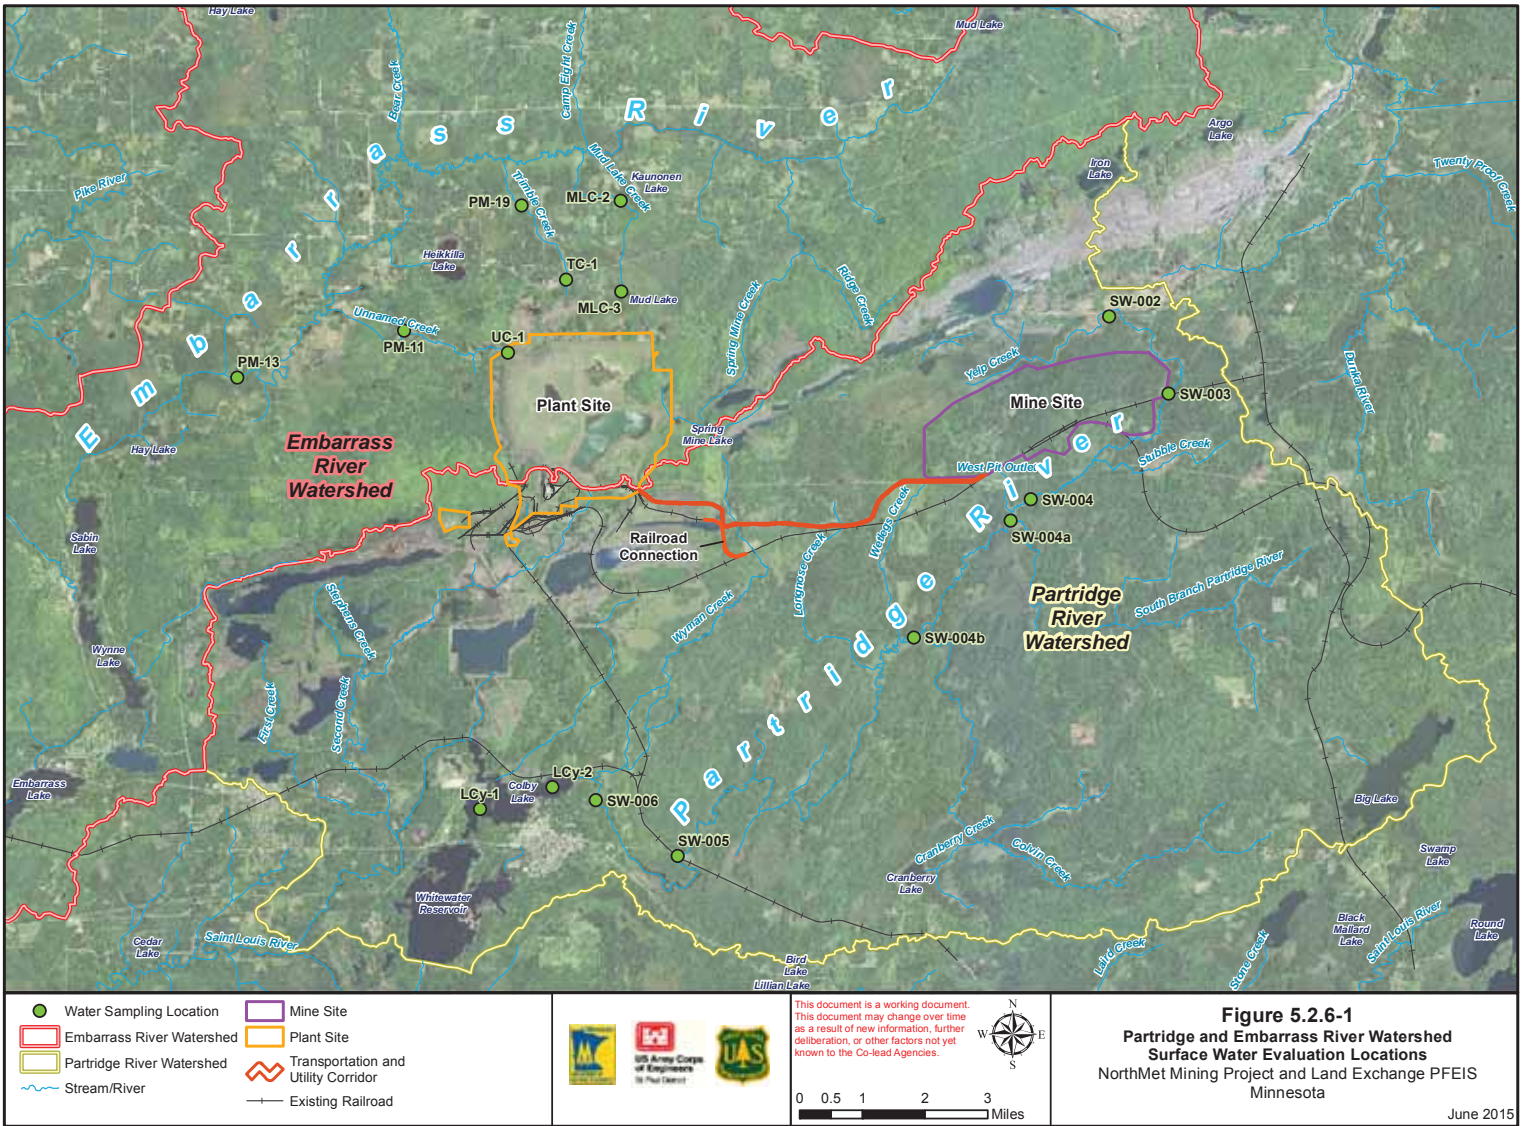

107 Flow monitoring methods have been determined by the MDNR based on professional judgement  
108 and accumulated data. Monitoring would be conducted at a minimum of three sites for each of  
109 the impacted streams whenever there is a 20 percent fluctuation in watershed area or an addition  
110 / reduction of flow that exceeds 20 percent of the mean annual flow located: 1) within 2,000 ft of  
111 each outflow; 2) at the endpoint of impact; and 3) midway between the two points (Chisholm  
112 2006).

113 Flow reductions within the Partridge River would be reduced by a maximum 8 percent. Varying  
114 degrees of hydrologic alteration can be tied to ecological condition using the Limits of  
115 Hydrologic Alteration (LOHA) Method, which is intended to provide a better articulation of the  
116 aspects of flow rate and timing thought to be most important to ecological condition, and provide  
117 more elaboration on the ecological changes that are associated with increasing degrees of  
118 hydrologic alteration. Research in review lists 10 percent, 20 percent, and greater than 20 percent  
119 flow alteration as setting the ecological condition of ‘natural,’ ‘minimally altered,’ and  
120 ‘moderately altered,’ respectively (Chisholm 2006). A review of case studies (Richter et al.  
121 2011) found that recommendations for flow protection are quite consistent, typically resulting in  
122 a range of allowable cumulative depletion of 6 percent to 20 percent of normal to low flows, but  
123 with occasional allowance for greater depletion in seasons or flow levels during which aquatic  
124 species are thought to be less sensitive. This review supports the conclusion that flow reductions  
125 in the Partridge River Watershed due to the NorthMet Project Proposed Action are anticipated to

126 be within the natural ecological condition and have minimal impacts to ecosystem function and  
127 aquatic species.

128 Proposed flow monitoring details would be finalized during the permitting process to ensure  
129 average annual flow standards are being met during mine operations, reclamation, and post-  
130 closure maintenance phases (see Table 5.2.2-53).

134 Source: PolyMet 2015m, Attachment J (Partridge River Hydrologic Impact Assessment Results)

DRAFT

136 No effects on aquatic resources are anticipated from hydrologic changes at the Partridge River  
137 tributary streams, Colby Lake, or Whitewater Reservoir, from the NorthMet Project Proposed  
138 Action. On an annual average basis, inflow to Colby Lake would be reduced about 1.7 percent  
139 during operations (in mine year 11) and have virtually no change during closure (see Section  
140 5.2.2.3.2) (PolyMet 2015m). Withdrawals at Colby Lake would create an average annual water  
141 level fluctuation of about 3.6 ft, compared to 3.9 ft for zero withdrawal. Withdrawals at the  
142 Whitewater Reservoir would create an annual fluctuation of about 4.2 ft compared to 2.9 ft for  
143 zero withdrawal. Effects on Colby Lake and Whitewater Reservoir are expected to be negligible  
144 as they would be well within the range of effects experienced during the former LTVSMC  
145 taconite mining operations.

146 Approximately 227 gpm of surface water seepage flows from the existing LTVSMC Tailings  
147 Basin to the headwaters of Second Creek. Under the current LTVSMC Consent Decree, most of  
148 this seepage is captured and pumped back to the Tailings Basin, resulting in a net reduction in  
149 base flow to Second Creek. The NorthMet Project Proposed Action would continue pumping this  
150 seepage back to the Tailings Basin for water quality protection reasons, but would augment  
151 flows in Second Creek at approximately 80 percent of the current seepage volume (i.e., about  
152 184 gpm) with WWTP effluent throughout NorthMet Project Proposed Action operations,  
153 reclamation, and long term closure. With these augmentation flows, total flow volume in Second  
154 Creek would be equivalent to at least 80 percent of historic flow volume and fluctuations through  
155 the year would mimic the natural hydrograph (PolyMet 2015j); therefore, the designed flow  
156 augmentation to Second Creek is not expected to affect the available aquatic species habitat by  
157 degrading the habitat with decreased flow to the headwater portions of this stream and would in  
158 fact help mitigate the hydrologic effect associated with the current pump back requirements.

### 159 **Riparian and Aquatic Connectivity**

160 The NorthMet Project Proposed Action activities would not occur within the riparian buffer of  
161 any streams; therefore, the NorthMet Project Proposed Action would not affect the extent of  
162 natural vegetative cover along riparian areas and would not result in a change in the RCI for the  
163 Partridge River.

164 The NorthMet Project Proposed Action would not result in any new dams, bridges, or culverts  
165 within perennial or intermittent streams; therefore, the NorthMet Project Proposed Action would  
166 not affect the hydrologic connectivity along streams and would not result in a change in the ACI  
167 for the Partridge River.

### 168 **Water Quality Effects**

169 Surface water chronic standards, specifically the Class 2B standards, were developed to be  
170 protective of aquatic life and to promote the “propagation and maintenance of a healthy  
171 community of cool or warm water sport or commercial fish and associated aquatic life, and their  
172 habitats” (*Minnesota Rules*, part 7050.0222). The chronic standards reflect “the highest water  
173 concentration of a toxicant to which organisms can be exposed indefinitely without causing  
174 chronic toxicity” (*Minnesota Rules*, part 7050.0218, subpart 3, item I).

175 As described in more detail in Section 5.2.2, the GoldSim water quality model results were  
176 screened to compare the single highest monthly P90 water quality prediction from among 2,400  
177 months covered over the 200 year model period by the simulation with CEC Scenario values and

178 the water quality evaluation criteria (see Section 5.2.2.1). The screening analysis indicates that  
179 the NorthMet Project Proposed Action would meet all Minnesota Class 2B water quality  
180 standards and proposed evaluation criteria with the exception of aluminum (see Table 5.2.6-2).

181 The results indicate aluminum would exceed the Class 2B chronic standard (125 µg/L) at all  
182 evaluation locations. Maximum aluminum P90 values for the NorthMet Project Proposed Action  
183 ranged from a low 306µg/L (SW-006) to a high of 313 µg/L (SW-002). However, Partridge  
184 River concentrations at the same locations for the CEC Scenario are nearly identical, also  
185 exceeding the standard. Therefore, the NorthMet Project Proposed Action would not worsen  
186 existing conditions relative to aluminum concentrations in the Partridge River.

187 Mercury was not included in the GoldSim model for either the Mine Site or the Plant Site, as  
188 insufficient data and unique modeling requirements for mercury dynamics prevented modeling  
189 mercury like the other solutes. Regardless, the NorthMet Project Proposed Action would still  
190 need to demonstrate that the mercury evaluation criteria would be protected (see Section 5.2.2.1).  
191 Therefore, a simple mass balance model estimation method was used. This simple estimation  
192 method was preferred over a detailed mechanistic model because it incorporated the important  
193 input and removal processes for mercury, was very transparent with regard to data inputs, and  
194 allowed for easy assessment of the effects of changing parameter values on mercury  
195 concentrations. For the Mine Site, this method, in combination with analog data from existing  
196 natural and mine pit lakes in the region, was used to assess future mercury concentrations in the  
197 West Pit lake and in the overflow water. The NorthMet Project Proposed Action is also estimated  
198 to result in a net decrease in mercury loadings to the Partridge River (see Sections 5.2.2.3.4 and  
199 6.2.2.4).

200 An exceedance of aluminum could potentially affect aquatic species by causing pulmonary  
201 problems, developmental issues, and osmoregulatory disturbances (Soucek 2006). However,  
202 given the similarity between the CEC Scenario and the NorthMet Project Proposed Action  
203 aluminum values at Partridge River evaluation locations, impacts from aluminum to aquatic  
204 species due to the NorthMet Project Proposed Action are not anticipated.

205 **Table 5.2.6-2 Partridge River Maximum P90 Solute Concentration Over Entire 200-Year Simulation at Each Evaluation**  
206 **Location Based on GoldSim Probabilistic Model**

207 Sources: PolyMet 2015m; PolyMet 2014v.

208 Notes:  
209 Bolded numbers show exceedances at the P90 modeled concentrations.

210 For each constituent at each location, the maximum solute concentration over the entire 500-year simulation period is recorded for each of 500 realizations of the Monte Carlo run.  
211 At the end of the Monte Carlo run, there is a list of 500 maximum concentration values for each constituent at each location. Each list is converted to a cumulative frequency  
212 distribution. Each value in this table is the 90th percentile concentration from the associated distribution.

213 <sup>1</sup> Parameter has a hardness-based evaluation criterion and is screened using a different procedure (see Table 5.2.2.-32)<sup>2</sup> TDS is calculated as the sum of 90th-percentile alkalinity,  
214 calcium, magnesium, sodium, potassium, chloride, sulfate, and fluoride using the formula provided in PolyMet (2013i, Section 6.2.6.25m)

215 ***Colby Lake***

216 As discussed in Section 5.2.2 and exhibited in Table 5.2.6-3, Colby Lake would exceed the  
 217 evaluation criteria for aluminum, arsenic, iron, and manganese under the NorthMet Project  
 218 Proposed Action. Potential effects of aluminum on aquatic species are discussed in Section  
 219 5.6.2.2.1. Exceedances of arsenic could potentially result in poor growth rates and mortality in  
 220 aquatic species; however, adverse effects have only been reported in water containing  
 221 concentrations between 19 and 48 µg/L (Eisler 1988a). However, comparing the evaluation  
 222 criteria exceedances to the CEC Scenario indicates no effects on aquatic species would result  
 223 from the NorthMet Project Proposed Action, as modeled values are nearly identical under the No  
 224 Action Continuation of Existing Conditions Scenario.

225 ***Table 5.2.6-3 Maximum P90 Surface Water Concentrations for Colby Lake***

| Parameter           | Colby Lake Evaluation Criteria | Units | CEC Scenario (Max P90 Value) | NorthMet Project Proposed Action (Max P90 Value) |

226  
 227 Source: PolyMet 2014v

228 Note: Bold font indicates an exceedance of the Class 2B water quality standards evaluation criteria.

229 ***Special Status Species***

230 There are no federally listed or state-listed threatened or endangered fish or macroinvertebrate  
 231 species known to occur in the Partridge River (USFWS 2011). There are four special status  
 232 aquatic species that have not been found in the NorthMet Project area, but suitable habitat is  
 233 likely to occur and the species could be present, including:

- 234 • Quebec emerald dragonfly – RFSS species,
- 235 • Ebony boghaunter – RFSS species,

- 236 • Creek heelsplitter mussel – SGCN and RFSS species, and  
237 • Northern brook lamprey – SGCN and RFSS species.

238 Since the NorthMet Project Proposed Action is not predicted to result in any measurable changes  
239 in low flows and negligible changes in average flows, no effects on RCI and ACI, and no change  
240 in water quality for any of the Class 2B water quality standards, no effects on aquatic special  
241 status species is expected within the Partridge River Watershed.

242 Furthermore, the USFS determined that the NorthMet Project Proposed Action would not affect  
243 three RFSS aquatic species on the Superior National Forest, which include lake sturgeon,  
244 nipigon cisco, and shortjaw cisco. In addition, the NorthMet Project Proposed Action may affect  
245 individuals, but would not likely cause a trend to federal listing or loss of viability for the  
246 remaining six RFSS aquatic species, discussed in Section 4.2.6, on the Superior National Forest.  
247 Please see the Biological Evaluation listed on the USFS website (<http://www.fs.usda.gov/goto/superior/northmet>) for more information about effects on RFSS aquatic species.  
248

#### 249 **5.2.6.2.2 Embarrass River Watershed**

250 This section describes the potential effects of the NorthMet Proposed Action on aquatic  
251 resources in the Embarrass River Watershed, including effects on physical habitat, riparian and  
252 aquatic connectivity, and water quality.

#### 253 **Physical Habitat Effects**

254 The NorthMet Project Proposed Action could potentially affect flows in the three tributary  
255 streams draining the Tailings Basin (i.e., Mud Lake Creek, Trimble Creek, and Unnamed Creek)  
256 and flow in the Embarrass River downstream of these tributary effects (i.e., PM-13). As  
257 discussed in Section 5.2.2, the NorthMet Project Proposed Action includes engineering controls  
258 that would capture nearly all seepage from the Tailings Basin, and to mitigate this effect by  
259 augmenting flows to two of the three Embarrass River tributary streams, Unnamed Creek and  
260 Trimble Creek, and Second Creek, a Partridge River tributary, with WWTP effluent to maintain  
261 average annual flows in these tributaries within 20 percent of existing conditions (see Table  
262 5.2.6-4). Mud Lake Creek would be augmented via a drainage swale on the east side of the  
263 Tailings Basin. The tributary streams flow augmentation would result in only about a two  
264 percent reduction in average annual flow at PM-13 in the Embarrass River. Changes in average  
265 annual flow of this magnitude (less than 20 percent) would fall into the range of annual natural  
266 variability in terms of precipitation and would have minimal impacts to ecosystem function and  
267 aquatic species within the Embarrass River Watershed; however, seasonal flow data was not  
268 available for this watershed—in particular the tributaries. Flow monitoring details under the  
269 NorthMet Project Proposed Action would be finalized during the permitting process to ensure  
270 average annual flow standards are being met during mine operations, reclamation, and post-  
271 closure maintenance phases (see Table 5.2.2-54).

272 Dampening of the hydrologic curve could have an adverse effect on aquatic biota due to stream  
273 destabilization, including aggradation, degradation, and resultant loss of habitat. Maintenance of  
274 spring bankfull flow is particularly important for the success of fish spawning in tributaries  
275 because high flows trigger spawning runs and maintain spawning habitat. Effects on the success  
276 of fish spawning in tributary streams would be addressed by maintenance of seasonal, bankfull

277 flows over the life of the NorthMet Project Proposed Action, especially when stream-related  
 278 flow augmentation occurs within the Embarrass River Watershed.

279 **Table 5.2.6-4 WWTP Minimum Flow Requirements for Stream Augmentation**

| <b>Tributary</b> | <b>Historical Average Annual Flow (gpm)</b> | <b>NorthMet Project Designed Average Annual Flow (gpm)<sup>1</sup></b> |
|------------------|---------------------------------------------|------------------------------------------------------------------------|
| Second Creek     | 227                                         | 184                                                                    |
| Trimble Creek    | 1,888                                       | 1,178                                                                  |
| Unnamed creek    | 1,180                                       | 336                                                                    |
| <b>Total</b>     | <b>3,295</b>                                | <b>1,698</b>                                                           |

281 Note:

282 <sup>1</sup> Includes predicted future flow contribution of headwaters watershed.

283 **Water Quality Effects**

284 As described in more detail in Section 5.2.2, the GoldSim water quality model results were  
 285 screened to compare the single highest monthly P90 water quality prediction from among 2,400  
 286 months (Partridge River) or 6,000 months (Embarrass River) covered over the 200- to 500-year  
 287 model period with the CEC Scenario modeled values and the water quality evaluation criteria  
 288 (see Section 5.2.2.1). The screening analysis indicates that the NorthMet Project Proposed  
 289 Action would meet all Minnesota Class 2B water quality standards and proposed evaluation  
 290 criteria with the exception of aluminum (see Table 5.2.6-5). In addition, surface water  
 291 constituents that have hardness-based evaluation criteria were screened. It was not possible to  
 292 develop a single evaluation criterion to which the GoldSim-predicted solute concentrations could  
 293 be compared. The approach to screening was therefore based on evaluating the frequency of the  
 294 occurrence of an exceedance for each monthly timestep. The value for lead at PM-11 is the only  
 295 value that exceeded the frequency of exceedance threshold of 5 percent (Section 5.2.2).

296 The results indicate the maximum P90 values of aluminum would exceed the Class 2B standard  
 297 (125 µg/L) at all evaluation locations except TC-1 for both the CEC Scenario and the NorthMet  
 298 Project Proposed Action. Maximum aluminum P90 values for the NorthMet Project Proposed  
 299 Action ranged from a low 112 µg/L (TC-1) to a high of 189 µg/L (MLC-3). As discussed in  
 300 Section 5.2.2, however, the predicted increases in aluminum are not the result of increased  
 301 aluminum loadings from the NorthMet Project Proposed Action, but rather the result of mass  
 302 loading from surface runoff and the loading from other minor sources. Given the similarity  
 303 between the CEC Scenario and the NorthMet Project Proposed Action aluminum values at  
 304 Embarrass River evaluation locations, impacts from aluminum to aquatic species due to the  
 305 NorthMet Project Proposed Action are not anticipated.

306 As discussed in Section 5.2.2.3.3, NorthMet Project Proposed Action lead concentrations at PM-  
 307 11 are generally higher than CEC Scenario concentrations. However, it is concluded that due to  
 308 the expected performance of the WWTP, it is likely that actual lead concentrations at PM-11  
 309 would have acceptably low frequencies of exceedance. Therefore, impacts from lead to aquatic  
 310 species due to the NorthMet Project Proposed Action are not anticipated. Potential impacts to  
 311 aquatic species caused by exposure to high levels of lead are discussed below.

312 Although maximum solute P90 concentrations are expected to meet Class 2B water quality  
 313 standards for solutes other than aluminum, the NorthMet Project Proposed Action is projected to

314 alter the existing water quality of the Embarrass River by increasing some solute concentrations  
315 from 2 to almost 30 times the existing level (Tables 4.2.2-32 and 5.2.2-45). Non-contact surface  
316 runoff and the addition of WWTP effluent to Unnamed Creek, Trimble Creek, and Second Creek  
317 as part of the augmentation program is projected to contribute to these loading increases.

318 Mercury was not included in the GoldSim model for either the Mine Site or the Plant Site, as  
319 insufficient data and unique modeling requirements for mercury dynamics prevented modeling  
320 mercury like the other solutes. Regardless, the NorthMet Project Proposed Action would still  
321 need to demonstrate that the mercury evaluation criteria would be protected (see Section 5.2.2.1).  
322 Therefore, a simple mass balance model estimation method was used. This simple estimation  
323 method was preferred over a detailed mechanistic model because it incorporated the important  
324 input and removal processes for mercury, was very transparent with regard to data inputs, and  
325 allowed for easy assessment of the effects of changing parameter values on mercury  
326 concentrations. For the Plant Site, this method, in combination with analog data from existing  
327 natural and mine pit lakes in the region, was used to assess future mercury concentrations in  
328 seepage, discharge from the WWTP, and volatilization from the Tailings Basin pond (this  
329 mechanism is discussed in Section 5.2.7, Air Quality). The NorthMet Project Proposed Action is  
330 predicted to result in a net increase in mercury loadings to the Embarrass River (see Sections  
331 5.2.2.3.4 and 6.2.2.4). This is primarily attributable to the redirection of surface runoff diverted  
332 via the drainage swale constructed east of the Tailings Basin East Dam directly to Mud Lake  
333 Creek as part of the Tailings Basin expansion to the Embarrass River.

334 Heavy metals have a wide spectrum of adverse effects on aquatic life that could include impacts  
335 to reproduction, growth, behavior, and metabolism. These effects are dependent upon such  
336 factors as species, age, weight, sex, trophic level, concentration of the metal, and ambient water  
337 conditions such as pH, salinity, hardness, temperature, and dissolved oxygen (Girgin et al. 2010).  
338 The bioavailability of heavy metals such as cadmium, copper, nickel, lead, and zinc generally  
339 decreases with increasing hardness in freshwater systems (Girgin et al. 2010). See Section  
340 5.2.2.1.2 for details regarding the relationship between heavy metals and hardness. Exceedances  
341 of mercury could cause adverse impacts such as reproduction, growth, and osmoregulation issues  
342 in aquatic organisms. Mercury rapidly accumulates in aquatic biota and can inhibit fish  
343 reproduction at water concentrations as low as 0.03 µg/L (Eisler 1987); however, seepage water  
344 from the Tailings Basin is expected to be less than 0.001 µg/L. Conversely, lead does not  
345 bioaccumulate and tends to decrease with increasing trophic levels in freshwater habitats.  
346 Exposure to high levels of lead could result in muscular and neurological degeneration and  
347 destruction, growth inhibition, reproductive problems, paralysis, and mortality in fish. It could  
348 also negatively affect invertebrate reproduction as well as reduce growth, photosynthesis,  
349 mitosis, and water absorption in aquatic plants (Eisler 1988b). The NorthMet Project Proposed  
350 Action is designed to capture metals with engineering controls and adaptive management. Water  
351 monitoring (see Table 5.2.2-54) would ensure that water quality standards would be met with  
352 engineering controls and adaptive management. In addition, spill prevention plans would be  
353 implemented. These measures would minimize any potential impacts to aquatic species.

354

357 Source: PolyMet 2014w and PolyMet 2015j.

358 Notes:

359 For each constituent at each location, the maximum solute concentration over the entire 500-year simulation period is recorded for each of 500 realizations of the Monte Carlo run.  
360 At the end of the Monte Carlo run, there is a list of 500 maximum concentration values for each constituent at each location. Each list is converted to a cumulative frequency  
361 distribution. Each value in this table is the 90th percentile concentration from the associated distribution.

362 Bold value indicates exceedance of the evaluation criterion at the P90 modeled concentrations.

363 <sup>1</sup> Parameter has a hardness-based evaluation criterion and is screened using a different procedure (see Table 5.2.2.-32).

364 <sup>2</sup> TDS is calculated as the sum of 90th-percentile alkalinity, calcium, magnesium, sodium, potassium, chloride, sulfate, and fluoride using the formula provided in PolyMet (2013i,  
365 section 6.2.6.25m).  
366

367 ***Special Status Species***

368 There are no federally listed or state-listed threatened or endangered fish or macroinvertebrate  
369 species known to occur in the Embarrass River (USFWS 2011). There are four special status  
370 aquatic species that have not been found in the NorthMet Project area, but suitable habitat is  
371 likely to occur and the species could be present, including:

- 372 • Quebec emerald dragonfly – RFSS species;
- 373 • Ebony boghaunter – RFSS species;
- 374 • Creek heelsplitter mussel – SGCN and RFSS species; and
- 375 • Northern brook lamprey – SGCN and RFSS species.

376 The NorthMet Project Proposed Action is not predicted to result in any measurable changes in  
377 low flows, and there would be negligible changes in average annual flows, no effects on RCI and  
378 ACI, and no change in water quality for any of the Class 2B water quality standards.

379 Similarly for the Embarrass River, as stated above for the Partridge River, the USFS determined  
380 that the NorthMet Project Proposed Action would not affect three RFSS aquatic species on the  
381 Superior National Forest, which include lake sturgeon, nipigon cisco, and shortjaw cisco. In  
382 addition, the NorthMet Project Proposed Action may affect individuals, but would not likely  
383 cause a trend to federal listing or loss of viability for the remaining six RFSS aquatic species,  
384 discussed in Section 4.2.6, on the Superior National Forest.

385 **5.2.6.3 NorthMet Project No Action Alternative**

386 Under the NorthMet Project No Action Alternative, the NorthMet Project Proposed Action  
387 would not occur and associated effects on fish and other aquatic life would not occur.

388 Although under the No Action Alternative, the NorthMet Project Proposed Action, including the  
389 proposed Tailings Basin seepage collection and water treatment engineering controls, would not  
390 occur, the No Action Alternative would not necessarily be static. In this case, it is anticipated  
391 that the water quality of seepage from the existing LTVSMC Tailings Basin would improve over  
392 time as a result of natural attenuation and/or possible additional mitigation measures at some  
393 point in the future pursuant to new requirements in permits or other state or federal remediation  
394 requirements.

DRAFT

## 1 **5.2.7 Air Quality**

2 This section assesses the effects of the NorthMet Project Proposed Action on air quality.  
3 Procedures for air quality assessments vary depending upon the level of emissions from a  
4 proposed project. The USEPA defines sources as “major” or “minor,” depending on their  
5 emissions levels of regulated pollutants (250 tpy of any criteria pollutant, 100,000 tpy of GHGs,  
6 10 tpy of a single HAP, or 25 tpy of all HAPs). As presented in this section, the NorthMet  
7 Project Proposed Action has been defined as a synthetic minor source according to this  
8 definition, since the project would limit its emissions through permit restrictions to less than the  
9 emission levels stated above. However, at the request of several state and federal agencies, much  
10 of the analyses were conducted to address requirements for major sources. Discussions of the air  
11 quality assessment methodologies, air quality effects, and potential mitigation measures are  
12 addressed for criteria pollutants, air toxics, and amphibole fibers.

### 13 **Summary**

14 The NorthMet Project Proposed Action has been designed so that it is considered a synthetic  
15 minor source for air permitting purposes. However, the evaluation of the NorthMet Project  
16 Proposed Action in this FEIS has treated it as a major source due to its sensitive nature.  
17 Compliance with state and federal ambient air quality standards and growth increments, designed  
18 to protect human health and the environment, were evaluated using generally accepted state and  
19 federal threshold criteria. The NorthMet Project Proposed Action has been shown to not cause or  
20 contribute to significant air quality effects. Local and regional effects, up to 300-km from the  
21 project facilities, were evaluated to incorporate federally sensitive, pristine area resources such as  
22 BWCAW and Voyageurs National Park. Effects of dust from mining and ore transport are  
23 generally confined to areas disturbed by project activities. The effects of reactive dust emissions  
24 on wetlands are discussed in Section 5.2.3. Control technologies similar to federal Best Available  
25 Control Technologies (termed BACT-like) were evaluated and applied to the project equipment  
26 in order to minimize the potential for air emissions. In particular, BACT-like controls were  
27 incorporated to reduce mercury emissions to levels that would not impede current State of  
28 Minnesota mercury emissions reduction goals. BACT-like fine-particulate matter emission  
29 controls were also incorporated to specifically control the release of more than  
30 99.9 percent of amphibole fibers in the ore.

### 31 **5.2.7.1 Methodology and Evaluation Criteria**

32 The following subsections describe the air quality standards used in the assessments, local and  
33 federal regulations that affect the NorthMet Project Proposed Action, and modeling  
34 methodologies and specific modeling assessments conducted, as well as the criteria used to  
35 define significant effects from operation of the NorthMet Project Proposed Action.

#### 36 **5.2.7.1.1 Regulatory Setting**

##### 37 **Air Quality Standards**

38 The USEPA has established NAAQS for seven criteria air pollutants including NO<sub>2</sub>, SO<sub>2</sub>, CO,  
39 O<sub>3</sub>, PM<sub>10</sub>, PM<sub>2.5</sub>, and lead. Primary standards are established to protect the public health;  
40 secondary standards are set to protect public welfare, including protection from damage to  
41 animals, crops, vegetation, visibility, and buildings. It should be noted that Title 42, Chapter 85,

42 Subchapter I, Part A, Section 7408 (a)(2) of the CAA directs the USEPA to develop air quality  
 43 criteria for air pollutants that have identifiable effects on public health or “welfare.” The term  
 44 "welfare" in the context of the CAA includes the protection of vegetation, and the secondary  
 45 NAAQS are designed to be protective of plant life including the effects of both concentration  
 46 and deposition of material.

47 The MPCA has also promulgated ambient air standards for the State of Minnesota, known as the  
 48 MAAQS. In addition to the criteria pollutants, the MAAQS contain standards for TSP and  
 49 hydrogen sulfide (H<sub>2</sub>S). As with the NAAQS, the MAAQS primary standards are established to  
 50 protect the public health; secondary standards are set to protect public welfare, including  
 51 protection from damage to animals, crops, vegetation, visibility, and buildings.

52 The NAAQS and MAAQS are summarized in Table 5.2.7-1.

53 **Table 5.2.7-1 Summary of NAAQS and MAAQS**

| Pollutant                                      | Averaging Period                    | Standard Value (ppm) | Standard Value (µg/m <sup>3</sup> ) | Standard Type <sup>1</sup> | Notes                                                                                                          |
|------------------------------------------------|-------------------------------------|----------------------|-------------------------------------|----------------------------|----------------------------------------------------------------------------------------------------------------|
| Carbon Monoxide                                | 1-Hour                              | 35                   | 40,000                              | Primary                    | Not to be exceeded more than once per year                                                                     |
|                                                | 1-Hour <sup>2</sup>                 | 30                   | 35,000                              | Primary                    |                                                                                                                |
|                                                | 8-Hour                              | 9                    | 10,000                              | Primary and Secondary      |                                                                                                                |
| Nitrogen Dioxide                               | Annual Arithmetic Mean              | 0.05                 | 100                                 | Primary and Secondary      | Not to be exceeded                                                                                             |
|                                                | 1-Hour                              | 0.10                 | 188                                 | Primary                    | Not to exceed the 98 <sup>th</sup> percentile of the Maximum Daily 1-hour Values averaged over a 3-year period |
| Ozone                                          | 8-Hour                              | 0.075                | 147                                 | Primary and Secondary      | 4 <sup>th</sup> highest daily maximum 8-hour average                                                           |
| Lead                                           | Quarterly                           |                      | 0.15                                | Primary and Secondary      | Rolling 3-month average                                                                                        |
| Total Suspended Particulate (TSP) <sup>2</sup> | Annual Geometric Mean               |                      | 75<br>60                            | Primary<br>Secondary       | Not to be exceeded                                                                                             |
|                                                | 24-Hour                             |                      | 260<br>150                          | Primary<br>Secondary       | Not to be exceeded more than once per year                                                                     |
| PM <sub>10</sub>                               | Annual Arithmetic Mean <sup>2</sup> |                      | 50                                  | Primary and Secondary      | Not to be exceeded                                                                                             |
|                                                | 24-Hour                             |                      | 150                                 | Primary and Secondary      | Not to be exceeded more than once per year on average over 3 years                                             |

| Pollutant                     | Averaging Period       | Standard Value (ppm) | Standard Value ( $\mu\text{g}/\text{m}^3$ ) | Standard Type <sup>1</sup>        | Notes                                                                                                          |
|-------------------------------|------------------------|----------------------|---------------------------------------------|-----------------------------------|----------------------------------------------------------------------------------------------------------------|
| PM <sub>2.5</sub>             | Annual Arithmetic Mean |                      | 12                                          | Primary and Secondary             | Not to exceed the 3-year average of the weighted annual mean concentrations                                    |
|                               | 24-Hour                |                      | 35                                          | Primary and Secondary             | Not to exceed the 3-year average of the 98 <sup>th</sup> percentile of 24-hour concentrations                  |

|                               | ½-Hour                 | 0.03                 | 42                                          | Primary                           | Not to be exceeded over 2 times in any 5 consecutive days                                                      |

54 Source: MPCA 2013b; USEPA 2013.

55 <sup>1</sup> Primary standards set limits to protect human health; secondary standards set limits to protect public welfare.

56 <sup>2</sup> MAAQS only.

57 **Federal Regulations**

58 **Attainment Status**

59 Under the CAA, the USEPA has defined all areas within the United States as one of two  
 60 classifications, attainment or non-attainment. “Attainment areas” are those areas that either have  
 61 collected ambient air quality data to demonstrate that they are in compliance or they do not have  
 62 demonstrated non-compliance with the NAAQS, and so they are known as “unclassified areas.”  
 63 An area that does not meet NAAQS is considered to be a “nonattainment area” for that pollutant,  
 64 and the USEPA requires the state to develop state implementation plans to control existing and  
 65 future emissions in order to bring the area into compliance with the NAAQS. The NorthMet  
 66 Project area has been designated by the USEPA as attainment or unclassified for all air quality  
 67 pollutants.

68 ***Prevention of Significant Deterioration Review***

69 Under the CAA, the federal Prevention of Significant Deterioration (PSD) requirements provide  
 70 for a pre-construction review and permit process for the construction and operation of a new or  
 71 modified major stationary source in attainment areas. The review includes the following:

- 72 • BACT demonstration;
- 73 • ambient air quality analysis to assess potential project effects with NAAQS and PSD  
 74 increments;
- 75 • an assessment of Air Quality Related Value (AQRV) of the direct and indirect effects of a  
 76 project on general growth, soil, vegetation, and visibility for Class I regions within 300 km;
- 77 • an ambient monitoring program if no representative data are available; and
- 78 • public comment.

79 The USEPA’s PSD program allows all attainment areas various levels of air quality protection  
 80 and growth depending upon its designated class. Class I areas are special areas of natural wonder  
 81 and scenic beauty—such as national parks, national monuments, and wilderness areas—where  
 82 air quality should be given special protection. Class II areas are non-Class I areas that are  
 83 allowed moderate growth and air quality degradation with Class II incremental limits. Class III  
 84 areas are all non-Class I areas that are deemed unclassified and allow maximum growth and air  
 85 quality degradation with no incremental limits. For attainment areas, the USEPA has  
 86 promulgated PSD increments for four pollutants (NO<sub>2</sub>, SO<sub>2</sub>, PM<sub>10</sub>, and PM<sub>2.5</sub>) for both Class I  
 87 and Class II regions. The increments are designed to allow for ambient concentrations within an  
 88 area to increase by the maximum allowable amount above baseline concentrations. Class I PSD  
 89 increments are designed to keep pristine areas clean and have more restrictive allowable  
 90 increment thresholds. Class II PSD increments are designed to allow further growth within the  
 91 rest of the country. Table 5.2.7-2 provides a summary of the Class I and Class II PSD  
 92 increments.

93 ***Table 5.2.7-2 Summary of Allowable Prevention of Significant Deterioration Class I and***  
 94 ***Class II Increments***

| Pollutant, Averaging Period | Allowable Increment (µg/m <sup>3</sup> ) |                 |
|-----------------------------|------------------------------------------|-----------------|
|                             | Class I Region                           | Class II Region |
| SO <sub>2</sub> , 3-hour    | 25                                       | 512             |
| SO <sub>2</sub> , 24-hour   | 5                                        | 91              |
| SO <sub>2</sub> , Annual    | 2                                        | 20              |
| NO <sub>2</sub> , Annual    | 2.5                                      | 25              |
| PM <sub>10</sub> , 24-hour  | 8                                        | 30              |
| PM <sub>2.5</sub> , 24-hour | 2                                        | 9               |
| PM <sub>2.5</sub> , Annual  | 1                                        | 4               |

95 The NorthMet Project area is located within a Class II attainment area, as designated by the  
 96 USEPA. In relation to the NorthMet Project Proposed Action, the federal CAA defines a source  
 97 as a major source in an attainment area if it has any criteria pollutant emissions above 250 tpy or  
 98 100,000 tpy of GHG emissions. Because the NorthMet Project Proposed Action is proposing to  
 99 limit its actual emissions below “major source” thresholds for the federal PSD program, the

100 NorthMet Project Proposed Action is not subject to PSD requirements and, thus, modeling of  
101 PSD increment consumption requirements do not specifically apply for permitting. For the  
102 purposes of this FEIS, NorthMet Project Proposed Action effects have been compared to the  
103 PSD Class I (generally pristine areas) and Class II (remaining areas) increments, as requested by  
104 several agencies, to ensure that the NorthMet Project Proposed Action is not contributing to any  
105 significant air quality effects.

### 106 *Air Quality Related Values*

107 In addition to PSD increments, major PSD sources that are located within 186 miles (300 km) of  
108 a Class I area may be required by the FLM to evaluate effects on AQRVs, which may include  
109 flora/fauna, visibility, water quality, soils, and odor for a specific Class I area. The NorthMet  
110 Project area is within 186 miles (300 km) of four Class I areas: BWCAW and Rainbow Lakes  
111 Wilderness (administered by the USFS) and Voyageurs National Park and Isle Royale National  
112 Park (under the administration of the National Park Service). Although the NorthMet Project  
113 Proposed Action is agreeing to emission limits to avoid being a major PSD source, an evaluation  
114 of the applicable AQRV was conducted for comparison in this FEIS. Table 5.2.7-3 provides the  
115 distances to each Class I area from the NorthMet Project area.

116 *Table 5.2.7-3 NorthMet Project Setting Relative to Class I Regions*

| Class I Region            | Distance from NorthMet Project Area (km/mi) |
|---------------------------|---------------------------------------------|
| BWCAW                     | 34/21                                       |
| Voyageurs National Park   | 82/51                                       |
| Rainbow Lakes Wilderness  | 142/88                                      |
| Isle Royale National Park | 218/135                                     |

### 117 *New Source Performance Standards*

118 The federal New Source Performance Standards are technology-based standards that are  
119 applicable to new or modified stationary sources of regulated emissions. The New Source  
120 Performance Standards program has defined emission limitations for approximately 70 source  
121 categories that are designated by size, as well as type of process. A comprehensive list of the  
122 applicable regulations for this facility would be included as part of the air quality permit. The  
123 following is a partial list of standards that apply to the NorthMet Project Proposed Action; these  
124 could vary depending on the final assessment of the permit application by the MPCA:

- 125 • Subpart A – General Provisions, which provides for general notification, recordkeeping, and  
126 monitoring requirements.
- 127 • Subpart LL – Standards of Performance for Metallic Minerals Processing Plants, which  
128 covers particulate and opacity emission limits for any new, modified, or reconstructed  
129 sources.
- 130 • Subpart OOO – Standards of Performance for Nonmetallic Mineral Processing Plants, which  
131 limits particulate emissions and opacity from new, modified, or reconstructed sources  
132 processing nonmetallic mineral (e.g., limestone or construction rock).

133

- 134 • Subpart III – Standards of Performance for Stationary Compression Ignition Internal  
135 Combustion Engines, which limits NO<sub>x</sub>, PM, CO, fuel oil sulfur content, and opacity for  
136 new, modified, and reconstructed stationary compression ignition internal combustion  
137 engines.
- 138 • Subpart Dc – Standards of Performance for Small Industrial-Commercial-Institutional Steam  
139 Generating Units which, depending on fuel type, can regulate PM and/or SO<sub>2</sub> emissions from  
140 new, modified, or reconstructed boilers.

#### 141 ***Air Conformity Determination***

142 A conformity determination must be conducted by the lead federal agency if a federal action  
143 would generate emissions exceeding the conformity threshold levels (de minimis) of the  
144 pollutant(s) for which a Class I or Class II region is designated as a nonattainment area or as a  
145 maintenance area. Since the NorthMet Project area is classified as in attainment for all criteria  
146 pollutants, a General Conformity Determination is not required.

#### 147 ***State of Minnesota Regulations***

148 Nonferrous Mineland Reclamation rules, *Minnesota Rules* part 6132.800, administered by the  
149 MDNR, require the control of dust from areas disturbed specifically by mining operations.

150 Also, the MPCA has promulgated rules concerning the control and permitting of all sources (not  
151 just for mining operations) throughout Minnesota. The following regulations are evaluated for  
152 the NorthMet Project Proposed Action.

#### 153 ***Prevention of Significant Deterioration Review***

154 *Minnesota Rules*, part 7007.3000, incorporate by reference the federal PSD requirements that  
155 provide for a pre-construction review and permit process for the construction and operation of a  
156 new or modified major stationary source in attainment areas.

157 The NorthMet Project Proposed Action is designed to limit emissions below major source  
158 thresholds (i.e., to be permitted as a synthetic minor source). Thus, for permitting purposes, the  
159 NorthMet Project Proposed Action would not be considered a major source for PSD (BACT  
160 demonstration, PSD increment assessment, and AQRV assessment would not be required via  
161 *Minnesota Rules*, part 7007.3000). However, a comprehensive analysis of NAAQS, MAAQS,  
162 PSD Class I and II increments, and AQRV is allowed, under *Minnesota Rules*, part  
163 7007.0100(7)(k) and (v), as part of the evaluation of effect. An evaluation of pollution control  
164 technology was conducted for the Mine Site and Plant Site (PolyMet 2014m, PolyMet 2014n,  
165 PolyMet 2015e).

#### 166 ***Minnesota Standards of Performance***

167 A comprehensive list of Minnesota Standards of Performance would be identified in the air  
168 quality permit. The following is a list of Minnesota Standards of Performance applicable to the  
169 NorthMet Project Proposed Action. This list may change, depending upon the final assessment  
170 of the permit application by the MPCA.

171 Control of Fugitive PM (*Minnesota Rules*, part 7011.0150), which applies to bulk material  
172 handling operation, roads, and other fugitive sources. The rule prohibits the release of “avoidable

173 amounts” of PM, and facilities are required to take reasonable precautions to prevent the  
174 discharge of visible fugitive emissions beyond the property line.

175 Standards of Performance of Stationary Internal Combustion Engines (*Minnesota Rules*, part  
176 7011.2300). This applies to the emergency fire water pumps and the emergency generators, and  
177 limits SO<sub>2</sub> emissions to 0.5 pound per million British thermal units (lb/MMBTU) heat input.

178 Standards of Performance for Post-1969 Industrial Process Equipment (*Minnesota Rules*, part  
179 7011.0715). This would apply to all new ore-handling equipment and other new sources that  
180 would generate PM emissions for which a standard of performance has not been promulgated in  
181 a specific rule. Due to the remote location of the NorthMet Project area (i.e., any source that is  
182 not in the Minneapolis-Saint Paul Air Quality Control Region or the City of Duluth, and which is  
183 located not less than 0.25 mile from any residence or public roadway), the required control  
184 equipment efficiency standard would be 85 percent.

185 Standards of Performance for Existing Indirect Heating Equipment (*Minnesota Rules*, part  
186 7011.0510). The rule limits the PM emissions to between 0.4 and 0.6 lb/MMBTU, limits SO<sub>2</sub>  
187 emissions to between 1.6 and 4.0 lb/MMBTU, and limits opacity to 20 percent. This may apply  
188 to existing indirect heaters if used in the mining and processing operations.

189 Standards of Performance for New Indirect Heating Equipment (*Minnesota Rules*, part  
190 7011.0515). The rule limits emissions of PM to between 0.1 and 0.4 lb/MMBTU, SO<sub>2</sub> emissions  
191 to between 0.8 and 4.0 lb/MMBTU, NO<sub>x</sub> emissions to between 0.2 to 0.7 lb/MMBTU, and  
192 opacity to 20 percent. This may apply to new indirect heaters that may be used in the mine  
193 processing operations.

194 Standards of Performance for Fossil-Fuel-Burning Direct Heating Equipment (*Minnesota Rules*,  
195 part 7011.0610). The rule limits PM emissions based upon process throughput and limits opacity  
196 to 20 percent. This may apply to process heaters that may be used in the mine processing  
197 operations.

198 Standards of Performance for Pre-1969 Industrial Process Equipment (*Minnesota Rules*, part  
199 7011.0710). The rule limits mass PM emissions based upon process weight and limits opacity to  
200 20 percent. Alternatively, due to the remote location of the NorthMet Project area, compliance  
201 can be demonstrated with a pollution control equipment efficiency of 85 percent. This may apply  
202 to existing ore-handling equipment that may be used in the mine processing operations.

203 Standards of Performance for Stationary Compression Ignition Internal Combustion Engines  
204 (*Minnesota Rules*, part 7011.3520). The rule incorporates federal Standards of Performance for  
205 Stationary Compression Ignition Internal Combustion Engines under 40 CFR, Part 60, Subpart  
206 IIII. This may apply to fire water pumps and emergency generators that may be used in the mine  
207 processing operations.

208 Stationary Reciprocating Internal Combustion Engines (*Minnesota Rules*, part 7011.8150). The  
209 rule incorporates federal National Emissions Standards for Hazardous Air Pollutants under 40  
210 CFR, Part 63, Subpart ZZZZ. This may apply to fire water pumps and emergency generators that  
211 may be used in the mine processing operations.

#### 212 **5.2.7.1.2 Evaluation Criteria**

213 Various state and federal air quality standards and emissions standards have been established to  
214 minimize degradation of air quality. The criteria used for the evaluation of potential effects on air

215 quality from the NorthMet Project Proposed Action or an alternative are whether it would cause  
216 an exceedance of NAAQS or MAAQS.

217 In addition to legally applicable statutory or regulatory requirements, the following criteria also  
218 were considered in evaluating effects from the NorthMet Project Proposed Action:

- 219 • Consumption of PSD increments as defined by the CAA Title I, PSD rule;
- 220 • Adverse effects on visibility in Class I areas;
- 221 • Adverse effects on other AQRV in Class I areas; and
- 222 • Adverse effects on human health as determined by an Air Emissions Risk Analysis (AERA)  
223 (MPCA 2013b).

### 224 **5.2.7.1.3 NorthMet Project Proposed Action Emissions**

225 From an air quality perspective, emissions from the NorthMet Project Proposed Action would be  
226 expected to occur from the mining operations at the Mine Site and ore/concentrate processing at  
227 the Plant Site. Although the emission generating activities at these two sites are separated  
228 geographically, they are joined by the rail line that would be used to transport ore from the Mine  
229 Site to the Plant Site. As such, the three components constitute a single project for permitting  
230 purposes, and, thus, the total emissions from both sites are summed for the purposes of this  
231 analysis.

232 The indirect non-GHG emissions from electrical purchases are not estimated for the NorthMet  
233 Project Proposed Action. If additional electrical capacity were required, then the electrical  
234 generating units would be subject to environmental permitting and regulation and would need to  
235 meet stringent emission limits for both criteria and non-criteria pollutants. In addition, no direct  
236 emissions of odor-causing compounds from the Mine Site or Plant Site are anticipated.

237 At the Mine Site, emissions were estimated for material handling sources associated with  
238 excavation, portable crushing and screening operations, blast hole drilling, use of unpaved roads,  
239 and vehicle exhaust.

240 Material handling includes the loading of overburden, waste rock, lean ore, and ore into trucks  
241 with shovels or loaders. After it is hauled, the ore would be dumped into the Rail Transfer  
242 Hopper and the overburden, waste rock, and lean ore would be unloaded at the appropriate  
243 stockpile or pit. The crushing and screening operations would be used to break up and separate  
244 the larger rocks from soil and gravel in the overburden to produce rock suitable for construction  
245 purposes. Haul trucks would travel over unpaved roads from the excavation site to the rail  
246 loading and stockpiling areas. Fugitive emissions would be generated as part of these operations.  
247 In order to minimize fugitive emissions, the NorthMet Project Proposed Action would utilize  
248 several control measures. These include minimization of drop distances for ore-screening, truck  
249 loading/unloading, and rail-loading; water and other dust suppressants on haul roads (90 percent  
250 control); water sprays for rock crushing and screening; down-hole watering during blasting  
251 operations; and environmental observations and recording. In addition, two PM<sub>10</sub> monitors are  
252 proposed to minimize fugitive dust effects at the mine.

253 At the Plant Site, point source emissions are predicted to occur from the crushing plant, flotation  
254 operation autoclaves and other hydrometallurgical processes, process consumables handling, and  
255 combustion. In addition, fugitive emissions are expected to occur from raw materials handling,

256 Plant Site roads, the Tailings Basin, and from vehicle use of Dunka Road. Water spraying or  
 257 other dust suppression would be used on all unpaved roads at the Plant Site, resulting in an 80  
 258 percent reduction in associated fugitive emissions.

259 PolyMet is proposing to accept emission limits below the major source threshold (stationary  
 260 sources less than 250 tpy for criteria pollutants and 100,000 tpy for GHGs) so as to be classified  
 261 as a synthetic minor PSD source and therefore not be subject to PSD requirements including  
 262 modeling attainment with PSD increments for permitting purposes. As demonstrated in Table  
 263 5.2.7-4, below, the NorthMet Project Proposed Action does not have projected controlled  
 264 emissions above major PSD thresholds on an annual basis. PSD required modeling analyses,  
 265 however, were performed for this FEIS to assess its effect to ensure that the minor-source  
 266 NorthMet Project Proposed Action does not cause or contribute to significant effects.

267 ***Criteria Pollutants***

268 Criteria pollutant emissions are expected from both the Mine Site and Plant Site. Detailed  
 269 information on the emission calculations for each site source is available as separate documents  
 270 (MPCA 2012e; PolyMet 2015e). Table 5.2.7-4 summarizes the NorthMet Project Proposed  
 271 Action maximum emissions for the Mine Site, Plant Site, and total emissions from PSD-  
 272 regulated stationary sources for comparison with PSD Major Source Thresholds.

273 **Table 5.2.7-4 Annual Criteria Air Pollutant Emissions for Prevention of Significant**  
 274 **Deterioration-regulated Stationary Sources**

| <b>Pollutant</b>  | <b>Plant Site Projected<br/>Controlled<br/>Emissions (tpy)<br/>(controlled<br/>potential)</b> | <b>Mine Site Projected<br/>Controlled<br/>Emissions (tpy)<br/>(controlled<br/>potential)</b> | <b>Total Projected<br/>Controlled<br/>Emissions (tpy)<br/>(controlled<br/>potential)</b> | <b>PSD Major<br/>Source<br/>Thresholds (tpy)</b> |
|-------------------|-----------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------|--------------------------------------------------|
| NO <sub>x</sub>   | 117                                                                                           | 5                                                                                            | 122                                                                                      | 250                                              |
| SO <sub>2</sub>   | 7                                                                                             | 0.8                                                                                          | 8                                                                                        | 250                                              |
| TSP               | 201                                                                                           | 9                                                                                            | 210                                                                                      | 250                                              |
| PM <sub>10</sub>  | 192                                                                                           | 4                                                                                            | 196                                                                                      | 250                                              |
| PM <sub>2.5</sub> | 190                                                                                           | 2                                                                                            | 192                                                                                      | 250                                              |
| VOC               | 50                                                                                            | 0.2                                                                                          | 50                                                                                       | 250                                              |
| Lead              | 0                                                                                             | 0                                                                                            | 0                                                                                        | 250                                              |
| CO                | 127                                                                                           | 2                                                                                            | 129                                                                                      | 250                                              |

275 <sup>†</sup> The Plant Site emissions shown in Table 5.2.7-4 are the basis for the air dispersion modeling an impact assessment for the  
 276 Project; however, planned changes to the Plant Site unit operations and configuration result in lower emissions of all criteria  
 277 pollutants; therefore, additional air dispersion modeling analysis is not necessary because the worst case emissions were  
 278 modeled.

279 In accordance with PSD permitting requirements, for this assessment, mobile emissions and  
 280 fugitive emissions sources are not included in the determination of a major source. Under PSD  
 281 requirements, fugitive sources are only included if the stationary source is defined as one of 28  
 282 named source categories. The NorthMet Project Proposed Action is not included in any of the  
 283 USEPA-listed source categories; therefore, fugitive sources are not included in the determination  
 284 of a major source. However, to assess modeled air effects, mobile and fugitive emissions from  
 285 the operations were evaluated. The non-PSD-regulated mobile source emissions and fugitive  
 286 emissions are summed in Table 5.2.7-5. Due to the size of the ore rock being transported, the  
 287 design of the railcars, and the short distance of transport from the Mine Site to the Plant Site, the

288 ore fines are expected to be coarse in nature. Thus, no significant reactive airborne fugitive dust  
 289 from the rail transport is expected (MDNR et al. 2011) and is not included in the fugitive  
 290 emissions. Any spillage of the ore fines is expected to be within 2 meters of the rail line, along  
 291 the path, and any effects of the reactive ore on the ground has been addressed in Section 5.2.3.

292 **Table 5.2.7-5 Annual Air Pollutant Emissions for non-Prevention of Significant**  
 293 **Deterioration-regulated Mobile Sources and Fugitive Sources**

| <b>Pollutant</b>  | <b>Plant Site Projected<br/>Controlled Emissions<br/>(tpy)</b> | <b>Mine Site Projected<br/>Controlled Emissions<br/>(tpy)</b> | <b>Total Projected<br/>Controlled Emissions<br/>(tpy)</b> |
|-------------------|----------------------------------------------------------------|---------------------------------------------------------------|-----------------------------------------------------------|
| NO <sub>x</sub>   | 58                                                             | 321                                                           | 379                                                       |
| SO <sub>2</sub>   | 0                                                              | 2                                                             | 2                                                         |
| PM <sub>10</sub>  | 238                                                            | 462                                                           | 700                                                       |
| PM <sub>2.5</sub> | 31                                                             | 77                                                            | 108                                                       |

294

295 **Hazardous Air Pollutants Emissions**

296 Small amounts of potentially toxic compounds, which are referred to as HAPs, are expected to  
 297 be associated with the NorthMet Project Proposed Action. Table 5.2.7-6 provides the estimate of  
 298 HAP emissions for the NorthMet Project Proposed Action stationary sources. These emission  
 299 levels reflect potential emissions taking into account the proposed pollution control equipment  
 300 for the NorthMet Project Proposed Action (controlled). As seen in the table, total emissions of a  
 301 single HAP are below 10 tpy and the combined HAP emissions are below 25 tpy, indicating that  
 302 the HAP emissions would not exceed USEPA major source thresholds for HAPs. Although HAP  
 303 emissions from mobile sources were not included in the table to address emission thresholds,  
 304 these emissions were used in assessing the potential effects on human health. The AERA itself is  
 305 not limited to an assessment of HAPs, but is inclusive of any air toxic pollutant that screened in  
 306 during the scoping process.

307 **Table 5.2.7-6 Annual Hazardous Air Pollutant Emissions**

| <b>Pollutant</b>        | <b>Plant Site<br/>Projected<br/>Controlled<br/>Emissions (tpy)<br/>(controlled<br/>potential)</b> | <b>Mine Site<br/>Projected<br/>Controlled<br/>Emissions (tpy)<br/>(controlled<br/>potential)</b> | <b>Total Projected<br/>Controlled<br/>Emissions (tpy)<br/>(controlled<br/>potential)</b> | <b>Major Source<br/>Threshold (tpy)</b> |
|-------------------------|---------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------|-----------------------------------------|
| Single HAP <sup>1</sup> | 4                                                                                                 | 1                                                                                                | 5                                                                                        | 10                                      |
| Combined HAPs           | 14                                                                                                | 3                                                                                                | 17                                                                                       | 25                                      |

308 <sup>1</sup> Nickel is the HAP with the highest emissions for the Plant Site; manganese has the highest emissions at the Mine Site (2 tpy).  
 309 Highest single HAP emissions for the NorthMet Project Proposed Action (Plant Site plus Mine Site) are the nickel emissions.  
 310 Values in Table 5.2.7-6 reflect nickel emissions.

311 **Greenhouse Gas Emissions**

312 Direct and indirect GHG emissions would be associated with the NorthMet Project Proposed  
 313 Action. Direct emissions are emitted from project sources; indirect emissions are from sources  
 314 that are not part of the project, but are generated from activities that support the project (e.g., off-  
 315 site electrical needs). These gases include primarily carbon dioxide (CO<sub>2</sub>), N<sub>2</sub>O, and methane

316 (CH<sub>4</sub>). GHG emissions are estimated based upon their global warming potential and are  
 317 expressed in carbon dioxide equivalents (CO<sub>2</sub>e). Global warming potential is the relative effect a  
 318 specific compound has on the overall global warming effects. The global warming potential  
 319 factors for the three pollutants are 1, 310, and 21, respectively. For this assessment, the CO<sub>2</sub>e is  
 320 estimated by multiplying the specific emissions by its global warming potential factor and then  
 321 summing the results. Table 5.2.7-7 summarizes the controlled direct GHG emissions for the  
 322 NorthMet Project Proposed Action. As seen from the table, total direct GHG emissions are less  
 323 than 100,000 tpy of CO<sub>2</sub>e and would not exceed the USEPA major source thresholds for GHGs.

324 **Table 5.2.7-7 Annual Greenhouse Gas Emissions for Prevention of Significant**  
 325 **Deterioration-regulated Stationary Sources<sup>2</sup>**

| <b>Pollutant</b>                         | <b>Plant Site<br/>Projected<br/>Controlled<br/>Emissions (tpy)</b> | <b>Mine Site<br/>Projected<br/>Controlled<br/>Emissions (tpy)</b> | <b>Total Projected<br/>Controlled<br/>Emissions (tpy)</b> | <b>Major Source<br/>Threshold (tpy)</b> |
|------------------------------------------|--------------------------------------------------------------------|-------------------------------------------------------------------|-----------------------------------------------------------|-----------------------------------------|
| CO <sub>2</sub>                          | 75,532                                                             | 1,740                                                             | 77,232                                                    | -                                       |
| N <sub>2</sub> O                         | 0.9                                                                | 0.08                                                              | 1.0                                                       | -                                       |
| CH <sub>4</sub>                          | 0.5                                                                | 0.02                                                              | 0.5                                                       | -                                       |
| <b>Total CO<sub>2</sub>e<sup>1</sup></b> | <b>75,836</b>                                                      | <b>1,764</b>                                                      | <b>77,600</b>                                             | <b>100,000</b>                          |

326 <sup>1</sup> CO<sub>2</sub>e is used to assess PSD applicability and considers only emissions from stationary sources. The PSD applicability is based  
 327 on short tons of emissions and the Table 5.2.7-7 values are all in short tons per year.

328 <sup>2</sup> The values in Table 5.2.7-7 are not proposed permit limits.

329 Estimated annual maximum potential emissions of the NorthMet Project Proposed Action are  
 330 based as it is currently proposed running at maximum capacity (potential) (see Table 5.2.7-7).  
 331 Potential annual GHG emissions from the NorthMet Project Proposed Action, as opposed to  
 332 maximum potential emissions, are shown below in Table 5.2.7-8. Potential emissions are the  
 333 sum of direct and indirect GHG emissions. Potential GHG emissions from the NorthMet Project  
 334 Proposed Action are calculated using The Climate Registry General Reporting Protocol (Climate  
 335 Registry 2008) and the MPCA General Guidance for Carbon Footprint Development in  
 336 Environmental Review (MPCA 2011e). Emissions are calculated using default emission factors  
 337 for specific fuels from the two documents. The annualized carbon footprint is summarized in  
 338 Table 5.2.7-8; the lifetime carbon footprint is provided in Table 5.2.7-9.

339 For this analysis, emission estimates for the direct and indirect source equipment used generally  
 340 accepted emission factors and estimation methods from the World Resource Institute  
 341 Greenhouse Gas Protocol Standard, the Intergovernmental Panel on Climate Change (IPCC), and  
 342 the MPCA General Guidance on Carbon Footprint in Environmental Review (MPCA 2009d).  
 343 Emissions estimates from secondary emissions sources generally utilized emissions factors that  
 344 would represent estimates greater than actual values (high estimation) or best estimates of actual  
 345 values based upon literature review (central tendency) (PolyMet 2015e).

346 **Table 5.2.7-8 NorthMet Project Proposed Action Annual Greenhouse Gas Emissions**

| <b>Pollutant</b>         | <b>Potential Direct Emissions<sup>1</sup> (CO<sub>2</sub>e – mtpy)<sup>2</sup></b> | <b>Potential Indirect Emissions<sup>3</sup> (CO<sub>2</sub>e – mtpy)</b> | <b>Potential Total Emissions (CO<sub>2</sub>e – mtpy)</b> |
|--------------------------|------------------------------------------------------------------------------------|--------------------------------------------------------------------------|-----------------------------------------------------------|
| Mine Site Point Source   | 1,600                                                                              | --                                                                       | --                                                        |
| Mine Site Mobile Source  | 38,086                                                                             | --                                                                       | --                                                        |
| Plant Site Point Source  | 138,641                                                                            | --                                                                       | --                                                        |
| Plant Site Mobile Source | 8,014                                                                              | --                                                                       | --                                                        |
| Terrestrial Carbon Loss  | 10,000                                                                             |                                                                          |                                                           |
| <b>Totals</b>            | <b>196,341</b>                                                                     | <b>511,000</b>                                                           | <b>707,342</b>                                            |

347 <sup>1</sup> Maximum Potential Direct Emissions are all emissions from sources that are under direct control of the NorthMet Project  
 348 Proposed Action and full maximum capacity.  
 349 <sup>2</sup> CO<sub>2</sub>e is in metric tons per year (mtpy). Emission estimates are expressed as metric tons per year in Table 5.2.7-8 because that  
 350 unit is the international discussion of CO<sub>2</sub>e emissions.  
 351 <sup>3</sup> Indirect emissions: Emissions that are a consequence of the activities of the reporting entity, but that occur at sources owned or  
 352 controlled by another entity. For example, emissions that occur at a power plant as a result of electricity being generated and  
 353 subsequently used by the NorthMet Project Proposed Action.  
 354

355 **Table 5.2.7-9 NorthMet Project Proposed Action Lifetime Greenhouse Gas Emissions**

| <b>Pollutant</b>                     | <b>Potential Direct Emissions<sup>1</sup> (CO<sub>2</sub>e – mt)<sup>2</sup></b> | <b>Potential Indirect Emissions (CO<sub>2</sub>e – mt)<sup>6</sup></b> | <b>Potential Total Emissions (CO<sub>2</sub>e – mt)</b> |
|--------------------------------------|----------------------------------------------------------------------------------|------------------------------------------------------------------------|---------------------------------------------------------|
| Mine Site Emissions <sup>3</sup>     | 793,734                                                                          |                                                                        |                                                         |
| Plant Site Emissions <sup>3</sup>    | 2,933,181                                                                        |                                                                        |                                                         |
| Construction Emissions <sup>4</sup>  | 94,186                                                                           |                                                                        |                                                         |
| Reclamation Emission <sup>5</sup>    | 1,549,688                                                                        |                                                                        |                                                         |
| <b>Subtotals</b>                     | <b>5,370,789</b>                                                                 | <b>10,220,000</b>                                                      | <b>15,590,789</b>                                       |
| Terrestrial Carbon Loss <sup>7</sup> | 199,963                                                                          | -                                                                      | 199,963                                                 |
| <b>Totals</b>                        | <b>5,570,752</b>                                                                 | <b>10,220,000</b>                                                      | <b>15,790,752</b>                                       |

356 <sup>1</sup> Maximum Potential Direct Emissions are all emissions from sources that are under direct control of the NorthMet Project  
 357 Proposed Action and full maximum capacity.  
 358 <sup>2</sup> CO<sub>2</sub>e is in metric tons (mt).  
 359 <sup>3</sup> Based upon maximum annual emissions occurring for 20 years.  
 360 <sup>4</sup> Includes Phase I (flotation concentration production only) and Phase II (Hydrometallurgical Plant) construction.  
 361 <sup>5</sup> Based on 20-year closure period and 30-year long-term closure period for the WWTF and WWTP.  
 362 <sup>6</sup> Indirect emissions: Emissions that are a consequence of the activities of the reporting entity, but that occur at sources owned or  
 363 controlled by another entity. For example, emissions that occur at a power plant as a result of electricity being generated and  
 364 subsequently used by the NorthMet Project Proposed Action.  
 365 <sup>7</sup> Terrestrial carbon loss includes: wetland carbon loss, 20 years of emissions from stockpiled peat, and emission from peat used  
 366 in reclamation.

367 **5.2.7.1.4 Predictive Modeling Approach**

368 Detailed air dispersion modeling was conducted to evaluate compliance with NAAQS and  
 369 MAAQS, to support PSD increment analysis, and to identify other potential effects on Class I  
 370 and Class II areas. Although the NorthMet Project Proposed Action is not considered a major  
 371 source for PSD considerations, the modeling analysis was conducted pursuant to the PSD  
 372 regulations. The methods used for modeling are summarized below.

373 **NAAQS, MAAQS, and Class II Increment Modeling Approach**

374 To assess the effects on air quality, air dispersion modeling techniques were utilized. The MPCA  
375 prefers the AERMOD modeling system, and USEPA has included AERMOD as an approved  
376 guideline model. Meteorological data (2006 to 2010) from the Hibbing station and concurrent  
377 International Falls mixing height data, suitable for input to AERMOD, were used to evaluate the  
378 NorthMet Project Proposed Action. The AERMINUTE meteorological processor was used to  
379 develop the meteorological dataset for AERMOD.

380 The air quality modeling addressed individual point sources, as well as all sources of fugitive  
381 particulate matter. The modeling was conducted to determine the extent of effects from criteria  
382 pollutant emissions on ambient air quality and to identify the significant impact area for each  
383 pollutant. Modeling was conducted for PM<sub>10</sub>, PM<sub>2.5</sub>, NO<sub>2</sub>, and SO<sub>2</sub> and their respective  
384 applicable averaging times at both the Mine Site and Plant Site (PolyMet 2014m; PolyMet  
385 2014n). Ozone emissions were not modeled or analyzed for NAAQS due to the regional nature  
386 of ozone formation involving complex interaction of multi-pollutants. It should be noted that  
387 ozone is not emitted directly from any mining or ore-processing source. Emissions of lead and  
388 CO were not modeled for the NorthMet Project Proposed Action following the MPCA-approved  
389 modeling protocols for the Plant Site and Mine Site. NorthMet Project Proposed Action  
390 emissions were initially modeled and compared to their respective Significant Impact Limit  
391 (SIL), as provided in Table 5.2.7-10 for each of the pollutants and averaging times. The SIL is  
392 the threshold for a given pollutant and averaging time, where no further modeling analysis is  
393 required. Modeled concentrations above the SIL do not define a significant effect in the context  
394 of the EIS; rather, where the modeled concentrations are above the SIL, more refined modeling  
395 is required in order to evaluate compliance with PSD increments and NAAQS. The farthest  
396 distance from the source where the concentration is above the SIL defines the circular region that  
397 would require further affect modeling.

398 All point and fugitive sources associated with the Mine Site and Plant Site were included in the  
399 source input files for PSD Class II increment modeling, with the exception of the Plant Site  
400 unpaved roads, which were in operation at the baseline date. Additionally, data on the following  
401 nearby major increment-consuming (or increment-expanding) sources, which were determined  
402 and provided by the MPCA, were also included as source input:

- 403 • Mesabi Nugget;
- 404 • Mesabi Mining Project;
- 405 • Cliffs Erie pellet yard; and
- 406 • Former LTVSMC processing plant.

407 It should be noted that the Northshore Mine was determined to be permitted before the PSD  
408 baseline date, and is not an increment-consuming source; therefore, it was not included in the  
409 increment modeling.

410 Model inputs for these sources were provided by the MPCA. For comparison to the NAAQS, a  
411 background concentration was added to the modeled concentration. PM<sub>10</sub> background  
412 concentrations represent the 2008 to 2010, 3-year average concentrations for the high-second-  
413 high 24-hour concentration and maximum annual average concentration from the Virginia,  
414 Minnesota air quality monitoring site. PM<sub>2.5</sub> background concentrations represent the 2008-2010

415 average concentrations for the highest 2<sup>nd</sup> high (H2H) 24-hour and annual average concentrations  
416 from the same station. Hourly SO<sub>2</sub> and NO<sub>2</sub> background concentrations are from 2008-2010  
417 MPCA update data for use in modeling assessments (MPCA 2012i) for sites outside  
418 Minneapolis.

419 Project design modifications were made to the NorthMet Project Proposed Action since  
420 modeling was undertaken. These modifications include the addition of a SAG Mill, relocation of  
421 the Coal Ash Landfill, installation of cement deep soil mixing, and construction of a water  
422 containment system on the eastern side of the Tailings Basin. The Co-lead Agencies considered  
423 information provided by PolyMet pertaining to these project modifications and determined that  
424 the existing air dispersion modeling was representative and additional modeling was not required  
425 for the EIS but may be required for permitting.

### 426 **Class I Area-Related Modeling Approach**

427 An air quality modeling analysis was conducted to estimate effects of the NorthMet Project  
428 Proposed Action on air quality in Class I areas. The Class I AQRV analyses addressed PSD  
429 Class I increments for SO<sub>2</sub>, PM<sub>10</sub>, NO<sub>2</sub>, sulfur and nitrogen deposition, and visibility impairment.  
430 Regional haze is addressed in Section 6.2.3.8.8. The dispersion modeling analysis used standard  
431 USEPA long-range transport modeling methodologies and followed guidance as presented in:  
432 1) USEPA's Guideline on Air Quality Models, the Interagency Workgroup on Air Quality  
433 Modeling Phase 2 report; 2) the Federal Land Managers' Air Quality Related Values Work  
434 Group (FLAG) Phase I report (revised November 2010); and 3) the "FLM Recommendations on  
435 Class I Area Analyses." The analyses also incorporated suggestions and guidance received from  
436 the USFS and the National Park Service. The California Puff (CALPUFF) air quality modeling  
437 system (version 5.8, June 23, 2007 release) was used for all Class I area analyses.

438 Input options and data utilized in the models generally corresponded to default or USEPA-  
439 recommended values along with representative, NorthMet Project Proposed Action-specific  
440 source input parameters. The CALPUFF modeling analysis used refined meteorological fields  
441 from the CALMET subprogram of CALPUFF, developed from the 5<sup>th</sup> Generation NCAR/Penn  
442 State Mesoscale Model prognostic meteorological data for the available years 2002, 2003, and  
443 2004. These were refined using concurrent surface, upper air, and precipitation data as outlined  
444 in the Final SDD. CALMET settings were based on the USEPA Office of Air Quality Planning  
445 and Standards memorandum "Clarification on EPA-FLM Recommended Settings for CALMET"  
446 (August 31, 2009) (USEPA 2009a). Hourly surface data from approximately 88 stations and  
447 precipitation data from 99 stations were used along with upper air data from four stations. No  
448 cloud data were used.

449 Pollutant emissions modeled in CALPUFF were SO<sub>2</sub>, NO<sub>x</sub>, PMC (coarse particulate matter),  
450 PMF (fine particulate matter), elemental carbon, secondary organic aerosols, and SO<sub>4</sub>.  
451 Additionally, the pollutants SO<sub>4</sub>, NO<sub>3</sub>, and HNO<sub>3</sub> were modeled as products of the chemical  
452 transformation of SO<sub>2</sub> and NO<sub>x</sub>. For the AQRV analysis, the MESOPUFF II scheme was used  
453 for the chemical mechanism to compute chemical transformation rates based on user-supplied  
454 background values for ozone and ammonia. Per MPCA guidance, the MESOPUFF II algorithm  
455 and secondary particulate formation were not used in the PM<sub>10</sub> increment consumption  
456 evaluation. Finally, the CALPOST and POSTUTIL post-processing programs were used to  
457 generate values of pollutant concentration, deposition, and visibility.

458 For the increment consumption analysis, emissions were modeled as the worst case over the  
459 expected life of the NorthMet Project Proposed Action. For the AQRV analysis, four emissions  
460 scenarios, representing emissions at different stages of the NorthMet Project Proposed Action,  
461 were modeled. The scenarios differ only in mobile source emissions (which were not included in  
462 the increment analysis). The effects of all four scenarios on visibility within the Class I areas are  
463 presented in Section 5.2.7.2.1.

#### 464 **5.2.7.2 NorthMet Project Proposed Action**

465 This section describes effects that may occur on local and regional air quality from implementing  
466 the NorthMet Project Proposed Action. Potential effects on visibility that could occur from  
467 increases in project emissions are also discussed. The results of the modeling are used to  
468 represent an upper bound for assessing potential effects from the NorthMet Project Proposed  
469 Action.

##### 470 **5.2.7.2.1 NAAQS and Prevention of Significant Deterioration Increment Impact Analysis**

471 State and federal air quality rules prohibit emissions from a new facility that cause or contribute  
472 to an exceedance of MAAQS or NAAQS. To demonstrate NorthMet Project Proposed Action  
473 effects relative to NAAQS and PSD increments, an air dispersion modeling analysis for the  
474 NorthMet Project Proposed Action was conducted (PolyMet 2014m; PolyMet 2014n; PolyMet  
475 2015e).

##### 476 **Initial Significant Impact Limit Analysis**

477 The Mine Site and Plant Site are located 8 miles apart, but are connected by a private railway  
478 that was originally constructed to transport iron ore pellets from Cliffs Erie's process plant to  
479 their ore dock. A portion of this railway is proposed to be used for the transportation of ore from  
480 the Mine Site to the Plant Site. Although the site may be permitted as a single facility, the Mine  
481 Site and Plant Site emission sources are not adjacent to each other but rather separated by a  
482 substantial (8 miles) distance. Therefore, it is appropriate and informative to perform individual  
483 air dispersion modeling for two distinct sets of receptors, one set surrounding the Mine Site and  
484 the second surrounding the Plant Site. For the Mine Site receptor grid, both Mine Site and Plant  
485 Site emissions were modeled explicitly. However, for the Plant Site receptor grid, only the  
486 emissions from the Plant Site were included, since previous modeling of the Mine Site emissions  
487 showed that effects were below the SIL in the region encompassing the Plant Site receptor grid.  
488 SILs have been established by the USEPA such that concentrations below these levels are not  
489 anticipated to contribute to a change in the overall effect when combined with other nearby  
490 source effects. The MPCA approved the exclusion of the Mine Site emissions in assessing the  
491 effects at the Plant Site receptor grid locations, as they would not likely contribute to a change in  
492 the overall effects. The results are discussed below.

493 The Plant Site PM<sub>10</sub> emissions were modeled with all sources operating at full capacity in a  
494 single modeling run. This conservatively predicts (overestimates) the effects, as not all sources  
495 would be capable of operating simultaneously at full capacity. PM<sub>10</sub> and PM<sub>2.5</sub> are the primary  
496 pollutants emitted from the Plant Site. Emissions of SO<sub>2</sub> and NO<sub>x</sub> would be relatively small  
497 because the process is conducted at relatively low temperatures and would not include any  
498 continuously operating fuel combustion sources. The Mine Site emission rates are based on a  
499 daily average mining rate of 32,000 tons of ore.

500 Table 5.2.7-10 shows modeled effects at the Mine Site and Plant Site receptors compared to the  
 501 SIL. The maximum modeled effects are maximums from either the Mine Site or the Plant Site  
 502 analyses, since each analysis includes all NorthMet Project emissions, as defined above. The  
 503 USEPA has developed SILs as a way to screen out, from further PSD analysis, pollutants that are  
 504 not expected to cause any significant contribution to existing air quality levels. The emissions  
 505 included are at 100 percent capacity for each averaging period.

506 The overall effects within the Plant Site receptor grid predicted higher maximum concentrations  
 507 than the effects within the Mine Site receptor grid for all pollutants modeled. As seen in the  
 508 table, maximum PM<sub>10</sub> and PM<sub>2.5</sub> concentrations in both regions (and for all averaging periods)  
 509 were above their respective SILs, so further analysis in those regions, for those pollutants, was  
 510 conducted. For NO<sub>2</sub> and SO<sub>2</sub>, the effects in the Plant Site receptor grid exceed their SILs for all  
 511 averaging periods and additional analysis was conducted for this receptor region. The NO<sub>2</sub> and  
 512 SO<sub>2</sub> effects in the Mine Site receptor grid are all below each respective SIL, and, thus, no  
 513 additional analysis was conducted.

514 **Table 5.2.7-10 Highest NorthMet Project Proposed Action Effects and Prevention of**  
 515 **Significant Deterioration Class II Significant Impact Limits**

| Pollutant         | Averaging Time | PSD Class II Significant Impact Limits (µg/m <sup>3</sup> ) | Plant Site Area Modeled Effects (µg/m <sup>3</sup> ) <sup>1</sup> | Mine Site Area Modeled Effects (µg/m <sup>3</sup> ) <sup>1</sup> |
|-------------------|----------------|-------------------------------------------------------------|-------------------------------------------------------------------|------------------------------------------------------------------|
| SO <sub>2</sub>   | 1-hour         | 7.83                                                        | <b><i>103</i></b>                                                 | 0.7                                                              |
|                   | 3-hour         | 25                                                          | <b><i>85</i></b>                                                  | 0.5                                                              |
|                   | 24-hour        | 5                                                           | <b><i>35</i></b>                                                  | 0.1                                                              |
|                   | Annual         | 2                                                           | <b><i>6</i></b>                                                   | 0.01                                                             |
| PM <sub>10</sub>  | 24-hour        | 5                                                           | <b><i>44</i></b>                                                  | <b><i>30</i></b>                                                 |
|                   | Annual         | 1                                                           | <b><i>12</i></b>                                                  | <b><i>6.3</i></b>                                                |
| PM <sub>2.5</sub> | 24-hour        | 1.2                                                         | <b><i>17</i></b>                                                  | <b><i>10</i></b>                                                 |
|                   | Annual         | 0.3                                                         | <b><i>6</i></b>                                                   | <b><i>2.2</i></b>                                                |
| NO <sub>2</sub>   | 1-hour         | 7.52                                                        | <b><i>88</i></b>                                                  | 5.3                                                              |
|                   | Annual         | 1                                                           | <b><i>3</i></b>                                                   | 0.1                                                              |

516 <sup>1</sup> Bold and italicized values exceed SIL.

517 **Prevention of Significant Deterioration Class II Increment Analysis**

518 Based upon the results of the SIL analysis, PSD Class II increment analyses were completed for  
 519 PM<sub>10</sub> for both the Mine Site and Plant Site receptor grid locations. In addition, a PSD Class II  
 520 increment analysis was conducted for NO<sub>2</sub> and SO<sub>2</sub> only at the Plant Site receptors. Even though  
 521 maximum PM<sub>2.5</sub> concentrations exceed the SILs, the minor source baseline date for increment  
 522 analysis in St. Louis County has not been set. Therefore, no increment analysis can be conducted  
 523 for this pollutant. However, modeling of PM<sub>2.5</sub> was conducted for comparison with the PM<sub>2.5</sub>  
 524 NAAQS; the results are presented later in this section. The modeling included all NorthMet  
 525 Project Proposed Action increment-consuming sources at maximum emission rates plus all  
 526 nearby increment-consuming (and expanding) emissions sources, including the Cliffs Erie pellet  
 527 yard, the former LTVSMC processing plant, and Mesabi Nugget. The results of the increment  
 528 analyses are shown in Table 5.2.7-11, along with a comparison to the allowable Class II PSD  
 529 increments.

530 **Table 5.2.7-11 Results of Class II Prevention of Significant Deterioration Increment**  
 531 **Analysis**

| Pollutant                       | Averaging Time | Plant Site Receptor Grid Modeled Effects ( $\mu\text{g}/\text{m}^3$ ) <sup>(1) (3)</sup> | Mine Site Receptor Grid Modeled Effects ( $\mu\text{g}/\text{m}^3$ ) <sup>(1) (3)</sup> | PSD Increment Limits ( $\mu\text{g}/\text{m}^3$ ) |
|---------------------------------|----------------|------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------|---------------------------------------------------|
| SO <sub>2</sub>                 | 3-hour         | 85                                                                                       | NA                                                                                      | 512                                               |
|                                 | 24-hour        | 35                                                                                       | NA                                                                                      | 91                                                |
|                                 | Annual         | 6                                                                                        | NA                                                                                      | 20                                                |
| PM <sub>10</sub> <sup>(2)</sup> | 24-hour        | 27                                                                                       | 27                                                                                      | 30                                                |
|                                 | Annual         | -0.1                                                                                     | 6                                                                                       | 17                                                |
| NO <sub>2</sub>                 | Annual         | 3.2                                                                                      | NA                                                                                      | 25                                                |

532 <sup>1</sup> SO<sub>2</sub> concentrations were not modeled due to negligible incremental effect.  
 533 <sup>2</sup> Modeled PM<sub>10</sub> concentrations are based on operating scenarios at year 8 and year 13.  
 534 <sup>3</sup> Plant Site modeled emissions include expansion credit and are evaluated at Plant Site boundary. Mine Site modeled emissions  
 535 include Plant Site, Mesabi Nugget, Cliffs Erie pellet yard, and former LTVSMC processing plant and existing LTVSMC  
 536 Tailings Basin.

537 The table displays the maximum predicted concentrations for each pollutant of concern and each  
 538 averaging period for both the Mine Site and Plant Site receptor grid locations. Since the receptor  
 539 grid locations for the Mine Site and Plant Site represent separate distinct regions, the maximum  
 540 modeled effect for each modeling region is compared separately with the PSD Class II increment  
 541 limit to assess potential significant effects. Overall, all modeled effects are below their respective  
 542 PSD Class II limits; however, the maximum 24-hour PM<sub>10</sub> effects in the Mine Site and Plant Site  
 543 modeling regions approach the Class II increment (27  $\mu\text{g}/\text{m}^3$  versus 30  $\mu\text{g}/\text{m}^3$ ).

544 **Mine Site Receptors Analysis**

545 The PM<sub>10</sub> modeling was conducted for two operating scenarios corresponding to the temporary  
 546 stockpile phase and the in-pit disposal/stockpile reclamation phase that would occur over the  
 547 20-year life of the mine. The worst case years for temporary stockpile phase waste rock (year 8)  
 548 and in-pit disposal (year 13) were chosen to represent the worst case for the entire mine life. Due  
 549 to the low modeled concentrations and constant emission rates for NO<sub>x</sub> and SO<sub>2</sub>, only one  
 550 scenario (year 8) was modeled for these two criteria pollutants. The modeling results for the  
 551 Mine Site receptors, including sources from the haul road, material handling, mine pits, and  
 552 diesel locomotives indicate that the highest modeled 24-hour H2H PM<sub>10</sub> concentration was 27  
 553  $\mu\text{g}/\text{m}^3$  for the year 8 operating scenario and 29  $\mu\text{g}/\text{m}^3$  for the year 13 operating scenario (shown  
 554 on Table 5.2.7.11). The H2H corresponds to not exceeding a standard more than once per year,  
 555 as defined by the applicable standard. NO<sub>2</sub> and SO<sub>2</sub> effects from the NorthMet Project Proposed  
 556 Action at the Mine Site were below the SILs, so no additional modeling including nearby sources  
 557 was performed.

558 **Plant Site Receptors Analysis**

559 The Plant Site PM<sub>10</sub> emissions were modeled with all sources operating at full capacity in a  
 560 single modeling run (independent of operating year). This conservatively predicts  
 561 (overestimates) the effects, as not all sources would be capable of operating simultaneously at  
 562 full capacity. The operation at the Plant Site, including fugitive sources, building vents,  
 563 limestone material handling, and vehicular traffic on unpaved roads results in a maximum  
 564 increment concentration for PM<sub>10</sub> of 27  $\mu\text{g}/\text{m}^3$  on the Plant Site boundary receptor grid, based on

565 the 24-hour H2H modeling. Modeled effects for SO<sub>2</sub> and NO<sub>x</sub> at the Plant Site receptors are also  
566 below the PSD Class II increments thresholds.

567 The data in Table 5.2.7-11 summarize the PSD increment modeling results and demonstrate that  
568 the NorthMet Project Proposed Action, in conjunction with all other neighboring PSD sources,  
569 would satisfy all state and federal increment requirements. The maximum concentrations for the  
570 Mine Site receptor grid and the Plant Site receptor grid are presented separately. Since the two  
571 receptor grids represent two separate AOCs, the maximum concentrations are not additive.

### 572 **NAAQS and MAAQS Impact Analysis**

573 The NAAQS modeling predicted the maximum effect of development at the Mine Site and Plant  
574 Site combined with activities at other regional sources. The highest total effects modeled, plus  
575 background concentrations, are compared to applicable MAAQS and NAAQS. Maximum  
576 emission rates were modeled for all NorthMet Project Proposed Action sources and key criteria  
577 pollutants (i.e., NO<sub>x</sub>, SO<sub>2</sub>, PM<sub>10</sub>, and PM<sub>2.5</sub>).

578 Table 5.2.7-12 summarizes the results of the NAAQS model analysis for the Mine Site and Plant  
579 Site separately and with both sites modeled together. The modeled concentration from either the  
580 Mine Site receptors or the Plant Site receptors was added to the ambient background to assess  
581 total effect, since, in each area, modeling analysis included the entire NorthMet Project area and  
582 nearby sources. The highest 6<sup>th</sup> high (H6H) PM<sub>10</sub> concentration for the 5-year modeling period  
583 was used for comparison to the NAAQS PM<sub>10</sub> 24-hour standard. The highest 8<sup>th</sup> high (H8H) 1-  
584 hour NO<sub>2</sub> and 24-hour PM<sub>2.5</sub> concentration for the 5-year modeling period was used for  
585 comparison to the NAAQS NO<sub>2</sub>  
586 1-hour standard and the PM<sub>2.5</sub> 24-hour standard, respectively. The H8H concentration represents  
587 the 98<sup>th</sup>-percentile daily maximum concentrations modeled over a 5-year period, as defined by  
588 each standard. The highest 4<sup>th</sup> high (H4H) 1-hour SO<sub>2</sub> concentration for the 5-year modeling  
589 period was used for comparison to the 1-hour SO<sub>2</sub> NAAQS. The H4H concentration represents  
590 the 99<sup>th</sup>-percentile daily maximum 1-hour concentrations modeled over a 5-year period, as  
591 defined by the standard. The H2H 3-hour and 24-hour SO<sub>2</sub> concentrations were used for  
592 comparison with the 3-hour and 24-hour SO<sub>2</sub> NAAQS. Maximum annual average concentrations  
593 for NO<sub>2</sub>, SO<sub>2</sub>, PM<sub>10</sub>, and PM<sub>2.5</sub> were compared against their respective annual average NAAQS.

### 594 ***Mine Site***

595 The analysis for the Mine Site included potential emissions from the nearby sources included in  
596 the NAAQS analysis, specifically Mesabi Nugget, Cliffs Erie Pellet Yard, Northshore Mine, and  
597 the Plant Site. The sources to the west of the Mine Site (Mesabi Nugget, Cliffs Erie Pellet Yard,  
598 and the Plant Site) were modeled collectively in a separate modeling run to determine their  
599 maximum modeled effect on the Mine Site receptor grid (PolyMet 2015b).

600 The PM<sub>10</sub> NAAQS modeling results conservatively added the maximum modeled emissions  
601 from the Mine Site and Plant Site and the maximum modeled effect from the other nearby  
602 sources to background concentrations for comparison to the NAAQS. Cumulative modeling and  
603 further analyses for NO<sub>2</sub> and SO<sub>2</sub> were not performed because the NO<sub>2</sub> and SO<sub>2</sub> concentrations  
604 at the Mine Site were shown to be well below the SILs.

605 The maximum effects from the Mine Site analysis are slightly higher for PM<sub>10</sub> and slightly lower  
606 for PM<sub>2.5</sub> than the effects from the Plant Site summarized below in Table 5.2.7-12. The

607 maximum predicted annual PM<sub>2.5</sub> concentration (Mine Site contribution plus background) was  
 608 10 µg/m<sup>3</sup> or approximately 83 percent of the corresponding NAAQS. The maximum predicted  
 609 24-hour PM<sub>2.5</sub> concentration was 32 µg/m<sup>3</sup> or approximately 91 percent of the short-term PM<sub>2.5</sub>  
 610 standard. All other predicted concentrations are at or below 60 percent of the allowable levels,  
 611 which demonstrates compliance with MAAQS and NAAQS.

612 **Table 5.2.7-12 Results of Class II NAAQS Modeling**

| Pollutant         | Averaging Time | Maximum Modeled – Plant Site (µg/m <sup>3</sup> ) <sup>1,2</sup> | Maximum Modeled – Mine Site (µg/m <sup>3</sup> ) <sup>1</sup> | Total (µg/m <sup>3</sup> ) <sup>2,3</sup> | NAAQS and MAAQS (µg/m <sup>3</sup> ) |
|-------------------|----------------|------------------------------------------------------------------|---------------------------------------------------------------|-------------------------------------------|--------------------------------------|
| SO <sub>2</sub>   | 1-hour         | <i>109</i>                                                       | NA                                                            | 109                                       | 1,300 <sup>(4)</sup>                 |
|                   | 1-hour         | <i>109</i>                                                       | NA                                                            | <i>109</i>                                | 196 <sup>(5)</sup>                   |
|                   | 3-hour         | <i>97</i>                                                        | NA                                                            | <i>97</i>                                 | 915                                  |
|                   | 24-hour        | <i>40</i>                                                        | NA                                                            | <i>40</i>                                 | 365                                  |

| PM <sub>2.5</sub> | 24-hour        | <i>34</i>                                                        | <i>32</i>                                                     | <i>34</i>                                 | 35                                   |
|                   | Annual         | <i>11<sup>(7)</sup></i>                                          | <i>10</i>                                                     | <i>11</i>                                 | 12                                   |
| NO <sub>2</sub>   | 1-hour         | <i>177</i>                                                       | NA                                                            | <i>177</i>                                | 188 <sup>(8)</sup>                   |
| NO <sub>2</sub>   | Annual         | <i>21</i>                                                        | NA                                                            | <i>21</i>                                 | 100                                  |

613 <sup>1</sup> Maximum concentrations include background.  
 614 <sup>2</sup> Concentrations exceeding the standard are bolded and italicized.  
 615 <sup>3</sup> Total concentration displayed is the maximum modeled concentration, from either the Plant Site receptors or Mine Site  
 616 receptors, added to the background concentration.  
 617 <sup>4</sup> MAAQS for 1-hour SO<sub>2</sub>.  
 618 <sup>5</sup> NAAQS for 1-hour SO<sub>2</sub>.  
 619 <sup>6</sup> The annual NAAQS for PM<sub>10</sub> was rescinded on October 17, 2006.  
 620 <sup>7</sup> The maximum modeled Plant Site concentration was calculated as the maximum design value as defined by the USEPA  
 621 guidance (USEPA 2013).  
 622 <sup>8</sup> NAAQS for 1-hour NO<sub>2</sub>.

623 **Plant Site**

624 The NAAQS modeling on the Plant Site ambient boundary included all Plant Site sources plus  
 625 emissions from the Tailings Basin and unpaved roads. Maximum predicted concentrations were  
 626 added to background values to calculate maximum ambient air concentrations. All predicted  
 627 concentrations are below allowable levels, and the results demonstrate compliance with all  
 628 MAAQS and NAAQS.

629 **5.2.7.2.2 Prevention of Significant Deterioration Class I Modeling Analysis**

630 Modeling analysis was conducted to assess the effects from the emissions of the NorthMet  
 631 Project Proposed Action in four USEPA-designated Class I areas within the NorthMet Project  
 632 area. Modeled effects were assessed against the PSD Class I Increment and AQRVs.

633 **Prevention of Significant Deterioration Class I Increment Modeling Results**

634 Maximum pollutant concentrations within the BWCAW, Voyageurs National Park, Isle Royale  
 635 National Park, and Rainbow Lakes Wilderness Class I areas were estimated for each of three  
 636 years and are provided in Table 5.2.7-13. As shown in the table, all of the concentrations, except

637 for the maximum 24-hour PM<sub>10</sub> concentration at BWCAW, are below their respective Class I  
 638 SIL threshold. This indicates that the NorthMet Project Proposed Action contribution to  
 639 increment consumption would be considered de minimis relative to other sources. The  
 640 exceedance of the PM<sub>10</sub> 24-hour Class I SIL at BWCAW triggers an additional cumulative  
 641 modeling analysis, including all nearby increment consuming and expanding PM<sub>10</sub> sources. The  
 642 cumulative analysis for this pollutant and averaging period are discussed in Section 6.2.7.

643 **Table 5.2.7-13 Summary of Prevention of Significant Deterioration Class I Increment**  
 644 **Analysis**

| Pollutant                                    | Averaging Period | Year Evaluated |       |       | Max (µg/m <sup>3</sup> ) | Class I Inc (µg/m <sup>3</sup> ) | Class I SIL (µg/m <sup>3</sup> ) |
|----------------------------------------------|------------------|----------------|-------|-------|--------------------------|----------------------------------|----------------------------------|
|                                              |                  | 2002           | 2003  | 2004  |                          |                                  |                                  |
| <b>Boundary Waters Canoe Area Wilderness</b> |                  |                |       |       |                          |                                  |                                  |

645 In 2010, the USEPA promulgated a Class I increment for PM<sub>2.5</sub>. However, the minor source  
 646 baseline date for PM<sub>2.5</sub> has not been triggered for the NorthMet Project area. Therefore, a  
 647 comparison of PM<sub>2.5</sub> concentration with the PM<sub>2.5</sub> Class I increment and SILs is not required and  
 648 was not performed.

649 ***Class I Areas – Air Quality Related Values Impact Analysis***

650 An air quality modeling analysis was conducted to estimate the effect of the NorthMet Project  
 651 Proposed Action on air quality in Class I areas. The analysis addressed visibility impacts on the  
 652 BWCAW, Rainbow Lakes Wilderness, Voyageurs National Park, and Isle Royale National Park.

653 The Class I AQRV analyses also included sulfur and nitrogen deposition and SO<sub>2</sub> effects on  
654 soils, water, and vegetation. The results are discussed below.

### 655 ***Class I Visibility Analysis***

656 A visibility impact analysis was carried out for BWCAW, Voyageurs National Park, and Isle  
657 Royale National Park. The Rainbow Lakes Wilderness does not have an AQRV for visibility.  
658 The recommended methodology for assessing visibility impacts, according to FLAG guidance,  
659 involves the use of CALPOST to process the data on concentrations of pollutants from the  
660 CALPUFF modeling of 24-hour emissions. In CALPOST, a daily value of light extinction is  
661 defined by the concentrations of each pollutant that can affect visibility, taking into account the  
662 efficiency of each particle type in scattering light and the relative humidity, which influences the  
663 size of sulfates and nitrates. The FLM has established threshold changes in light extinction  
664 ( $\Delta b_{\text{ext}}$ ) as a percentage of natural background that represent potential adverse effects on visibility.  
665 These thresholds are 5 percent (a potentially detectable change) and 10 percent (a level that may  
666 represent an unacceptable degradation). In the revised FLAG guidance of 2010, the FLM also  
667 lists a threshold of less than 5 percent as “presumptive no adverse impact” when compared to the  
668 highest 98<sup>th</sup> percentile daily predicted impact.

669 The FLAG 2010 guidance indicates that CALPOST Method 8 is now the preferred visibility  
670 impact calculation method for Class I AQRV analysis. Method 8 uses Class I area-specific  
671 monthly average relative humidity to calculate light extinction. Method 8 also compares  
672 visibility impacts with the 20 percent best pristine days. The previous preferred methodology,  
673 Method 2, used the CALPUFF-generated hourly relative humidity data to calculate light  
674 extinction. Method 2 compares visibility impacts on annual average pristine conditions. Since  
675 previous NorthMet Project Proposed Action modeling used the FLAG 2000 guidance, NorthMet  
676 Project Proposed Action visibility impact results calculated using both Method 8 and Method 2  
677 are presented below for comparison.

678 Table 5.2.7-14 presents results of the initial CALPUFF visibility analysis following the previous  
679 FLAG methodology, Method 2, for each NorthMet Project Proposed Action scenario. The  
680 maximum change in light extinction for Voyageurs National Park and Isle Royale National Park  
681 is below the 5 percent threshold with changes predicted at 4.50 percent and 1.23 percent,  
682 respectively. The maximum change in light extinction at the BWCAW for the three years  
683 modeled was predicted to be 11.08 percent. The data in Table 5.2.7-14 indicate that calculated  
684 visibility impacts greater than 5 or 10 percent could occur at some point within the BWCAW on  
685 a small number of days each year.

| <b>Scenario 4</b>                                |                                                          |                                                           |                                                |
| BWCAW 2002/2003/2004                             | 3/1/0                                                    | 0/0/0                                                     | 9.44/6.80/3.97                                 |
| Voyageurs National Park 2002/2003/2004           | 0/0/0                                                    | 0/0/0                                                     | 1.84/3.80/2.39                                 |
| Isle Royale National Park 2002/2003/2004         | 0/0/0                                                    | 0/0/0                                                     | 0.93/0.93/0.99                                 |

688 Table 5.2.7-15 presents results of the initial CALPUFF visibility analysis following the current  
 689 FLAG methodology, Method 8, for each NorthMet Project Proposed Action scenario. Method 8  
 690 requires the eighth-highest visibility impact to be compared with the 5 percent and 10 percent  
 691 thresholds. The eighth-highest changes in light extinction for the BWCAW, Voyageurs National  
 692 Park, and Isle Royale National Park are below the 5 percent threshold with changes predicted at  
 693 4.86 percent, 1.11 percent, and 0.44 percent, respectively, and demonstrate no expected adverse  
 694 visibility impacts compared to pristine conditions. These results of the NorthMet Project  
 695 Proposed Action reflect emission reduction measures to reduce the potential for visibility  
 696 impacts in the BWCAW, which include: upgrades to the insulation in the existing Crusher and  
 697 Concentrator buildings, utilization of low-NO<sub>x</sub> space heating equipment, a plan to phase in  
 698 vehicles that meet Tier 4 emission standards, use of efficient gen-set locomotives, the reduction  
 699 of dust collector exhaust for heating demand reductions, use of appropriate pollution control  
 700 equipment, and use of lower emitting fuels where feasible.

703 ***Effects on Soils, Waters, and Vegetation***

704 ***Deposition of Nitrogen and Sulfur***

705 Potential effects on soils, waters, and vegetation in Class I areas due to deposition of sulfur and  
 706 nitrogen were evaluated based upon model-predicted annual deposition for the NorthMet Project  
 707 Proposed Action emissions from the Mine Site and Plant Site. Impacts were evaluated according  
 708 to the USFS publication “Screening Procedures to Evaluate Effects of Air Pollution on Eastern  
 709 Wildernesses Cited as Class I Air Quality Areas.” Criteria for assessment of deposition impacts  
 710 are different for USFS areas (BWCAW and Rainbow Lakes Wilderness) and National Park  
 711 System areas (Voyageurs National Park and Isle Royale National Park). The National Park  
 712 Service has established a Deposition Analysis Threshold (DAT) of 0.01 kilograms per hectare  
 713 per year (kg/ha/yr) for both sulfur and nitrogen deposition for Class I areas in the eastern United  
 714 States. The DAT is a level below which adverse effects from a new or modified source are not  
 715 anticipated and are considered insignificant. The USFS has established Green Line Values for  
 716 assessing impacts of deposition at BWCAW and Rainbow Lakes Wilderness, which account for  
 717 soil conditions and water chemistry in development of safe levels. The Green Line values  
 718 represent the total pollutant loading below which there are no adverse effects (PolyMet 2015e).  
 719 As such, for BWCAW and Rainbow Lakes Wilderness, background deposition levels are added  
 720 to the maximum NorthMet Project Proposed Action impacts from all scenarios to assess against  
 721 Green Line Values. The current background nitrogen deposition for Rainbow Lakes Wilderness

722 (5.88 kg/ha/yr) is at the Green Line Value range for nitrogen (5 to 8 kg/ha/yr). All other  
723 background deposition values for BWCAW and Rainbow Lakes Wilderness are below their  
724 respective Green Line Values (see Table 5.2.7-16).

725 The CALPUFF results for each of the Class I areas were processed with CALPOST to calculate  
726 total annual deposition of sulfur and nitrogen at each receptor as a result of the NorthMet Project  
727 Proposed Action maximum annual average emissions. Total sulfur deposition is calculated from  
728 the wet (rain, snow, fog) and dry (particle, gas) deposition of SO<sub>2</sub> and sulfate; total nitrogen is  
729 represented by the sum of nitrogen from wet and dry fluxes of nitric acid, nitrate, ammonium  
730 sulfate, and ammonium nitrate, and the dry flux of NO<sub>x</sub>.

731 Terrestrial effects of nitrogen and sulfur deposition for the Class I areas are shown in Table  
732 5.2.7-16. As stated earlier, Green Line Values (Wilderness Areas) are compared to the maximum  
733 modeled NorthMet Project Proposed Action deposition plus background; the DAT values  
734 (National Parks) are compared to the modeled NorthMet Project Proposed Action effects only.  
735 As seen from the table, the maximum predicted total sulfur and nitrogen deposition are all below  
736 Green Line Value ranges for BWCAW. The maximum predicted total sulfur deposition is also  
737 below the Green Line Value for Rainbow Lakes Wilderness. However, the maximum predicted  
738 total nitrogen deposition at Rainbow Lakes Wilderness (5.9 kg/ha/yr) is within the Green Line  
739 Value range of 5 to 8 kg/ha/yr. The nitrogen deposition contribution from the NorthMet Project  
740 Proposed Action emissions is 0.02 percent of the total nitrogen deposition impact  
741 (0.001 kg/ha/yr). Table 5.2.7-16 also compares the ambient annual and 3-hour SO<sub>2</sub>  
742 concentrations due to the NorthMet Project Proposed Action to the Green Line Values. Modeled  
743 concentrations of SO<sub>2</sub> in both wilderness areas are below the Green Line Values for SO<sub>2</sub>  
744 concentration.

745 Finally, Table 5.2.7-16 compares terrestrial impacts of sulfur and nitrogen deposition in the Class  
746 I areas to the DAT values. The maximum predicted total sulfur and nitrogen values are below the  
747 DAT value of 0.01 kg/ha/year.

748 **Table 5.2.7-16 Terrestrial Effects of Annual Deposition of Sulfur and Nitrogen from the**  
 749 **NorthMet Project Proposed Action in Class I Areas**

| Class I Area                                     | Proposed Action Effects | Background Level | Total (Proposed Action + Background) | Terrestrial Green Line Value | Deposition Analysis Threshold |
|--------------------------------------------------|-------------------------|------------------|--------------------------------------|------------------------------|-------------------------------|
| <b>BWCAW</b>                                     |                         |                  |                                      |                              |                               |

| Nitrogen                                         | 0.001                   | NA               | NA                                   | NA                           | 0.01 kg/ha/yr                 |

750 Table 5.2.7-17 summarizes the aquatic effects from sulfur and nitrogen deposition for the Class I  
 751 areas. Green Line Values for aquatic effects at the wilderness areas are based upon total sulfur  
 752 deposition, as well as total sulfur deposition plus 20 percent of the total nitrogen deposition  
 753 (sulfur + 20 percent nitrogen). Maximum predicted values for these two measures for all  
 754 scenarios were below the Green Line Value ranges for BWCAW. The maximum predicted total  
 755 sulfur deposition and total sulfur plus 20 percent nitrogen deposition for Rainbow Lakes  
 756 Wilderness are just below the Green Line Value, and nearly all of the effects are associated with  
 757 the current background level. Aquatic effects at the National Parks are also compared to the DAT  
 758 values. The modeled maximum annual nitrogen and sulfur deposition effects due to the  
 759 NorthMet Project Proposed Action have levels below the respective National Park Service DAT  
 760 levels for both Voyageurs National Park and Isle Royale National Park. The highest effects are  
 761 predicted in Voyageurs National Park, with values approximately one-tenth of the incremental  
 762 DAT level for sulfur and one-fifth of the incremental nitrogen DAT level.

765 *SO<sub>2</sub> Effects on Flora and Fauna*

766 Potential SO<sub>2</sub> effects on flora and fauna in Class I areas were evaluated using the model-  
 767 predicted concentrations from NorthMet Project Proposed Action emissions. The USFS has set  
 768 screening criteria for potential air pollution effects on vegetation for SO<sub>2</sub> as a total annual  
 769 average ambient concentration of 5 µg/m<sup>3</sup>. As stated earlier, Green Line screening values “were  
 770 set at levels at which it was reasonably certain that no significant change would be observed in  
 771 ecosystems that contain large numbers of sensitive components.”

772 Though the USFS screening levels were established specifically for Class I areas administered  
 773 by the USFS (i.e., BWCAW and Rainbow Lakes Wilderness) the same criteria were applied to  
 774 Voyageurs National Park and Isle Royale National Park, which are administered by the National  
 775 Park Service but do not have published standards similar to the USFS. Table 5.2.7-18 compares  
 776 maximum CALPUFF NorthMet Project Proposed Action impacts from all scenarios and existing  
 777 background concentrations to the Green Line screening levels for each Class I area. The  
 778 summation of the NorthMet Project Proposed Action and background contributions is well below  
 779 the Green Line levels so no threat to sensitive vegetation in Class I areas is expected from direct  
 780 SO<sub>2</sub> emissions produced by the NorthMet Project Proposed Action.

781 There are no established screening criteria for NO<sub>2</sub> and PM<sub>10</sub> for effects on flora and fauna. As  
 782 shown in Class I increment modeling results (PolyMet 2015e), modeled maximum annual  
 783 concentrations of NO<sub>2</sub> and PM<sub>10</sub> from the NorthMet Project Proposed Action are below the  
 784 secondary NAAQS standards (protecting vegetation), so it is not expected that there would be  
 785 impacts on the Class I areas from these pollutants.

786 **Table 5.2.7-18 Comparison of Projected Class I SO<sub>2</sub> Concentrations to Green Line**  
 787 **Screening Criteria for Vegetation Effects**

| Class I Area              | Background Air Concentration (µg/m <sup>3</sup> ) | Max. Modeled Proposed Action Contribution (µg/m <sup>3</sup> ) | Total Proposed Action Air Concentration (µg/m <sup>3</sup> ) | Green Line Concentration (µg/m <sup>3</sup> ) |
|---------------------------|---------------------------------------------------|----------------------------------------------------------------|--------------------------------------------------------------|-----------------------------------------------|

788 **5.2.7.2.3 Potential Estimated Human Health Risk from the Plant and Mine Sites Air**  
 789 **Emissions**

790 This section includes the assessment of potential human health effects from the NorthMet Project  
 791 Proposed Action. Separate AERAs were conducted for the Mine Site and Plant Site due to the  
 792 large distances (approximately 6 miles) between the Mine Site and Plant Site sources. It should  
 793 be noted that AERAs from the Mine Site and Plant Site are also considered cumulatively in  
 794 Section 6.7.5.

795 Estimations of additional lifetime cancer risk, potential for non-cancer effects from chronic  
 796 exposures, and potential non-cancer health effects from short-term exposures were conducted for  
 797 hypothetical residents, farmers, off-site workers, and/or for short-term visitors. The hypothetical  
 798 individuals were assumed to breathe outdoor air for the entire exposure duration. Inhalation  
 799 exposures were assessed for an approximate lifetime (approximately 70 years) for the resident  
 800 and farmer; a maximum hour for the short-term visitor; and 8-hour days, 250 days per year for  
 801 25 years for the off-site worker (USEPA 1993). Hypothetical short-term and off-site worker  
 802 ingestion exposures were not assessed. The farmer ingestion exposure was assessed for a 40-year  
 803 duration and the resident ingestion exposure was assessed for a 30-year duration. When both  
 804 ingestion and inhalation risks were assessed, these were summed for a total multi-pathway risk.  
 805 This screening procedure is conservative and is intended as a regulatory tool to define whether  
 806 more detailed analysis is warranted rather than estimating risk levels for actual individuals.

807 **Mine Site Air Emissions Risk Analysis**

808 An AERA was conducted for the Mine Site in January 2008 for the DEIS. A Supplemental  
 809 AERA was conducted as part of the project changes defined with the current NorthMet Project  
 810 Proposed Action (Barr 2013i). The screening human health risk analysis followed the MPCA-  
 811 accepted November 2011 Work Plan (PolyMet 2015e). Sulfuric acid aerosol emissions were  
 812 screened out of the quantitative assessment for potential acute inhalation effects by scaling the  
 813 Plant Site 2005 modeled acute inhalation hazard quotients to the current potential sulfuric acid  
 814 emissions. As identified in the Mine Site AERA, the quantitative evaluation identified 11  
 815 chemicals for evaluation (CFEs), which are summarized in Table 5.2.7-19. The identified CFEs  
 816 include six risk-driver chemicals from the 2008 AERA (dibenzo(a,h)anthracene, indeno(1,2,3-  
 817 cd)pyrene, manganese compounds, nickel compounds, NO<sub>2</sub>, and dioxins/furans). The remaining  
 818 five compounds are from the 2008 AERA that now have toxicity values (acetaldehyde, arsenic  
 819 compounds, cobalt compounds, crystalline silica, and diesel particulate).

820 **Table 5.2.7-19 Chemicals for Evaluation of the Incremental Human Health Risk Assessment**  
 821 **for the Mine Site**

| Chemical                             | Total Mine Site                               | Total Mine Site                                       | Total Mine Site                                | Total Mine Site                                        |

822 g/sec = gram(s) per second

823 Estimations of additional lifetime risk and potential non-cancer effects from chronic (long-term)  
 824 exposures were conducted for both inhalation and ingestion exposures for the hypothetical  
 825 resident and farmer. The resident is assumed to inhale outdoor air and ingest soil and produce  
 826 grown at a site of maximum air concentration. The farmer scenario assumed inhalation of  
 827 outdoor air and ingestion of soil and produce, and also includes ingestion of meat and dairy  
 828 products grown at the location of maximum air concentration.

829 Air dispersion modeling was conducted for the Mine Site to estimate maximal annual and hourly  
 830 air concentrations for the CFE using the AERMOD model with 5 years of hourly meteorological  
 831 data from the Hibbing weather station. The assessment was conducted for the years 8 and 13,  
 832 which were determined to be the years of highest air emissions. Direct (inhalation) and indirect  
 833 (ingestion) risk estimates were made for inhalation and bioaccumulative toxic pollutant  
 834 ingestion, respectively, using the MPCA Risk Analysis Screening Spreadsheet, which estimates  
 835 potential incremental cancer and noncarcinogenic human health effects for long-term exposures.

836 Acute inhalation risks were estimated for the ambient air at and beyond the Mine Site property  
 837 boundary (see Large Figure 4 in PolyMet 2015e). Because of the historical and present mining  
 838 and industrial land use around the Mine Site, the reasonable future land use for residential and  
 839 farming was considered in assessing chronic risks for areas (i.e., receptors) outside of the  
 840 Mineral Mining/Industrial District air boundary (see Large Figure 5 in PolyMet 2015e). The  
 841 Mineral Mining/Industrial District air boundary encompasses an area approximately 1 km  
 842 beyond the Mine Site air boundary and no farmers or residents are expected to be present within  
 843 this area either presently or for the foreseeable future.

844 The results of the Mine Site assessment demonstrate that the chronic additional lifetime cancer  
 845 and non-cancer effects, as well as the potential acute non-cancer health effects from direct  
 846 exposure (inhalation) at the Mine Site property boundary for off-site workers were below

847 guidance levels (PolyMet 2015e). The MEI inhalation pathway additional lifetime cancer risk at  
848 the Mine Site ambient air boundary was estimated from the assessment of year 13 emissions with  
849 a maximum value of 5E-06, which is below the MDH guideline value of 1E-05. The maximum  
850 potential sub-chronic and acute non-cancer risk estimates were calculated to be 0.2 and 0.8  
851 respectively, which are both below the guidance level of 1.0.

852 The multi-pathway cancer risk for the hypothetical farmer was estimated to be 1E-05. This is at  
853 the MDH additional lifetime cancer risk guidance level of 1E-05. The major risk drivers were  
854 dioxins and dibenzo(a,h)anthracene associated with potential emissions from mine vehicles. It  
855 should be noted that maximum multi-pathway additional lifetime cancer risk is located at the  
856 Mining/Industrial District boundary. The nearest small farms are located 6.5 miles from the Mine  
857 Site.

858 The multi-pathway additional lifetime cancer risk for a hypothetical nearby resident at the  
859 Mining/Industrial District boundary was 8E-07, which is below the MDH guidance value of  
860 1E-05. The major risk drivers for cancer endpoints for this receptor were nickel compounds,  
861 arsenic compounds, and dioxins.

862 The non-cancer chronic multi-pathway hazard indices (HIs) for the farmers and residents were  
863 each calculated to be 0.04, which is below the MDH guidance value of 1.0. Due to the variation  
864 (i.e., each compound has a unique concentration where health effects are expected for a target  
865 organ) in estimating the health effects for noncarcinogenic effects, the HI is the sum of the  
866 individual ratios of the maximum concentration divided by the chemicals' health benchmark.  
867 This ratio is then compared to a general guidance value of 1.0. Thus, the chronic non-cancer  
868 results for both the hypothetical farmer and resident were approximately 4 percent of the  
869 guidance value where health effects become more likely to occur.

870 The acute non-cancer HI was predicted at the Mine Site operating boundary with a value of 0.8,  
871 as compared to the MDH's acute HI guidance level of 1.0. This screening value sums all of the  
872 acute HIs for all pollutants regardless of their toxic endpoint (specific target organ) and the  
873 specific locations of maximum modeled air concentrations of the compounds. The risk driver for  
874 acute inhalation was NO<sub>2</sub> from the diesel fuel combustion. When adjusting HIs for the various  
875 locations of the maximum modeled annual average air concentration for risk-driver pollutants  
876 (i.e., risk-driver pollutant concentrations differ in space), the maximum acute HI for the off-site  
877 worker was reduced to 0.8, below the acute guidance level. Table 5.2.7-20 provides a summary  
878 of the Mine Site risk assessment.

879 **Table 5.2.7-20 Summary of the Incremental Human Health Risk Assessment for the**  
 880 **Mine Site**

| Exposure Route           | Exposure Scenario   | Location and Type of Receptor | Potential Non-cancer Health Effects (HI) <sup>1</sup> | Potential Cancer Effects (Risk Estimate) <sup>2</sup> |
|--------------------------|---------------------|-------------------------------|-------------------------------------------------------|-------------------------------------------------------|
| Inhalation Exposure Only | Acute (1-hour)      | Mine Site Property Boundary   | 0.80                                                  | NA                                                    |
|                          | Chronic (~lifetime) | Mine Site Property Boundary   | 0.20                                                  | 5E-06                                                 |
| Multi-pathway Exposure   | Chronic (~lifetime) | Farmer                        | 0.04                                                  | 1E-05                                                 |
|                          |                     | Resident                      | 0.04                                                  | 8E-07                                                 |

881 <sup>1</sup> HI is the sum of individual non-cancer chemical quotients for acute or chronic exposure. Incremental non-cancer (chronic and  
 882 acute) guideline value is 1.0.

883 <sup>2</sup> Potential human health risks from carcinogenic chemicals (summed for all chemicals) were estimated using the MPCA's Risk  
 884 Assessment Screening Spreadsheet. Incremental cancer risk guideline value is 1E-05.

885 **Plant Site Air Emission Risk Analysis**

886 As with the Mine Site, an AERA was conducted for the Plant Site and results were reported in  
 887 the scoping EAW (May 2005). The 2005 AERA included specific chemicals for potential  
 888 evaluation as defined in MPCA's AERA Guidance (MPCA 2004). NorthMet Project Proposed  
 889 Action changes since May 2005 resulted in the AERA being revised for the DEIS. A  
 890 Supplemental AERA was conducted, as part of the changes defined with the FEIS NorthMet  
 891 Project Proposed Action (PolyMet 2015e) and although some project modifications have been  
 892 made to the Plant Site since the SDEIS (Section 3.2), the Supplemental AERA is adequate for  
 893 the FEIS (PolyMet 2015e). The screening human health risk analysis followed the MPCA-  
 894 accepted August 2011 Work Plan (PolyMet 2015e). Sulfuric acid aerosol emissions were  
 895 screened out of the quantitative assessment for potential acute inhalation effects by scaling the  
 896 2005 modeled acute inhalation hazard quotients to the current potential sulfuric acid emissions.  
 897 As identified in the Plant Site AERA, the quantitative evaluation identified 10 CFEs, which are  
 898 summarized in Table 5.2.7-21. The identified CFEs include three risk-driver chemicals from the  
 899 2007 AERA (arsenic compounds, nickel compounds, and NO<sub>2</sub>) and four compounds from the  
 900 2007 AERA that now have toxicity values (acetaldehyde, cobalt compounds, crystalline silica,  
 901 and diesel particulate). The remaining three were added either because of increased emissions  
 902 (hydrochloric acid and manganese) or new emissions from mobile diesel sources included in the  
 903 analysis (dioxins/furans).

904 **Table 5.2.7-21 Chemicals for Evaluation of the Incremental Human Health Risk Assessment**  
 905 **for the Plant Site**

| <b>Chemical</b>                      | <b>Maximum Hourly<br/>Emission Rate 2012<br/>(g/sec)</b> | <b>Annual Emission Rate<br/>2012 (g/sec)</b> |
|--------------------------------------|----------------------------------------------------------|----------------------------------------------|
| Acetaldehyde                         | 1.66E-05                                                 | 9.49E-07                                     |
| Arsenic                              | 3.03E-03                                                 | 7.75E-04                                     |
| Cobalt                               |                                                          | 5.44E-03                                     |
| Crystalline Silica                   |                                                          | 1.30E+00                                     |
| Diesel Particulate Matter            |                                                          | 4.47E-02                                     |
| Hydrochloric Acid                    | 2.45E+00                                                 | 2.90E-02                                     |
| Manganese                            |                                                          | 5.91E-02                                     |
| Nickel                               | 1.33E-01                                                 | 1.36E-01                                     |
| Oxides of Nitrogen                   | 1.10E+01                                                 |                                              |
| Dioxins/Furans (as 2,3,7,8-TCDD TEQ) |                                                          | 1.12E-10                                     |
| Number of CFEs                       |                                                          | 10                                           |

906 g/sec = gram(s) per second

907 Similar to the Mine Site AERA, air dispersion modeling was conducted to estimate air  
 908 concentrations for the CFE, using the AERMOD model with 5 years of hourly meteorological  
 909 data from the Hibbing weather station. Direct and indirect risk estimates were made for  
 910 inhalation and bioaccumulative toxic pollutant ingestion, respectively, using the MPCA Risk  
 911 Analysis Screening Spreadsheet, which estimates potential incremental cancer and  
 912 noncarcinogenic human health risks for both acute and long-term effects.

913 Acute risks were estimated for the ambient air at and beyond the NorthMet Project area  
 914 ownership boundary for off-site workers. Because of the historical and present mining and  
 915 industrial land use around the Plant Site, the reasonable future land use for residential and  
 916 farming was considered in assessing chronic risks for areas (i.e., receptors) outside of the former  
 917 LTVSMC processing plant air boundary. The former LTVSMC processing plant ambient air  
 918 boundary encompasses most of the industrial land use in the Hoyt Lakes area and no farmers or  
 919 residents are expected to be present within this area for the foreseeable future.

920 Initially, a screening level human health risk is conducted where all CFEs maximum  
 921 concentrations are assumed to occur at the same location. A refinement to the risk assessment is  
 922 the calculation of maximal potential health effects paired in both space and time. That is, when  
 923 the health effect impacts are calculated for all pollutants at each receptor and meteorological  
 924 condition modeled. The results of the Plant Site assessment demonstrate that the chronic  
 925 additional lifetime cancer and noncarcinogenic effects are at or below guidance levels and the  
 926 acute noncarcinogenic health effects are also below the guidance level, when adjusted for  
 927 locational differences (PolyMet 2015e).

928 The multi-pathway (ingestion and inhalation) additional lifetime cancer risk at the former  
 929 LTVSMC processing plant ambient air boundary was estimated to be 1E-05 for farmers and  
 930 5E-06 for a hypothetical nearby residents, which is below the MDH guidance level value of  
 931 1E-05. Similarly, the off-site worker inhalation additional lifetime cancer risk at the NorthMet  
 932 Project area boundary was predicted at 1E-05, also at the MDH additional lifetime cancer risk

933 guidance level. The major risk drivers for these estimated cancer endpoints were cobalt, nickel,  
 934 and dioxins/furans (farmers only).

935 The non-cancer chronic multi-pathway HI for the farmers and residents were each calculated to  
 936 be 0.2, primarily from the potential nickel emissions. Due to the variation (i.e., each compound  
 937 has a unique concentration where health effects are expected for a target organ) in estimating the  
 938 health effects for noncarcinogenic effects, the HI is the sum of the individual ratios of the  
 939 maximum concentration divided by the chemicals' reference exposure level and compared to a  
 940 general guidance value for chronic HI as 1.0. Thus, the chronic non-cancer results for both the  
 941 hypothetical farmer and resident were approximately 20 percent of the chronic guidance level,  
 942 below which health effects would not occur. The chronic HI for the hypothetical off-site worker  
 943 was estimated to be 1, which is at the chronic guidance level.

944 The acute inhalation HI at the former LTVSMC processing plant ambient air boundary was 0.5,  
 945 as compared to the MDH's acute HI guidance level of 1.0. This boundary was the location  
 946 assessed in consideration of a potential resident. This HI is a summation of all of the acute  
 947 hazard quotients for all pollutants regardless of their toxic endpoint (specific target organ) and  
 948 the specific locations of maximum modeled air concentrations of the compounds. The risk  
 949 drivers for the acute inhalation pathway at the location of a potential resident were NO<sub>2</sub>  
 950 emissions from the natural gas combustion and nickel from the Hydrometallurgical Plant. When  
 951 adjusting HIs for the various locations of the maximum modeled annual average air  
 952 concentration for risk-driver pollutants (i.e., risk-driver pollutant concentrations differ in space),  
 953 the acute inhalation HI for the off-site worker was 1.0, at the acute guidance level. Table  
 954 5.2.7-22 provides a summary of the Plant Site risk estimates.

955 **Table 5.2.7-22 Summary of the Incremental Human Health Risk Impacts for the Plant Site**

| Exposure Route           | Exposure Scenario    | Location and Type of Receptor                   | Potential Non-cancer Health Effects (HI) <sup>1</sup> | Potential Cancer Effects (Risk Estimate) <sup>2</sup> |
|--------------------------|----------------------|-------------------------------------------------|-------------------------------------------------------|-------------------------------------------------------|
| Inhalation Exposure Only | Acute (1-hour)       | Off-Site Worker<br>Plant Site Property Boundary | 1.0                                                   | NA                                                    |
|                          | Acute (1-hour)       | Resident at former LTVSMC ambient air boundary  | 0.5                                                   | NA                                                    |
| Multi-pathway Exposure   | Chronic (~ lifetime) | Plant Site Property Boundary                    | 1.0                                                   | 1E-05                                                 |
|                          | Chronic (~ lifetime) | Farmer                                          | 0.2                                                   | 1E-05                                                 |
|                          |                      | Resident                                        | 0.2                                                   | 5E-06                                                 |

956 <sup>1</sup> HI is the sum of individual non-cancer chemical risks for acute or chronic exposure. Incremental non-cancer (chronic and  
 957 acute) guideline value is 1.0.

958 <sup>2</sup> Potential human health risks from carcinogenic chemicals (summed for all chemicals) were estimated using the MPCA's Risk  
 959 Assessment Screening Spreadsheet. Incremental cancer risk guideline value is 1E-05.

#### 960 **5.2.7.2.4 Greenhouse Gases Impact Analysis**

961 The science, policy, and regulatory frameworks regarding GHGs are continually evolving and  
962 are often subject to differing interpretation. For the purposes of the FEIS, the information  
963 presented below is intended to provide the current understanding through June 15, 2012 with  
964 subsequent information regarding climate change updated in the FEIS.

#### 965 ***Global Effects***

966 According to the IPCC, since preindustrial times, human activities, particularly the burning of  
967 fossil fuels, have resulted in increases in the concentrations of GHGs in the earth's atmosphere  
968 (Solomon et al. 2007). It is estimated that 40 percent of a pulse emission of CO<sub>2</sub> remains in the  
969 atmosphere for approximately 100 years. Approximately 15 to 30 percent of the emissions are  
970 expected to remain after 1,000 years and 10 to 15 percent are expected to remain after 10,000  
971 years. The estimated mean lifetime of emitted fossil CO<sub>2</sub> is between 30,000 and 50,000 years  
972 (Archer 2005). As such, the atmospheric GHG levels are likely to continue to rise over the next  
973 few decades. GHGs absorb in the infrared part of the electromagnetic spectrum. At elevated  
974 atmospheric concentrations, they act to warm the lower atmosphere and surface of the earth. The  
975 IPCC's most recent report (Solomon et al. 2007) found that, under a business-as-usual scenario,  
976 globally averaged surface temperature would increase 2.5 to 10.4°F between 1990 and 2100.

977 Globally, an "unequivocal" warming of 1.3°F (plus or minus 0.3°F) occurred between 1905 and  
978 2005 (Solomon et al. 2007). Other data have shown that the global average temperature has  
979 increased by about 1.2 to 1.4°F since 1890, with the 14 warmest years of the past century  
980 occurring between 1997 and 2012 (Hansen et al. 2013). The observed increases in global average  
981 surface temperature may also be seen in the records of average annual temperatures at the  
982 regional and state level. Over the past century, temperatures in the United States have risen at an  
983 average rate of 0.11°F per decade, with the past 25 years showing temperature increases of  
984 approximately 0.56°F per decade (NOAA 2007). The annual average temperature of Minnesota  
985 has increased approximately 1°F in the last century, from 43.9°F (1888 to 1917 average) to  
986 44.9°F (1963 to 1992 average) (MPCA 2009a). The winter season has brought even more  
987 dramatic increases of up to five degrees in parts of northern Minnesota (MPCA 2009a). Much of  
988 the warming observed in Minnesota has occurred over the last few decades. The observed rate  
989 and total increase in temperatures appear more extreme when the more recent years on record are  
990 averaged.

991 Climate changes can involve changes in temperature as well as changes in other meteorological  
992 conditions, such as precipitation patterns and shifts in seasons. These changes could affect forest  
993 ecosystems, water resources, other unique ecosystems, agriculture, and human health over the  
994 next century. Future emissions scenarios, using an ensemble of results from multiple global  
995 climate models, suggest an increase in annual precipitation of 10 to 15 percent over the next 70  
996 to 90 years in the Great Lakes Region (USGCRP 2009), although regional results from these  
997 models are more uncertain than global results. The current modeling also suggests that winter  
998 and spring precipitation would increase 20 to 25 percent; summer rainfall declines 5 to 10  
999 percent in the model results.

1000 Although the degree of effect is uncertain, particularly when analyzed at the regional and local  
1001 levels, water resources could be affected by changes in climate patterns. Due to increased  
1002 temperature, evaporation would likely increase which could reduce levels in lakes, rivers, and

1003 streams up to 12 inches (MDNR 2009). Increased precipitation could also affect flooding  
1004 conditions. In addition, severe weather patterns could be affected, resulting in more frequent  
1005 maximum 25- and 100-year precipitation events and flood patterns. Warmer temperatures may  
1006 shorten winter seasons, resulting in decreased ice cover on the lakes and streams, as well as early  
1007 ice breakup in the spring.

1008 If Minnesota's climate becomes drier, forest areas near the prairie-forest border could be  
1009 replaced with grassland ecosystems (Frelich and Reich 2009). Minnesota's forested areas could  
1010 decrease by 50 to 70 percent (MPCA 2003). On the other hand, if increased precipitation occurs,  
1011 resulting in a wetter climate, over long periods of time the current conifers would be replaced  
1012 with hardwood trees. Pine, birch, and maple forests would be replaced with oak, elm, and ash.

1013 Minnesota's wetland and bog ecosystems may also face changes due to increased precipitation.  
1014 Variation in wet periods, dry periods, and severe storm frequency could lead to changes in  
1015 wetland type and distribution that includes wetland losses in some areas and wetland gains in  
1016 other areas.

1017 Due to the negative effects of peak daytime temperatures during anthesis and grain filling on  
1018 crop growth, climate change could have a dramatic effect on agriculture. However, climate  
1019 change would also lengthen the growing season of certain crops within the region, leading in  
1020 some instances to increased, rather than decreased, agricultural productivity. Droughts, floods,  
1021 and damage from insects and invasive weeds, could increase the challenges by farmers in the  
1022 day-to-day management of farms and livestock.

1023 Increased temperatures could increase the potential for heat-related illnesses and insect-borne  
1024 diseases. Changes in air quality health effects could occur due to the increased temperatures.  
1025 Higher VOC and ozone levels may occur, as increased temperatures may increase duration and  
1026 frequency of stagnation conditions that would allow air pollution to build up.

### 1027 **Regulatory Actions**

1028 The USEPA has issued regulations under the CAA, and in some cases other statutory authorities,  
1029 to address issues related to climate change. In addition, MPCA has recently modified its air  
1030 permit rules to incorporate new federal permit requirements for GHG emissions and currently  
1031 requires an evaluation of GHG emissions in the environmental review process for projects that  
1032 must obtain stationary source air permits.

1033 On October 30, 2009, the Final Mandatory Greenhouse Gas Reporting Rule was published  
1034 requiring suppliers of fossil fuels or industrial GHGs, manufacturers of vehicles and engines, and  
1035 facilities that emit 25,000 or more mtpy of GHGs to submit annual emission reports to USEPA.  
1036 The gases covered by the emissions reporting rule are CO<sub>2</sub>, CH<sub>4</sub>, N<sub>2</sub>O, HFCs, PFCs, SF<sub>6</sub>, and  
1037 other fluorinated gases including nitrogen trifluoride and hydrofluorinated ether. The rule  
1038 required that the first annual GHG emission report be submitted on March 31, 2011, for 2010  
1039 emissions. The first reporting deadline was extended to September 20, 2011.

1040 In response to the 2007 United States Supreme Court ruling in Massachusetts v EPA, 549 US  
1041 497 (2007), on April 17, 2009 the USEPA Administrator signed a Proposed Endangerment and  
1042 Cause or Contribute Findings for Greenhouse Gases under the Section 202a of the CAA. The  
1043 Administrator found that current and projected concentrations of the mix of six key GHGs in the  
1044 atmosphere threaten the public health and welfare of current and future generations. The  
1045 Administrator further found that the combined emissions of CO<sub>2</sub>, CH<sub>4</sub>, N<sub>2</sub>O, and HFCs from

1046 motor vehicles and motor vehicle engines contribute to rising atmospheric concentrations of  
1047 these key GHGs and hence are a threat to public health and welfare. These findings were a  
1048 prerequisite to finalizing the GHG standards for light-duty vehicles. On April 1, 2010, USEPA  
1049 and the DOT's National Highway Safety Administration issued the first national rule limiting  
1050 GHG emissions from cars and light trucks. This rule confirmed that January 2, 2011 was the first  
1051 date that a 2012 model year vehicle meeting these rule requirements may be sold in the U.S.

1052 Based upon the above and USEPA's "PSD Interpretive Memo" (identifying that a pollutant is  
1053 subject to regulation either by a specific provision in the CAA or a regulation adopted by  
1054 USEPA), USEPA issued a final rule on May 13, 2010 that set GHG thresholds for permits for  
1055 new and existing sources under New Source Review PSD permit and Title V operating permit  
1056 requirements, known as the Greenhouse Gas Tailoring Rule. Under the rule and beginning on  
1057 July 1, 2011, new sources, such as the NorthMet Project Proposed Action, with greater than  
1058 100,000 tpy of GHG or existing facilities that increase their GHG emissions by more than 75,000  
1059 tpy are subject to PSD and would require BACT for GHG emissions.

1060 Concurrent with USEPA actions, a series of Congressional proposals were developed that, had  
1061 they been passed, would have changed the U.S. climate policy. GHG emissions legislation  
1062 considered during the 109<sup>th</sup> and 110<sup>th</sup> sessions (January 2005 to January 2007, and January 2007  
1063 to January 2009, respectively) of the U.S. Congress ranged from carbon taxes to cap-and-trade  
1064 and from energy efficiency requirements to moratoriums on coal-fired power plant approvals. Of  
1065 the legislation proposed during the 109<sup>th</sup> and 110<sup>th</sup> Congresses, notable legislative actions  
1066 include the following:

- 1067 • Lieberman-Warner Climate Security Act of 2007 (S. 2191);
- 1068 • Boxer-Lieberman-Warner Climate Security Act Substitution Amendment of 2008 (S. 3036);
- 1069 • American Clean Energy and Security Act of 2009 (Waxman-Markey – H.R. 2454);
- 1070 • Clean Energy Jobs and American Power Act of 2009 (Kerry-Boxer (S. 1733)); and
- 1071 • Kerry-Lieberman American Power Act of 2010.

1072 None of these bills have passed both houses of Congress.

1073 At the state level, efforts to curb statewide and regional GHG emissions are underway. More  
1074 than half of U.S. states have joined in regional efforts to reduce GHG emissions. In 2007, as part  
1075 of the Midwestern Greenhouse Gas Reduction Accord, Minnesota committed (along with  
1076 Illinois, Iowa, Kansas, Michigan, Wisconsin, and the Province of Manitoba, Canada) to long-  
1077 term GHG reduction targets of 60 to 80 percent below 2005 emission levels. Participants have  
1078 agreed to pursue the implementation of a regional cap-and-trade system as well as a consistent  
1079 regional GHG emissions tracking system.

1080 In May 2008, the Governor of Minnesota signed legislation requiring the Minnesota Department  
1081 of Commerce (MDC) and the MPCA to track and report GHG emissions. In 2007 legislation was  
1082 passed and signed into law that established GHG emissions reduction targets for 2015 and 2025  
1083 of 15 percent and 30 percent, respectively, and directed the Department of Commerce to develop  
1084 interim reduction recommendations through a length stakeholder process. The 2015 and 2025  
1085 goals were designed as milestones toward meeting the State's goal of reducing GHG emissions  
1086 to a level at least 80 percent below 2005 levels by 2050. Developments in Minnesota's climate

1087 change and GHG policy would likely continue as Minnesota strives to meet the goals established  
1088 in the Next Generation Energy Act of 2007.

1089 On January 13, 2013, the MPCA adopted permanent rules to implement the new GHG permit  
1090 requirements set by the USEPA. These rules set Part 70 permit thresholds for GHGs at 100,000  
1091 tpy. The rule changes also modify requirements for capped and registration permits and  
1092 insignificant activities. The MPCA has implemented USEPA's final decision to defer including  
1093 biogenic CO<sub>2</sub> emissions in permitting through permanent rulemaking for biogenic sources for  
1094 PSD and Title V purposes.

1095 In addition to policies directed at reducing statewide GHG emissions, Minnesota has instituted  
1096 policies requiring the evaluation of GHG emissions as a part of the environmental review process  
1097 for certain proposed actions that require stationary source air emissions permits. In July 2008,  
1098 MPCA issued a General Guidance for Carbon Footprint Development in Environmental Review.  
1099 The MPCA guidance requests that proposers, in the course of environmental review under  
1100 MEPA, prepare a GHG inventory for proposed actions that would require stationary source air  
1101 emissions permits.

#### 1102 **NorthMet Project Proposed Action and Climate Change**

1103 The NorthMet Project Proposed Action results in direct on-site emissions of GHGs and off-site  
1104 indirect emissions associated with power generation. There are no analytical or modeling tools to  
1105 reliably evaluate the incremental effect of a proposed action's discrete GHG emissions on the  
1106 global and regional climate. In addition, there are no analytical or modeling tools to reliably  
1107 evaluate any cascading effects, or cumulative effects, from a particular proposed action's GHG  
1108 emissions on natural ecosystems and human economic systems in a given state or region.

1109 The total potential direct annual emissions from the NorthMet Project Proposed Action are  
1110 projected to be 196,342 mtpy of CO<sub>2</sub>e. This is 0.12 percent of the statewide emissions for  
1111 Minnesota, 0.003 percent of the United States emissions, and 0.00038 percent of the annual  
1112 global emission estimations. Combining the direct and indirect emissions from the NorthMet  
1113 Project Proposed Action (697,342 mtpy CO<sub>2</sub>e), the total represents 0.44 percent, 0.01 percent,  
1114 and 0.0014 percent of the annual statewide, U.S., and global emissions, respectively (PolyMet  
1115 2015e). It is possible that, due to global demand for copper, nickel, and precious metals, some of  
1116 these emissions would occur regardless of the development of the NorthMet Project Proposed  
1117 Action.

1118 With climate change, average annual temperatures in Minnesota may increase 3 to 5°F over the  
1119 lifetime of the facility. There may also be a 5 to 15 percent increase in precipitation over the life  
1120 of the operation (20 years) and reclamation (60 years) (NOAA 2013). Increased temperatures  
1121 and precipitation may have effects on wetlands, forests, and other cover types that are likely to  
1122 affect carbon storage and sequestration in these ecosystems. There could be localized impacts  
1123 due to meteorological changes. Even though a quantitative assessment of the effects could not be  
1124 conducted, proposed reclamation and mitigation activities described in Section 5.2.7.4.3 can  
1125 offset some of the carbon emissions caused by NorthMet Project Proposed Action. Overall,  
1126 climate change could also affect visibility.

#### 1127 **5.2.7.2.5 Mercury Deposition Impact Analysis**

1128 Total potential mercury emissions to air are estimated to be 4.6 lbs/year from the Plant Site. The  
1129 primary sources of air emissions are expected to be two emission units that are part of the  
1130 hydrometallurgical process: the autoclave vent and the autoclave flash vent. The combined air  
1131 emissions from these two units are estimated to be 4.1 lbs/year. Most of the remaining estimated  
1132 mercury emissions (0.4 lb/year) are from natural gas used to fuel a package boiler and for space  
1133 heating. Less than 0.1 lb/year are estimated to be released by the mining, crushing, and milling  
1134 processes and through wind erosion from the Tailings Basin. Additional information regarding  
1135 each of these emission sources is summarized in *Mercury Emission Control Technology Review*  
1136 *Version 2* (Barr 2012k). Overall, about 95 percent of the mercury originating in the ore is  
1137 expected to remain within—or be adsorbed to—the tailings and the hydrometallurgical residue,  
1138 where it would remain isolated from further transport to the environment. Mine Site mercury air  
1139 emissions would contribute a maximum of 0.17 lbs/year from Tailings Basin construction  
1140 vehicles (diesel fuel combustion emissions) and approximately 0.6 lbs/year from diesel fuel  
1141 combustion (PolyMet 2015e). For comparison, Minnesota’s statewide mercury air emissions  
1142 were estimated to be 3,011 pounds in 2005 and about 2,835 pounds in 2011 (PolyMet 2015e).

1143 The low percentage of estimated mercury released to the air is primarily because the oxidizing  
1144 conditions in the autoclave would cause most of the mercury that is released from the  
1145 concentrate into the exhaust gas to be in either the oxidized ( $\text{Hg}^{+2}$ ) or particle-bound ( $\text{Hg}(\text{p})$ )  
1146 form. Oxidized mercury is water soluble and would be captured in the facility’s wet scrubber  
1147 system. Particle bound mercury would be collected in any device designed to control particulate  
1148 emissions, such as the autoclave scrubber system. Speciation of mercury air emissions from the  
1149 autoclave is uncertain, but expected to be primarily in the elemental ( $\text{Hg}^0$ ) form (PolyMet  
1150 2015e). Detailed calculations for all Plant Site emission units are provided in UpdatedCalcsPlant  
1151 Ver7.0\_2\_26\_13 (PolyMet 2015e). The estimated 4.1 lb/yr of  $\text{Hg}^0$  emitted from the Plant Site  
1152 would add to the estimated 19,580,000 pound atmospheric mercury loading and would ultimately  
1153 return to the terrestrial environment through long-range transport and atmospheric processes  
1154 (Gaffney and Marley 2014).

1155 The MMREM was used to conduct an evaluation for the potential deposition of mercury related  
1156 to the Plant Site air emissions to assess the NorthMet Project Proposed Action’s potential effects  
1157 on mercury concentrations in fish and the potential health risks to a hypothetical recreational  
1158 fisher, as well as a subsistence fisher consuming locally caught fish. The analysis was conducted  
1159 for five nearby lakes: Heikkila Lake, Colby Lake, and Whitewater Lake (located within 10 km of  
1160 the Plant Site) and Wynne Lake and Sabin Lake (located within 12 km of the Plant Site). The  
1161 analysis used the MMREM to assess the potential incremental change in fish mercury  
1162 concentrations and the potential incremental risks to human health.

1163 Only the Plant Site’s potential mercury air emissions were evaluated, as they represent  
1164 essentially all of the NorthMet Project Proposed Action-related mercury air emissions (PolyMet  
1165 2015e). The Mine Site AERA did not assess potential local mercury deposition because potential  
1166 emissions are less than 1.0 lb/yr (PolyMet 2015e).

1167 Because of uncertainty in speciation of emissions associated with autoclave operations, two  
1168 speciation scenarios were used for assessing potential effects for the local impacts assessment  
1169 (PolyMet 2015e). The results of the analysis from the two mercury speciation scenarios on the  
1170 five nearby lakes estimated that the potential incremental increase in mercury concentrations in

1171 the top predator fish would range from 0.002 ppm (Scenario 2, Whitewater Lake) to 0.016 ppm  
1172 (Scenario 1, Wynne Lake), depending upon the lake and scenario evaluated (see PolyMet 2015e,  
1173 Attachment T). Scenario 1 assumed that the oxidized and particle-bound mercury released would  
1174 be 50 percent and 25 percent of the total mercury, respectively. Scenario 2 assumed maximum  
1175 control efficiency for these fractions, reducing the total percentage released to 10 percent for  
1176 each. It should be noted that due to the conservatively higher oxidized and particle-bound  
1177 mercury speciation assumption in Scenario 1, the effects for Scenario 1 are greater than the  
1178 mercury effects for Scenario 2 for each lake evaluated. These are small compared to the existing  
1179 Hg concentrations in the top predator fish (95<sup>th</sup> percentile), which range from 0.35 ppm at  
1180 Whitewater Lake to 1.34 ppm at Wynne Lake. The NorthMet Project Proposed Action  
1181 incremental risk quotients for a recreational fisher ranged from 0.013 (Scenario 1) at Whitewater  
1182 Lake to 0.081 at Wynne Lake; both are below the incremental risk guideline level of 1.0. The  
1183 incremental risk quotients for subsistence and tribal anglers ranged from 0.098 (Whitewater  
1184 Lake) to 0.606 (Wynne Lake) for Scenario 1, also below the incremental risk guidance level.  
1185 Finally, the incremental risk quotients for the subsistence fisher (Treaty Protected catch rate)  
1186 ranged from 0.132 (Scenario 1, Whitewater Lake) to 0.538 (Scenario 1, Wynne Lake), again  
1187 below the incremental risk guidance level. Additional information pertaining to fish mercury  
1188 concentration and the specific Hazard Quotients summarized in the report *Cumulative Impacts*  
1189 *Analysis: Local Deposition and Bioaccumulation in Fish* (Barr 2012b) have been included in  
1190 Section 6.2.6.3.3 summarizing the cumulative effects assessment for mercury deposition. It  
1191 should be noted that all of the lakes' mercury background concentrations result in a background  
1192 risk quotient above 1.0 without any incremental increase from the NorthMet Project Proposed  
1193 Action, which is a common occurrence in Minnesota lakes. Widespread contamination of fish  
1194 from atmospheric pollution is why Minnesota established a statewide mercury TMDL. The  
1195 TMDL seeks to reduce atmospheric deposition everywhere in the state in order to make the  
1196 state's lakes and streams fishable, as required by federal regulations.

1197 In September 2009, the MPCA published Guidelines for New and Modified Mercury Air  
1198 Emission Sources. The guidelines were developed to limit the mercury emissions from new and  
1199 expanding sources in order to meet the TMDL goal of total statewide mercury emissions of 789  
1200 lbs/year by 2025. In 2012, MPCA revised the guidelines (MPCA 2012h), which includes the  
1201 following requirements that apply to the NorthMet Project Proposed Action:

- 1202 • Define and employ BACT on mercury emitting sources. If best controls reduce emissions by  
1203 less than 90 percent, the new source would be subject to periodic review for opportunities for  
1204 improved control efficiency and must comply with TMDL requirements.
- 1205 • Complete environmental review as required by Minnesota law, including for a proposed  
1206 action and associated cumulative effects.
- 1207 • For facilities where the MPCA determines a project's mercury emissions would not impede  
1208 the statewide mercury emissions reduction goals within the mercury TMDL, an emissions  
1209 limit would be placed into the facility's permit and the project is not be required to submit a  
1210 mitigation plan.

1211 The NorthMet Project Proposed Action mercury air emissions are about 0.16 percent of 2011  
1212 estimated statewide emissions and about 0.6 percent of the TMDL statewide target emissions.  
1213 The NorthMet Project Proposed Action selected a two-stage mercury control system that is  
1214 expected to achieve 25 percent control for elemental mercury and 90 percent control for particle

1215 bound and oxidized mercury (PolyMet 2015e). Because the total mercury control is less than 90  
1216 percent, PolyMet moved forward with the remaining TMDL requirement. In addition, PolyMet  
1217 has conducted a cumulative effects analysis on the local mercury deposition and bioaccumulation  
1218 in fish (PolyMet 2015e) and the assessment of the cumulative effects is provided in Section  
1219 6.2.3.7.2.

1220 The MPCA has conducted a review of the NorthMet Project Proposed Action mercury emissions  
1221 and has determined that it would not impede the reduction goals (MPCA 2013b). Thus, no  
1222 minimization and mitigation plan would be required for the NorthMet Project Proposed Action.

#### 1223 **5.2.7.2.6 Sulfur Deposition and Potential Indirect Effects on Mercury Methylation**

1224 The Ecosystem Acidification report, in support of the Minnesota Steel EIS, indicates that up to  
1225 90 percent of the sulfate deposition in Minnesota is due to out-of-state emissions of SO<sub>2</sub> and that  
1226 sulfate deposition has been on a downward trend since the mid-1980s. Given the current  
1227 downward trend of sulfate deposition in Minnesota and the relatively small contribution from  
1228 Minnesota sources to sulfate deposition in Minnesota, the NorthMet Project Proposed Action is  
1229 not expected to have a measurable effect on sulfate deposition in the state. The trend of  
1230 decreasing sulfate deposition in Minnesota is expected to continue into the future due to  
1231 foreseeable regulatory actions that are expected to further reduce sulfur dioxide emissions on a  
1232 national basis as well as from specific Minnesota sources. A supplemental assessment of the  
1233 potential additional sulfur from stack and fugitive dust air emissions was conducted to evaluate  
1234 the NorthMet Project Proposed Action's effects from sulfate as related to mercury methylation  
1235 and fish concentrations. Sulfur related emissions include SO<sub>2</sub>, sulfuric acid mist (SAM), reduced  
1236 sulfur compounds and sulfur in particulate (e.g., sulfur in the mineral matrix of the ore). Because  
1237 the estimated Plant Site and Mine Site emissions for each of these are below the PSD permitting  
1238 thresholds and Significant Emission Rate (SER), no further consideration of these sources were  
1239 required for environmental impact purposes (Barr 2015f). However, a summary of each is  
1240 included in Section 4.0 of the document *Mercury Overview a Summary of Potential Mercury*  
1241 *Releases from the NorthMet Project and Potential Effects on the Environment* (Barr 2015f). The  
1242 evaluation estimates the potential sulfur deposition to the Partridge River (Colby Lake) and  
1243 Embarrass River (Sabin Lake) watersheds and is summarized below.

#### 1244 **Sulfur Dioxide**

1245 Plant Site stack SO<sub>2</sub> emissions are estimated at about 7 tpy, while stack emissions of SO<sub>2</sub> at the  
1246 Mine Site are estimated at about 1.9 tpy. The values are too small for PSD air permitting and  
1247 therefore are not required to be modeled and are not considered to have significant impacts  
1248 according to the PSD program. Nevertheless, air concentrations of SO<sub>2</sub> were modeled for the  
1249 Plant Site Class II Air Quality Air Dispersion Modeling Report (Barr 2012j) and can be used to  
1250 estimate a potential deposition of sulfur related to SO<sub>2</sub> air emissions. Average watershed air  
1251 concentrations for SO<sub>2</sub> are based on Class II modeling and reflect the Class II modeling receptor  
1252 grid (Barr 2012j).

1253 Because SO<sub>2</sub> emissions are in the gas phase and are emitted from a taller stack, they tend to  
1254 disperse further, and therefore represent a more reasonable approximation of a potential air  
1255 concentration. Additional inputs such as deposition velocity, lake surface area, and water mixing  
1256 zone were included for evaluation. Based on the results of the modeling, the potential deposition  
1257 over the Partridge River (Colby Lake) would be 0.003 g/m<sup>2</sup>/yr or about 2 percent of background,

1258 with a potential surface water concentration from deposition to the lake surface of 0.03 mg/L.  
1259 The potential deposition over the Embarrass River (Sabin Lake) would be 0.002 g/m<sup>2</sup>/yr or about  
1260 2 percent of background), with potential surface water concentration from deposition to the lake  
1261 surface of 0.02 mg/L. With conservative estimates of potential air concentrations and general  
1262 overestimates of potential deposition associated with screening equations, potential sulfur  
1263 deposition from SO<sub>2</sub> emissions is a small percent of background sulfur deposition for both the  
1264 Embarrass River and Partridge River watersheds.

### 1265 **Sulfuric Acid Mist**

1266 The revised air concentration estimate for SAM is 0.12 µg/m<sup>3</sup>, as adjusted for the current  
1267 estimate of SAM emissions of 5.02 tpy (PolyMet 2015e). Additional inputs such as deposition  
1268 velocity, lake surface area, and water mixing zone were included for evaluation. Based on the  
1269 results of the modeling, the potential deposition over the Partridge River (Colby Lake) would be  
1270 0.0005 g/m<sup>2</sup>/yr or about 0.4 percent of background, with a potential surface water concentration  
1271 from deposition to the lake surface as 0.005 mg/L. The potential deposition and estimated  
1272 potential incremental sulfate concentration for Embarrass River (Sabin Lake) would also be  
1273 0.0005 g/m<sup>2</sup>/yr and 0.005 mg/L, respectively. Overall, the deposition from SAM emissions is a  
1274 small percentage of background sulfur deposition to both the Embarrass River and Partridge  
1275 River watersheds.

### 1276 **Reduced Sulfur Compounds**

1277 Potential NorthMet Project Proposed Action emissions of total reduced sulfur (TRS) compounds,  
1278 includes hydrogen sulfide (1.88 tpy) and carbon disulfide (5.1 tpy) as estimated to be 6.98 tpy.  
1279 All of the TRS emissions are from the Plant Site (PolyMet 2015e). No modeling of TRS  
1280 emissions was required for ambient air quality purposes or the Supplemental Plant Site AERA.  
1281 However, the potential deposition of sulfur is estimated to be small due to factors such as the  
1282 ability to remain as a gas under normal environmental conditions, further transport from an  
1283 emissions source due to oxidation by molecular oxygen and hydroxyl radicals, residence times  
1284 ranging from 1 day to 40 days, volatilization from the atmosphere, and gas phase at ambient  
1285 temperatures reacting with photochemically produced hydroxyl radicals (Barr 2015f). Overall,  
1286 the potential local deposition of sulfur from TRS compounds is uncertain, but it is not expected  
1287 to exceed evaluation criteria.

### 1288 **Sulfur in Particulate**

1289 The estimate of potential sulfur deposition from sulfur in particulate was calculated using the air  
1290 concentration for the annual averaging time period of 5.8 µg/m<sup>3</sup> at the Plant Site property  
1291 boundary (PolyMet 2015e). It is assumed that ore processing would be responsible for all  
1292 modeled air concentrations. Additional inputs such as deposition velocity, lake surface area, and  
1293 water mixing zone were included for evaluation. Based on the results of the modeling, the  
1294 potential deposition over the Partridge River (Colby Lake) would be 0.0045 g/m<sup>2</sup>/yr or about 4  
1295 percent of background, with a potential surface water concentration from deposition to the lake  
1296 surface as 0.04 mg/L. The potential deposition and estimated potential incremental sulfate  
1297 concentration for Embarrass River (Sabin Lake) would also be 0.0045 g/m<sup>2</sup>/yr and 0.04 mg/L,  
1298 respectively. Overall, the sulfur in the particulate and the potential sulfur surface water  
1299 concentrations would be a small percentage of background deposition for the Embarrass River  
1300 and Partridge River watersheds.

1301 Based on the results of the additional assessment of sulfur deposition, the potential addition of  
1302 sulfur from these emissions sources would be small to negligible, and therefore would not be  
1303 expected to have effects on mercury methylation or fish mercury concentrations. Additional  
1304 information regarding to mercury methylation is provided in Section 5.2.2.3.4. Mercury  
1305 deposition and bioaccumulation in fish (PolyMet 2015e) and the assessment of the cumulative  
1306 effects is provided in Section 6.2.3.7.2.

### 1307 **5.2.7.3 NorthMet Project No Action Alternative**

1308 Since this alternative would not involve introducing new emission sources, the NorthMet Project  
1309 No Action Alternative would have no additional effects on air quality either regionally or locally.  
1310 Therefore, air quality would be substantially similar to existing conditions.

### 1311 **5.2.7.4 Mitigation Measures**

1312 If, during permitting, it is determined that mitigation measures are necessary, the measures  
1313 described in this section could be considered; however, most of the mitigation measures  
1314 described are incorporated into the design. PolyMet has proposed the following mitigation  
1315 measures to reduce effects on air quality associated with GHGs.

#### 1316 **5.2.7.4.1 Greenhouse Gas Reduction Measures**

##### 1317 **Review of Current Mitigation Included In the NorthMet Project Proposed Action**

1318 The NorthMet Project Proposed Action incorporates both energy and production efficiency to  
1319 reduce associated GHGs (Barr 2011e). The potential to minimize and reduce GHG emissions  
1320 from changes in existing land cover (i.e., release of carbon tied up in terrestrial biomass, soils, or  
1321 peat and the loss of carbon sequestration capacity from the environment) are also discussed  
1322 (PolyMet 2015e). The following provides a summary of the reduction measures.

1323 PolyMet proposes a hydrometallurgical process, rather than a pyrometallurgical process, which  
1324 would result in reduced energy usage. The hydrometallurgical process is expected to reduce the  
1325 NorthMet Project Proposed Action's energy demand by 50 percent over comparable  
1326 pyrometallurgical processes. However, while energy use is reduced by one-half, GHG emissions  
1327 do not decline per unit of production from what would be expected from a pyrometallurgical  
1328 process, principally because of the large load of non-energy process emissions associated with  
1329 hydro processing.

1330 PolyMet also proposes to use premium efficiency motors in selected locations rather than  
1331 standard motors. Motor efficiencies typically vary between 85 and 96 percent, depending upon  
1332 the size and load of the motor. Gravity transport of process slurries would also be used where  
1333 possible, instead of pumps. PolyMet proposes to configure the processing plant such that the  
1334 overall power factor for the facility is as close to one (energy input to energy output) as practical,  
1335 which would help minimize electricity use.

1336 The primary production excavators and two of the three blast-hole drills would be electric rather  
1337 than diesel powered, eliminating a direct source of GHG emissions. PolyMet would purchase  
1338 new gen-set locomotives, which are more efficient and use less fuel than conventional  
1339 locomotives. Space heating in the former LTVSMC processing plant is a major contributor to  
1340 total direct GHG emissions and PolyMet would employ natural gas heaters. Per unit of useful

1341 energy, the combustion of natural gas results in lower CO<sub>2</sub>e emissions than does the combustion  
1342 of other fuels. Of the three feasible space heating options, electric heating, propane-fired heating,  
1343 and natural gas-fired heating, natural gas-fired heating would result in aggregate in CO<sub>2</sub>  
1344 emissions that would be about 80 percent lower than those for electric heating and 66 percent  
1345 lower than those for propane-fired heaters.

1346 PolyMet evaluated additional methods to reduce the NorthMet Project Proposed Action's GHG  
1347 emissions but found the additional methods infeasible (PolyMet 2015e). The methods evaluated  
1348 included electric drive mine haul trucks, electric locomotives, newer mill technology, flotation  
1349 alternatives, and the use of waste heat from autoclaves for space heating.

### 1350 **Additional Mitigation**

1351 To mitigate GHG effects associated with a change in existing land cover (i.e., secondary effects),  
1352 PolyMet would provide compensatory wetland mitigation (see Section 5.2.3 of this FEIS) for  
1353 direct effects on wetlands as well as for indirect effects on fragmented wetlands. One of the goals  
1354 of the compensatory mitigation is to restore high-quality wetland communities of the same type,  
1355 quality, function, and value as those affected by the NorthMet Project Proposed Action. Given  
1356 site limitations and technical feasibility, it is impracticable to replace all affected wetland types  
1357 with an equivalent area of in-kind wetlands. Off-site wetland compensation of 1,631.4 acres  
1358 wetland restoration and/or preservation, and 225.0 acres of upland buffer have been planned.  
1359 This off-site mitigation would take place at three sites in northern Minnesota. Based upon the  
1360 proposed wetland mitigation plan, the number of acres replaced would equal and/or exceed the  
1361 total number of acres of all types of wetlands lost to NorthMet Project Proposed Action-related  
1362 activities, other than deep marsh and the final ratios would be determined during wetland  
1363 permitting. However, the excess replacement would contribute to some degree to compensation  
1364 of the NorthMet Project Proposed Action's effects on deep marsh wetlands.

### 1365 **5.2.7.4.2 Rail Car Ore Transport Fugitive Dust Mitigation Measures**

1366 Rail cars have been designed to centralize the ore fines to the central portion of the rail car to  
1367 minimize the potential for spillage during transport. Due to the natural moisture content and  
1368 large size of the ore being mined, fugitive dust from rail car transport is expected to be minimal.  
1369 Three additional fugitive dust control measures have been identified as part of the Mine Site  
1370 Fugitive Emission Control Plan. These include the minimizing the drop distance of the ore into  
1371 the railcars, reporting dusty conditions during loading and transport, and conducting one  
1372 observation per train to evaluate rail car loading conditions. In addition, annual training would be  
1373 conducted for all locomotive workers on methods to minimize fugitive dust during ore transport  
1374 and loading.

### 1375 **5.2.7.4.3 Voluntary Mitigation Measures**

1376 Based upon the emissions defined in Section 5.2.7.1.3, the majority of the NO<sub>x</sub> and SO<sub>2</sub>  
1377 emissions are associated with mobile sources (e.g., diesel trucks, locomotives, mining  
1378 equipment). Although the analysis of these pollutants showed that the NorthMet Project  
1379 Proposed Action would not cause or significantly contribute to air quality exceedances, a  
1380 voluntary anti-idle program could further reduce these emissions, as well as PM and GHG.  
1381 Although there is no regulatory requirement for a program, PolyMet is considering the  
1382 implementation of an idling reduction policy that would consider the size, fuel type, and function

1383 of each type of vehicle, as well as weather conditions and anticipated duration of vehicle  
1384 stoppage. The policy would need to account for extreme weather conditions in order to avoid  
1385 potential construction or production delays from the inability of vehicles to restart once turned  
1386 off. In addition, vehicle owner's policies and maintenance requirements would have to be  
1387 incorporated for heavy construction equipment and light vehicles that are not owned and  
1388 operated by PolyMet. The results of such a policy would benefit by reducing environmental  
1389 impacts, improving worker health and safety, and reducing fuel usage and engine wear.

## 1390 **5.2.7.5 Amphibole Mineral Fibers**

### 1391 **5.2.7.5.1 Environmental Consequences**

#### 1392 **Background**

1393 The NorthMet Project Proposed Action would mine ore from the Duluth Complex, which may  
1394 contain amphibole mineral fibers. Taconite ore mined from the Biwabik Iron Formation at the  
1395 Northshore Mine and processed at the Silver Bay plant, has received public attention with regard  
1396 to potential releases of amphibole mineral fibers such as those found with taconite ore on the east  
1397 end of the Mesabi Iron Range in northeast Minnesota.

1398 Asbestiform amphibole fibers consist of aggregates of long, thick, flexible fibrils that separate  
1399 along grain boundaries between fibrils. There is little scientific debate that the asbestiform  
1400 varieties of amphibole fibers are carcinogenic. But the term "mineral fibers" has also  
1401 encompassed other prismatic crystals and cleavage fragments that meet specified dimensional  
1402 criteria. Cleavage fragments are generated by crushing and fracturing minerals, including the  
1403 nonasbestiform analogs of the asbestos minerals. Although the substantial hazards of inhalational  
1404 exposure to airborne asbestos fibers have been well documented, there is ongoing debate about  
1405 whether exposure to thoracic-size elongated mineral particles from nonasbestiform analogs of  
1406 the asbestos mineral is also hazardous.

#### 1407 ***Regulatory Definitions and Mineralogy***

1408 Amphibole minerals are a group of silicate minerals that can occur as either fibrous (asbestiform)  
1409 or non-fibrous (non-asbestiform). Asbestiform is a mineralogical term describing mineral  
1410 crystals that form as long, thin, and flexible mineral fibers. Most amphiboles occur in a non-  
1411 asbestiform habit and asbestiform amphiboles are relatively rare. So while a mineral fiber can be  
1412 elementally and chemically identical to an asbestos fiber, they can be morphologically different.  
1413 Mineral fragments, called cleavage fragments, are created and could be emitted into the  
1414 atmosphere when the ore is ground and crushed. These cleavage fragments tend to be shorter and  
1415 wider than the fibrous amphiboles but are often indistinguishable from fibrous amphiboles, even  
1416 at a microscopic scale. This means that a short, blocky mineral fiber might be chemically  
1417 indistinguishable from a long, thin, flexible asbestos fiber, but due to these morphological  
1418 differences these fibers may have different properties and different health risks.

1419 Asbestos is a commercial/industrial term with a long history, and is not a mineralogical  
1420 definition. Asbestos is the name of a group of highly fibrous minerals with separable, long, and  
1421 thin fibers. Individual asbestos fibers are strong and flexible, heat resistant, and chemically inert.  
1422 There are six regulated types of asbestos. The six regulated minerals and their associated mineral  
1423 group are:

- 1424 • Chrysotile (Serpentine),
- 1425 • Crocidolite (Reibeckite) (Amphibole),
- 1426 • Amosite (Cummingtonite-grunerite) (Amphibole),
- 1427 • Anthophyllite Asbestos (Amphibole),
- 1428 • Tremolite Asbestos (Amphibole), and
- 1429 • Actinolite Asbestos (Amphibole).

1430 From a mineral perspective, amphibole minerals are distinguished from each other by the amount  
1431 of sodium, calcium, magnesium, and iron that they contain.

1432 A mineral fiber can be analyzed and classified using a microscope. Chrysotile is easily identified  
1433 by microscopic analysis because of its distinct particle shape. For amphiboles, the distinction  
1434 between asbestiform and non-asbestiform is less clear. Amphibole particles have a spectrum of  
1435 shapes from blocky to prismatic to acicular. Amphiboles also break (or cleave) into smaller  
1436 fragments when finely ground. Long, thin cleavage fragments resemble asbestos fibers, but may  
1437 not be asbestiform. Cleavage fragments tend to be roughly twice as thick as asbestos fibers  
1438 (Addison and McConnell 2008). The aspect ratio distributions (i.e., length-to-width ratio) of a  
1439 population of cleavage fragments and a population of asbestos fibers can overlap. This overlap  
1440 means that some fibers may be classified as either cleavage fragments or asbestos fibers (Millette  
1441 2006). An analyst can compare particle shapes to asbestos reference materials but it can be  
1442 difficult to classify individual fibers as asbestiform or cleavage fragments because individual  
1443 fibers do not exhibit all the characteristics of a population.

1444 Regulatory definitions for classifying asbestos and other mineral fibers vary and often do not  
1445 differentiate between asbestiform and non-asbestiform minerals. The USEPA defines the  
1446 dimensions of an “asbestos fiber” as a particle 5 micrometers ( $\mu\text{m}$ ) in length or longer with an  
1447 aspect ratio of at least 20:1 (USEPA 1993). The National Institute for Occupational Safety and  
1448 Health (NIOSH) defines an “occupational fiber” as a particle 5  $\mu\text{m}$  in length or longer with an  
1449 aspect ratio of at least 3:1 (NIOSH 1994). Minnesota agencies define a Minnesota regulated fiber  
1450 (MN-fiber) as an amphibole or chrysotile mineral particle with an aspect ratio of 3:1 or greater  
1451 with no limit on length (MDH Methods 851 and 852). The State of Minnesota’s definition of  
1452 fibers does not distinguish between asbestiform and non-asbestiform amphibole fibers, including  
1453 cleavage fragments.

#### 1454 ***Health Impact***

1455 There are known health impacts from asbestos and similar asbestiform amphibole minerals. Less  
1456 certain are the health risks from non-asbestiform minerals—chemically and elementally identical  
1457 analogs of those minerals. While chemically and elementally identical to asbestos, these fibers  
1458 have different physical properties. It is not certain exactly what properties of a mineral fiber  
1459 affect its potency and, in turn, impact the health of an exposed population.

1460 The toxicological literature review prepared for the MDNR (MDNR 2009b) discussed non-  
1461 asbestiform fibers. A brief summary follows.

1462 Palekar et al. (1979) found non-asbestiform particles to be cytotoxic (meaning toxic to cells);  
1463 however, epidemiological studies have found limited potential for carcinogenesis from cleavage

1464 fragments. Gamble and Gibbs (2008) provided a review of several epidemiological studies  
1465 regarding exposure to cleavage fragments including several involving taconite miners. They  
1466 found that there was no statistically significant increase in either lung cancer or mesothelioma  
1467 from exposure to taconite mining. Ilgren (2004) reviewed animal and human studies and came to  
1468 the same conclusion. Additionally, Gylseth et al. (1981) performed a study in which non-  
1469 asbestiform amphibole dust in the lungs of taconite miners was examined. Whereas Gylseth et al.  
1470 (1981) concluded that exposure to the miners constituted a minor carcinogenic risk, they could  
1471 not exclude exposure to taconite as a contributing factor to the lung cancer found in the miners  
1472 examined. Asbestosis and mesothelioma latency periods of 15 to 50 years are not uncommon,  
1473 creating uncertainties in the interpretation of studies performed to date. It should be noted that  
1474 taconite is mined in the Biwabik Formation, whereas the ore proposed to be mined for the  
1475 NorthMet Project Proposed Action is from the Duluth Complex, which is not in contact with the  
1476 Biwabik Formation at the NorthMet Deposit.

1477 The University of Minnesota conducted a research effort, known as the Minnesota Taconite  
1478 Workers Health Study (University of Minnesota 2013), funded by the State of Minnesota, to  
1479 better understand of taconite worker health issues, including an epidemiological investigation  
1480 into causes of excess rates of disease, including mesothelioma, among taconite workers. The  
1481 Study did not rule out amphibole mineral fibers as a potential source of health risk or from  
1482 playing some role in the incidence of disease among taconite workers.

1483 The MDH considers the role of non-asbestiform amphibole fibers in the induction of health  
1484 effects to be uncertain at this time. MDH concludes that amphibole mineral fibers have the  
1485 potential for an undetermined toxicity and potency.

#### 1486 Occurrence in the Duluth Complex

1487 The October 2005 SDD for the NorthMet Proposed Action EIS identified that the "... EIS will  
1488 provide information about the presence of fibers in the NorthMet deposit." Since February 2006  
1489 fibers-related information has been submitted to the Minnesota State Agencies (MDNR; MPCA;  
1490 MDH) for their review and consideration. The report entitled *Fiber Information, NorthMet Mine  
1491 and Ore Processing Facilities Project, Fibers Data Related to the Processing of NorthMet  
1492 Deposit Ore* (2007l), hereafter referred to as the "2007 Mineral Fibers Report," provided the bulk  
1493 of the fibers-related data and information.

1494 The Minnesota Environmental Quality Board (MEQB) has reported that the Duluth Complex  
1495 contains minor amounts of amphibole minerals, but did not identify chrysotile as a mineral of  
1496 concern (MEQB 1979). The MEQB (1979) identified that the concentration of asbestiform  
1497 amphibole minerals in the Duluth Complex ore is expected to be low, "...less than 0.1 ppm by  
1498 weight in the mineralized areas of the Duluth Complex..." Composite samples using ore from  
1499 the NorthMet Deposit collected during flotation pilot plant studies in 2000 conducted for  
1500 PolyMet (SGS 2004) provided results for amphibole and serpentine minerals representative of  
1501 the MEQB (1979) conclusions. Recognizing the differences between the NorthMet Deposit  
1502 versus the Biwabik Iron Formation, the MPCA, MDNR, and MDH requested that PolyMet  
1503 provide additional information on fiber-related data for its mining and processing operations in  
1504 the NorthMet Deposit.

1505 PolyMet conducted additional flotation pilot testing in July and August 2005. Collected samples  
1506 considered to be representative of the head feed, tailings, and flotation process water associated  
1507 with processing ore from the NorthMet Deposit were prepared for analysis by Transmission

1508 Electron Microscopy by additional grinding of the ore and tailings samples with mortar and  
1509 pestle to produce a very fine powder. Stevenson (1978) states that the finer a material is ground,  
1510 the higher the number of fibers identified by MDH counting rules (MDH Methods 851 and 852).  
1511 According to the laboratory conducting this analysis, this only affects fiber counts, not the  
1512 identification of asbestiform fibers since asbestiform fibers have high tensile strength and  
1513 flexibility (PolyMet 2015e).

1514 Overall, amphibole mineral fibers were found to represent a relatively small percent of the  
1515 mineral fibers associated with the processing of NorthMet Deposit ore (Flotation Pilot Testing in  
1516 July and August 2005); approximately 9 percent of the fibers identified from all collected  
1517 samples of ore, tailings, and process water. Chrysotile mineral fibers were not identified in  
1518 samples of ore, tailings, or process water collected from the flotation pilot testing. However,  
1519 PolyMet's petrographic observations indicate that chrysotile minerals are about 2 percent of the  
1520 minerals associated with the waste rock from the NorthMet Project Proposed Action.

1521 It is not possible to accurately quantify the amount of fibers that might be emitted from the  
1522 facility. Instead, this data was used to confirm the presence of amphibole minerals in the ore  
1523 body and, thus, that the potential exists for MN-fibers to be emitted from the facility.

1524 Data provided in the 2007 Mineral Fibers Report indicates that about 95 percent of the mineral  
1525 fibers identified in samples collected from the flotation pilot testing were 3 microns or smaller in  
1526 size, with most being less than 2 microns in size. Therefore, PM<sub>2.5</sub> (fine particulate) could be  
1527 used as a surrogate for all mineral fibers, including amphibole mineral fibers.

#### 1528 **5.2.7.5.2 Evaluation Criteria**

1529 Because the exact human health risk of exposure to non-asbestiform amphibole mineral particles  
1530 is unknown as well and because there is no method to quantify the potential fiber emissions,  
1531 there is no accepted methodology for performing a formal health risk assessment for the  
1532 quantitative assessment of human health effects from the proposed operations. Thus, there is an  
1533 uncertain level of potential health risk from airborne amphibole mineral fibers for the NorthMet  
1534 Project Proposed Action. As such, the focus is on minimizing and mitigating any potential  
1535 release of airborne amphibole mineral fibers.

#### 1536 **5.2.7.5.3 NorthMet Project Proposed Action**

1537 The presence of amphibole minerals in the Duluth Complex indicates that the potential exists for  
1538 the emissions of amphibole mineral fibers from the proposed operations. MN-fibers identified in  
1539 samples collected from the 2005 flotation pilot testing of material representative of processing  
1540 NorthMet Deposit ore (Barr 2007d) were predominately less than 2.5 µm in aerodynamic  
1541 diameter (99.6 percent less than 2.5 µm), placing them in the fine fraction of particulate matter  
1542 (PM<sub>2.5</sub>). A small fraction of these fibers were identified as amphibole (approximately 9 percent).  
1543 Therefore, the MPCA and the MDH have emphasized additional control of airborne fine  
1544 particles to minimize potential exposure to asbestiform and non-asbestiform amphibole mineral  
1545 fibers.

1546 There is the potential that amphibole mineral fibers may be found in water that has come in  
1547 contact with ore at the Mine Site.

1548 **Fugitive Dust Control**

1549 Several measures of regulatory requirements would assist in minimizing emissions of fibers.  
1550 Compliance with the requirements for blasting, found in *Minnesota Rules*, Chapter 6132, would  
1551 minimize fugitive dust from blasting operations. A fugitive dust suppression plan for the Tailings  
1552 Basin would be evaluated and approved by the MPCA as part of the air permit. In addition, the  
1553 NorthMet Project Proposed Action would be required to comply with Federal Mine Safety and  
1554 Health Administration's regulations for mining operations that include implementation of  
1555 standards for asbestos exposure to minimize worker exposure. Such measures would also  
1556 minimize release of amphibole mineral fibers.

1557 The potential for the release of amphibole mineral fibers to the air at the Mine Site would be low  
1558 because the ore would not be crushed at the Mine Site and the unpaved road surfaces would be  
1559 constructed of material that is not likely to contain amphibole minerals. PolyMet's decision to  
1560 use larger haul trucks at the Mine Site, as well as the incorporation of an updated mine plan into  
1561 the emission calculations, has reduced the estimated fugitive particulate emissions, further  
1562 reducing the potential for emissions of airborne amphibole mineral particles.

1563 The Tailings Basin would be operated to minimize all fugitive particulate emissions by  
1564 management to minimize exposed beach areas and wind erosion fugitive dust by treatment of the  
1565 Tailings Basin roads and inactive beach areas. The deposition of wet tailings would keep the  
1566 active work area wet and prevent wind erosion. Capillary action near the pond edge is expected  
1567 to keep the fines wet and minimize the potential for entrainment of the fines into the air.

1568 **Particulate Emissions Control Technology**

1569 In order to minimize amphibole mineral fiber emissions, and since MN-fibers are predominately  
1570 in the PM<sub>2.5</sub> size range, a PM<sub>2.5</sub> BACT-like analysis for the proposed PolyMet operations was  
1571 performed in accordance with the USEPA's guidance. The NorthMet Project Proposed Action is  
1572 not subject to PSD, so this analysis is not otherwise required. The purpose of this analysis was  
1573 solely to determine the best control for PM<sub>2.5</sub> and thus for fibers. For this analysis, control  
1574 technologies are ranked in order of effectiveness, and starting with the most stringent  
1575 technology, each are evaluated until a technology cannot be ruled out on technological or  
1576 economic grounds.

1577 The vast majority of potential emissions of MN-fibers for the NorthMet Project Proposed Action  
1578 would occur from the ore crushing operations at the Plant Site, with minor potential emissions  
1579 from the Tailings Basin and the Mine Site (PolyMet 2015e).

1580 As a result of the BACT-like analysis, the NorthMet Project Proposed Action would install  
1581 emission controls in the crushing plant, such that the emissions of fine particulate matter from  
1582 the ore crushing and associated material handling sources are controlled consistent with recent  
1583 BACT determinations. The controls would include the use of fabric filters (baghouse or  
1584 cartridge) designed to reduce emissions to 0.0025 gram per dry standard cubic foot at each unit  
1585 (PolyMet 2015e). These controls would be applied to all emission sources within the coarse  
1586 crushing operations (10 units), the drive house (2 units), the fine crushers (8 units), and the  
1587 concentrator (15 units).

1588 In addition to these controls, the NorthMet Project Proposed Action would also use high-  
1589 efficiency particulate air (HEPA) filters following the fabric filters on selected units. The HEPA  
1590 filters would be used when exhaust air from the fabric filters is routed back into the building to

1591 provide an added level of assurance that worker exposure to inhalable dust is minimized. In this  
1592 case, the venting of exhaust air back into a building provides a benefit of reducing the heating  
1593 fuel demand that offsets the additional cost and energy usage associated with re-routing of air  
1594 back into a building (PolyMet 2015e). The combination of the cartridge and HEPA filters for  
1595 fine particulates has a removal efficiency of 99.97 percent. Six units within the coarse crushing  
1596 operations and nine units within the concentrator would utilize the HEPA filters year-round.  
1597 Eight of the 10 units within the drive house and fine crusher operations would utilize the HEPA  
1598 filters during heating season only (PolyMet 2015e).

1599 The use of HEPA filters, during non-essential operations, would provide little air quality benefits  
1600 for reducing exposure to fine particulates outside the facility boundary. In addition, the modeled  
1601 PM<sub>2.5</sub> effects demonstrate that the PM<sub>2.5</sub> concentrations, which are in the same size range as the  
1602 amphibole mineral fibers, rapidly decrease in magnitude in all directions. As such, the  
1603 operational and air pollution equipment controls for the NorthMet Project Proposed Action  
1604 represent the highest feasible level of fine particulate matter control and, coupled with Hoyt  
1605 Lakes being 5 miles from the Plant Site, further reduce the potential for public exposure to  
1606 airborne amphibole mineral fibers.

#### 1607 **Amphibole Mineral Fibers in Water Discharges**

1608 There is the potential that amphibole mineral fibers may be found in water that has come in  
1609 contact with ore at the Mine Site. There is no applicable water quality standard specific to non-  
1610 asbestiform amphibole mineral fibers. The USEPA has developed drinking water standards for  
1611 asbestos that drinking water utilities must comply with based upon information on the USEPA  
1612 website(<http://water.epa.gov/drink/contaminants/basicinformation/asbestos.cfm>). This standard,  
1613 an MCL, is 7 million fibers per liter. The USEPA has provided proven methods of water  
1614 treatment to meet the MCL, including coagulation/filtration, direct and diatomite filtration, and  
1615 corrosion control.

1616 Water in contact with waste rock, ore, and pit walls would be treated during operations utilizing  
1617 a greensand filter. No discharge would occur off site. During post-closure, a greensand filter,  
1618 pre-filters, and a RO system would be used to treat water to meet water quality standards prior to  
1619 discharge. This treated water would be discharged into the Partridge River, which flows into  
1620 Colby Lake, the only lake in the area used for drinking water. It is the source of drinking water  
1621 for the City of Hoyt Lakes. Currently, the City utilizes sand filters, coagulation, and settling and  
1622 has been in compliance with the USEPA asbestos standard. When the RO treatment system is  
1623 constructed at the Mine Site, it would operate in the same fashion as the City's treatment system.  
1624 As such, the discharge from the Mine Site is expected to be in compliance with the federal  
1625 standard prior to it being treated again by the City of Hoyt Lakes.

#### 1626 **Nearby Ambient Fiber Monitoring**

1627 Baseline ambient air monitoring for mineral fiber concentration is currently being done at Hoyt  
1628 Lakes. The monitoring location was approved by the MPCA and the monitoring is being  
1629 conducted according to MPCA methodology. Ambient air monitoring for mineral fibers would  
1630 also be conducted following facility startup. The mineral fibers data collected after the facility  
1631 start-up would enable MPCA ample data to compare ambient concentrations, including  
1632 NorthMet Project Proposed Action emissions, with the baseline conditions.

## 1 **5.2.8 Noise and Vibration**

2 This section describes effects on humans, including effects on recreational and cultural/spiritual  
3 activity, of noise, vibration, and airblast related to the NorthMet Project Proposed Action. The  
4 effects on wildlife are described in Section 5.2.5.

### 5 **Summary**

6 Both noise and vibration dissipate with distance. The residences closest to the mine are at a  
7 distance where blasting and other NorthMet Project Proposed Action-related noise would not be  
8 heard. The NorthMet Project Proposed Action would comply with all daytime and nighttime  
9 regulatory noise limits at sensitive receptors, and the changes in total noise level from current  
10 conditions during nighttime operations would not be perceptible. Immediate access to areas  
11 around the mine would be restricted. Members of the general public who may be recreating near  
12 the NorthMet Project area and tribal members who may have a cultural and spiritual connection  
13 to archeological sites in the Superior National Forest, in areas immediately near the mine, may  
14 occasionally experience noise and/or vibration associated with the NorthMet Project Proposed  
15 Action.

### 16 **5.2.8.1 Methodology and Evaluation Criteria**

17 This section describes the methodologies and criteria used to evaluate potential noise, ground  
18 vibration, and airblast at areas of the Mine Site and Plant Site. NorthMet Project Proposed  
19 Action-related sound levels were estimated using the International Standards Organization (ISO)  
20 9613-2 sound-propagation model. The Site Law Formula was the basis for estimating vibration  
21 effects. Airblast was estimated using the Terrock model. Each is a desktop model that estimates  
22 project effects using site-specific conditions. Estimated effects were compared to federal, state,  
23 or local regulations or to project design standards, as appropriate. For noise and vibration, the  
24 area of potential effect was defined as a 20-mile radius from the Mine Site and a 20-mile radius  
25 from the Plant Site. The area of potential effect for airblast was the distance from the source  
26 where measured effects were below the known level for human effects.

#### 27 **5.2.8.1.1 Noise**

##### 28 **Noise Impact Assessment Methodology**

29 The noise impact assessment areas for the NorthMet Project Proposed Action include the noise-  
30 sensitive receptors within a 20-mile radius of the Mine Site and a 20-mile radius of the Plant  
31 Site. The 20-mile radius was selected in order to include the southern edge of the BWCAW,  
32 which is located approximately 20 miles north of the Mine Site and Plant Site. The ISO 9613-2  
33 sound-propagation model (*Acoustics-Attenuation of Sound during Propagation Outdoors*) is  
34 accepted worldwide and was used to determine the extent of noise effects from the NorthMet  
35 Project Proposed Action. This model is the only one that encompasses a standardized method for  
36 calculating sound propagation and is the basis for most sophisticated computer modeling  
37 programs (Ray 2010). This sound-propagation model consists of octave-band algorithms with  
38 nominal mid-band frequencies from 63 to 8,000 Hz for computing the attenuation of sound  
39 originating from a point sound source or an assembly of point sources. The source(s) may be  
40 mobile or stationary. The model predicts equivalent continuous A-weighted sound pressure

41 levels ( $L_{eq}$ ) from sources of known sound emission and accounts for the following site  
42 conditions and physical effects:

- 43 • Meteorological conditions favorable to sound propagation (i.e., downwind propagation with  
44 wind speeds between 1 and 5 meters per second when measured 3 to 11 meters above the  
45 ground). This is a conservative approach because not all receptors may be located downwind  
46 of the sources (i.e., receptors located upwind would experience less noise since noise  
47 propagates farther downwind than upwind).
- 48 • Topography and the extent of ground absorption from different surfaces.
- 49 • Noise emission of each source, as well as its location and elevation.
- 50 • Location and elevation above local ground level of all sensitive receptors.
- 51 • Screening from any enclosures, barriers, earth berms, buildings, or vegetation.
- 52 • Attenuation due to distance (geometrical divergence) and atmospheric absorption.
- 53 • Increase in noise level due to reflections from nearby facades and reflective objects.

54 For the noise assessment of the NorthMet Project Proposed Action, ground topography or  
55 surface effects were modeled assuming that the area around the source and the receptors would  
56 be a mixed 50 percent hard non-absorptive ground (e.g., paved surfaces, water, ice, concrete, and  
57 all other ground surfaces having a low porosity) and 50 percent soft absorptive surface (e.g.,  
58 ground covered by grass, trees, and farm land, and all other ground surfaces having a high  
59 porosity). This is a conservative assumption, as almost 100 percent of the ground adjacent to the  
60 mine sound sources and closest receptors is porous with more absorptive capacity that can  
61 attenuate noise levels. Temperature and relative humidity of 20 °C and 70 percent, respectively,  
62 were used in estimating the attenuation due to atmospheric absorption. Attenuation due to  
63 geometric divergence or spreading is mainly a function of the distance between the sound source  
64 and the receiver. A further conservative assumption is that the modeling analysis did not include  
65 any potential shielding effects from pit walls, waste rock stockpiles, berms, or vegetation.

66 Sound power levels for all equipment and trucks at the Mine Site and Plant Site were based on  
67 measured octave-band sound power data obtained from similar mine projects in Australia  
68 (Bassett Acoustics 2004; URS 2005). For modeling purposes, it was conservatively assumed that  
69 all equipment at the Mine Site and Plant Site would be steady noise sources (except for high-  
70 energy impulsive noise from blasting [explosives]) and would operate simultaneously and  
71 continuously for 24 hours per day. Impact assessment methodology for blasting noise (i.e.,  
72 airblast overpressures) discussed in Section 5.2.8.1.2, Vibration and Airblast.

### 73 **Noise Impact Assessment Criteria**

74 Noise effects are commonly judged according to two general criteria: the extent to which a  
75 project would exceed federal, state, or (where applicable) local noise regulations, and the  
76 estimated degree of disturbance to people who live in or use an area.

77 According to the noise standards for Minnesota (*Minnesota Rules*, part 7030.0040, subpart 2),  
78 permissible noise levels are broadly classified according to land uses such as residential,  
79 commercial, or industrial. The standards distinguish between daytime and nighttime noise, with  
80 less noise permitted at night. The standards list the sound levels not to be exceeded for more than

81 10 and 50 percent of the time ( $L_{10}$  and  $L_{50}$ ) during any 1 hour period. The applicable Minnesota  
 82 Noise Standards are shown in Table 5.2.8-1. Section 4.2.8 provides additional discussion of  
 83 common noise levels.

84 **Table 5.2.8-1 Applicable Noise Standards for Different Land Uses in Minnesota**

| Noise Area<br>Classification <sup>1</sup> | Noise Standard (dBA)        |          |                               |          |
|-------------------------------------------|-----------------------------|----------|-------------------------------|----------|
|                                           | Daytime (7 a.m. to 10 p.m.) |          | Nighttime (10 p.m. to 7 a.m.) |          |
|                                           | $L_{50}$                    | $L_{10}$ | $L_{50}$                      | $L_{10}$ |
| 1                                         | 60.0                        | 65.0     | 50.0                          | 55.0     |
| 2                                         | 65.0                        | 70.0     | 65.0                          | 70.0     |
| 3                                         | 75.0                        | 80.0     | 75.0                          | 80.0     |

85 Source: *Minnesota Rules*, part 7030.0040, subpart 2; MPCA 2008a.

86 <sup>1</sup> The land use activities associated with each Noise Area Classification (NAC) are described in Minnesota Rules, part  
 87 7030.0040, subpart 2 and MPCA 2008a.

- 88 - Land use activities under NAC 1 include household units, group quarters, residential hotels, transient lodging camp  
 89 grounds, correctional institutions, mobile home parks or courts, health and educational services, religious activities,  
 90 resorts, camping and picnicking areas, motion picture production, and other cultural, entertainment, and recreational  
 91 activities.
- 92 - Land use activities under NAC 2 include rail, road, water, and air transportation activities (passenger), wholesale and  
 93 retail trade, parks, recreational activities (except entertainment assembly and race tracts), automobile parking, personal  
 94 services, business services, and other professional services (repair, legal, and contract construction services).
- 95 - Land use activities under NAC 3 include manufacturing, petroleum refining and related industries, primary metal  
 96 industries, race tracks, fair grounds and amusement parks, agricultural and fishing-related activities, retail trade (eating  
 97 and drinking) and transportation, communication, and utilities (except transportation services and arrangements).

98 As shown in Table 5.2.8-1, the most stringent standard is the nighttime (10 p.m. to 7 a.m.)  
 99 standard in a NAC 1, which is 50 dBA for no more than 50 percent of the time ( $L_{50}$ ). In other  
 100 words, a nighttime  $L_{50}$  of 50 dBA means that from 10 p.m. to 7 a.m., noise levels may not exceed  
 101 50 dBA more than 30 minutes in an hour. Similarly, a nighttime  $L_{10}$  of 55 dBA means that  
 102 during these same hours, noise levels may not exceed 55 dBA more than 6 minutes in an hour.  
 103 Land use activities under NAC 1 include household units or private residences, mobile home  
 104 parks, transient lodging campgrounds and picnic areas, churches, schools, hospitals, and other  
 105 cultural, entertainment, and recreational activities.

106 There are no federal or local noise regulations that would apply to the NorthMet Project  
 107 Proposed Action.

108 In addition to state and federal standards, the degree of disturbance becomes a key factor in the  
 109 evaluation of noise effects, which, in this case, includes a focus on residents in the vicinity of the  
 110 NorthMet Project Proposed Action, as well as people who frequent the area for recreation,  
 111 fishing, and hunting, and tribal members who may be involved in traditional natural resource  
 112 harvests on national forest lands. The concept of human disturbance is known to vary with a  
 113 number of interrelated factors including: changes in noise levels; the presence of other, non-  
 114 project-related noise sources in the vicinity; people's attitudes toward the project; the number of  
 115 people exposed; and the type of human activity affected (e.g., sleep or quiet conversation as  
 116 compared to physical work or active recreation).

117 NorthMet Project Proposed Action-related noise effects have been evaluated at sensitive  
 118 receptors using the state daytime and nighttime noise standards ( $L_{50}$  and  $L_{10}$ ) for NAC 1. These  
 119 noise standards would apply to the NorthMet Project area throughout the years that the mine is

120 operating (years 1 to 20), when elevated sound level activities from mining, hauling, and  
121 crushing operations would occur. The same noise standards would also apply to any potential  
122 noise source during closure and post-closure (i.e., after year 20).

### 123 **Area of Audibility for Boundary Waters Canoe Area Wilderness**

124 Sound from project activities may be audible even if the sound level is lower than the  
125 background ambient level. This is because stationary (e.g., drill rigs, crushers) and mobile  
126 sources (e.g., dump trucks, graders) associated with mining and crushing activities at the Mine  
127 Site and Plant Site may be of a different quality (e.g., electric motor or diesel engine versus a  
128 bird call) than natural ambient sound.

129 It is assumed that noise associated with drilling, excavating, hauling, and crushing activities may  
130 be audible up to the location that sound level emitted from these project-related sources  
131 attenuates to a level that is 8 dBA below ambient A-weighted sound level. This is identified by  
132 the National Park Service at 64 FR 3969-3972 for noise emitted by aircraft that may affect Park  
133 visitors. There may be some variability when comparing sound propagation from aircraft engines  
134 as done by the National Park Service versus project-related sources (electric motors, diesel  
135 engines, etc.). However, for the purpose of this analysis, the 8 dBA method is considered  
136 adequate to estimate audible distance from noise sources at the Mine Site and Plant Site. It  
137 should be noted that the area of audibility usually applies to certain areas considered by the  
138 National Park Service to require substantial restoration of natural quiet (64 FR 3969-3972). For  
139 the NorthMet Project Proposed Action, the area of audibility or audibility impacts applies to the  
140 BWCAW only. An area of audibility could also be calculated for other non-wilderness receptor  
141 locations such as recreational sites within the vicinity of the NorthMet Project area. However,  
142 since the area of audibility is based on measured baseline levels for each receptor of concern,  
143 separate areas of audibility would be needed for each receptor type. Applying the area of  
144 audibility for the BWCAW for other receptor locations is conservative due to the expected  
145 higher baseline levels in these areas.

### 146 **5.2.8.1.2 Vibration and Airblast**

#### 147 **Ground Vibration Impact Assessment Methodology**

148 The ground vibration impact assessment area for the NorthMet Project Proposed Action  
149 encompasses a 20-mile radius from the Mine Site. When an explosive is detonated in a blasthole,  
150 a pressure wave is generated in the surrounding rock. As this pressure wave moves from the  
151 borehole, it forms seismic waves by displacing particles in the earth (e.g., glacial till, bedrock).  
152 Ground vibration varies with distance from the blast, charge mass per hole, type of explosive,  
153 geological conditions, and blasting specifications. For similar geological conditions and blasting  
154 specifications, ground vibration varies with distance from the blast and charge mass per hole,  
155 according to the Site Law formula. This formula has been used for assessing ground vibration  
156 effects from blasting activities at multiple mine and quarry sites in Australia and has also been  
157 used in this assessment. The formula accounts for different rock types with a site constant  $K_g$  (see  
158 note in Table 5.2.8-4 for definition of  $K_g$ ). Typical  $K_g$  factors for free-face hard or highly  
159 structured rock, free-face average rock, and heavily confined rock are 500, 1,140, and 5,000,  
160 respectively (Dyno Nobel 2010). This vibration assessment has been conducted using a range of  
161 these three  $K_g$  factors to allow for varying degrees of vibration transmission through different  
162 rock types.

163 **Airblast Overpressures Impact Assessment Methodology**

164 The impact assessment area for airblast overpressure (or blasting noise) for the NorthMet Project  
165 Proposed Action is the same area that was used to evaluate ground vibration. An airblast is an  
166 airborne shock wave that results from the detonation of explosives. The magnitude of airblast  
167 overpressure levels at a point remote from the blast is a function of many parameters including  
168 charge mass (mass of explosive per drilled hole), confinement, burden (distance between two  
169 drilled holes and perpendicular to the free face), attenuation rate, shielding direction relative to  
170 the blast, and meteorological conditions at the time of the blast. The attenuation rate for low-  
171 frequency blast vibration has been found from experience to be a 9 dBL reduction per doubling  
172 of distance (Terrock Consulting Engineers 2009).

173 Analysis of blasting data from mines and quarries has permitted a relationship to be established  
174 between the maximum 120 dBL distance (the distance in front of the blast that the 120 dBL  
175 contour occurs), charge mass per hole, and burden using the Terrock model. This model has been  
176 used for assessing airblast effects from blasting activities at multiple mine and quarry sites in  
177 Australia and has also been used in this assessment. The model accounts for a dimensionless  
178 empirical constant,  $k_a$  (usually 250 for quarry and mine blasting), and determines the maximum  
179 distance to the 120 dBL contour from the blast site.

180 **Ground Vibration and Airblast Overpressure Evaluation Criteria**

181 Humans can feel ground vibration and airblast overpressures at levels well below those that can  
182 cause damage to property. Ground vibration and airblast overpressure limits, therefore, have two  
183 aspects: an environmental or acceptable human response (annoyance) limit, and a limit to  
184 prevent structural damage (which should be considered separately).

185 To minimize human annoyance and prevent structural damage to properties outside mining  
186 areas, the effects of ground vibration and air overpressure from blasting operations must meet the  
187 requirements of *Minnesota Rules*, part 6132.2900, subpart 2. According to the *Minnesota Rules*,  
188 the maximum PPV from blasting should not exceed 1 in/s (25.4 mm/s) at the location of a  
189 structure located on lands not owned or controlled by the permittee. Air overpressure on lands  
190 not owned or controlled by the permittee should not exceed 130 dB, as measured on a linear peak  
191 scale (dBL) sensitive to a frequency band ranging from 6 cycles per second to 200 cycles per  
192 second.

193 Ground vibration and air blast (overpressure) from rock blasting are primarily related to the  
194 weight of explosive detonated at any single instant and the distance to a structure or sensitive  
195 receptor.

196 Aside from the *Minnesota Rules*, there are no specific federal or local vibration regulations  
197 associated with mine blasting that would apply to the NorthMet Project Proposed Action.

198 **5.2.8.2 NorthMet Project Proposed Action**

199 **5.2.8.2.1 Noise**

200 The primary sources of noise from the Mine Site (3,014.5 acres) during operations would be  
201 drilling; blasting; excavation work (hydraulic excavators, front-end loaders); dump trucks  
202 hauling material along mine haul roads; material-handling activities at the Rail Transfer Hopper,  
203 Overburden Storage and Laydown Area, and waste rock stockpiles; and train horns. Noise would

204 also be generated from auxiliary and support equipment such as tracked dozers, wheel dozers,  
 205 graders, water trucks, backhoes, and fuel trucks. The sound power levels for each of these  
 206 sources, based on data from operating mines, are summarized in Table 5.2.8-2.

207 **Table 5.2.8-2 Maximum Sound Power Levels of Major Equipment and Trucks during**  
 208 **Operations at the Mine Site and Plant Site**

| Noise Source Description    | Octave Band Center Frequency (Hz) |       |       |       |        |        |        |        | Overall Linear-Weighted Sound Power Level (dBL) | Overall A-Weighted Sound Power Level (dBA) |
|-----------------------------|-----------------------------------|-------|-------|-------|--------|--------|--------|--------|-------------------------------------------------|--------------------------------------------|
|                             | 63.0                              | 125.0 | 250.0 | 500.0 | 1000.0 | 2000.0 | 4000.0 | 8000.0 |                                                 |                                            |
| <b>Mine Site</b>            |                                   |       |       |       |        |        |        |        |                                                 |                                            |
| Rotary Drill Rig            | 110.0                             | 123.0 | 114.0 | 119.0 | 111.0  | 109.0  | 103.0  | 98.0   | 125.0                                           | 119.0                                      |
| Hydraulic Excavator (31-cy) | 111.0                             | 122.0 | 118.0 | 117.0 | 115.0  | 110.0  | 104.0  | 99.0   | 125.0                                           | 119.0                                      |

209 <sup>1</sup> Assumes all mine equipment and trucks would be in continuous operation at any given time at the Mine Site.  
 210 <sup>2</sup> Sound power levels for all equipment and trucks at the Mine Site were taken from the Noise and Vibration Assessment for the  
 211 Clermont Coal Mine Project, Queensland Australia, August 2004 (Bassett Acoustics 2004). Sound power levels for backhoe  
 212 and fuel trucks were not available and were assumed to be the same as for the graders due to their similar hp ratings.  
 213 <sup>3</sup> Sound power levels for the primary crusher at the Plant Site (116 dBA) were taken from the McArthur River Mine Open Cut  
 214 Project, Australia (URS 2005).  
 215 <sup>4</sup> All mine and plant equipment were assumed to be approximately 5 meters from ground level.  
 216 <sup>5</sup> Total sound power level from all equipment at the Mine Site was calculated by logarithmically adding all the octave-band  
 217 sound power levels for each piece of equipment at the site.

218 To estimate potential noise effects on closest receptors, noise from proposed mine operations  
 219 was modeled using the ISO 9613-2 sound-propagation model, as described in Section 5.2.8.1.  
 220 The Mine Site assessment predicted effects at nine different receptor locations scattered  
 221 throughout the vicinity of the site. The closest noise-sensitive areas to the Mine Site are shown  
 222 on Figure 4.2.8-1; the closest of these is the City of Babbitt, located 6.5 miles north of the Mine  
 223 Site. In addition to the nine identified receptors, other sensitive receptors such as trails and  
 224 recreational sites (family campgrounds, camp sites, boating, fishing, swimming, and family  
 225 picnic areas) within the NorthMet Project are vicinity are also shown on Figure 4.2.8-1.

226 All major mine equipment and trucks shown in Table 5.2.8-2 were assumed to be steady noise  
 227 sources (see Section 4.2.8.1, Types of Noise) operating simultaneously and continuously for 24  
 228 hours per day. This is a conservative assumption, as most noise sources identified in Table  
 229 5.2.8-2 are mobile sources such as dump trucks, fuel trucks, dozer, graders, etc., which are non-  
 230 steady sources (i.e., fluctuating or intermittent sources) that would not operate simultaneously or  
 231 continuously for 24 hours per day. Tonal noise may occur as a result of the moving parts of  
 232 internal combustion engines of mobile sources; however, the overestimated sound power levels

233 resulting from the conservative assumption described above (i.e., that all mobile sources are  
 234 steady sources operating simultaneously) would likely offset any noise increases associated with  
 235 tonal sounds. The NorthMet Project Proposed Action would not generate highly impulsive  
 236 sounds such as drop hammering, pile driving, or pavement breaking. High-energy impulsive  
 237 sounds associated with the use of explosives during blasting (i.e., blasting noise or airblast  
 238 overpressures) are discussed in Section 5.2.8.2.2. As indicated in Section 4.2.8.1, Types of  
 239 Noise, annoyance to sounds with strong low-frequency content is virtually only an indoor  
 240 problem. Because the closest residences (i.e., indoor receptors) are over 8 and 4 miles from the  
 241 Mine Site and Plant Site, respectively (see Tables 5.2.8-3 and 5.2.8-4), the likelihood of low-  
 242 frequency-induced annoyance at such distances is very low.

243 Modeled sound levels from all mine equipment and trucks experienced at the nearest receptors  
 244 during daytime and nighttime mine operations (excluding baseline levels and plant sources), are  
 245 shown in Table 5.2.8-3.

246 **Table 5.2.8-3 Predicted Noise Levels at Nearest Receptors to Mining and Hauling**  
 247 **Operations at Mine Site (excludes Baseline Levels)**

248 <sup>1</sup> N=North, S=South, E=East, W=West, NW=Northwest, NE=Northeast, SW=Southwest

249 Table 5.2.8-3 indicates that the highest noise levels that would be experienced during operations  
 250 at the Mine Site would occur at the closest receptors in Babbitt. Excluding baseline levels, L<sub>50</sub>  
 251 and L<sub>10</sub> noise levels from the Mine Site are 14.2 and 18.0 dBA, respectively. Due to the low  
 252 noise contribution from the Mine Site sources, total L<sub>50</sub> and L<sub>10</sub> noise levels at Babbitt and other  
 253 receptors during daytime and nighttime, inclusive of baseline noise levels, would remain the  
 254 same (i.e., no change in baseline levels when combined with Mine Site noise levels). The  
 255 predicted L<sub>eq</sub> at noise-sensitive receptors around the Mine Site were converted to L<sub>50</sub> and L<sub>10</sub>  
 256 using a USEPA calculation methodology (USEPA 1974). The calculation was based on an  
 257 assumed standard deviation of 3 dBA for sound level distribution.

258 The primary sources of noise along the Transportation and Utility Corridor would be trains and  
 259 train horns used during ore transport from the Mine Site to the Plant Site. The noise from the  
 260 trains and their horns is expected to have minimal effects because the railroad route between the  
 261 two locations is approximately 4 to 5 miles from the nearest receptors. Up to 22 trains per day  
 262 are expected to deliver ore to the Plant Site. This frequency of traffic is less than that experienced  
 263 on the rail line during past mining operations.

264 The primary sources of noise from the Plant Site would be crushers. Noise from other sources  
 265 such as pumps at the existing LTVSMC Tailings Basin is expected to be minor in comparison to  
 266 noise from the crushers, and, as such, was not quantified. The sound power level for the crushers  
 267 was estimated to be 116 dBA (Table 5.2.8-2). Sound-propagation modeling was performed for  
 268 the crushers using the ISO 9613-2 sound-propagation model and assumptions described in  
 269 Section 5.2.8.1. Modeled sound levels experienced at the nearest receptors during ore-crushing  
 270 operations, plus baseline levels (excluding baseline levels and mine sources), are shown in  
 271 Table 5.2.8-4.

272 **Table 5.2.8-4 Predicted Noise Levels at Nearest Receptors to Ore-crushing Operations at**  
 273 **Plant Site (excludes Baseline Levels)**

| Receptor                 | Distance to Mine Site (miles) <sup>2</sup> |           | Daytime Noise Levels at Closest Receptors to Plant Site (excludes Baseline Levels) (dBA) |                 |                 | Nighttime Noise Levels at Closest Receptors to Plant Site (excludes Baseline Levels) (dBA) |                 |                 |

| Tower (R-9)              | 15.4                                       | NW        | 0.0                                                                                      | 0.0             | 3.8             | 0.0                                                                                        | 0.0             | 3.8             |

274 <sup>1</sup> N=North, S=South, NW=Northwest, NE=Northeast, SW=Southwest, SE=Southeast

275 Table 5.2.8-4 indicates the highest nighttime L<sub>50</sub> and L<sub>10</sub> levels that would be experienced at the  
 276 closest receptor (private residences, 4.2 miles north of the Plant Site) due to operations at the  
 277 Plant Site are 13.5 and 17.3 dBA, respectively, exclusive of baseline levels. Due to the low noise  
 278 contribution from the Plant Site crushers, total L<sub>50</sub> and L<sub>10</sub> at the private residences and other  
 279 receptors during daytime and nighttime, inclusive of baseline noise levels, would remain the  
 280 same (i.e., no change in baseline levels at closest receptors when combined with Plant Site noise  
 281 levels).

282 PolyMet plans to relocate the coal ash landfill from its current location to disposal in the  
 283 hydrometallurgical residue facility. This relocation of the coal ash landfill would result in

284 temporary noise associated with the use of tracked excavators or front-end loaders for removing  
285 fill materials, truck movements along a 2.5-mile haul road to the future Hydrometallurgical  
286 Residue Facility, and other construction equipment such as a grader, dozer, and water truck.  
287 These activities would be short-term (approximately 50 shifts with 8 hours per shift) and would  
288 occur mostly during daytime when noise increases are more tolerable. In addition, there are no  
289 noise sensitive receptors in close proximity or within a 1-mile radius of these activities. Based on  
290 the information above, noise impacts associated with the relocation of the coal ash landfill would  
291 not exceed applicable evaluation criteria.

292 Aside from the relocation of the landfill, PolyMet also plans to replace the existing conventional  
293 ball mills at the Plant Site with semi-autogenous mills. The sound power levels for the  
294 replacement semi-autogenous mills are expected to generate a less or equal amount of noise level  
295 when compared to the existing ball mills and, as such, are not likely to result in any noise  
296 increases. Therefore, noise impact from this change would not exceed applicable evaluation  
297 criteria.

298 The total combined noise effect from operations at the Mine Site, Transportation and Utility  
299 Corridor, and Plant Site plus baseline levels is discussed in Section 5.2.8.2.3, Total Noise Effects  
300 from NorthMet Project Proposed Action Operations. The area of audibility and noise effects on  
301 off-site transportation are also discussed in Section 5.2.8.2.3.

#### 302 **5.2.8.2.2 Ground Vibration and Airblast Overpressure**

303 The potential for ground vibration from hauling material via dump trucks along the mine haul  
304 road is expected to be low since rubber-tired vehicles do not generate any significant amount of  
305 ground vibration. However, blasting at the Mine Site could affect surrounding residential  
306 receptors and structures or buildings with regard to ground vibration and airblast overpressure.  
307 The potential effects of ground vibration and airblast overpressure are discussed below. PolyMet  
308 has committed to develop an ore and rock blasting program with industry standard methods and  
309 experiences from other area mines, including blast vibration damage prevention and monitoring.

#### 310 **Ground Vibration from Blasting at the Mine Site**

311 Except at very close distances to a blast, when permanent ground displacement could occur,  
312 ground vibration is an elastic wave motion and the ground returns to its original position after the  
313 wave passes. The attenuation rate varies based on the characteristics of the rock through which  
314 the vibration travels. Characteristics such as faults and jointing planes, degree and depth of  
315 weathering, and the top soil profile contribute to a wide variation of vibration levels.

316 The potential effect of ground vibration from blasting at the Mine Site was assessed using the  
317 Site Law formula, as described in Section 5.2.8.1. The vibration assessment was conducted over  
318 a range of  $K_g$  factors that represent the vibration transmission through different types of ore or  
319 waste rock. Using the Site Law formula and appropriate blast parameters, the limiting distances  
320 (i.e., distances beyond which an effect would not occur using different  $K_g$  factors) for ore and  
321 waste rock blasts at ground vibration levels ranging from 0.5 to 25.4 mm/s were calculated and  
322 are shown in Table 5.2.8-5. Ground vibration contours from blasting at the Mine Site are shown  
323 on Figure 5.2.8-1 (based on a maximum  $K_g$  factor of 5,000 for heavily confined rocks).

324

325 **Table 5.2.8-5 Limiting Distances for Ore and Waste Rock Blasts at Incremental Ground**  
 326 **Vibration Levels**

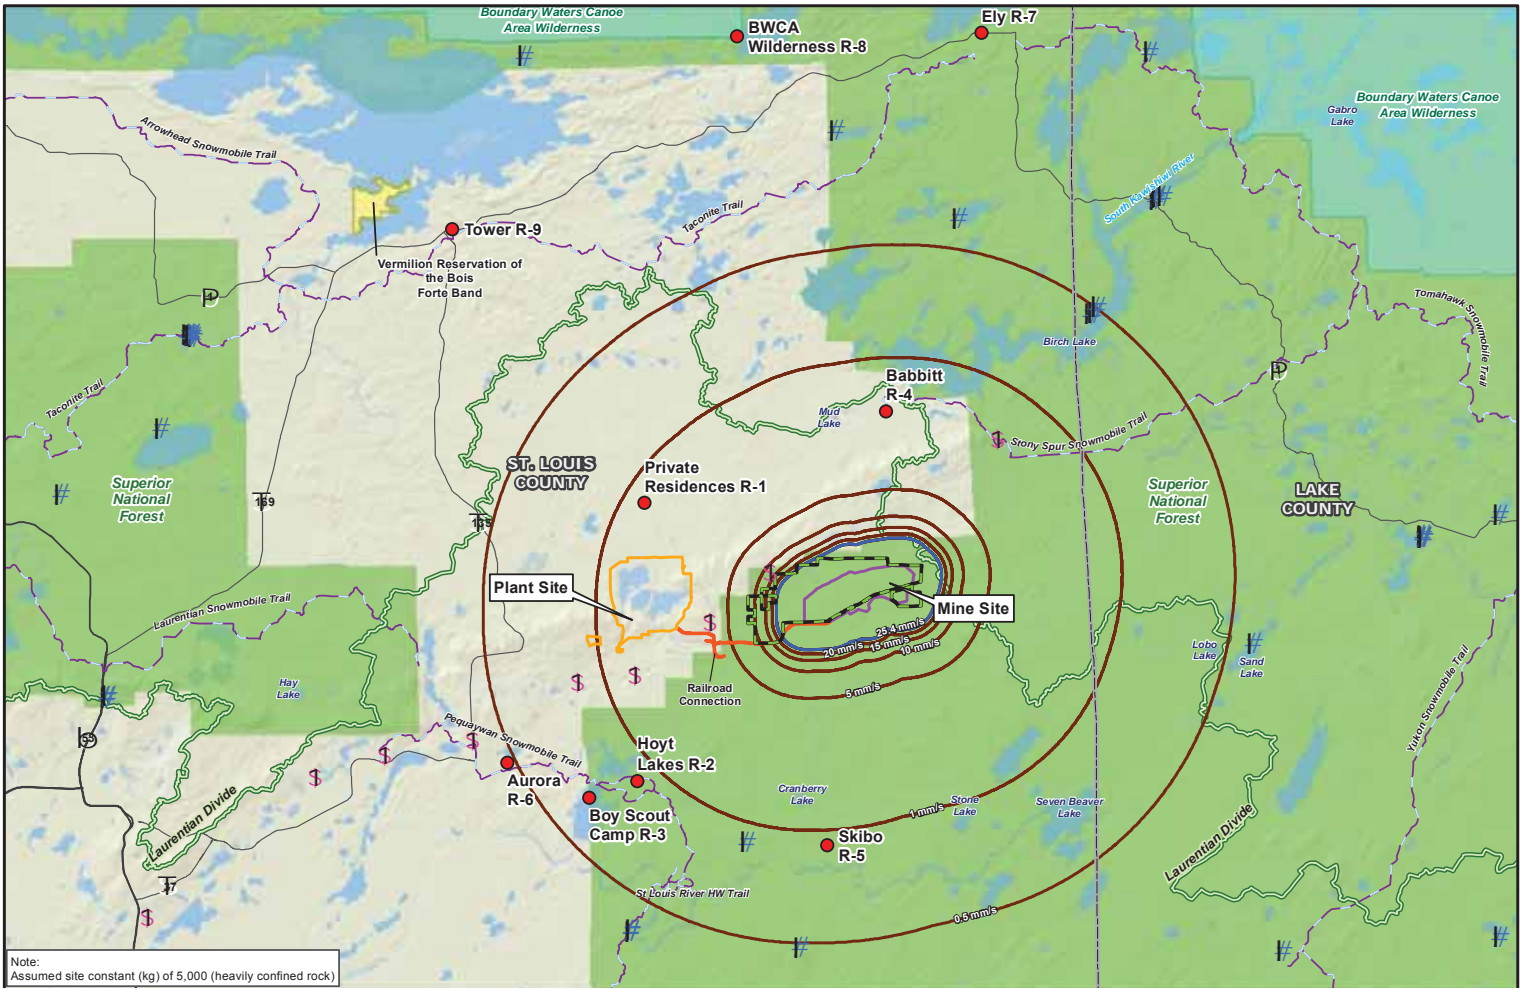

| Ground Vibration, PPV<br>(mm/sec) | Limiting Distance from Blast, D (m) <sup>1</sup> |                        |                        |
|-----------------------------------|--------------------------------------------------|------------------------|------------------------|
|                                   | k <sub>g</sub> = 500                             | k <sub>g</sub> = 1,140 | k <sub>g</sub> = 5,000 |
| 25.4                              | 375                                              | 627                    | 1,581                  |
| 20                                | 435                                              | 728                    | 1,835                  |
| 15                                | 521                                              | 872                    | 2,197                  |
| 10                                | 671                                              | 1,123                  | 2,830                  |
| 5                                 | 1,035                                            | 1,733                  | 4,365                  |
| 3                                 | 1,424                                            | 2,384                  | 6,007                  |
| 1                                 | 2,830                                            | 4,738                  | 11,936                 |
| 0.5                               | 4,365                                            | 7,306                  | 18,407                 |

327 Notes:

328 k<sub>g</sub> = Site specific empirical constant for predicting ground vibration levels (dimensionless). Usually determined by site  
 329 calibration. Typical K<sub>g</sub> factors for free face hard /highly structured rock, free face average rock, and heavily confined rock are  
 330 500, 1140, and 5000, respectively.

331 <sup>1</sup> Limiting distances for predicting ground vibration levels from blasting were estimated based on the charge mass per hole  
 332 (3,388 kg/hole). The charge mass per hole was estimated using the blast parameters and specification for this project such as  
 333 blasthole diameter (311 mm), hole length (22.6 m), burden (8.84 m), spacing (10.1 m), and explosive density (1.69 kg/m<sup>3</sup>).

**Blasting at the Mine Site**  
 NorthMet Mining Project and Land Exchange PFEIS  
 Minnesota  
 June 2015

DRAFT

338 The environmental effects of blasting at non-ferrous mining operations are regulated by the  
339 MDNR to ensure that the effects of ground vibrations from production blasts would not be  
340 detrimental to human health or welfare or property outside the mining area. According to  
341 *Minnesota Rules*, part 6132.2900, subpart 2, the maximum PPV from blasting shall not exceed 1  
342 in/s (25.4 mm/s) at the location of a structure located on lands not owned or controlled by the  
343 permittee. Assuming a worst-case  $K_g$  of 5,000 (heavily confined rocks) and 3,388 kg (7,471 lbs)  
344 of explosives per blast hole, the limiting distance for blasts at ground vibration levels of 25.4  
345 mm/s (1 in/s) is 1,581 meters (0.98 mile) and the impact area for this Minnesota ground vibration  
346 limit is approximately 11,334 acres (see Table 5.2.8-5; Figure 5.2.8-1). None of the human or  
347 structural receptors are located within this ground vibration impact area. The maximum ground  
348 vibration level for the closest human or structural receptor in the City of Babbitt, 6.5 miles north  
349 of the Mine Site, from the blast site is predicted to be on the order of 1.24 mm/s (0.05 in/s). The  
350 predicted ground vibration at all nearby human and structural receptors resulting from blasting at  
351 the Mine Site would be well below the applicable limits in Minnesota. Blasting would not occur  
352 at night.

353 Figure 5.2.8-1 shows that there are no residences, recreational sites, trails, or MPCA staff  
354 recommended wild rice waters within the Minnesota ground vibration impact area (i.e., the  
355 Minnesota ground vibration limit of 25.4 mm/s, which is the blue contour line on the figure  
356 [11,334 acres]). The closest recreational site is a family picnic area located approximately 9  
357 miles south of the Mine Site and Plant Site (near Skibo). This family picnic area as well as other  
358 recreational sites located further away such as those near Birch Lake and South Kawishiwi River  
359 are outside the impact area. The closest wildlife corridor located northeast of the Mine Site is  
360 also outside the impact area. The Upper St. Louis River contains wild rice beds used by tribal  
361 members for traditional resource harvests. The wild rice beds are usually in close proximity to  
362 MPCA staff-recommended wild rice waters such as Mud Lake and Birch Lake (north of Mine  
363 Site), Lobo Lake and Sand Lake (east of Mine Site), Stone Lake and Seven Beaver Lake  
364 (southeast of Mine Site), Cranberry Lake (south of Mine Site), and Hay Lake (west of Plant  
365 Site). There are no wild rice beds or MPCA staff-recommended wild rice waters within the  
366 impact area.

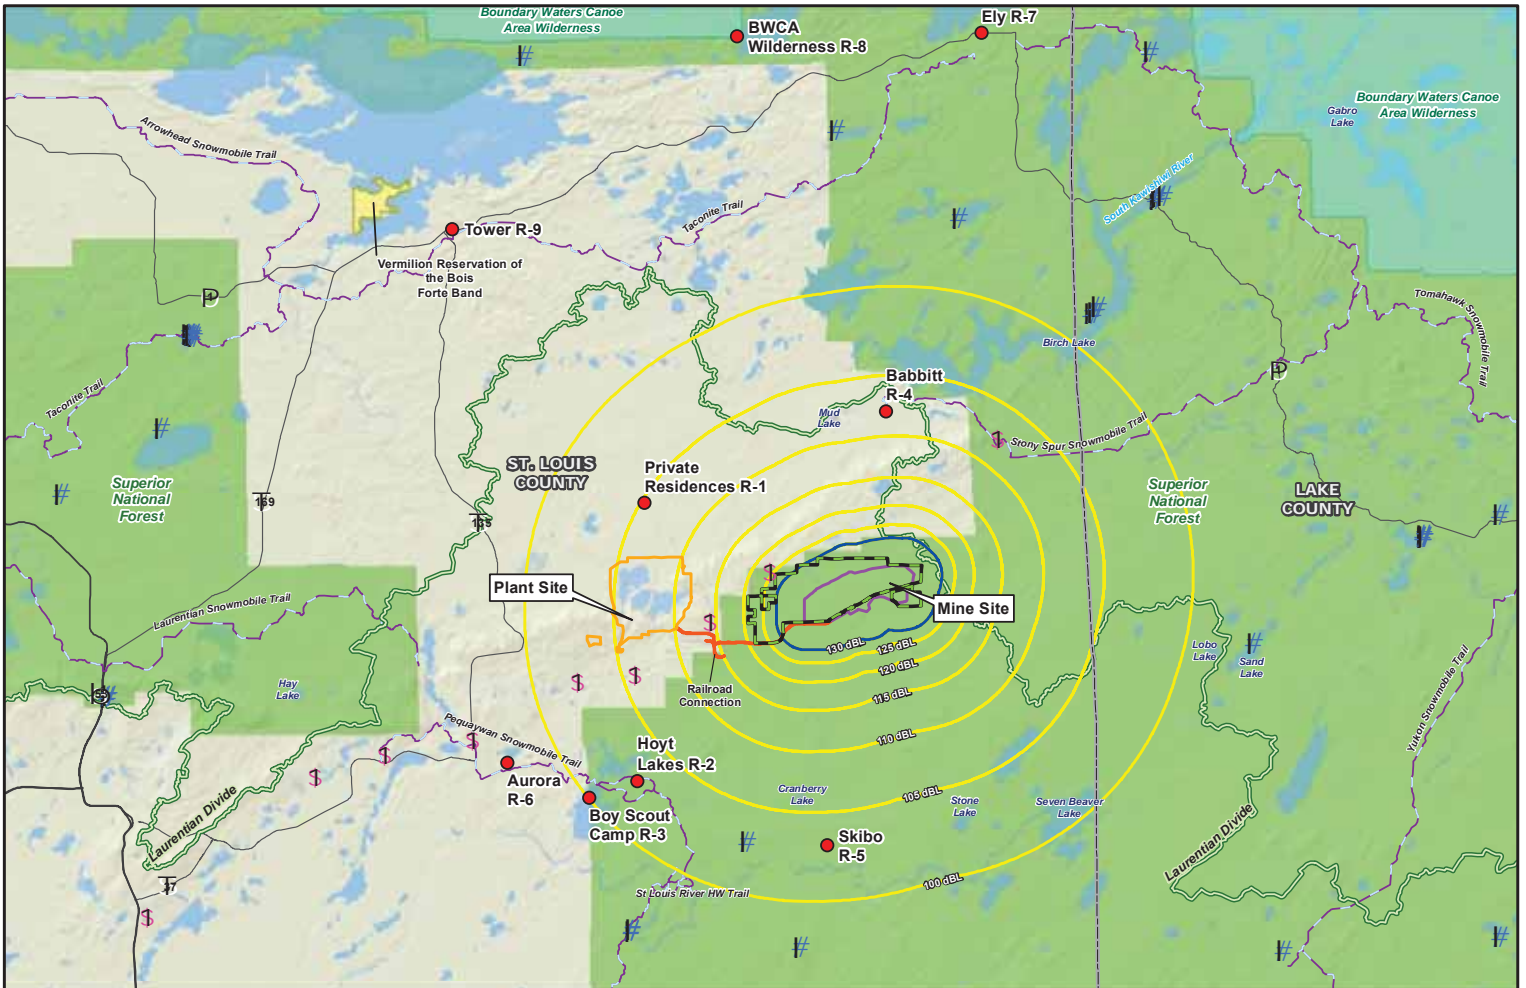

367 Though not depicted on Figure 5.2.8-1 due to sensitivity regarding cultural resources and  
368 locations, three archaeological sites have been identified within the NorthMet Project area:  
369 Spring Mine Lake Sugarbush, *Mesabe Widjiu* [Laurentian Divide], and BBLV Trail Segment #1  
370 (USFS #01-569). The Spring Mine Lake Sugarbush and the *Mesabe Widjiu* are located more  
371 than 2 miles away from the Mine Site (approximately 1 mile from the Plant Site). Since ground  
372 vibration impacts from blasting at the Mine Site would be experienced less than a mile from the  
373 blast site, both archaeological sites are expected to be outside the ground vibration impact area  
374 (11,334 acres). The BBLV Trail Segment #1 (USFS #01-569), used by the Ojibwe people during  
375 early mineral exploration hundreds of years ago, remains an important cultural and spiritual  
376 connection for the Bands. The BBLV Trail Segment #1 (USFS #01-569) crosses the NorthMet  
377 Project area. Portions of the trail segment that cross the Mine Site are expected to be within the  
378 ground vibration impact area and may experience ground vibration levels close to the Minnesota  
379 standards. Details of the location and uses of the archaeological sites are discussed in Section  
380 4.2.9, Cultural Resources.

381 Based on the information above, ground vibration levels from mine blasting are expected to be  
382 below the Minnesota ground vibration standards for humans and structures (*Minnesota Rules*,

383 part 6132.2900, subpart 2), including people that use the Superior National Forest for  
384 recreational activities such as family campgrounds, camp sites, fishing, boating, swimming, and  
385 family picnic areas. Immediate access to areas around the Mine Site would be restricted, but  
386 tribal members who may have a cultural and spiritual connection to archaeological sites in the  
387 Superior National Forest, in areas immediately near the mine, may occasionally experience  
388 ground vibration associated with the NorthMet Project Proposed Action. Mitigation measures for  
389 the impacted cultural resource areas are discussed in Section 5.2.9, Cultural Resources. During  
390 the closure and post-closure phases (i.e., after year 20), blasting at the Mine Site would cease, so  
391 no blast-related ground vibration would occur. Machinery, such as planters used to restore and  
392 rehabilitate the Mine Site during the closure phase, would not generate a significant amount of  
393 ground vibration. Therefore, potential ground vibration levels during the closure and post-closure  
394 phases are expected to be below the Minnesota ground vibration standards for humans and  
395 structures (*Minnesota Rules*, part 6132.2900, subpart 2).

396 **Airblast Overpressure from Blasting at the Mine Site**

397 The airblast overpressure (or blasting noise) effect from the Mine Site was assessed using the  
398 Terrock model, as described in Section 5.2.8.1. Using this analytical method for ore and/or waste  
399 rock blasts at the Mine Site, the 120 dBL distance for the assumed blast specifications is a  
400 maximum of 3,451 meters (2.2 miles) in front of the blast (see Table 5.2.8-6). The incremental  
401 distances for airblast overpressure levels from 100 to 130 dBL were calculated using an  
402 attenuation rate of a 9 dBL decrease per doubling of distance (Terrock Consulting Engineers  
403 2009). Airblast contours for these overpressure levels from blasting at the Mine Site are shown  
404 on Figure 5.2.8-2.

|                                     |                                       |                                    |
|-------------------------------------|---------------------------------------|------------------------------------|
| Noise Sensitive Receptor            | Federal Lands                         | Recreational Site                  |
| Plant Site                          | Wildlife Travel Corridor              | Airblast Contour                   |
| Mine Site                           | Native American Reservation           | Minnesota Airblast Limit (130 dBL) |
| Transportation and Utility Corridor | Boundary Waters Canoe Area Wilderness | National Forest                    |

This document is a working document. This document may change over time as a result of new information, further deliberation, or other factors not yet known to the Co-lead Agencies.

| Hole Diameter, d (mm) | Burden, B (mm) | Charge Mass per Hole, M (kg/hole) | Distance to the 120 dBL Contour, D <sub>120</sub> (m) | Distance to the 130 dBL Contour, D <sub>130</sub> (m) | Distance to the 125 dBL Contour, D <sub>125</sub> (m) | Distance to the 115 dBL Contour, D <sub>115</sub> (m) | Distance to the 110 dBL Contour, D <sub>110</sub> (m) | Distance to the 105 dBL Contour, D <sub>105</sub> (m) | Distance to the 100 dBL Contour, D <sub>100</sub> (m) |
|-----------------------|----------------|-----------------------------------|-------------------------------------------------------|-------------------------------------------------------|-------------------------------------------------------|-------------------------------------------------------|-------------------------------------------------------|-------------------------------------------------------|-------------------------------------------------------|
| 311                   | 8,839          | 3,388                             | 3,451                                                 | 1,602                                                 | 2,351                                                 | 5,065                                                 | 7,434                                                 | 10,912                                                | 16,016                                                |

409 Note: Based on the computed distance for the 120 dBL contours, the distances for the other airblast contour levels (130 dBL, 125  
 410 dBL, 115 dBL, 110 dBL, 105 dBL, and 100 dBL) were calculated using an attenuation rate of 9 dBL decrease per doubling of  
 411 distance.

412 As with ground vibration, the environmental effects of airblasts are regulated by the MDNR.  
 413 According to *Minnesota Rules*, part 6132.2900, subpart 2, air overpressure on lands not owned or  
 414 controlled by the permittee shall not exceed 130 dBL. The distance from the Mine Site to the 130  
 415 dBL compliance level is 1,602 meters (1 mile) and the impact area for this Minnesota airblast  
 416 overpressure limit is approximately 11,469 acres. None of the receptors (buildings or structures)  
 417 is close enough to the Mine Site to achieve this level of exposure (Figure 5.2.8-2). The maximum  
 418 airblast overpressure level for the closest receptor in the City of Babbitt is predicted to be  
 419 approximately 106 dBL. The predicted airblast overpressures at all nearby receptors resulting  
 420 from blasting activities at the Mine Site would be below the applicable limits in Minnesota.  
 421 Blasting would not occur at night.

422 Figure 5.2.8-2 shows that there are no residences, recreational sites, trails, or state wild rice beds  
 423 within the Minnesota airblast overpressure impact area (11,469 acres). The closest recreational  
 424 site is a family picnic area located approximately 9 miles south of the Mine Site and Plant Site  
 425 (near Skibo). This family picnic area as well as other recreational sites located further away such  
 426 as those near Birch Lake and South Kawishiwi River are outside the impact area. The closest  
 427 wildlife corridor located northeast of the Mine Site is also outside the impact area.

428 Though not depicted on Figure 5.2.8-2 due to sensitivity regarding cultural resources and  
 429 locations, three archaeological sites have been identified within the NorthMet Project area:  
 430 Spring Mine Lake Sugarbush, *Mesabe Widjiu* [Laurentian Divide], and BBLV Trail Segment #1  
 431 (USFS #01-569). The Spring Mine Lake Sugarbush and the *Mesabe Widjiu* are located more  
 432 than 2 miles away from the Mine Site and (approximately 1 mile from the Plant Site). Since  
 433 airblast impacts from blasting at the Mine Site would be experienced approximately 1 mile from  
 434 the blast site, both archaeological sites would be outside the airblast impact area (11,469 acres).  
 435 As noted previously, the BBLV Trail Segment #1 (USFS #01-569) crosses the NorthMet Project  
 436 area. Portions of the trail segment that cross the Mine Site would be within the airblast impact  
 437 area and may experience airblast levels close to the Minnesota standards. Details of the location  
 438 and uses of the archaeological sites are discussed in Section 4.2.9, Cultural Resources.

439 Based on the information above, airblast overpressure levels from mine blasting would be below  
 440 the Minnesota airblast standards for humans and structures (*Minnesota Rules*, part 6132.2900,  
 441 subpart 2); including people that use the Superior National Forest for recreational activities such  
 442 as family campgrounds, camp sites, hiking, fishing, boating, swimming, and family picnic areas.  
 443 Immediate access to areas around the mine would be restricted, but tribal members who may  
 444 have a cultural and spiritual connection to archaeological sites in the Superior National Forest, in

445 areas immediately near the mine, may occasionally experience airblast overpressures associated  
446 with the NorthMet Project Proposed Action. Mitigation measures for the impacted cultural  
447 resource areas are discussed in Section 5.2.9, Cultural Resources.

448 During the closure and post-closure phases (i.e., after year 20), blasting at the Mine Site would  
449 cease, so no airblast overpressures would occur during the closure and post-closure phases.

#### 450 **Vibration and Airblast Overpressure from Rail Transport**

451 The transport of ore via trains from the Mine Site to the Plant Site could generate ground  
452 vibration within a few ft of the rail ROW, but due to the low volume of trains, such vibration  
453 levels are expected to be below the Minnesota ground vibration standards for humans and  
454 structures (*Minnesota Rules*, part 6132.2900, subpart 2). No blasting would occur along the  
455 Transportation and Utility Corridor, so ground vibration or airblast overpressure effects are not  
456 expected in this area.

#### 457 **Vibration and Airblast Overpressure at Plant Site**

458 The crushers, water pumps (near the Tailings Basin) and other large stationary equipment that  
459 would be located at the Plant Site are designed to ensure that potential ground vibration effects  
460 are minimized to acceptable levels. Therefore, during operation, vibration levels at the receptors  
461 closest to the Plant Site would be below the Minnesota vibration standards for humans and  
462 structures (*Minnesota Rules*, part 6132.2900, subpart 2). No blasting would occur at the Plant  
463 Site, so ground vibration or airblast overpressure effects are not expected.

#### 464 **5.2.8.2.3 Total Noise Effects from NorthMet Project Proposed Action Operations**

465 To determine the combined noise effect of the NorthMet Project Proposed Action, the total noise  
466 generated from operations at both the Mine Site and Plant Site was logarithmically added to the  
467 existing ambient daytime and nighttime baseline levels. Noise effects from rail transport were  
468 also assessed, but qualitatively.

469 Operations at the Mine Site and Plant Site would occur 24 hours per day. The total noise that  
470 would be experienced at any receptor location during the daytime (7 a.m. to 10 p.m.) and  
471 nighttime (10 p.m. to 7 a.m.) would be equal to the combined noise from both the mining and  
472 hauling operations at the Mine Site and the ore-crushing operations at the Plant Site, plus  
473 baseline noise levels.

474 Decibels are logarithmic values, so calculating the additive effect of two separate noise sources  
475 is a logarithmic calculation rather than an algebraic addition. This means that individual sound  
476 levels cannot be added directly to get the combined sound level. This also means that the greater  
477 the distance between two sound levels, the smaller the effect the lesser dB level would have on  
478 the total sound level.

479 The total noise associated with NorthMet Project Proposed Action operations when mining,  
480 hauling, and ore-crushing operations occur concurrently was calculated using data from Tables  
481 5.2.8-3 (Mine Site) and 5.2.8-4 (Plant Site), along with baseline noise levels, and is summarized  
482 in Table 5.2.8-7. The calculations for daytime and nighttime noise levels are presented for  
483 comparison with the Minnesota noise standards. Aside from comparison to absolute noise limits,  
484 the NorthMet Project Proposed Action was also evaluated based on projected noise increases  
485 above baseline levels (i.e., 3 dB threshold of perception per MPCA 2008a). In all cases, the

486 NorthMet Project Proposed Action, when in operation, would comply with the applicable  
487 standard. Figures 5.2.8-3, 5.2.8-4, 5.2.8-5, and 5.2.8-6 show  $L_{50}$  and  $L_{10}$  noise contours at 5 dBA  
488 intervals during the daytime and nighttime.

DRAFT

489 **Table 5.2.8-7 Total Noise Associated with Concurrent Operations at the Mine Site and Plant Site (includes Baseline Levels)**

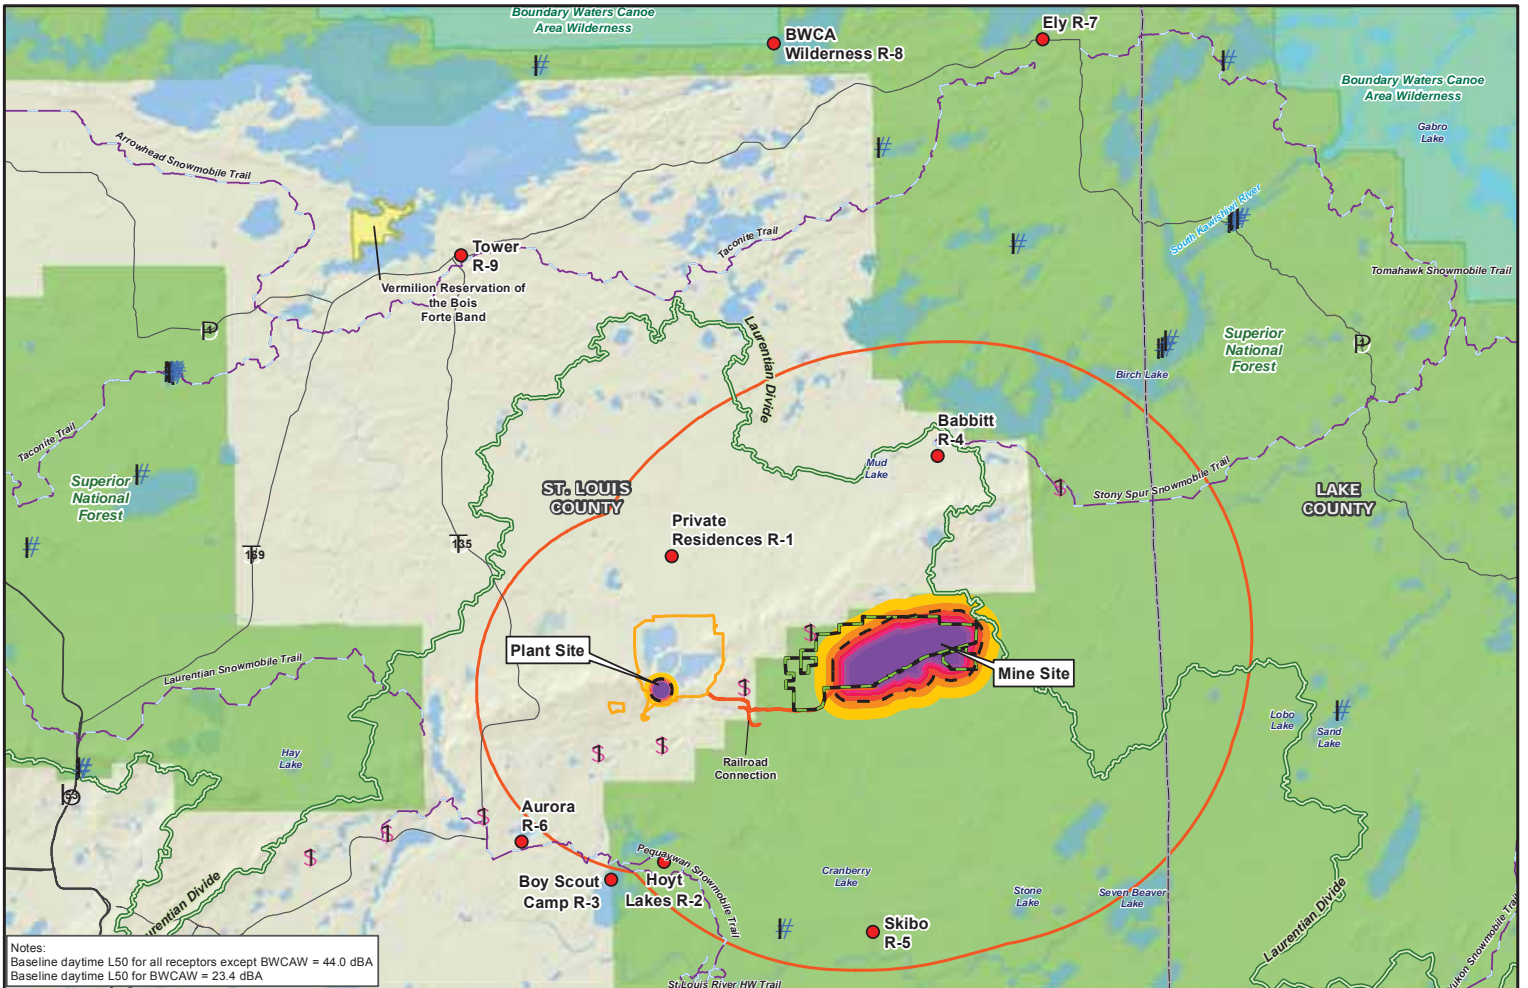

| Receptor                 | Daytime and Nighttime Baseline Noise Levels (dBA) |                               |                                  | Daytime Noise Levels at Closest Receptors to Mine Site and Plant Site Operations (plus Baseline Levels) <sup>1</sup> , (dBA) |                 |                 | Nighttime Noise Levels at Closest Receptors to Mine Site and Plant Site Operations (plus Baseline Levels), (dBA) |                 |                 | Minnesota Daytime and Nighttime Noise Standards for Residential Areas (dBA) |                                  |                               |

490 Notes:

491 D= Daytime; N = Nighttime; NA = Not applicable (there are no L<sub>eq</sub> standards for noise under the Minnesota Noise Standards).

492 <sup>1</sup> Total noise levels during daytime and nighttime were estimated by logarithmically adding the predicted noise levels from operations at the Mine Site (Table 5.2.8-3) and Plant  
493 Site (Table 5.2.8-4) with the existing baseline noise levels (baseline levels are provided in Table 4.2.8-3).

Notes:  
 Baseline daytime L50 for all receptors except BWCAW = 44.0 dBA  
 Baseline daytime L50 for BWCAW = 23.4 dBA

This document is a working document. This document may change over time as a result of new information, further deliberation, or other factors not yet known to the Co-lead Agencies.

**Figure 5.2.8-6**  
**Predicted Nighttime L10 Noise Contours at Closest Receptors (Includes Baseline L10 Levels)**  
 NorthMet Mining Project and Land Exchange PFEIS  
 Minnesota  
 June 2015

DRAFT

502 **Daytime Operation Impacts (7 a.m. to 10 p.m.)**

503 Table 5.2.8-7 and Figures 5.2.8-3 and 5.2.8-4 present the total estimated daytime L<sub>50</sub> and L<sub>10</sub>  
504 levels that would be experienced at the closest receptors to the Mine Site and Plant Site. Noise  
505 from Mine Site and Plant Site operations, plus baseline levels, are predicted to be well below the  
506 Minnesota daytime noise standards of 60 dBA (L<sub>50</sub>) and 65 dBA (L<sub>10</sub>) for residential areas, trails,  
507 recreational sites (family campgrounds, campsites, boating, fishing, swimming, and family  
508 picnic areas), and MPCA staff-recommended wild rice waters and beds (used by tribal members  
509 for traditional resource harvests).

510 As an example of how the total noise level is calculated, the L<sub>50</sub> daytime level of 44 dBA for  
511 private residences shown in Table 5.2.8.7 is the result of adding 10.9 dBA (daytime L<sub>50</sub> levels  
512 from Mine Site operations only, excluding Plant Site operations and baseline levels), 13.5 dBA  
513 (daytime L<sub>50</sub> levels from Plant Site operations only, excluding Mine Site operations and baseline  
514 levels), and 44 dBA, which is the assumed daytime L<sub>50</sub> baseline level. The result of the  
515 logarithmic addition indicates that noise from the Mine Site and Plant Site has no measureable  
516 effect on the baseline conditions of the closest receptors. Figure 5.2.8-3 shows that the daytime  
517 L<sub>50</sub> impact area for the closest receptors would be 6,629 and 255 acres at the Mine Site and Plant  
518 Site, respectively. Similarly, Figure 5.2.8-4 shows that the daytime L<sub>10</sub> impact area for the closest  
519 receptors would be 6,266 and 242 acres at the Mine Site and Plant Site, respectively. These  
520 receptors are well outside the daytime impact areas. The closest recreational site is a family  
521 picnic area located approximately 9 miles south of the Mine Site and Plant Site (near Skibo).  
522 This family picnic area as well as other recreational sites located further away such as those near  
523 Birch Lake and South Kawishiwi River are outside the daytime impact area.

524 The Upper St. Louis River contains wild rice beds harvested by tribal members. The wild rice  
525 beds are usually in close proximity to MPCA staff-recommended wild rice waters such as Mud  
526 Lake and Birch Lake (north of Mine Site), Lobo Lake and Sand Lake (east of Mine Site), Stone  
527 Lake and Seven Beaver Lake (southeast of Mine Site), Cranberry Lake (south of Mine Site), and  
528 Hay Lake (west of Plant Site). Details of the location and uses of the cultural/tribal resource  
529 areas are discussed in Section 4.2.9, Cultural Resources.

530 The closest wildlife corridor located northeast of the Mine Site is also outside the daytime impact  
531 area. The highest daytime noise levels, including baseline levels, predicted for the closest NAC 1  
532 receptor to the Mine Site (i.e., Babbitt (R-4)) were 44 dBA (L<sub>50</sub>) and 48.8 dBA (L<sub>10</sub>). The  
533 daytime noise effect of the Mine Site on Babbitt is an increase of 0 dBA (L<sub>50</sub>) and 0 dBA (L<sub>10</sub>)  
534 from baseline levels. Similarly, the highest daytime noise levels, including baseline levels,  
535 predicted for the closest NAC 1 receptor to the Plant Site (i.e., Private Residences (R-1)) were 44  
536 dBA (L<sub>50</sub>) and 48.8 dBA (L<sub>10</sub>). The daytime noise effect of the Plant Site on the private  
537 residences is an increase of 0 dBA (L<sub>50</sub>) and 0 dBA (L<sub>10</sub>) from baseline levels. This 0 dBA  
538 increase is below the 3 dBA threshold of perception per the MPCA's *Guide to Noise Control in*  
539 *Minnesota* (MPCA 2008a) and would not be perceptible to residents, recreational users, or tribal  
540 members that use the MPCA staff-recommended wild rice waters and beds for harvesting  
541 purposes.

542 As discussed earlier, noise from trains and train horns during ore transportation during the day  
543 from the Mine Site to the Plant Site is expected to be minimal because the railroad route between  
544 the two is approximately 4 to 5 miles from the nearest receptors. Up to 22 trains per day are  
545 expected to deliver ore to the Plant Site. This frequency of traffic is less than that experienced on  
546 the rail line during past mining operations.

547 Blasting at the Mine Site is a source of impulsive or non-continuous noise. Blasting noise is not  
548 included in the noise level estimates shown in Table 5.2.8-7 because mine-blasting is typically an  
549 instantaneous event (not continuous or steady), and would occur only during daytime periods.  
550 PolyMet expects that blasting of ore and waste rock would take place approximately once every  
551 2 or 3 days. This would usually include separate blasts of ore and waste rock benches. Rock-  
552 blasting could potentially have noise levels ranging from 111 to 115 dBA at 50 ft from the  
553 blasting site. With modern blasting techniques, the blasting would be experienced by the nearest  
554 receptors as a faint warning whistle or siren, followed by a very brief, muted clap of thunder.

555 Public acceptance is generally improved by scheduling blasting at the same time every day to  
556 further reduce the startle factor. The closest receptor (City of Babbitt) is located 6.5 miles from  
557 the Mine Site, so noise effects from blasting are not expected to be significant. In addition, noise  
558 effects from blasting would only occur during the early stages of mining, when blasting occurs at  
559 the surface down to a few ft below ground levels. As the depth of the pit increases over the life  
560 of the mine, noise effects from blasting would be attenuated by the pit walls.

561 Though not depicted on Figures 5.2.8-3 and 5.2.8-4 due to sensitivity regarding cultural  
562 resources and locations, three archaeological sites have been identified within the NorthMet  
563 Project area: Spring Mine Lake Sugarbush, *Mesabe Widjiu* [Laurentian Divide], and BBLV Trail  
564 Segment #1 (USFS #01-569). The Spring Mine Lake Sugarbush and the *Mesabe Widjiu* are  
565 located more than 2 miles away from the Mine Site and approximately 1 mile from the Plant Site  
566 (approximated 2 miles from the plant crushers). Based on these distances, both archaeological  
567 sites are expected to be outside the daytime noise impact area for the Mine Site (6,629 acres) and  
568 Plant Site (255 acres). As noted previously, the BBLV Trail Segment #1 (USFS #01-569) crosses  
569 the NorthMet Project area. Portions of the trail segment that cross the Mine Site and Plant Site  
570 are expected to be within the daytime impact area and may experience daytime noise levels close  
571 to the Minnesota standards.

572 Details of the location and uses of the archaeological sites are discussed in Section 4.2.9,  
573 Cultural Resources.

#### 574 **Nighttime Operation Impacts (10 p.m. to 7 a.m.)**

575 Table 5.2.8-7 and Figures 5.2.8-5 and 5.2.8-6 indicate that the total estimated nighttime  $L_{50}$  and  
576  $L_{10}$  levels that would be experienced at the receptors closest to the Mine Site and Plant Site are  
577 expected to be below the Minnesota nighttime noise standards of 50 dBA ( $L_{50}$ ) and 55 dBA  
578 ( $L_{10}$ ). Figure 5.2.8-5 shows that the nighttime  $L_{50}$  impact areas for the closest residential areas,  
579 trails, MPCA staff-recommended wild rice waters (used by tribal members for traditional  
580 resource harvests), and recreational sites would be 11,456 acres and 568 acres at the Mine Site  
581 and Plant Site, respectively.

582 Similarly, Figure 5.2.8-6 shows that the nighttime L<sub>10</sub> impact areas for the closest residential  
583 areas, trails, MPCA staff-recommended wild rice waters, and recreational sites would be 10,695  
584 acres and 503 acres at the Mine Site and Plant Site, respectively. These receptors are well outside  
585 the nighttime impact areas. As indicated above, the closest recreational site is a family picnic  
586 area located approximately 9 miles south of the Mine Site and Plant Site (near Skibo). This  
587 family picnic area as well as other recreational sites located further away such as those near  
588 Birch Lake and South Kawishiwi River are outside the nighttime impact area. There are no  
589 MPCA staff-recommended wild rice waters or beds within the nighttime impact area. Details of  
590 the location and use of cultural/tribal resource areas are discussed in Section 4.2.9 and 5.2.9. The  
591 closest wildlife corridor located northeast of the Mine Site is also outside the impact area. The  
592 highest nighttime L<sub>50</sub> and L<sub>10</sub> levels, including baseline levels, predicted for the closest receptor  
593 to the Mine Site (i.e., Babbitt (R-4)) were 34 dBA and 37.8 dBA, respectively. The nighttime  
594 noise effect of Mine Site operations on Babbitt is a net increase of 0 dBA (L<sub>50</sub>) and 0 dBA (L<sub>10</sub>)  
595 from baseline levels. Similarly, the highest nighttime L<sub>50</sub> and L<sub>10</sub> levels, including baseline  
596 levels, predicted for the closest receptor to the Plant Site (i.e., Private Residences (R-1)) were  
597 34.1 dBA and 37.9 dBA, respectively. The nighttime noise effect of the Plant Site on the private  
598 residences is an increase of 0.1 dBA (L<sub>50</sub>) and 0.1 dBA (L<sub>10</sub>) from baseline levels. This increase  
599 of 0.1 dBA is below the 3 dBA threshold of perception per the MPCA's *Guide to Noise Control*  
600 *in Minnesota* (MPCA 2008a) and would not be perceptible to residents, recreational users, and  
601 tribal members that use MPCA staff-recommended wild rice waters and beds for traditional  
602 resource harvests. It should be noted that the noise model conservatively assumes that all mine  
603 equipment shown in Table 5.2.8-2 would be operating simultaneously during daytime and  
604 nighttime. Under actual conditions, the predicted noise levels would be lower because not all  
605 equipment would be operating simultaneously and some equipment would not operate at all  
606 during nighttime.

607 Though not depicted on Figures 5.2.8-5 and 5.2.8-6 due to sensitivity regarding cultural  
608 resources and locations, three archaeological sites have been identified within the NorthMet  
609 Project area: Spring Mine Lake Sugarbush, *Mesabe Widjiu* [Laurentian Divide], and BBLV Trail  
610 Segment #1 (USFS #01-569). The Spring Mine Lake Sugarbush and the *Mesabe Widjiu* are  
611 located more than 2 miles from the Mine Site and approximately 1 mile from the Plant Site  
612 (approximated 2 miles from the plant crushers). Based on the distances, both archaeological sites  
613 are expected to be outside the nighttime noise impact areas for the Mine Site (11,456 acres) and  
614 Plant Site (568 acres). As noted previously, the BBLV Trail Segment #1 (USFS #01-569) crosses  
615 the NorthMet Project area. Portions of the trail segment that cross the Mine Site and Plant Site  
616 are expected to be within the nighttime impact area and may experience nighttime noise levels  
617 close to the Minnesota standards. Details of the location and uses of the archaeological sites are  
618 discussed in Section 4.2.9, Cultural Resources.

619 Mine-blasting and ore transportation via trains along the Transportation and Utility Corridor  
620 would not occur between 10 p.m. and 7 a.m., so there would not be noise effects associated with  
621 these activities at night.

### 622 **Summary of Daytime and Nighttime Operation Noise Impacts**

623 Based on the information above, the total predicted daytime and nighttime noise (L<sub>50</sub> and L<sub>10</sub>)  
624 level experienced at NAC 1 areas such as the closest residential areas (the City of Babbitt north  
625 of the Mine Site, and private residences located north of the Plant Site), trails, recreational sites

626 (including recreational sites at Birch Lake and South Kawashiwi River), and MPCA staff-  
627 recommended wild rice waters and beds used by tribal members for traditional resource harvests  
628 would meet the Minnesota daytime and nighttime noise standards. In addition, the projected  
629 noise increase above baseline levels would be below the 3 dBA threshold of perception.  
630 Immediate access to areas around the mine would be restricted, but tribal members who may  
631 have a cultural and spiritual connection to archaeological sites in the Superior National Forest, in  
632 areas immediately near the Mine Site or Plant Site, may occasionally experience noise associated  
633 with the NorthMet Project Proposed Action. Mitigation measures for the impacted cultural  
634 resource areas are discussed in Section 5.2.9, Cultural Resources.

635 During closure and post-closure (i.e., after year 20), the major noise sources and activities at the  
636 Mine Site and Plant Site (e.g., drilling, blasting, mining, excavation work, hauling, and crushing  
637 operations) would cease. Progressive reclamation would occur throughout the 20-year mine life  
638 for features such as the permanent stockpile and pit areas at the Mine Site and at the exterior  
639 slopes of the Tailings Basin at the Plant Site. This would leave a smaller portion of the Mine Site  
640 and Plant Site needing to be reclaimed at closure. During the closure phase, machinery, such as  
641 planters, used to restore and/or rehabilitate the Mine Site and Plant Site and conduct other  
642 reclamation activities (e.g., structure demolition, dike removal, etc.) would generate some noise;  
643 however, such noise would occur over a short time period and mostly during daytime periods  
644 when increased noise levels would be more tolerable. Therefore, noise levels at the Mine Site  
645 and Plant Site during the closure and post-closure phases are expected to be below the Minnesota  
646 noise standards and below the 3 dBA threshold of perception.

#### 647 **Area of Audibility for the Boundary Waters Canoe Area Wilderness**

648 The L<sub>50</sub> audibility area would be approximately 247,612 acres around the Mine Site and Plant  
649 Site, assuming all noise sources are operating simultaneously during daytime and nighttime  
650 (Figure 5.2.8-3 and 5.2.8-5). Similarly, the L<sub>10</sub> audibility area would be approximately 131,035  
651 acres around the Mine Site and Plant Site, assuming all noise sources are operating  
652 simultaneously during daytime and nighttime (see Figures 5.2.8-4 and 5.2.8-6). The BWCAW is  
653 outside this area of audibility. Therefore, sound from the Mine Site and Plant Site operations  
654 would not be audible at the BWCAW. While some receptors (e.g., residential areas like Babbitt  
655 and Hoyt Lakes and a family picnic area near Skibo) are within this area of audibility shown on  
656 Figures 5.2.8-3 to 5.2.8-6, it should be noted that the area of audibility was calculated based on  
657 the low measured baseline levels for BWCAW, which is a place of natural quiet (L<sub>50</sub> of  
658 23.4 dBA and L<sub>10</sub> of 33.2 dBA). The baseline levels for the recreational sites and residential  
659 areas are likely higher than the BWCAW baseline levels (though actual measurements have not  
660 been taken at these areas), so actual area of audibility for these other receptors would be much  
661 smaller than that for BWCAW.

#### 662 **Noise Effects on Off-Site Transportation**

663 Transportation of NorthMet Project Proposed Action consumables and products could result in  
664 some noise from increased traffic on public roads and commercial railroads. Public roads could  
665 also experience minor increase in noise levels due to additional traffic from employees and  
666 service providers, particularly along State Highway 135 and County Road 666.

667 Traffic noise from employee vehicles, service provider vehicles, and trucks transporting process  
668 consumables and products result in a small increase in daily traffic volumes (approximately 7

669 trucks per day and 149 employee and service provider vehicles per day along State Highway  
670 135; and approximately 42 employee and service provider vehicles per day along County Road  
671 666 [see BA provided in Appendix D]) in comparison to the existing annual average daily traffic  
672 (AADT) volumes of State Highway 135 and County Road 666. Based on AADT data that Barr  
673 Engineering Company obtained from the Minnesota Department of Transportation (Barr 2014a),  
674 the NorthMet Project offsite traffic volumes are approximately 2 to 18 percent and 5 to 30  
675 percent of existing AADT at State Highway 135 (850 to 8300 vehicles per day) and County  
676 Road 666 (140 to 810 vehicles per day), respectively.

677 Similarly, railway noise from trains carrying process consumables and concentrates from the  
678 Plant Site to Virginia, Minnesota, and/or vice versa (via Canadian National Railroad) are not  
679 expected to be significant due to the small increase in monthly railway traffic volumes  
680 (approximately 100-car train once per month and a 30-car train four times per month, year round,  
681 for product shipment; and approximately 100-car train once per week, April through October, for  
682 process consumables [see BA provided in Appendix D]) in comparison to the existing monthly  
683 traffic volumes of the Canadian National Railroad Based on existing rail traffic information that  
684 Barr Engineering Company obtained from Canadian National Railway Company (Pat Sheehy,  
685 Senior Environmental Specialist, Barr, Pers. Comm., November 6, 2014) the NorthMet Project  
686 Proposed Action off-site traffic volumes are approximately 3.0 and 3.8 percent of existing rail  
687 traffic near the Plant Site (i.e., the Iron Junction to Allen Junction rail segment) during non-  
688 summer months (8 trains per day or approximately 240 trains per month) and during summer  
689 months (10 trains per day or approximately 300 trains per month), respectively.

690 Based on the off-site traffic information described above, noise effects on off-site transportation  
691 are not expected to be significant. In addition, all NorthMet Project Proposed Action-related off-  
692 site roadway and railway traffic would occur during daytime hours only, and the off-site trucks  
693 would not exceed 40 miles per hour and would avoid densely populated areas to the extent  
694 practicable. Any noise sensitive receptor near the Canadian National Railroad, State Highway  
695 135, and County Road 666 would not be exposed to a new noise source since these  
696 infrastructures have been in operation for decades.

### 697 **5.2.8.3 NorthMet Project No Action Alternative**

698 Under the NorthMet Project No Action Alternative, the NorthMet Project Proposed Action  
699 would not occur and there would be no increase in noise and vibration levels in any of the areas  
700 proposed for project development Therefore, there would be no change in existing noise and  
701 vibration levels at the closest receptors.

702

DRAFT

1 **5.2.9 Cultural Resources**

2 This section summarizes the environmental consequences of the NorthMet Project Proposed  
3 Action on historic properties, including the potential effects, types of avoidance, effect  
4 minimization measures, and potential mitigation measures that are relevant to these historic  
5 properties. Additionally, this section summarizes the environmental consequences of the  
6 NorthMet Project Proposed Action on 1854 Treaty resources—i.e., those areas and species that  
7 are traditionally or culturally important to the Bands.

8 The federal Co-lead Agencies have identified several historic properties in consultation with the  
9 SHPO, Bands, and PolyMet. The federal Co-lead Agencies have also consulted with the SHPO,  
10 Bands, and PolyMet concerning NRHP eligibility of the Spring Mine Lake Sugarbush; *Mesabe*  
11 *Widjiu*; BBLV Trail Segment; Erie Mining Company Railroad Mine and Plant Track, Main Line  
12 Segment, and Dunka Railroad Segment; Erie Mining Company Concentrator Building; Erie  
13 Mining Company Administration Building; Erie Mining Company Landscape Historic District;  
14 Erie Mining Company Railroad Corridor Historic District; and DM&IR Segment. All other  
15 cultural resources identified as part of the NorthMet Project Proposed Action, as identified in  
16 Section 4.2.9.2.4, were determined to be not eligible for inclusion in the NRHP, and therefore  
17 will not receive further consideration under Section 106 during review of the NorthMet Project  
18 Proposed Action. The federal Co-lead Agencies are currently refining statements of significance  
19 and boundaries for these properties.

20 Effect determinations have been drafted by the federal Co-lead Agencies for review and  
21 comment by the SHPO, Bands, and PolyMet. The federal Co-lead Agencies believe that there  
22 would be no adverse effect on the Erie Mining Company Railroad Mine and Plant Track, Main  
23 Line Segment, and Dunka Railroad Segment; Erie Mining Company Administration Building;  
24 Erie Mining Company Railroad Corridor Historic District; and DM&IR Segment. However, the  
25 *Mesabe Widjiu*, BBLV Trail Segment, Spring Mine Lake Sugarbush, Erie Mining Company  
26 Concentrator Building, and Erie Mining Company Landscape Historic District would be  
27 adversely affected by the NorthMet Project Proposed Action. These determinations would be  
28 used to facilitate ongoing consultation with the SHPO, Bands, and PolyMet pertaining to the  
29 application of adverse effect criteria to these properties. Mitigation measures to resolve adverse  
30 effects would be developed after consultation on the effect determinations and consideration of  
31 any measures to avoid or minimize adverse effect.

32 Although not required by NEPA and MEPA, the Co-lead Agencies committed to providing an  
33 appendix in the FEIS that contains the Tribal Cooperating Agencies' comments and supporting  
34 documentation representing MDOs. See Appendix C for comments and supporting  
35 documentation from the Bois Forte, Grand Portage, Fond du Lac, GLIFWC, and the 1854 Treaty  
36 Authority. These take the form of eight position papers and a Co-lead Agency Preliminary  
37 SDEIS comment disposition spreadsheet for the Tribal Cooperating Agencies.

38 The Tribal Cooperating Agency submittals in Appendix C are provided verbatim and in identical  
39 form as they were for the SDEIS. They were considered in the development of the FEIS. Refer to  
40 Chapter 8 for more information.

### 41 **5.2.9.1 Methodology and Evaluation Criteria Overview**

42 In consultation with the SHPO, the Bands, and PolyMet, the federal Co-lead Agencies must  
43 apply the criteria of adverse effects to historic properties within the APE to evaluate the potential  
44 effect of the NorthMet Project Proposed Action on the historic properties, as codified in 36 CFR  
45 800.5.

46 An adverse effect is found when an undertaking may alter, directly or indirectly, any of the  
47 characteristics of a historic property that qualify the property for inclusion in the NRHP in a  
48 manner that would diminish the integrity of the property's location, design, setting, materials,  
49 workmanship, feeling, or association. These elements of integrity are discussed at length in  
50 Section 4.2.9. Adverse effects may include reasonably foreseeable indirect effects that occur  
51 later in time, are farther removed, or are cumulative.

52 Direct effects caused by the undertaking occur at the same time and place. Indirect effects caused  
53 by the undertaking are later in time or further removed in distance but are still reasonably  
54 foreseeable. The federal Co-lead Agencies confer with consulting parties to determine the  
55 undertaking's effects on historic properties, to resolve adverse effects, and to develop mitigation  
56 measures as necessary. For the NorthMet Project Proposed Action, the following is a summary  
57 of potential effect types:

- 58 • physical disturbance or damage to all or part of the property caused by ground disturbance  
59 (e.g., digging, trenching, etc.);
- 60 • introduction of visual, atmospheric, or audible elements that could diminish the integrity of  
61 the property's significant historic features during short-term NorthMet Project Proposed  
62 Action-related construction and operation of aboveground facilities and roads, as well as  
63 long-term effects from operation;
- 64 • change in the character of the use or of physical features within the property's setting that  
65 contribute to its significance; and
- 66 • transfer of property out of federal ownership without adequate conditions to ensure  
67 consideration of historic properties.

68 Effects determinations have the following three possible outcomes:

- 69 1. Finding of no historic property affected – The undertaking does not have the potential to  
70 cause effects on historic properties that may be present.
- 71 2. Finding of no adverse effect – The historic property would be affected; however, the effects  
72 of an undertaking do not meet the criteria of adverse effect, or measures have been taken to  
73 avoid or minimize adverse effects.
- 74 3. Finding of adverse effect – The undertaking may affect the integrity, which would alter,  
75 directly or indirectly, any of the characteristics of a historic property that qualify it for  
76 inclusion in the NRHP. If an adverse effect is found, the federal Co-lead Agencies shall  
77 consult further to resolve the adverse effect.

### 78 **5.2.9.1.1 Types of Potential Effects**

79 The potential for the NorthMet Project Proposed Action to affect a historic property may depend  
80 on the project stage and the development and use of the NorthMet Project area. Potential effects  
81 that may occur during the construction and operations of the NorthMet Project Proposed Action  
82 are discussed in the following subsections.

#### 83 **Construction**

84 NorthMet Project Proposed Action construction activities could affect cultural resources in a  
85 variety of ways, including the following:

- 86 • possible direct damage to cultural resources within the construction footprint;
- 87 • possible indirect damage to cultural resources through vibrations caused by earth-moving and  
88 heavy equipment;
- 89 • temporary loss of community access to cultural resources, such as cultural resources of  
90 traditional significance;
- 91 • potential permanent visual effects that alter the viewshed to or from a cultural resource as it  
92 pertains to the cultural resource's setting and feeling;
- 93 • potential temporary visual effects on cultural resources while heavy equipment and numerous  
94 personnel are present;
- 95 • increased dust and noise that may affect historic structures or cultural resources of traditional  
96 significance near the construction area; and
- 97 • discovery of previously unknown cultural resources within the construction footprint.

98 The duration of the construction phase would affect the degree of effects on cultural resources.  
99 Potential indirect effects during construction—such as noise, dust, vibrations, heavy equipment  
100 traffic, and changes in viewshed—could be temporary and would be expected to last for the  
101 duration of construction in specific areas and for discrete periods of time.

#### 102 **Operations**

103 During the operations phase of the NorthMet Project Proposed Action, only previously surveyed  
104 and assessed areas would be expected to require periodic disturbance; therefore, the potential for  
105 additional direct effects to cultural resources would be limited.

106 Indirect effects during operations could consist of a permanent change in viewshed to historic  
107 structures near NorthMet Project area facilities, and a periodic increase in noise, vibration, and  
108 dust created by vehicular traffic conducting operation and maintenance activities.

### 109 **5.2.9.1.2 Mitigation Measures**

110 Mitigation measures would be taken to avoid or minimize effects on historic properties, to the  
111 extent practicable. The following are potential mitigation measures:

- 112 • avoidance, which could be accomplished by shifting the footprint away from the resource,  
113 limiting activities in the vicinity of the resource, monitoring construction activities near the

114 resource to inform whether additional actions are warranted, or through any combination of  
115 these techniques;

116 • minimization, which would reduce the effects on the resource through avoidance measures as  
117 described above, but would not completely eliminate the effects; and

118 • mitigation, which would offset that effect through some of the following means:

119 – protection of a similar resource nearby;

120 – detailed documentation of the resource through data recovery (i.e., excavations, in the  
121 case of archaeological sites, or Historic American Buildings Survey/Historic American  
122 Engineering Record documentation, in the case of historic structures);

123 – contributions to the preservation of cultural heritage in the affected community;

124 – interpretative exhibits highlighting information gained about cultural resources through  
125 the NorthMet Project Proposed Action; or

126 – some combination of these strategies.

127 The federal Co-lead Agencies would take into account the effects of the NorthMet Project  
128 Proposed Action on properties that are listed on, or considered eligible for listing on, the NRHP  
129 per Section 106 of the NHPA and consistent with USFS and USACE practices. Because the  
130 NorthMet Project Proposed Action would likely result in an adverse effect, the federal Co-lead  
131 Agencies would consult with the SHPO, the Bands, and PolyMet to identify practicable ways to  
132 avoid, minimize, or mitigate the harmful effects of the undertaking. The ACHP would become  
133 involved in consultation if requested by an agency, SHPO, Bands, other consulting parties, or  
134 member of the public with a demonstrated interest. If an adverse effect were identified, federal  
135 agencies would have to notify the ACHP, who may become involved if the effect met their  
136 criteria for involvement. The federal Co-lead Agencies are currently in the process of developing  
137 a Memorandum of Agreement (MOA), which identifies the steps the federal Co-lead Agencies  
138 would take to avoid, minimize, or mitigate the adverse effect.

### 139 **5.2.9.2 Affected Cultural Resources**

140 This section describes the environmental consequences of the NorthMet Project Proposed Action  
141 on historic properties within the APE. As outlined in Section 4.2.9, the federal Co-lead Agencies,  
142 the SHPO, Bands, and PolyMet agree that the Erie Mining Company Railroad Mine and Plant  
143 Track, Main Line Segment, and Dunka Railroad Segment; Erie Mining Company Concentrator  
144 Building; Erie Mining Company Administration Building; Erie Mining Company Landscape  
145 Historic District; Erie Mining Company Railroad Corridor Historic District; DM&IR Segment,  
146 Spring Mine Lake Sugarbush, *Mesabe Widjiu*, and BBLV Trail Segment are eligible for  
147 inclusion in the NRHP. The federal Co-lead Agencies, in consultation with the SHPO, Bands,  
148 and PolyMet, have determined effects for the eligible properties and are currently working to  
149 resolve adverse effects.

### 150 **5.2.9.2.1 Historic Properties**

#### 151 **Erie Mining Company Concentrator Building**

152 The Concentrator Building is a key property and reflects Erie Mining Company's decades of  
153 experimentation in production and engineering design (Zellie 2007). The Co-lead Agencies have  
154 determined the Concentrator Building eligible for inclusion in the NRHP under Criterion A in  
155 the areas of industry and engineering, and also under Criterion C in the area of engineering.

156 Direct effects to this property would consist of interior and exterior refurbishment and use. For  
157 example, emission controls on ore grinding equipment would be replaced with components that  
158 meet or exceed the particulate emission standard required of new sources at taconite plants. To  
159 reduce space heating requirements, the building insulation would be improved. Additionally, the  
160 concentrator building would be demolished at mine closure and decommissioning, consistent  
161 with Minnesota state mining standards. There would be minor exterior and interior alterations to  
162 the other primary plant buildings and structures. The NorthMet Project Proposed Action would  
163 include the construction of several new buildings adjacent to the Concentrator Building. Based  
164 on the above considerations, the federal Co-lead Agencies believe that the NorthMet Project  
165 Proposed Action would adversely affect the Concentrator Building.

#### 166 **Erie Mining Company Railroad Mine and Plant Track, Main Line Segment, and Dunka** 167 **Railroad Segment**

168 The federal Co-lead Agencies have determined the Erie Mining Company Railroad Mine and  
169 Plant Track, Main Line Segment, and Dunka Railroad Segment (SL-HLC-015) eligible for  
170 inclusion in the NRHP under Criterion A in the areas of Commerce, Industry, and  
171 Transportation. Although the majority of the main track of railroad is outside of the NorthMet  
172 Project area, the segments of the Erie Main Line Railroad and Mine and Plant Track, and Dunka  
173 Railroad within the APE would be directly affected near the NorthMet Project area.

174 Direct effects to this property would consist of refurbishment and use. Refurbishment, however,  
175 is not expected to result in significant alterations. Nonetheless, the Erie Mining Company  
176 railroad would be removed at mine closure and decommissioning, consistent with Minnesota  
177 state mining standards. There would be no expected indirect effects, as the use of the Plant Site  
178 and mining activities would be consistent with the railroad's original use. Based on the above  
179 considerations, the federal Co-lead Agencies believe that the NorthMet Project Proposed Action  
180 would not adversely affect the Erie Mining Company railroad. The federal Co-lead Agencies, in  
181 consultation with the SHPO, Bands, and PolyMet, are currently working to resolve adverse  
182 effects.

#### 183 **Erie Mining Company Administration Building**

184 The Erie Mining Company Administration Building remains a well-preserved component of the  
185 original taconite plant design. It is significant under NRHP Criterion A in the areas of Industry  
186 and Engineering and is associated with the statewide historic context, "Minnesota's Iron Ore  
187 Industry, 1880s-1945." The Administration Building is within the APE for the NorthMet Project  
188 Proposed Action; however, refurbishment is not part of the current undertaking. While the  
189 federal Co-lead Agencies believe the Administration Building would need to be updated  
190 subsequent to mine permitting, no plans have been provided to the Co-lead Agencies for analysis

191 of effects. The Co-lead Agencies have evaluated the potential for ambient air quality to adversely  
192 affect the structure pursuant to air modeling data analyzed during the FEIS process. The  
193 Administration Building would not be affected by isopleths (dust particulate) as modeled. The  
194 Administration Building is located in an area of the APE where air quality is not expected to  
195 exceed current background levels; therefore, no adverse effect is anticipated from changes in air  
196 quality. Therefore, the federal Co-lead Agencies believe that the NorthMet Project Proposed  
197 Action would not adversely affect the Erie Mining Company Administration Building. The  
198 federal Co-lead Agencies, in consultation with the SHPO, Bands, and PolyMet, are currently  
199 working to resolve adverse effects.

#### 200 **Erie Mining Company Railroad Corridor Historic District**

201 The federal Co-lead Agencies have considered the available information concerning potential  
202 effects on the Erie Mining Company Railroad Corridor Historic District. The NorthMet Project  
203 Proposed Action would reuse many of the facilities and transportation infrastructure associated  
204 with the Erie Mining Company period of significance (circa 1954 to 1969). The NorthMet  
205 Project Proposed Action does not include plans to alter the alignment, grade, or setting of the  
206 extant rail line; however, a new connection would be constructed to connect the Erie Plant track  
207 to the mainline in the vicinity of Erie Mining Company Mine Area No. 2. This connection would  
208 minimally alter the historic patterns of circulation, as they relate to the 1957 to 1969 period of  
209 significance. However, it would not materially diminish the setting, feeling, and or association of  
210 the district as a whole. As was the case with Erie during the period of historic significance, the  
211 NorthMet Project Proposed Action would continue to transport ore to the Erie Plant Site for  
212 additional processing and subsequent rail shipment. During the period of significance, mine track  
213 placement was constantly evolving and shifting in response to development of new ore bodies  
214 and abandonment of areas already mined. When viewed in light of this historic use, the proposed  
215 connection between the plant track and the mainline would not be incompatible; therefore, the  
216 federal Co-lead Agencies have determined that there would be no adverse effect.

#### 217 **Erie Mining Company Landscape Historic District**

218 The NorthMet Project Proposed Action is contingent upon reuse of the Erie Plant Site and  
219 existing railroad infrastructure. Proposed new construction within the Erie Plant Site area  
220 includes an oxygen plant, Hydrometallurgical Plant, Hydrometallurgical Residue Facility, and  
221 WWTP. The Erie Heating and Additive Plan (SL-HLC-049), which is considered as a  
222 contributing element of the Erie Mining Company Landscape Historic District, is proposed for  
223 demolition under the NorthMet Project Proposed Action. Several non-contributing temporary  
224 structures associated with the LTVSMC period of use (from 1986 to 2001) within the footprint  
225 of the proposed WWTP would be relocated and repurposed on site. Key infrastructure at the  
226 Plant Site would be refurbished and reused under the NorthMet Project Proposed Action.

227 Processes at the Beneficiation Plant would include ore crushing, grinding, floatation, dewatering,  
228 storage, and shipping. Crushing and grinding would occur at the existing coarse-crusher  
229 building, fine-crusher building, and concentrator building, all of which are associated with the  
230 overall industrial processes of Erie operations during the period of significance. The Co-lead  
231 Agencies believe that the proposed refurbishment and reuse of these facilities is compatible with  
232 the industrial processes that occurred during the period of historic significance. Ore would  
233 continue to be transported to the Plant Site by rail from an adjacent Mine Site, and the buildings

234 would continue to function in a similar fashion as they did during the period of historic  
235 significance. Dewatering would take place at a new concentrate dewatering and storage building.  
236 This building would be constructed near the new Hydrometallurgical Plant, on the footprint of  
237 the Erie (LTVSMC) Heating and Additive Plant (SL-HLC-049), which would be demolished.  
238 The Area 1 Shop, rail car maintenance shop (Area 2 Shops), and Colby Lake pumphouse would  
239 be reused under the current proposal. The expected activities at each location would be  
240 consistent with those carried out during the period of significance. The current information  
241 suggests that refurbishment would be limited to painting and exterior rehabilitation, as needed.  
242 Refurbishment would likely include updates to building interiors; however, outside of the  
243 concentrator building, these interior renovations are not expected to diminish the integrity of  
244 those structures that contribute to the Erie Hoyt Lakes Operation mining landscape historic  
245 district.

246 The Co-lead Agencies have considered the potential effects on both the properties determined to  
247 be individually eligible and to those properties considered as contributing elements to the larger  
248 mining landscape historic district. Given that both new construction and demolition of  
249 contributing buildings is proposed within the Plant Site boundaries, the federal Co-lead Agencies  
250 have determined that an adverse effect finding is warranted for this larger mining landscape  
251 historic district.

#### 252 **DM&IR Segment**

253 The Canadian Northern Railway currently owns the DM&IR segment of track within the APE of  
254 the NorthMet Project Proposed Action. While PolyMet asserts that reuse of part of the  
255 DM&IR segment is “likely,” there are no immediate plans for reuse of this railroad as part of the  
256 current NorthMet Project Proposed Action. Although it is possible that the DM&IR segment  
257 would be reused if permitting proceeds, since there are no reasonably foreseeable proposals, there  
258 are no adverse effects to be identified in this analysis. Therefore, the federal Co-lead Agencies  
259 have determined that there would be no adverse effect. The federal Co-lead Agencies, in  
260 consultation with the SHPO, Bands, and PolyMet, are currently working to resolve adverse  
261 effects.

#### 262 **Spring Mine Lake Sugarbush**

263 The federal Co-lead Agencies have determined the Spring Mine Lake Sugarbush eligible for  
264 inclusion in the NRHP under Criterion A for its association with important Ojibwe spiritual and  
265 cultural practices. Under Criterion D, the site is significant for its potential to answer important  
266 questions about possible 19<sup>th</sup> century and 20<sup>th</sup> century Ojibwe maple sugaring practices.

267 Direct effects on this property would not result from the NorthMet Project Proposed Action. The  
268 Spring Mine Lake Sugarbush is not within the footprint of the Mine Site, the Plant Site, or any  
269 other ancillary NorthMet Project area features.

270 Based on an indirect visual effects analysis conducted for the NorthMet Project Proposed Action  
271 and the site visits conducted in 2010, the federal Co-lead Agencies believe that the NorthMet  
272 Project Proposed Action would not result in a visual intrusion that would diminish the integrity  
273 of setting, feeling, or associations. The Spring Mine Lake Sugarbush is a number of miles from  
274 the Mine Site and sufficiently screened from the Plant Site and the Tailings Basin where those  
275 project features are not visible. The Plant Site and Tailings Basin are existing LTVSMC mine

276 features. Their footprint would not be expanded to any significant extent, nor would the addition  
277 of material be visible from the Spring Mine Lake Sugarbush to a significantly greater extent than  
278 current conditions.

279 The analysis of possible atmospheric effects that was completed for the NorthMet Project  
280 Proposed Action indicates that the Spring Mine Lake Sugarbush is not in an area expected to be  
281 affected by dust deposition. The Spring Mine Lake Sugarbush and its grove of mature maple  
282 trees has existed throughout the past 50 years of mining, which included the use of the existing  
283 Plant Site and Tailings Basin as well as numerous mineral extraction locations (mine pits) in  
284 close proximity to the Spring Mine Lake Sugarbush in comparison to the Mine Site.

285 The Spring Mine Lake Sugarbush may be associated with the trail systems, such as the BBLV  
286 Trail Segment, that are known to have traversed this area. The portion of that trail corridor in  
287 proximity to the Spring Mine Lake Sugarbush has been for the most part destroyed by past  
288 mining operations. The NorthMet Project Proposed Action would not result in the loss of any  
289 additional portions of that corridor, or trails, in proximity to the Spring Mine Lake Sugarbush.  
290 For further discussion, see the discussion of effects on the BBLV Trail Segment.

291 Based on this analysis, the federal Co-lead Agencies made the determination that there would be  
292 no direct effects resulting from the NorthMet Project Proposed Action nor would there be any  
293 significant changes to the setting, feeling, or associations of the Spring Mine Lake Sugarbush.

294 After consultation with the Bands concerning effects on the Spring Mine Lake Sugarbush, the  
295 federal Co-lead Agencies acknowledged that the analysis of atmospheric effects on the Spring  
296 Mine Lake Sugarbush was an estimation based on modeling and that dust deposition is expected  
297 to occur near this property. The Co-lead Agencies, through consultation with the Bands, are also  
298 aware of concerns among the consulting parties for potential inadvertent damage to the site given  
299 the proximity of the site to key operational areas associated with the proposed Plant Site. After  
300 consideration of concerns and perceptions raised by the consulting parties, the federal Co-lead  
301 Agencies have determined that the NorthMet Project Proposed Action would adversely affect the  
302 Spring Mine Lake Sugarbush.

### 303 **Mesabe Widjiu**

304 The federal Co-lead Agencies have determined the *Mesabe Widjiu* eligible for inclusion in the  
305 NRHP under Criterion A for its association with important Ojibwe spiritual and cultural  
306 practices. Although the federal Co-lead Agencies are assessing the effects of the NorthMet  
307 Project Proposed Action on only the portion of the *Mesabe Widjiu* within the APE, it is  
308 recognized that the property and its significance extends beyond the APE.

309 Direct effects on the *Mesabe Widjiu* would occur at the Tailing Basin, which currently abuts a  
310 portion of that land form. Expansion of the Tailings Basin would intrude on that portion of the  
311 *Mesabe Widjiu*. Direct effects on the *Mesabe Widjiu* at the Mine Site would not occur as the  
312 *Mesabe Widjiu* is not considered to be within the footprint of the Mine Site. However, the  
313 boundaries of the *Mesabe Widjiu* are still the subject of consultation with the SHPO and the  
314 Bands.

315 Indirect effects to the *Mesabe Widjiu* would result from the features at the Mine Site location.  
316 Although there are existing mine features between the *Mesabe Widjiu* and the Mine Site location,  
317 the NorthMet Project Proposed Action would further diminish the integrity of setting and feeling.  
318 The large-scale alterations to the landscape resulting from mine pits, stockpiles, material

319 handling facilities, etc., would be long-term changes that would further diminish the association  
320 of the *Mesabe Widjiu* with the natural features of the Partridge River headwaters. Although the  
321 Mine Site has been disturbed by logging, roads brushed out for mineral exploration, and linear  
322 features, such as Dunka Road or the railroad, these disturbances are smaller. The effect of the  
323 NorthMet Project Proposed Action would also remove a portion of the BBLV Trail Segment  
324 corridor, further diminishing the *Mesabe Widjiu*'s association with that historic property.

325 Although the federal Co-lead Agencies are not aware of specific locations adjacent to the  
326 NorthMet Project area that are used by the Bands, this does not diminish the significance of  
327 effects for that portion of the *Mesabe Widjiu*. Given the nature of Ojibwe spiritual practices,  
328 which is a personal connection to the natural elements of the environment, locations of this type  
329 are very difficult to identify. The *Mesabe Widjiu* is a historic property to which the Ojibwe have  
330 had a spiritual connection for hundreds of years.

331 Based on the above considerations, the federal Co-lead Agencies believe that the NorthMet  
332 Project Proposed Action would adversely affect the *Mesabe Widjiu*.

### 333 **BBLV Trail Segment**

334 The federal Co-lead Agencies have determined that the BBLV Trail Segment is significant for  
335 the role it played in the broad patterns of Ojibwe land use and early mineral exploration. It is  
336 eligible for inclusion in the NRHP under Criteria for Evaluation A and D.

337 The portion of the BBLV Trail Segment that lies within the Mine Site would be directly affected  
338 by the NorthMet Project Proposed Action, which would result in its permanent removal. Based  
339 on this, the federal Co-lead Agencies believe that the NorthMet Project Proposed Action would  
340 adversely affect the BBLV Trail Segment.

### 341 **Potential for Properties of Tribal Significance Constituting a Historic District**

342 The federal Co-lead Agencies have consulted with the Bands regarding the possibility of the  
343 historic properties of tribal significance being considered as part of a National Register District.  
344 A District, as defined in National Register Bulletin 15 *How to Apply the National Register*  
345 *Criteria for Evaluation*, in addition to having integrity, “possesses a significant concentration,  
346 linkage, or continuity of sites, buildings, structures, or objects united historically or aesthetically  
347 by plan or physical development” (NPS 1995). While the BBLV Trail Segment and the Spring  
348 Mine Lake Sugarbush appear to share a similar period of significance and are related to 19<sup>th</sup>  
349 century Ojibwe land use and transportation contexts, the federal Co-lead Agencies do not believe  
350 that these properties collectively retain integrity of setting and association nor are they arranged  
351 in such a way that they could be considered a “unified entity” (*ibid*). In addition, prior resource  
352 extractive developments have significantly altered the landscape within and adjacent to the  
353 NorthMet Project area. These developments and landscape alterations make it difficult to  
354 ascertain the linkages that may have historically existed between these properties. The federal  
355 Co-lead Agencies do not find that the identified historic properties constitute a “significant  
356 concentration” of sites, as further defined in Bulletin 15 (*ibid*). While the federal Co-lead  
357 Agencies recognize and affirm that overland trails (and at least one reported “encampment”)  
358 existed in the NorthMet Project area at the time of the initial Government Land Office surveys,  
359 the level of post-19<sup>th</sup> century development has destroyed and largely obscured the ability of the  
360 extant historic properties to convey a sense of continuity and linkage. The oral interview  
361 information that has been provided to the Co-lead Agencies does not contain details that speak

362 specifically to these sites; however, the information provided in the oral interviews regarding the  
363 *Mesabi Widjiu* was fully considered, and played a key role in the federal Co-lead Agencies prior  
364 determination of adverse effect. That said, the federal Co-lead Agencies recognize the position of  
365 the consulting Bands regarding the connected nature of cultural resources throughout the 1854  
366 Ceded Territory and affirm that the historical context of these properties should be a key  
367 component of resolution of adverse effects discussions going forward.

368 The federal Co-lead Agencies have previously commented on the consulting Bands request  
369 (Grand Portage 2013) to consider a much larger historic district that extends down to the north  
370 shore of Lake Superior for the purposes of Section 106 review for the NorthMet Project  
371 Proposed Action. For the reasons stated in the above paragraph, the Co-lead Agencies, at this  
372 time, believe that additional identification and evaluation efforts within this area would be  
373 outside of the scope of NorthMet Project Proposed Action.

#### 374 **5.2.9.2.2 Treaty Resources**

375 Natural resources important to Ojibwe culture can be recognized even when tribal use of a  
376 natural resource may not qualify that resource as a historic property for further consideration  
377 under Section 106. The right to hunt, fish, and gather on lands within the 1854 Ceded Territory is  
378 protected by the 1854 Treaty. Limitation or elimination of access to public lands within the 1854  
379 Ceded Territory for these purposes may be considered an effect on 1854 Treaty rights. The loss  
380 of 1854 Treaty resources may also have an effect on the Bands' ability to exercise 1854 Treaty  
381 rights.

382 An analysis of effects on 1854 Treaty resources, as described and discussed in Section 4.2.9, is  
383 limited by the lack of available information concerning the use of such resources. To help  
384 determine how the Bands have traditionally exercised their usufructuary rights on or near the  
385 NorthMet Project area, the Bands conducted interviews of individual members of Bois Forte,  
386 Fond du Lac, and Grand Portage, although only the results of interviews with Bois Forte were  
387 made available.

388 There is little specific information concerning the use of natural resources by the Bands in the  
389 NorthMet Project area, other than the Spring Mine Lake Sugarbush, which is being considered  
390 under Section 106 of the NHPA. This likely reflects limited present day or recent past  
391 subsistence gathering in the NorthMet Project area due to general inaccessibility. This lack of  
392 data also precludes the quantitative analysis of how Band members would be affected  
393 socioeconomically by effects on 1854 Treaty resources, further discussed in Section 5.2.10. The  
394 primary source of data for assessing effects from the NorthMet Project Proposed Action on 1854  
395 Treaty resources is from the analysis of the environment discussed in detail in Section 4.2.9 of  
396 this FEIS.

397 As stated in Table 5.2.9-1 below, the NorthMet Project Proposed Action would affect 4,028.3  
398 acres within the Nashwauk Uplands and Laurentian Uplands subsections, which constitutes a  
399 total of 0.3 percent of these two subsections.

400 **Table 5.2.9-1 Acres of the Laurentian Uplands and Nashwauk Uplands Subsections**  
 401 **Affected by the NorthMet Project Proposed Action**

| <b>Land Cover</b>            | <b>Total Acres</b> | <b>Acres Affected by the NorthMet Project Proposed Action</b> | <b>Percent of Combined Nashwauk Uplands and Laurentian Uplands Subsections Affected by the NorthMet Project Proposed Action</b> |
|------------------------------|--------------------|---------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------|
| Aquatic Environments         | 396,966            | 581.7                                                         | 0.1                                                                                                                             |
| Disturbed                    | 46,174             | 1,242.4                                                       | 2.7                                                                                                                             |

402 Source: MDNR 2011f; MDNR 2011i.

403 The cover type most affected by the NorthMet Project Proposed Action is disturbed land, which  
 404 includes reuse of the existing LTVSMC Tailings Basin. Less than 1 percent of each of the  
 405 remaining cover types would be affected. Effects on the 1854 Treaty resources associated with  
 406 these cover types are discussed below.

407 **Vegetation**

408 Vegetation that would be affected by the NorthMet Project Proposed Action is covered in the  
 409 vegetation analysis in Section 5.2.4. Consequences of the NorthMet Project Proposed Action  
 410 would include direct effects on land cover types.

411 The NorthMet Project Proposed Action would disturb 1,718.6 acres of land at the Mine Site,  
 412 with the largest effects to upland conifer forest and lowland conifer forest. Consequently, the  
 413 plant species or resources regulated by the 1854 Treaty Authority for gathering within these  
 414 cover types would likely be most affected (see Table 5.2.9-2). The Plant Site contains 2,189.7  
 415 acres that would be disturbed, although most effects occur in areas already previously disturbed.  
 416 Though the aquatic environment cover type would be heavily affected at the Plant Site, it  
 417 consists mostly of tailings ponds where no regulated plant species or resources would be present.  
 418 The majority of the 120.1 acres of the Transportation and Utility Corridor has also already been  
 419 disturbed.

420 **Table 5.2.9-2 Affected Cover Types of Associated Species and Resources Regulated by the**  
 421 **1854 Treaty Authority at the NorthMet Project Area**

| Cover Types                           | Associated Plant Species or Resource                                                          | Affected Mine Site (Acres) <sup>1</sup> | Affected Transportation and Utility Corridor (Acres) <sup>1</sup> | Affected Plant Site (Acres) <sup>1</sup> |
|---------------------------------------|-----------------------------------------------------------------------------------------------|-----------------------------------------|-------------------------------------------------------------------|------------------------------------------|
| Upland coniferous forest              | Conifer boughs, princess pine, birch bark, firewood, other plants or forest products          | 741.9                                   | 2.6                                                               | 52.0                                     |
| Lowland coniferous forest             | Conifer boughs, princess pine, firewood, other plants or forest products                      | 437.2                                   | 0.2                                                               | 20.7                                     |
| Upland deciduous forest               | Princess pine, ginseng, birch bark, firewood, other plants or forest products                 | 354.7                                   | 2.7                                                               | 295.1                                    |
| Shrubland                             | Firewood, other plants or forest products                                                     | 133.0                                   | 7.7                                                               | 144.9                                    |
| Disturbed                             | NA                                                                                            | 44.0                                    | 94.4                                                              | 1,104.0                                  |
| Aquatic environments                  | Wild rice, other plants or forest products                                                    | 6.0                                     | 2.7                                                               | 573.0                                    |

422 Source: 1854 Treaty Authority 2007.

423 <sup>1</sup> Acres from Section 5.2.4.

424 In addition to the direct effects discussed above, there may also be indirect effects on cover  
 425 types. Hydrology changes and dust from traffic and mining operations could affect plant  
 426 communities near the NorthMet Project area, which could further reduce plant species or  
 427 resources regulated by 1854 Treaty Authority. Mitigation measures, which would minimize these  
 428 effects, are discussed in Section 5.2.4. Subsistence gathering at these locations is probably  
 429 limited because of general inaccessibility.

430 According to the NorthMet Project Cultural Landscape Study (Zellie 2012), some of the most  
 431 common species include balsam fir, speckled alder, and low-bush blueberry (see Table 4.2.9-4).  
 432 These species were identified in multiple community types and are more likely to remain within  
 433 the NorthMet Project area, despite the direct and indirect effects from the NorthMet Project  
 434 Proposed Action. Within the combined Laurentian Uplands and Nashwauk Uplands ecological  
 435 subsections, less than 0.3 percent would be affected by the NorthMet Project Proposed Action.  
 436 As an estimate, the species or resources listed in Table 4.2.9-4 could likely decrease by the same  
 437 margin within these Ecological Classification System (ECS) subsections.

438 **Wildlife**

439 Similar to the effects on SGCNs discussed in Section 5.2.5, the NorthMet Project Proposed  
 440 Action would affect 1854 Treaty Authority-regulated species as a result of increased human  
 441 activity and noise, potential collisions with vehicular and rail traffic, and decrease of habitat.  
 442 Generally, effects on common and/or game animals (such as white-tailed deer, fox, grouse,  
 443 waterfowl, etc.) would be similar to the effects on ETSC species (e.g., gray wolf, moose, etc.),  
 444 which are discussed in Sections 5.2.5.2.1 and 5.2.5.2.2. Local effects are expected due to

445 competition from migrating individuals, but these would not threaten overall populations. See  
446 Section 5.2.5 for a more thorough discussion of the types of effects on wildlife.

447 As there is likely limited present day or recent past subsistence gathering in the NorthMet Project  
448 area due to general inaccessibility, the NorthMet Project Proposed Action is unlikely to further  
449 diminish the exercise of 1854 Treaty rights in the area.

#### 450 ***Increased Human Activity***

451 The 1854 Treaty Authority-regulated species would be directly and indirectly affected through  
452 increased human activity due to mining activities. Factors such as noise, dust, light, and vehicle  
453 traffic may frighten some species and discourage their use of otherwise suitable habitat.  
454 Displaced to other habitat, individuals could face increased competition for resources. Less  
455 mobile species, such as herptiles (e.g., frogs, turtles), would likely incur relatively high mortality  
456 rates due to less ability to leave the affected area. Cliff-nesting birds could be affected by  
457 disturbance if they were to nest along the cliffs created by the pit rims.

#### 458 ***Noise Effects***

459 Noise associated with mining activities, including noise from vehicle and rail traffic, would  
460 likely affect wildlife, including 1854 Treaty Authority-regulated species. Section 5.2.8 provides  
461 further discussion on the noise modeling predictions for the NorthMet Project area. Though  
462 wildlife species are likely to be sensitive to changes in noise levels, there are no local, national,  
463 or international standards or limits that are applicable to the NorthMet Project Proposed Action.  
464 State standards are discussed Section 5.2.8, Noise. Wildlife species may be affected by noise in  
465 the NorthMet Project area, though adjacent habitat is available.

#### 466 ***Vehicular and Rail Traffic Effects***

467 Traffic effects from collisions with wildlife depend upon factors such as traffic volume, traffic  
468 speed, and the species involved. Species that utilize the small preserved forest island remnants  
469 between haul roads at the Mine Site would be most affected. Indirect effects from vehicle  
470 activities are expected locally at the Mine Site for 1854 Treaty Authority-regulated species and  
471 the overall local ecosystem. Effects at the Transportation and Utility Corridor are primarily  
472 related to vehicle and rail traffic. The 1854 Treaty Authority-regulated species may be affected  
473 by noise and light associated with vehicle and rail traffic, and by collisions with vehicles or  
474 trains. Transportation effects at the Plant Site are primarily related to vehicle traffic associated  
475 with the construction of the Tailings Basin embankments and bentonite application, primarily  
476 during the construction phase of the NorthMet Project Proposed Action. The 1854 Treaty  
477 Authority-regulated species may be affected by noise and light associated with vehicle traffic  
478 and by collisions with vehicles.

#### 479 ***Habitat Effects***

480 The direct effect on wildlife habitat, and thus on species regulated by the 1854 Treaty Authority,  
481 was assessed by evaluating the acres of habitat types that would be lost under the NorthMet  
482 Project Proposed Action. The changes in cover type are summarized in Table 5.2.9-3.

483 **Table 5.2.9-3 Direct Effects on Key Habitat Types**

| <b>Key Habitat Types</b>                                         | <b>Total Acres<sup>1</sup> of Cover Type Directly Affected at the Mine Site</b> | <b>Total Acres<sup>1</sup> of Cover Type Directly Affected at the Transportation and Utility Corridor</b> | <b>Total Acres<sup>1</sup> of Cover Type Directly Affected at the Plant Site</b> |
|------------------------------------------------------------------|---------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------|
| Mature Upland Forest, Continuous Upland/Lowland Forest (MIH1-13) | 1,535.3                                                                         | 5.5                                                                                                       | 367.8                                                                            |
| Open Ground, Bare Soils (no MIH)                                 | 44.0                                                                            | 94.4                                                                                                      | 1,104.0                                                                          |
| Grassland and Brushland, Early Successional Forest (no MIH)      | 133.2                                                                           | 17.5                                                                                                      | 144.9                                                                            |
| Aquatic Environments (MIH 14)                                    | 6.0                                                                             | 2.7                                                                                                       | 573.0                                                                            |
| <b>Total</b>                                                     | <b>1,718.6</b>                                                                  | <b>120.1</b>                                                                                              | <b>2,189.7</b>                                                                   |

484 Data from Tables 5.2.4-1, 5.2.4-4, and 5.2.4-6.

485 <sup>1</sup> Total acres may be more or less than presented due to rounding.

486 *Mature Upland/Lowland Forest*

487 At the Mine Site, 1,535.3 acres of the mature forest would be lost as a result of the NorthMet  
 488 Project Proposed Action. All 5.5 acres of mature upland/lowland forest along the Transportation  
 489 and Utility Corridor would be affected. Approximately 368 acres of forest habitat at the Plant  
 490 Site would be disturbed, most of which is in small or isolated patches of aspen-birch forest that  
 491 are in poor to fair condition (MDNR 2013a).

492 The 1854 Treaty Authority-regulated species consist of several common and/or game animals.  
 493 These species are largely mobile and would likely be displaced, not injured or killed, during  
 494 mine construction and operation. Reclamation of the Mine Site would include revegetating  
 495 nearly all disturbed ground according to *Minnesota Rules*, part 6132.2700. Reclamation and  
 496 revegetation of the NorthMet Project area would improve wildlife habitat relative to conditions  
 497 during mine operations; however, the quality of habitat for 1854 Treaty Authority-regulated  
 498 species would remain degraded for decades after closure relative to pre-mining conditions.

499 *Open Ground/Bare Soils*

500 No 1854 Treaty Authority-regulated species are identified as utilizing open ground or bare soils  
 501 habitat at the Mine Site, Transportation and Utility Corridor, or Plant Site. These areas were the  
 502 result of past mining activity, are generally of low-quality, and are expected to decrease after  
 503 mine closure as a result of reclamation.

504 *Brush/Grassland*

505 Approximately 133 acres of brush/grassland at the Mine Site would be directly affected by the  
 506 NorthMet Project Proposed Action. Young trees (less than 4 inches dbh) make up most of this  
 507 habitat type (ENSR 2005). Although all 17.5 acres of brush/grassland at the Transportation and  
 508 Utility Corridor would be directly affected, activities at the Transportation and Utility Corridor  
 509 would not affect grassland/brush 1854 Treaty Authority-regulated species based on the

510 fragmented nature of this habitat. Approximately 145 acres of brush/grassland at the Plant Site  
511 would be directly affected by the activities at the Plant Site. The reclaimed Plant Site,  
512 specifically the Tailings Basin, would be revegetated with grassland vegetation species. Overall,  
513 the NorthMet Project Proposed Action would have a minimal effect on grassland/brush 1854  
514 Treaty Authority-regulated species.

#### 515 Open Water

516 The NorthMet Project Proposed Action would create approximately 321 acres of open water at  
517 the Mine Site by eventually flooding the West Pit, which is estimated to fill between years 40  
518 and 45. At the Plant Site, open water habitat primarily occurs in the existing LTVSMC Tailings  
519 Basin. Existing open water habitat would be maintained during operations, though the acreage of  
520 open water would fluctuate according to processing needs. See Section 5.2.5 for further  
521 discussion of wildlife use of the open water at the NorthMet Project area.

#### 522 Wetlands

523 Based on the site-specific wetland delineation, the NorthMet Project Proposed Action would  
524 directly affect 758.2 acres of wetlands at the Mine Site, though surrounding similar wetland  
525 habitat would likely be adequate to absorb the displaced wildlife. There are 7.2 acres of wetlands  
526 along the Transportation and Utility Corridor, all of which would be affected by activities along  
527 the corridor. There would be 148.4 acres of wetland at the Plant Site directly affected (see  
528 Section 4.2.3 and 5.2.3). On-site wetland use by 1854 Treaty Authority-regulated species may be  
529 limited. Wetlands at the Mine Site are considered 99 percent high quality and 1 percent moderate  
530 quality, 100 percent high quality along the Transportation and Utility Corridor, and 94 percent  
531 low quality and 6 percent moderate quality at the Plant Site.

532 Wetland mitigation is proposed both on and off site at three mitigation sites (See Section 5.2.3).  
533 Approximately 101.8 acres of wetland creation is proposed for on-site mitigation. Off-site  
534 mitigation would consist of 1,799.8 acres of wetland restoration and preservation and upland  
535 buffer.

#### 536 Aquatic Species

537 The potential environmental effects of the NorthMet Project Proposed Action on fish and aquatic  
538 macroinvertebrate communities found in the vicinity of the NorthMet Project area are primarily  
539 discussed in Section 5.2.6. Direct and indirect effects could include changes in water quality and  
540 alteration of physical habitat.

541 The NorthMet Project Proposed Action would not result in physical habitat effects on the  
542 Partridge River or Embarrass River watersheds as a result of hydrologic changes. Generally, fish  
543 species regulated by the 1854 Treaty Authority (see Table 4.2.9-7) that occur in the NorthMet  
544 Project area would not experience effects from physical habitat loss or alteration.

545 For the 29 solutes evaluated, the GoldSim model predicted that the NorthMet Project Proposed  
546 Action would not cause any significant water quality impacts because: 1) exceedances of the P90  
547 threshold did not occur, 2) the NorthMet Project Proposed Action concentrations were no higher  
548 than concentrations predicted for the CEC scenario, or 3) the frequency of exceedances for  
549 NorthMet Project Proposed Action conditions was within an acceptable range or not attributable  
550 to NorthMet Project Proposed Action discharges or both. See Section 5.2.2 for a more thorough

551 discussion of water quality effects and 5.2.6 for a discussion of water quality effects pertaining to  
552 aquatic species.

553 The NorthMet Project Proposed Action is expected to result in a net decrease in mercury  
554 loadings to the Partridge River from 24.2 to 23.0 grams per year, primarily as a result of a  
555 decrease in natural runoff and a proportional increase in water discharged from the West Pit via  
556 the WWTF. It is also expected to result in a net increase in mercury loadings to the Embarrass  
557 River from 22.3 to 22.5 grams per year, primarily due to the redirection of flow associated with  
558 the construction of the East Dam as part of the Tailings Basin expansion to the Embarrass River.  
559 However, the NorthMet Project Proposed Action would also result in a 45 percent reduction in  
560 sulfate loads (P50 modeling results) at PM-13, which would reduce the potential for mercury  
561 methylation. Overall, the NorthMet Project Proposed Action is not expected to increase the  
562 mercury content in fish in the St. Louis River. See Sections 5.2.2 and 5.2.6 for a more thorough  
563 discussion of mercury bioaccumulation.

#### 564 **Overall Effects on 1854 Treaty Resources**

565 As discussed above, the NorthMet Project Proposed Action would have effects on 1854 Treaty  
566 resources—i.e., those areas and species that are traditionally or culturally important to the Bands.  
567 There are two categories of effects: those relating to plant and animal species of interest to Band  
568 members, and those relating to areas where these plant and animal species are hunted, fished, or  
569 gathered. As discussed above and in other resource-specific sections of the FEIS, the NorthMet  
570 Project Proposed Action would result in direct environmental effects due to ground-disturbing  
571 activities. Band members' use of the NorthMet Project area is not well-defined, and did not  
572 emerge through interviews. A good faith effort was made on the part of the Co-lead Agencies to  
573 identify use areas in or adjacent to the NorthMet Project area; however, those efforts resulted in  
574 little specific information concerning historic subsistence use and no information regarding  
575 recent subsistence activity at the Mine Site, Transportation and Utility Corridor, or Plant Site. In  
576 addition, as described in Section 5.2.11, the NorthMet Project area is surrounded by private land  
577 and cannot be easily accessed due to private roads. Without private landowner permission, there  
578 is minimal opportunity for the Bands to exercise usufructuary rights (hunting, fishing, and  
579 gathering) on this property.

580 Construction and operation of the NorthMet Project Proposed Action is not likely to significantly  
581 reduce overall availability of 1854 Treaty resources that are typically part of subsistence  
582 activities in the 1854 Ceded Territory. Some individuals and localized populations may be  
583 affected, but overall species populations are expected to remain available. Additionally, noise  
584 and other consequences of operations would affect migration or other animal species behavior.

585 The importance of fish as a subsistence resource in Ojibwe communities is well documented  
586 historically, and fish continue to be an important component of the day-to-day diet, while fishing  
587 itself remains an important socio-cultural and economic activity in Tribal communities across the  
588 Upper Great Lakes. The NorthMet Project Proposed Action could affect the availability of 1854  
589 Treaty resources for some Band members because of real or perceived factors. For instance,  
590 bioaccumulation of mercury in fish could affect Band members' willingness to rely on  
591 subsistence fishing as a contribution to household economies, as well as affect continuation of  
592 traditional fishing practices, but there is no evidence that this availability would significantly  
593 affect subsistence use given the lack of information showing recent or historic fishing activity in  
594 the NorthMet Project area.

595 Effects on the environment, including any from increased mercury, are all expected to meet the  
596 standards and regulations set forth by the appropriate state or federal agency or program. These  
597 laws are intended to protect important natural and cultural resources and include, but are not  
598 limited to the ESA, CWA, and CAA. Effects on 1854 Treaty resources are difficult to quantify  
599 when the effects are within environmental standards, yet above current baseline conditions. As  
600 such, cultural effects on the Bands would be difficult to quantify in regards to such incremental  
601 increases below standards or effects to species where appropriate mitigation is used.  
602

DRAFT

DRAFT

1 **5.2.10 Socioeconomics**

2 This section describes the potential socioeconomic consequences of the NorthMet Project  
3 Proposed Action on communities in the study area (consisting of St. Louis, Lake, and Cook  
4 counties—see Section 4.2.10 and Figure 4.2.10-1). Socioeconomics includes demographic  
5 characteristics of the study area’s population, economic characteristics (employment, income,  
6 market composition—i.e., the types of firms and employers located in the study area), public  
7 finance, housing, public services, and the economic characteristics of subsistence activities. The  
8 cultural aspects of subsistence, specifically for Native American populations, are discussed in the  
9 Section 5.2.9. Individual subsistence products (e.g., wild rice, game animals, etc.) are discussed  
10 in appropriate resource-specific sections of the FEIS.

11 **Summary**

12 The NorthMet Project Proposed Action would generate as many as 500 direct jobs during peak  
13 construction and 360 direct jobs during operation. These direct jobs would generate additional  
14 indirect and induced employment, estimated to be 332 additional construction-phase jobs and  
15 631 additional operations-phase jobs. While some skilled workers would be involved only  
16 temporarily and possibly relocate from outside the region, the majority of the NorthMet Project  
17 Proposed Action-related jobs are expected to be filled by those currently residing in the  
18 Arrowhead region.

19 Federal, state, and local taxes would total up to an estimated \$80 million annually. During  
20 operations, there would be approximately \$231 million per year in direct value added through  
21 wages and rents and \$332 million per year in direct output related to the value of the extracted  
22 minerals. As with employment, these direct economic contributions would create indirect and  
23 induced contributions estimated at \$99 million in value added and \$182 million in output.

24 The NorthMet Project Proposed Action would create slightly increased demand for housing and  
25 public services in cities and towns near the NorthMet Project area. The resulting increase in  
26 housing demand and prices could have minor effects on the Environmental Justice (EJ)  
27 populations.

28 The NorthMet Project No Action Alternative would have no effects.

29 **5.2.10.1 Methodology and Evaluation Criteria**

30 As discussed in Section 4.2.10, the study area for socioeconomics includes Cook, Lake, and St.  
31 Louis counties. Because socioeconomic consequences are measured and felt across a broad  
32 geographic area, this section does not distinguish between the Mine Site, Transportation and  
33 Utility Corridor, and Plant Site. Rather, this section describes the socioeconomic consequences  
34 of the NorthMet Project Proposed Action across the entire three-county study area and, where  
35 appropriate, includes the study area communities listed in Section 4.2.10.

36 **5.2.10.1.1 Evaluation Criteria**

37 Specific criteria used to evaluate socioeconomic consequences include the following:

- 38 • Changes in local population, employment, or earnings associated with NorthMet Project  
39 Proposed Action operations.
- 40 • Changes in public sector revenues, expenditures, or the underlying fiscal conditions of local  
41 governments.
- 42 • Changes in economic activity for non-mining industries in the region, particularly the  
43 tourism industry.
- 44 • Changes in demand for temporary or permanent housing during NorthMet Project Proposed  
45 Action construction, operation, and closure periods.
- 46 • Changes in long-term demands on public services and infrastructure that reduce capacities in  
47 these systems, either triggering the need for capital expansion or resulting in a discernible  
48 reduction in the level of service provided.
- 49 • Displacement or other use of property that affects residences or businesses.
- 50 • Disproportionate effects on minority (including Native American) or low-income  
51 populations, including human health or environmental effects, and subsistence—especially if  
52 the NorthMet Project Proposed Action results in large reductions in abundance or major  
53 redistribution of subsistence resources, substantial interference with harvestable access to  
54 active subsistence sites, or major increases in non-rural resident hunting (Barnard  
55 Dunkelberg 2009).

56 **5.2.10.1.2 Determination of Study Area**

57 As discussed in Section 4.2.10, the socioeconomic study area for this section includes all of  
58 Cook, Lake, and St. Louis counties (the three counties that comprise the Arrowhead region of  
59 Northeastern Minnesota). This study area includes the Mine Site, Transportation and Utility  
60 Corridor, and Plant Site, as well as all of the tracts involved in the Land Exchange Proposed  
61 Action. The size of this study area also captures much of the region’s recreational resources  
62 (which are important economic engines) and a substantial portion of the 1854 Ceded Territory,  
63 which is important to the Bands. Finally, the three-county study area is large enough to reflect a  
64 regional economic picture against which the NorthMet Project Proposed Action’s effects can be  
65 compared.

66 Where possible, the analysis of effects is based on a quantitative comparison of baseline  
67 conditions (see Section 4.2.10) against predicted future conditions in the entire three-county area.  
68 In cases where such quantitative data are not available for the entire region (e.g., the IMPLAN  
69 model discussed in Section 5.2.10.1.3), the evaluation of effects is either limited to St. Louis  
70 County—the site of the NorthMet Project area—or includes the other counties but only  
71 qualitatively.

72 **5.2.10.1.3 IMPLAN Model Methodology**

73 Many of the socioeconomic effects of the NorthMet Project such as increased population,  
74 housing demand, and effects on public facilities and services are functions of the jobs and  
75 revenue that the NorthMet Project Proposed Action creates. To model these effects, the

76 University of Minnesota Duluth Labovitz Bureau of Business and Economic Research (BBER)  
77 used the IMPLAN software package. IMPLAN uses an input-output approach to model the  
78 economic effects of changes in baseline conditions (e.g., a large industrial project such as the  
79 NorthMet Project Proposed Action). IMPLAN reports direct, indirect, and induced effects  
80 (definitions of these terms are provided below) in terms of employment, output (the value of  
81 production), and value added (wages, rents, taxes, etc.).

82 For both the SDEIS and the FEIS, BBER used version 3.0 of IMPLAN; this version uses  
83 economic baseline data from 2009, the most recent year for which data were available to BBER  
84 at the time the model was developed (BBER 2012). (The model does assume a recovery—by the  
85 mining industry, and the overall economy—from the recession that was in place in 2009.) Due to  
86 their small populations, workforces, and their distance from the NorthMet Project area, Cook and  
87 Lake counties are not expected to experience substantial additional effects from the NorthMet  
88 Project Proposed Action. As a result, the IMPLAN model includes only St. Louis County, which  
89 acts as a proxy for the entire three-county study area.

90 Economic effects were modeled for two construction phases: a 15-month Phase I and a 12-month  
91 Phase II that would begin 6 months after completion of Phase I. The phases represent two  
92 distinct periods of activity in mine construction involving distinct skill sets and activities. Two  
93 operations phases were also modeled: a 6-month Startup Phase and a Typical Year (BBER  
94 2012). The IMPLAN model did not project the number of years of operation, due to the inherent  
95 difficulty of predicting how variations in the grade of the extracted material or macroeconomic  
96 forces—such as industry cycles or metal prices (see below)—would affect mine life. The Typical  
97 Year estimate is intended to model the economic effects of standard operations, recognizing that  
98 “some years will be a little better, others a little worse” (BBER 2012). The IMPLAN model also  
99 did not include effects during the closure phase or the post-closure period, again due to the  
100 difficulty of predicting the timing and extent of those phases.

101 The IMPLAN model focuses on three categories of economic effects:

- 102 • Employment: calculated in terms of jobs, not full-time equivalent (FTE) positions. The  
103 model does not make a distinction between full-time, part-time, permanent, or temporary  
104 jobs. Direct employment estimates were provided by PolyMet.
- 105 • Value added: measures economic contributions to the local economy through wages, rents,  
106 interest, and profits.
- 107 • Output: the value of the goods or services (e.g., minerals and processed mineral products)  
108 produced.

109 Each category of effects comprises three separate components:

- 110 • Direct effects: new jobs, spending, and output resulting directly from the NorthMet Project  
111 Proposed Action (e.g., PolyMet employees, salaries, spending, and sales).
- 112 • Indirect effects: additional inter-industry spending and employment resulting from direct  
113 effects (e.g., wholesale purchase of tires by tire retailers who are NorthMet Project Proposed  
114 Action vendors).
- 115 • Induced effects: additional household expenditure resulting from the direct and indirect  
116 effects (e.g., increased patronage of local restaurants by employees of PolyMet or affiliated  
117 industries).

118 The findings of the IMPLAN model are presented in section 5.2.10.2.

119 **5.2.10.1.4 Sources of Uncertainty and Variability**

120 The anticipated socioeconomic effects of the NorthMet Project Proposed Action are based on the  
 121 best available data, economic modeling, and lessons learned from the history of metal mining in  
 122 the Mesabi Iron Range. As this history shows, there are numerous sources of economic  
 123 uncertainty surrounding a project such as the NorthMet Project Proposed Action. The largest  
 124 overarching socioeconomic concerns related to the NorthMet Project Proposed Action are listed  
 125 below. Their relationship to the determination of effects is discussed, as appropriate, throughout  
 126 the remainder of Section 5.2.10.

127 **Industry Cycles**

128 The feasibility of mining is strongly tied to the market price of the commodities being extracted.  
 129 When prices are high, mining activity is high (the “boom”); when prices drop, mining activity  
 130 can often slow down or cease entirely (the “bust”). Such changes in mining activity would have  
 131 effects on host communities. The diverse economy of the study area could offset the degree to  
 132 which the effects of a bust are experienced. Though this “boom and bust” phenomenon is often  
 133 present in mining economies, IMPLAN does not model this phenomenon (or assume that it  
 134 would occur) because the duration of a boom or bust and the severity relative to modeled  
 135 commodity prices cannot be predicted. Table 5.2.10-1 shows the metal prices assumed in the  
 136 IMPLAN model, along with recent average prices and the lowest prices experienced during the  
 137 2008-9 recession. The potential effects of major changes in commodity prices are addressed in  
 138 the discussions of effects during the operations phase.

139 ***Table 5.2.10-1 Comparison of Assumed (IMPLAN) and Actual Commodity Prices***

| Commodity | Price Assumed in IMPLAN <sup>1</sup> | Average Actual Price <sup>2</sup> | Recent Low Price <sup>3</sup> |
|-----------|--------------------------------------|-----------------------------------|-------------------------------|
| Copper    | \$2.90/lb                            | \$3.56/lb                         | \$1.39/lb                     |
| Nickel    | \$12.20/lb                           | \$9.47/lb                         | \$4.39/lb                     |
| Cobalt    | \$23.50/lb                           | \$111.69/lb                       | \$13.56/lb                    |
| Platinum  | \$1,230.00/oz                        | \$1,689.00/oz                     | \$843.00/oz                   |
| Gold      | \$635.00/oz                          | \$1,485.00/oz                     | \$755.00/oz                   |

140 Sources: BBER 2012 (commodity prices); Foth 2012 (average actual price); PolyMet, Pers. Comm., March 29, 2012 (recent low  
 141 price).

142 <sup>1</sup> Prices based on PolyMet’s 2008 Bankable Feasibility Study (PolyMet 2008b). This is the most detailed published information  
 143 available, and PolyMet is legally bound to these data.

144 <sup>2</sup> Three-year rolling average metal prices as of June 30, 2012 (Foth 2012).

145 <sup>3</sup> Monthly low during 2008-2009 recession.

146 **Changes in Industrial Productivity**

147 Throughout the nation, “regional labor productivity [in mining and overall]...has increased  
 148 dramatically” since publication of the 2009 DEIS (BBER 2012). Over the longer term (since  
 149 approximately 1980), mining productivity in the Arrowhead region has also increased, due to  
 150 mechanization and technological innovation (Powers 2007). As a result, far fewer miners are  
 151 now required per unit of extracted material than before, which therefore lessens the effects of

152 booms and busts in mining communities. Continued technologically driven productivity  
153 increases could lead to lower employment than assumed by IMPLAN or other projections.

#### 154 **Local Employment**

155 The NorthMet Project Proposed Action's socioeconomic effects may be influenced by the degree  
156 to which PolyMet hires employees who already live in the socioeconomic study area. The FEIS  
157 assumes that at least some (but not all) direct and indirect jobs would be filled by current study  
158 area residents; more specific assumptions about the construction, operations, and closure phases  
159 are discussed in subsequent portions of this section, as are the ways in which changes in "local"  
160 employment shares would affect different aspects of the study area's socioeconomic character.

#### 161 **Environmental Costs and Non-market Value**

162 The FEIS contains extensive discussion of the environmental and social effects of the NorthMet  
163 Project Proposed Action (and the Land Exchange Proposed Action) in this section and other  
164 resource-specific sections. These effects could, in turn, have real and/or perceived economic  
165 costs. Non-market values refer to the importance given to characteristics of the land that have  
166 personal or community value, but that are not typically expressed in monetary value. Beauty,  
167 quiet, and the ability to view nature are examples of non-market values.

168 Neither NEPA nor CEQ requires the cost and benefits of a proposed action to be quantified in  
169 dollars or any other common metric; however, this FEIS acknowledges that economic costs and  
170 loss of non-market value may result from environmental and social effects. Also acknowledged  
171 is that the agreement on the value (i.e., the "cost") of environmental effects is often difficult to  
172 achieve. Therefore, the approach of this FEIS is to evaluate environmental and social effects  
173 directly, in the appropriate resource-specific section (e.g., the impacts on wildlife are discussed  
174 in the Wildlife section, and impacts on water quality are discussed in the Water Resources  
175 section).

### 176 **5.2.10.2 NorthMet Project Proposed Action**

177 This section evaluates the NorthMet Project Proposed Action's effects on socioeconomics in the  
178 three-county study area.

#### 179 **5.2.10.2.1 Population and Population Trends**

180 This section discusses the changes in the study area's population resulting from the NorthMet  
181 Project Proposed Action. These population changes would be driven primarily by NorthMet  
182 Project Proposed Action-related changes in employment.

#### 183 **Construction**

184 IMPLAN modeling estimates that construction activities would create an average of 500 direct  
185 and 128 indirect construction jobs over the 18-month Phase I period (the most labor-intensive  
186 portion of the construction phase). The 204 induced jobs during this phase are likely to be  
187 existing residents hired to accommodate the additional demand from direct and indirect jobs.

188 Typical mine construction involves fluctuating work flows and specialized crews that may be  
189 employed for short duration tasks within the construction time frame. Very few construction

190 phase employees would work within the NorthMet Project area for the entire 30-month  
191 construction period (including Phase I, the 6-month gap, and Phase II).

192 Given the NorthMet Project area, most construction employees would likely be from Minnesota,  
193 and many would already live in the study area. Many direct and indirect employees are likely to  
194 reside outside of the communities in the immediate vicinity of the NorthMet Project area (e.g.,  
195 Hoyt Lakes, Babbitt, Biwabik, Aurora). However, mine workers in the Arrowhead region and  
196 beyond “are willing to commute considerable distance to...well-paid jobs...to protect investment  
197 in their homes” (Powers 2007). This finding is generally true of mine construction workers as  
198 well. As a result, most employees (regardless of project phase) would not need to relocate.

199 Due to the proximity of the NorthMet Project area to population centers such as Duluth  
200 (80 miles), Hibbing (50 miles), and Virginia (25 miles), the FEIS assumes that 80 percent of  
201 direct and indirect construction labor (approximately 500 employees during Phase I of  
202 construction, which requires more workers than Phase II) would commute to the NorthMet  
203 Project Proposed Action construction site on a regular basis (PolyMet 2012d). The FEIS assumes  
204 that another 5 to 10 percent of direct and indirect workers (approximately 25 to 50 employees)  
205 would temporarily reside in the study area, at local hotels or in designated mobile home  
206 facilities, but would not relocate their families to the region.

207 The remaining 10 to 15 percent of the direct and indirect workforce (as many as approximately  
208 100 employees) would relocate to the study area for portions (or all) of the construction process  
209 (PolyMet 2012i). An influx of 100 workers would equate to as many as 225 total new residents  
210 (including family members—see the average population per housing unit in Table 4.2.10-14)  
211 who would seek long-term (e.g., more than a few months) residences in nearby communities.  
212 This represents an increase of less than one quarter of 1 percent over the 2010 population of the  
213 study area (approximately 216,000 residents—see Table 4.2.10-1), and slightly more than a 2  
214 percent increase in the population of nearby cities (Aurora, Babbitt, Biwabik, Hoyt Lakes,  
215 Tower, and Virginia). Such a small increase would not meaningfully change the demographic  
216 composition of the study area; thus, construction of the NorthMet Project Proposed Action would  
217 have negligible effects on population.

## 218 **Operations**

219 During typical operations, the NorthMet Project Proposed Action would generate 360 direct and  
220 330 indirect jobs. Direct and indirect employees are likely to work at the Mine Site, Plant Site,  
221 and in the study area for a substantial period of time (perhaps as long as the 20-year projected  
222 life of the mine). Direct and indirect employees who do not already live within commuting  
223 distance of the Mine Site and Plant Site (i.e., in the study area) are likely to relocate to the study  
224 area. It is not known how many direct employees would be current study area residents. PolyMet  
225 estimates that as many as 338 of the 360 new direct operations-phase positions (94 percent of  
226 these positions) could be filled by study area residents (PolyMet 2012c).

227 For purposes of this analysis, the FEIS assumes that approximately 75 percent of direct and  
228 indirect operations phase employees would be local residents who would not need to relocate as  
229 a result of employment. The FEIS also assumes that the vast majority of the 301 induced jobs  
230 created during operations would be filled by existing residents or the spouses and children of  
231 new NorthMet Project Proposed Action employees.

232 The remaining 25 percent of operations-phase workers (approximately 175 employees) would  
233 relocate to the study area with their families, causing a total increase of approximately 400 new  
234 residents (see the average population per housing unit in Table 4.2.10-14). This is less than one  
235 quarter of one percent of the study area population (approximately 216,000 residents).

236 These workers are likely to be younger, on average, than the existing populations of the study  
237 area communities, and may have higher overall incomes. Other demographic characteristics  
238 (race, level of education) cannot be determined. The effect of such a shift on housing and public  
239 services is discussed below.

240 Increases in worker productivity spurred by technological change could reduce the anticipated  
241 number of direct, indirect, and induced employees. The effect of such reductions would be to  
242 reduce the overall new population of the study area. This in turn would diminish the NorthMet  
243 Project Proposed Action's demographic effects.

#### 244 **Reclamation and Closure**

245 During the closure of the NorthMet Project Proposed Action, PolyMet estimates that a reduced  
246 number of employees and contractors would remain employed for approximately 3 to 4 years for  
247 building demolition, but other closure activities would likely be followed by several years of  
248 reclamation activities (e.g., surface water quality monitoring). PolyMet is in the process of  
249 finalizing reclamation designs and estimates. Current estimates are based on experience at  
250 closure of the former LTVSMC processing plant and include 30 to 50 FTEs for the first 7 years,  
251 which includes demolition, remediation, reclamation, construction, and monitoring, and 5 to 10  
252 FTEs for the following 30 years, which includes a period of monitoring, reporting, and active  
253 water treatment. During closure, direct, indirect, and induced employment associated with the  
254 project would decline. All other factors being equal, by the end of the seven-year closure period,  
255 the demographic characteristics of the study area would likely revert to levels that could be  
256 expected under the NorthMet Project No Action Alternative.

#### 257 **5.2.10.2.2 Employment and Income**

258 Table 5.2.10-2 shows the anticipated economic contributions of the NorthMet Project Proposed  
259 Action, as modeled using IMPLAN. Detailed estimates of jobs by type are provided in the  
260 IMPLAN Report (BBER 2012). The IMPLAN model includes assumptions about the portion of  
261 employment, value added, and output that accrues to the study area (in the case of the IMPLAN  
262 model, this is limited to St. Louis County), as opposed to the amount that "leaks" to locations  
263 outside of St. Louis County (BBER 2012). While the data in Table 5.2.10-2 depict the economic  
264 effects of the project specifically on St. Louis County alone, they capture the vast majority of the  
265 NorthMet Project Proposed Action's effects in the entire three-county study area. By  
266 comparison, the total value added to the Minnesota economy in 2009 (from all sources) was  
267 \$268 billion (Henry Eichman, USFS Economist, Pers. Comm., July 26, 2013).

268 **Table 5.2.10-2 Summary of IMPLAN Model Results**

| Phase <sup>1</sup>                     | Direct Effect | Indirect Effect | Induced Effect | Total                |
|----------------------------------------|---------------|-----------------|----------------|----------------------|
| <b>Construction Phase I</b>            |               |                 |                |                      |
| Value Added <sup>2</sup>               | \$143,637,243 | \$41,774,260    | \$61,120,854   | <b>\$246,532,357</b> |
| Output <sup>3</sup>                    | \$312,000,009 | \$75,343,964    | \$101,199,927  | <b>\$488,543,900</b> |
| Employment                             | 500           | 128             | 204            | <b>832</b>           |
| <b>Construction Phase II</b>           |               |                 |                |                      |
| Value Added                            | \$75,501,628  | \$21,958,266    | \$32,127,628   | <b>\$129,587,122</b> |
| Output                                 | \$164,000,005 | \$39,603,897    | \$53,194,833   | <b>\$256,798,717</b> |
| Employment                             | 264           | 68              | 107            | <b>439</b>           |
| <b>Operations Phase – Startup</b>      |               |                 |                |                      |
| Value Added                            | \$44,619,571  | \$12,117,664    | \$6,865,833    | <b>\$63,603,068</b>  |
| Output                                 | \$64,122,003  | \$23,821,174    | \$11,367,855   | <b>\$99,311,032</b>  |
| Employment                             | 300           | 275             | 251            | <b>826</b>           |
| <b>Operations Phase – Typical Year</b> |               |                 |                |                      |
| Value Added                            | \$231,315,193 | \$62,819,962    | \$35,593,610   | <b>\$329,728,765</b> |
| Output                                 | \$332,418,993 | \$123,492,880   | \$58,932,833   | <b>\$514,844,706</b> |
| Employment                             | 360           | 330             | 301            | <b>991</b>           |

269 Source: BBER 2012.

270 <sup>1</sup> The IMPLAN model did not include effects during the closure phase or post-closure period.

271 <sup>2</sup> Defined in BBER 2012 as “a measure of the affecting industry’s contribution to the local community; it includes wages, rents,  
272 interest and profits.”

273 <sup>3</sup> Defined in BBER 2012 as “the value of local production required to sustain activities.”

274 **Construction**

275 Construction of the NorthMet Project would create as many as 832 jobs during the peak of Phase  
276 I, of which 500 would be mine construction jobs. Indirect and induced employment would be  
277 spread across a variety of industries, such as engineering, restaurants, medical providers, and  
278 hospitals (see Table 10 in BBER 2012). The NorthMet Project Proposed Action-related  
279 construction employment would increase overall study area employment by less than one percent  
280 at its peak (less during Phase II).

281 As discussed in Section 5.2.10.2.1, the FEIS assumes that a substantial share of direct  
282 construction jobs would be filled by study area residents—particularly those with construction  
283 experience—while other study area residents would obtain indirect and induced jobs.  
284 Construction is therefore expected to at least marginally reduce the unemployment rate in the  
285 study area.

286 It is not known how much of the estimated \$376 million in total value added during the two parts  
287 of the construction phase would be dedicated to employee salaries, although employee pay is  
288 assumed to be a substantial share. The value added from the NorthMet Project Proposed Action  
289 is likely to be substantial compared to other non-ferrous (e.g., copper, nickel, lead, zinc) mining  
290 activity, but would be limited to the construction phase.

291 While employment related to the construction phase of the NorthMet Project Proposed Action  
292 would have minimal effects, the earnings from construction employees would be positive, albeit  
293 relatively short-lived (e.g., for no more than the 36-month overall construction phase).

## 294 **Operations**

### 295 ***Overall Effects***

296 During typical year operations, the NorthMet Project Proposed Action would generate nearly  
297 1,000 total direct, indirect, and induced jobs. This would increase study area employment by  
298 approximately one percent. One-third of new employment (360 jobs) would be direct mine-  
299 related jobs. The remainder would be spread among a variety of industries, such computer  
300 programming, restaurants, engineering, and health care (BBER 2012).

301 As discussed in Section 5.2.10.2.1, the FEIS assumes that a substantial share of direct operations  
302 jobs would be filled by study area residents, particularly those with mining experience. In 2009,  
303 there were approximately 3,000 mining jobs in the study area (U.S. Census Bureau 2009). This  
304 figure does not include residents who have skills appropriate for the mining sector but who are  
305 not currently employed in mining. Other local residents are likely to obtain indirect and induced  
306 jobs. Operation of the NorthMet Project Proposed Action could reduce unemployment in the  
307 study area by nearly one percent (991 new jobs out of 111,090 members of the workforce, see  
308 Table 4.2.10-9).

309 It is not known how much of the estimated \$330 million in total value added during typical  
310 operations would be dedicated to employee salaries, although employee pay is assumed to be a  
311 substantial share. The NorthMet Project Proposed Action's estimated value added (and thus  
312 earnings) is substantial compared to the 2007 estimate of \$250 million in annual statewide value  
313 added economic effects from non-ferrous mining (BBER 2009).

314 Earnings and all economic contributions of the NorthMet Project are influenced by external  
315 market factors, such as those discussed in Section 5.2.10.1.4. Significant decreases in metal  
316 prices and/or competition from other regions or countries can lead to reduced production.  
317 PolyMet states that, due to its structure as a "low-cost producer," the NorthMet Project Proposed  
318 Action would be unlikely to completely cease operations during a recession (PolyMet, Pers.  
319 Comm., March 29, 2012). That statement notwithstanding, complete suspension of mining  
320 activity is not an uncommon response to recession or significant drops in commodity prices. This  
321 "bust" aspect of the cyclical economy is familiar to mining regions in Minnesota and beyond  
322 (Powers 2007; Freudenberg and Wilson 2002). Increases in productivity may not affect the  
323 output of the NorthMet Project Proposed Action (i.e., the sales price of the extracted and  
324 processed materials), but could reduce employment and value added.

325 To account for some of these concerns, commodity prices in the IMPLAN model are generally  
326 conservative, compared to price trends. In particular, copper, gold, and platinum prices used in  
327 the IMPLAN model are significantly below recent average prices. Nickel and cobalt, which are  
328 expected to comprise a small share of the total volume extracted by PolyMet, are significantly  
329 above current average prices, but were also conservative compared to contemporary prices that  
330 formed the basis of PolyMet's 2008 Bankable Feasibility Study (see notes in Table 5.2.10-1)  
331 (PolyMet 2008b). Section 5.2.10.1.4 provides more information about sources of uncertainty and  
332 variability.

333 ***Effects on Regional Tourism***

334 Effects on species (game animals, fish, and vegetation) and resources (water quality, air quality,  
335 and noise) that contribute to the tourism industry are discussed in appropriate sections of Chapter  
336 5. Housing is also an important component of the tourism industry—the Arrowhead region is  
337 often regarded as a location for long vacations, rather than short day-trips—and is discussed in  
338 Section 5.2.10.2.4. To the degree that the NorthMet Project Proposed Action adversely affects  
339 those resources, then it also has the potential to affect the tourism industry. However, the  
340 presence of the NorthMet Project Proposed Action would not significantly affect regional  
341 recreation or visual resources (see Section 5.2.11.2.1), nor would it affect air or water quality or  
342 increase noise levels in popular regional recreation resources such as BWCAW (see Section  
343 5.2.12). Consequently, there is also insufficient evidence to suggest that the presence of the  
344 NorthMet Project Proposed Action would affect the tourism industry as a whole.

345 As discussed in 5.2.10.2.1, the NorthMet Project Proposed Action would retain a small  
346 workforce, generating a corresponding small number of indirect and induced jobs, to perform  
347 post-mining activities such as demolition and reclamation as well as to maintain a very small  
348 post-closure staff. Using the IMPLAN model's construction-phase employment multipliers  
349 (BBER 2012) a 50-person closure staff (direct employment) could equate to as many as 30  
350 indirect and induced jobs (a decline, compared to the 1,000 operations-phase jobs generated by  
351 the NorthMet Project Proposed Action). Because no minerals or other commodities would be  
352 extracted, the value added from the closure phase would be limited to employee salaries, rents,  
353 and other contributions.

354 **Closure**

355 Overall, the employment, output, and value added from the closure phase would be small  
356 compared to the study area's overall economy. More important, at mine closure, workers who  
357 held operations-phase direct, indirect, and induced jobs would be expected to secure alternative  
358 local employment, retire, or relocate out of area. There would likely be a spike in unemployment  
359 and a resulting decline in income during the transition between the operations and closure  
360 phases. The 991 operations-phase jobs (including direct, indirect, and induced jobs) collectively  
361 account for less than one percent of the overall study area workforce (111,090 individuals—see  
362 Table 4.2.10-9). Any increase in study area unemployment during and after closure—resulting  
363 from individuals who remain in the study area workforce but who cannot find jobs—would be  
364 minimal. As former employees moved, found new work in the area, or retired, unemployment  
365 and income would normalize to levels predicted for the NorthMet Project No Action Alternative  
366 (holding all other economic variables constant).

367 **5.2.10.2.3 Public Finance**

368 The IMPLAN model estimates the value of several federal and state taxes, including personal  
369 income taxes (i.e., taxes paid by employees on their salaries), indirect business taxes, and other  
370 taxes paid as a result of the NorthMet Project Proposed Action for the duration of the project  
371 (BBER 2012). PolyMet provided the tax estimates for taxes that would be paid directly by the  
372 company (PolyMet, Pers. Comm., March 29, 2012). The remainder of this section discusses  
373 those tax estimates.

374 **Construction**

375 Construction of the NorthMet Project Proposed Action would generate approximately \$51  
 376 million in federal tax revenue, and \$24 million in state tax revenue (combined, both construction  
 377 phases) (BBER 2012). A portion of these tax contributions would be returned to the study area  
 378 through various federal programs (e.g., grants to school systems and state governments) and  
 379 through distributions from the state’s general fund. However, such effects on local public  
 380 finances are indirect and difficult to quantify. Other construction-phase revenues could include  
 381 sales and use tax on some materials used for NorthMet Project Proposed Action construction,  
 382 although most such materials and supplies are exempt from the tax (MDR 2011).

383 **Operations**

384 The majority of economic benefits to the local community through taxes would be realized  
 385 during the operations period. IMPLAN modeling estimates that, during a typical year of  
 386 operation, the federal government would receive approximately \$30 million, and the state and  
 387 local governments would receive approximately \$39 million in taxes from the operation of the  
 388 NorthMet Project Proposed Action.

389 PolyMet estimates that, if the NorthMet Project Proposed Action was currently in operation, its  
 390 direct federal and state tax payments would have ranged from approximately \$37 to \$80 million  
 391 per year during the previous 5-year period (PolyMet, Pers. Comm., March 29, 2012). Table  
 392 5.2.10-3 details how these direct tax payments would be divided among different state and  
 393 federal taxes (as described in Section 4.2.10.1.3), if the NorthMet Project Proposed Action would  
 394 have been in full operation in 2011. A substantial portion of state taxes would be returned to  
 395 study area school systems, local governments, and local general funds.

396 ***Table 5.2.10-3 Estimated Annual NorthMet Project Proposed Action Taxes Paid, 2011***  
 397 ***Dollars (millions)***

|                                                  | <b>Minnesota Taxes<sup>1</sup></b> | <b>Federal Taxes<sup>1</sup></b> |
|--------------------------------------------------|------------------------------------|----------------------------------|
| Net Proceeds Tax                                 | \$5.9                              | NA                               |
| Occupation Tax                                   | \$7.1                              | NA                               |
| Sales and Use Tax                                | \$2.4                              | NA                               |
| Withholding Tax on Royalty Payments <sup>2</sup> | Undetermined                       | Undetermined                     |
| Ad Valorem Tax                                   | \$0.2                              | NA                               |
| <b>Total</b>                                     | <b>\$15.6</b>                      | <b>\$64</b>                      |

398 Source: PolyMet, Pers. Comm., March 29, 2012.

399 <sup>1</sup> Assumes-full operation at 2011 metal prices.

400 <sup>2</sup> Royalty payments would be subject to a 6.25% withholding tax. The value of this tax cannot be calculated or estimated at this  
 401 time.

402 The magnitude of tax contributions is strongly linked to commodity prices. A significant drop in  
 403 commodity prices would likely result in a significant reduction in tax revenue generated by the  
 404 NorthMet Project Proposed Action. Even under such circumstances, operation of the NorthMet  
 405 Project Proposed Action would benefit the local economy.

406 **Reclamation and Closure**

407 Closure activities would last approximately 20 years after cessation of operations. The first seven  
408 years of this period would be the most active, and would include reclamation, demolition, and  
409 restoration of the site. Years 7 to 20 of closure would include low-intensity monitoring,  
410 maintenance, and water treatment activities, followed by covering of the Tailings Basin at the  
411 end of this period. Low-intensity post-closure activities (such as long-term monitoring and  
412 maintenance) would extend indefinitely beyond year 20 of closure.

413 During closure and post-closure, the NorthMet Project Proposed Action would generate a small  
414 amount of tax revenue from the above activities, primarily from income taxes and business taxes.  
415 Other revenue sources, such as net proceeds taxes, and local ad valorem taxes would no longer  
416 apply. By the end of the closure phase, contributions to public finances would return to levels  
417 that would be expected for the NorthMet Project No Action Alternative. Relative to existing  
418 conditions, closure of the NorthMet Project Proposed Action would generate a negligible benefit  
419 for public finances in the study area.

420 **5.2.10.2.4 Housing**

421 Housing effects are tied to both employment and earnings; increases in both of these factors can  
422 cause increased demand for housing. There are more than 24,000 vacant housing units in the  
423 study area, of which approximately 7,000 are “permanent” (not seasonal) vacant units (see Table  
424 4.2.10-14). Of that total, approximately 4,000 non-seasonal vacant units are located in the  
425 individual study area communities listed in Section 4.2.10 (the remainder are scattered  
426 throughout St. Louis, Lake, and Cook counties). All of these communities are within a  
427 reasonable commuting distance of the NorthMet Project area (Powers 2007).

428 **Construction**

429 As described in Section 5.2.10.2.1, 75 percent of the construction-phase employees are expected  
430 to commute to their jobs from existing residences in or near the study area. Relatively few  
431 construction-phase employees (approximately 100) are expected to permanently relocate to the  
432 study area, due to the short-term and transient nature of mine construction. Given the existing  
433 vacant housing stock (and including seasonal units, which could be converted to permanent units  
434 at the owners’ discretion), this added demand in permanent housing in the study area would be  
435 largely imperceptible.

436 Approximately 25 to 50 employees may choose to procure temporary housing. This could consist  
437 of short-term rentals of available housing units (seasonal or otherwise), and use of mobile home  
438 parks or hotels/motels. Lodging and mobile home facilities close to the NorthMet Project area,  
439 such as those in Aurora, Hoyt Lakes and Babbitt, could be more heavily occupied throughout  
440 both phases of the construction period, affecting both availability and pricing for the region’s  
441 tourist demand. However, there are approximately 5,400 hotel rooms and more than 1,400  
442 mobile home berths (as well as park facilities that permit mobile homes) in the study area  
443 (Northland Connection 2012). Construction-phase demand for these accommodations would not  
444 substantially limit availability.

445 **Operations**

446 Demand for permanent housing is likely to increase during the operations phase. As discussed in  
447 Section 5.2.10.2.1, approximately 175 workers would choose to relocate to the study area. The  
448 actual number of housing units required to accommodate this demand may be lower (less than  
449 380), due to the presence of two-worker in-migrating households (e.g., the spouse of a direct  
450 employee may obtain an indirect or induced job). Even if there are no multiple-worker in-  
451 migrating households (an unlikely scenario), the study area has approximately 7,000 vacant non-  
452 seasonal housing units. Thus, the study area has adequate housing to accommodate the influx of  
453 workers associated with the NorthMet Project Proposed Action.

454 Individual communities close to the NorthMet Project area may experience more competition for  
455 available housing units. While it is unlikely that any single community would achieve 100  
456 percent non-seasonal occupancy, such competition could drive up housing prices and could also  
457 encourage the renovation of existing housing units and/or construction of new housing units  
458 (either on vacant land or as replacements of older housing units). Given the small number of new  
459 residents, such effects would be minor.

460 As with other economic effects of the NorthMet Project Proposed Action, effects on housing are  
461 tied to market fluctuations and workforce productivity. Major changes in levels of production  
462 (caused by major changes in commodity prices) could cause effects on housing demand and  
463 value. However, the total estimated new housing demand associated with the NorthMet Project  
464 Proposed Action is relatively small compared to the region's existing housing supply. Even a  
465 market "bust" (a drop in commodity prices so severe that it causes shutdown of the NorthMet  
466 Project Proposed Action) should not dramatically alter the housing market in any single  
467 community, let alone the study area as a whole.

468 There are concerns that the presence of the NorthMet Project Proposed Action could reduce  
469 housing demand (and thus housing value) in the study area, because of the conflict between the  
470 NorthMet Project Proposed Action's heavy industrial character and the high-quality natural  
471 environment that supports the region's tourism economy and thus the housing market. As  
472 described in Section 5.2.11, the NorthMet Project Proposed Action's effects on recreation and  
473 visual resources would be very limited.

474 Given the coexistence of mining and tourism in the Arrowhead region, the NorthMet Project  
475 Proposed Action's effects on the study area's housing values would be minimal. The most likely  
476 result of the operation of the NorthMet Project Proposed Action is a minor increase in housing  
477 demand and prices in study area communities, with moderate effects in individual communities  
478 closest to the NorthMet Project area. Increased housing prices may or may not be a negative  
479 effect; average housing values in the communities closest to the NorthMet Project area are  
480 relatively low compared to other study area communities. Minor to moderate increases in  
481 housing value would likely be seen as a benefit by homeowners, and the opportunity to add  
482 newer housing stock (either through rehabilitation of existing units or the construction of new  
483 units) to the study area would generally improve property values, thus improving local property  
484 tax revenues in those communities.

485 **Reclamation and Closure**

486 During and following reclamation and closure of the NorthMet Project Proposed Action, it is  
487 likely that the demand for housing would drop as workers migrate from the area. Housing

488 characteristics (vacancy rates and values) would likely revert to levels that would be expected for  
489 the NorthMet Project No Action Alternative. However, increases in housing demand spurred by  
490 the strength of the tourism industry and the increasing popularity of the study area for retirement  
491 could obscure any such declines.

#### 492 **5.2.10.2.5 Public Services and Facilities**

493 The NorthMet Project Proposed Action would affect public services and facilities in the study  
494 area both directly and indirectly. Direct effects would include services provided to the NorthMet  
495 Project Proposed Action itself, and would largely be limited to demand for emergency response  
496 in the case of an accident. Indirect effects would include increased demand for public services  
497 such as potable water, sewer, emergency services, and schools in communities where direct,  
498 indirect, and induced employees and their families live.

499 Most public water and sewer infrastructure in the study area was designed to accommodate  
500 larger populations than currently exist; therefore, the NorthMet Project Proposed Action would  
501 generally have no effect on these services (see Table 4.2.10-15). As Section 4.2.10.1.5 shows,  
502 emergency and medical services are equipped to handle existing demand, and most have mutual  
503 aid agreements in place with nearby cities to cooperatively respond to major emergencies.

504 The public schools in the study area were constructed to accommodate larger populations than  
505 currently exist in the study area (e.g., the larger populations that were associated with the iron  
506 and taconite mining industry in the 1960s and 1970s). Collectively, public schools in the study  
507 area have capacity for nearly 22,000 students, with existing enrollment of nearly 16,000 students.  
508 Thus, these schools are able to support new students without building new facilities. To address  
509 concerns about maintenance of older buildings, several school facilities in the region have  
510 already established renovation programs, and some schools in Duluth plan to downsize (see  
511 Section 4.2.10.1.5). These plans predate the NorthMet Project Proposed Action, and would not  
512 be accelerated or changed by new population associated with any phase of the NorthMet Project  
513 Proposed Action.

514 The five technical and community colleges and two four-year colleges located throughout the  
515 study area provide a variety of degree programs. These schools would continue to provide  
516 educational opportunities to new and existing study area residents seeking further education,  
517 including high school graduates and existing employees seeking to enhance their job skills.  
518 Several community colleges and universities in the study area offer, or are developing,  
519 educational curriculum related to jobs in the mining industry.

#### 520 **Construction**

521 Direct demands from construction of the NorthMet Project Proposed Action would primarily fall  
522 on local emergency service providers who would respond to any emergencies at the NorthMet  
523 Project area.

524 A small number of construction-phase employees and their families (approximately 225 total  
525 new residents, as described in Section 5.2.10.2.1) are expected to permanently relocate to the  
526 study area, while another 150 employees would stay in the study area for moderate periods of  
527 time (from several weeks to several months), in hotels or mobile homes. All of these employees  
528 would generate indirect demand for drinking water, wastewater capacity, and emergency  
529 services; the relocated residents would also generate demand for space in public schools.

530 Public schools in the study area generally have sufficient capacity to accommodate new students.  
531 As described in Section 4.2.10.1.5, several school facilities in the region are in need of  
532 renovation. This need predates the NorthMet Project Proposed Action, and would not be  
533 exacerbated by the relatively small number of new students added by NorthMet Project Proposed  
534 Action construction.

### 535 **Operations**

536 Direct demands from operation of the NorthMet Project Proposed Action would primarily fall on  
537 local emergency service providers who would respond to any emergencies within the NorthMet  
538 Project area. Approximately 400 operation-phase employees and family members are expected to  
539 relocate to the study area (see Section 5.2.10.2.1). All of these employees and their families  
540 would generate demand for drinking water, wastewater capacity, emergency services, and school  
541 capacity.

542 Additional police, fire, and ambulance staff may be required to service increased populations in  
543 study area cities, particularly in smaller cities. However, these expansions are likely to consist of  
544 one to two employees per service (e.g., one new police officer, two new firefighters), per city, as  
545 well as upgrades of existing equipment, rather than wholesale expansions of police and fire  
546 departments. Increased tax revenues from the NorthMet Project Proposed Action would be  
547 expected to cover the costs of these expansions.

### 548 **Reclamation and Closure**

549 During reclamation and closure of the NorthMet Project Proposed Action, direct and indirect  
550 demands for public service would decrease to baseline levels (those present at the start of the  
551 NorthMet Project Proposed Action) due to the anticipated decrease in population and activity at  
552 the Mine Site and Plant Site. Any cap upgrades to public services and facilities constructed to  
553 accommodate operations-phase demands, such as newer police and fire vehicles, would be  
554 available to the remaining residents of the study area during closure and post-closure activities.

### 555 **5.2.10.2.6 Environmental Justice and Subsistence**

556 Evaluation of EJ effects—the degree to which the potential effects of the NorthMet Project  
557 Proposed Action or any alternative are felt disproportionately across a community, considering  
558 ethnicity, age, and income—follows criteria set forth in the following federal EOs:

- 559 • EO 12898, (*Federal Actions to Address Environmental Justice in Minority Populations and*  
560 *Low-Income Populations*, 1994), directs federal agencies to incorporate EJ into their mission  
561 and activities. Federal agencies are to accomplish this by conducting programs, policies, and  
562 activities that substantially affect human health or the environment in a manner that does not  
563 exclude communities from participation in, deny communities the benefits of, or subject  
564 communities to discrimination under such actions, because of their race, color, or national  
565 origin.
- 566 • EO 13045, (*Protection of Children from Environmental Health Risks and Safety Risks*,  
567 1997), requires each federal agency give high priority to the identification and assessment of  
568 environmental health and safety risks to children.

569 In particular, this EJ analysis focuses on the degree to which the NorthMet Project Proposed  
570 Action could disproportionately affect the populations described above and includes residents of

571 the study area, as well as Band members who use the study area for subsistence, regardless of  
572 where they live.

573 Minority (non-white) populations comprise less than 5 percent of the study area, and less than 5  
574 percent of the individual communities listed in Table 4.2.10-3 (except for the three reservations).  
575 By comparison, the minority population of Minnesota was approximately 15 percent. The  
576 following groups in the study area meet the criteria described above:

- 577 • Approximately 13.5 percent of the study area population is below the federal poverty level,  
578 compared to 10 percent for the state.
- 579 • Native Americans comprise 2.3 percent of the study area, compared to 1.1 percent of the  
580 state population.
- 581 • Children (individuals under 18 years of age) comprise nearly 29 percent of the study area  
582 population, compared to 24 percent for the state.

583 Native American tribes exercise usufructuary rights to hunt, fish, and gather plants within the  
584 1854 Ceded Territory, which includes the study area. This section discusses the degree to which  
585 the NorthMet Project Proposed Action would disproportionately affect these subsistence  
586 practices, with the understanding that these practices have both socioeconomic and cultural value  
587 for the Native American tribes. Section 5.2.9 discusses the cultural aspects of subsistence in  
588 greater detail.

### 589 **Construction**

590 As described in Section 5.2.10.2.2, the economic effects of construction of the NorthMet Project  
591 Proposed Action would be largely positive. Construction would provide new jobs, substantial  
592 new earnings, and indirect contributions to public finances. Potential negative socioeconomic  
593 effects of construction of the NorthMet Project Proposed Action include increased demand for  
594 short-term housing (hotels and mobile home facilities)—although this is a benefit for the owners  
595 of those facilities—and increased demand for public services (especially emergency services).  
596 These negative effects are generally minor.

597 Increased public service demands would not disproportionately affect EJ populations. Increased  
598 prices would negatively affect the study area's poorest residents who did not receive a  
599 commensurate direct or indirect economic benefit from the NorthMet Project Proposed Action.  
600 Approximately 150 workers are expected to relocate to or occupy short-term housing in the study  
601 area during construction. This number of new and temporary residents, and therefore demand for  
602 public services, is small compared to available vacant housing, although poor residents closer to  
603 the NorthMet Project area may experience higher prices and demand than in the study area as a  
604 whole.

605 The NorthMet Project area is within the 1854 Ceded Territory. Section 4.2.10.1.6 and Table  
606 4.2.9-1 in Section 4.2.9 summarize available information about subsistence patterns and  
607 resources within the 1854 Ceded Territory. Construction of the NorthMet Proposed Action  
608 would make the Mine Site unavailable for subsistence use. The degree to which construction of  
609 the NorthMet Project Proposed Action would affect individual subsistence resources (i.e., fish,  
610 game, and plant species) outside of the Mine Site, Transportation and Utility Corridor, and Plant  
611 Site is discussed in Section 5.2.9 (Cultural Resources).

612 **Operations**

613 As described in Section 5.2.10.2.2, the economic effects of operation of the NorthMet Project  
614 Proposed Action would be largely positive. Operations would provide new jobs, substantial new  
615 earnings, and substantial direct and indirect contributions to public finances. In addition, the  
616 Bands operate four casinos in or near the study area (the Fond-du-Luth Casino in Duluth,  
617 operated by the Fond du Lac Band; the Black Bear Casino in Carlton, operated by the Fond du  
618 Lac Band; the Fortune Bay Resort Casino in Tower, operated by the Bois Forte Band; and the  
619 Grand Portage Lodge and Casino in Grand Portage, operated by the Grand Portage Band). While  
620 the Black Bear Casino is outside of the study area, it is nonetheless close enough to study area  
621 communities to potentially benefit from increased visitation and spending. Increased  
622 employment and income associated with the NorthMet Project Proposed Action could increase  
623 visitation and revenues at these facilities.

624 Potential negative socioeconomic effects of operation of the NorthMet Project Proposed Action  
625 include increased demand for housing (which could negatively affect the study area's poorest  
626 residents who did not receive a direct or indirect commensurate economic benefit from the  
627 NorthMet Project Proposed Action) and increased demand for public services and facilities.

628 Increased public service demands would not disproportionately affect minority and low income  
629 populations. The influx of direct, indirect, and induced NorthMet Project Proposed Action  
630 employees could cause demand for as many as 175 housing units across the study area. While  
631 this number is small compared to available vacant housing in the study area, some marginal  
632 increase in housing demand and cost, as well as demand for public services, is possible,  
633 particularly in communities closer to the NorthMet Project area. Increased housing competition  
634 would likely affect the study area's poorest residents, particularly renters (whose housing costs  
635 are more volatile), and particularly those living closer to the NorthMet Project area.

636 Operation of the NorthMet Project Proposed Action would make the Mine Site unavailable for  
637 subsistence use; noise and other consequences of operations could affect migration or other  
638 animal species behavior in the vicinity of the Mine Site and Plant Site (see Section 5.2.5,  
639 Wildlife).

640 Operations could affect individuals who consume fish harvested from nearby waterbodies. The  
641 NorthMet Project Proposed Action would increase mercury concentrations in the Embarrass  
642 River Watershed, as well as some nearby lakes, although it would decrease mercury  
643 concentrations in the Partridge River watershed (see Section 5.2.2.3.4). As described in Section  
644 4.2.10.1.6, subsistence fishing and consumption is a common activity for Native American bands  
645 in the 1854 Ceded Territory. Members of the Grand Portage and Fond du Lac bands are known  
646 to consume substantially more fish than the assumed statewide average. As a result, increased  
647 mercury concentrations, and potential increases in mercury bioaccumulation in fish tissue could  
648 therefore constitute an EJ impact for Band members and other subsistence consumers of fish.  
649 However, the AERA assessed health effects for recreational and tribal fishermen and their  
650 families consuming fish that could potentially contain elevated bioaccumulated levels of  
651 methylmercury. A potential small change in fish mercury concentration was estimated based on  
652 modeled emissions and deposition. The potential change in methylmercury concentration is not  
653 statistically measureable given variability in background concentrations and current laboratory  
654 analytical methods (Barr 2013j). Therefore, there is no expected change in fish mercury

655 concentrations, and no subsequent change in human health risks related to fish consumption (see  
656 Section 5.2.7.2.5). This information is summarized in Section 7.3.4.4.3 of the FEIS.

### 657 **Reclamation and Closure**

658 During reclamation and closure, socioeconomic characteristics of the study area would revert to  
659 conditions that would be expected for the NorthMet Project No Action Alternative. Employment,  
660 earnings, and contributions to public finances generated by the NorthMet Project Proposed  
661 Action would end (potentially with a phase-out period); housing demand and prices would ease  
662 as would demands for public services and facilities. Poorer residents of the study area would  
663 have more difficulty coping with this transition if they hold lower-paying, less secure “induced”  
664 jobs (as opposed to direct or indirect jobs), as they may have more difficulty moving out of the  
665 study area to secure new jobs (particularly if housing values drop). However, given the relatively  
666 small number of jobs generated by the NorthMet Project Proposed Action (compared to the total  
667 number of jobs held by study area residents), these difficulties would not be substantially higher  
668 than existing conditions.

669 As during other phases, the NorthMet Project area would remain closed to the public—and thus  
670 unavailable for subsistence use—during and following the closure phase, thus preventing  
671 subsistence activities. Deposition of mercury from the NorthMet Project Proposed Action would  
672 cease at closure, but mercury bioaccumulation in fish tissue and existing fish consumption limits  
673 are not anticipated to persist beyond the mine’s operational life. Per the AERA assessment, there  
674 is no expected change in mercury concentrations in fish, and no subsequent change in human  
675 health risks related to fish consumption (see Sections 5.2.7.2.5).

### 676 **5.2.10.3 NorthMet Project No Action Alternative**

677 Under the NorthMet Project No Action Alternative, the NorthMet Project Proposed Action  
678 would not be developed. There would be no NorthMet Project Proposed Action-related change to  
679 the study area. Externally existing demographic trends such as population growth or decline, and  
680 shifts in employment patterns would continue. The study area would not accrue the economic  
681 benefits of the NorthMet Project Proposed Action, nor would it experience any of the negative  
682 effects identified in this FEIS. As described in Section 5.2.10.2, the presence of the NorthMet  
683 Project Proposed Action would not hamper growth of the Arrowhead region’s tourism industry;  
684 the NorthMet Project No Action Alternative would not hasten this growth, either. Overall, the  
685 NorthMet Project No Action Alternative would have no effect on socioeconomics in the study  
686 area.

### **5.2.11 Recreation and Visual Resources**

This section describes the potential environmental effects of the NorthMet Project Proposed Action on recreational facilities and activities that typically take place in the NorthMet Project area, as well as the surrounding Arrowhead region. Recreation in this region is strongly tied to the aesthetic condition of the landscape so this section also describes the effects of anticipated project activities on visual resources in the NorthMet Project area and surrounding land.

#### **Summary**

Most of the Mine Site, a part of the Superior National Forest, is currently public land. However, the Mine Site is surrounded by private land that lacks public roads or trails and is therefore not publicly accessible by land. The Transportation and Utility Corridor and Plant Site are privately owned lands and are not open to the public for recreation. Direct effects on recreation in this area from the NorthMet Project Proposed Action would be limited. With the exception of the Skibo Vista Scenic Outlook, views of project activities would be limited by topography and distance. The NorthMet Project could reduce recreational use of nearby lands, including portions of the Superior National Forest, but would not affect recreational patterns and facilities in the Arrowhead region as a whole. The BWCAW and Voyageurs National Park (recreational resources that are discussed in greater detail in Section 5.2.12) are each more than 19 miles from the NorthMet Project Area. An analysis of potential air quality effects demonstrated that there are no expected effects on visibility in these areas when compared to pristine conditions.

#### **5.2.11.1 Methodology and Evaluation Criteria**

##### **5.2.11.1.1 Recreation**

The primary issues related to recreational facilities and activities on and near the proposed project facilities include the following:

- direct effects due to construction, operation, and closure of the NorthMet Project Proposed Action resulting in the reduction of the number and/or acreage of recreational facilities (parks, lakes, trails, etc.) potentially available for public use;
- indirect effects of the NorthMet Project Proposed Action, including reduction in the use of recreational facilities in areas surrounding the proposed project facilities due to noise, dust, and other disturbances; and
- the net effect of local (i.e., the area surrounding the Mine Site and Plant Site) and regional recreation during post closure.

Evaluation of the NorthMet Project Proposed Action against these criteria was based on comparison to the USFS ROS for land that is controlled by USFS. The USFS uses the ROS to inventory recreational settings and characteristics (see Section 4.2.11.1 for further explanation of the ROS).

Effects on the region's overall recreation resources (e.g., lands not necessarily controlled by USFS) are based on qualitative analysis of NorthMet Project Proposed Action activities, as they relate to the region's recreational opportunities (as summarized in Section 4.2.11). Specific considerations include distance (both direct and via road or trail) between the NorthMet Project and various recreation resources, and the likelihood that the NorthMet Project Proposed Action

would change the noise or visual environment, or the character of water, flora, and fauna present in these resources. These evaluations are based on extensive touring of the region and review of available mapping and descriptive material about the region's recreation resources.

#### **5.2.11.1.2 Visual Resources**

The primary issues related to visual resources on and near the Mine Site and Plant Site include the following:

- the nature and severity of effects of the NorthMet Project Proposed Action on sensitive viewpoints, including nearby homes, businesses, and vistas;
- changes to the extent or scale of visible mining disturbances; and
- the ultimate appearance of the NorthMet Project Proposed Action after reclamation is completed versus current and interim stages of active mining.

Evaluation of the NorthMet Project Proposed Action against these criteria was based on comparison to the USFS Scenery Management System classes for land that is or would be controlled by the USFS. The USFS uses the Scenery Management System to identify desired visual conditions, as expressed by SIOs (see Section 4.2.11.1 for further explanation of SIOs).

Effects on the region's overall visual environment (e.g., lands not necessarily controlled by USFS) are based on qualitative analysis of the NorthMet Project's activities (particularly structures, stockpiles, and other visible activities), as they relate to what observers are likely to see in the region. This understanding is based on extensive touring and photo-documentation of views and visual conditions in the region. In addition, GIS, printed maps, and aerial photography were used to identify potential sensitive viewpoints, for which visual simulations of future mine facilities were developed.

### **5.2.11.2 NorthMet Project Proposed Action**

#### **5.2.11.2.1 Recreation**

Surface rights to most of the Mine Site are held by the USFS, as part of the Superior National Forest. As described in Section 4.2.11, the ROS classes for the portion of the Mine Site located on federal lands are Semi-Primitive Motorized and Roaded Natural. The setting and characteristics of the portion of the Mine Site located on private lands is similar to the Roaded Natural class. However, there is no officially established public access (e.g., roads or trails) to the Mine Site (see Section 4.2.11.1), and thus limited opportunity for recreational activity. No access (or recreational opportunities) would be allowed during construction, operation, or closure of the NorthMet Project Proposed Action. Accordingly, the NorthMet Project Proposed Action would have no effect on recreation within the Mine Site.

Construction and operation of the NorthMet Project Proposed Action would be entirely contained within the NorthMet Project area (i.e., the Mine Site, Transportation and Utility Corridor, and Plant Site). Thus, the NorthMet Project Proposed Action would not directly affect access to or use of regional recreational facilities such as other portions of the Superior National Forest, nearby parks and other public lands, or the BWCAW.

The public's enjoyment of recreational activities in the region—such as hunting, fishing, boating, hiking, and winter sports—is tied in part to visual resources, as discussed below, and also to a

wide variety of factors evaluated in other sections of Chapter 5.0. Such factors include, but are not limited to, the availability and quality of fish and other aquatic species, vegetation, wildlife (particularly game species), noise, air quality, water quality, and wetlands. Effects on these resources are presented in the corresponding sections in Chapter 5.0.

The mine facilities such as mine pits, stockpiles, and associated facilities would be set back from most publicly accessible land, including portions of the Superior National Forest south of the Transportation and Utility Corridor. In addition, the lack of designated trails in these portions of the Superior National Forest means that the number of recreational users who would approach the Mine Site would be limited. Nonetheless, the presence of the NorthMet Project Proposed Action would likely make recreational activities in the immediate vicinity of to the Mine Site, Transportation and Utility Corridor, and Plant Site less enjoyable (and therefore less likely) for some observers. In particular, three potential effects of the NorthMet Project Proposed Action could reduce recreational activity: noise, effects on fish populations (related to recreational fishing), and effects on wildlife populations (related to recreational hunting).

The presence of noise could discourage use of the portions of the Superior National Forest closest to the Mine Site and Plant Site (e.g., immediately south of the Transportation and Utility Corridor). Noise levels, including operational noise, ground vibration, and airblast overpressure, that exceed the most stringent category of state noise standards generally would not extend more than 0.9 mile from the Mine Site during the day and 2.3 miles at night (see Figures 5.2.8-1 through 5.2.8-4).

The ROS classes for those portions of the Superior National Forest within 2.3 miles of the Mine Site are Semi-Primitive Motorized and Non-Motorized. NorthMet Project Proposed Action-related noise would affect up to 6,450 acres of the Superior National Forest within this 2.3 mile area. In these areas, project-related noise could limit full realization of the intended ROS classifications. Outside of the 2.3 mile area, NorthMet Project Proposed Action-related noise would not be inconsistent with ROS classes.

NorthMet Project Proposed Action-related noise, air emissions, and water discharges could potentially influence wildlife behavior in portions of the Superior National Forest closest to the Mine Site and Plant Site, as discussed in the wildlife Section 5.2.5. To the degree that game species are disturbed by NorthMet Project Proposed Action-related noise, they could choose to avoid this portion of the Superior National Forest, leading to reduced hunting opportunities in these areas. However, the area affected by noise comprises approximately 0.2 percent of the more than 3 million acres of the Superior National Forest. Species displaced by noise are likely to remain in surrounding areas of the Superior National Forest; overall opportunities for hunting and wildlife viewing on public lands in the region are not expected to change substantially.

Excluding effects related to noise, fisheries, air quality, and other effects described elsewhere in Chapter 5.0, and given the proximity of active and past mining and industrial activity to high-quality recreational activity in the Arrowhead region (such as the BWCAW), there is no evidence that the presence of the NorthMet Project Proposed Action in and of itself would affect the public's ability to hunt, fish, and conduct other recreational activities, or that it would affect the overall recreational experience (apart from specific activities) in the Arrowhead region as a whole.

After closure, PolyMet would retain ownership of the Mine Site and the federal lands, and public access would likely remain restricted.

The Plant Site is located at the former LTVSMC processing plant. It is owned by PolyMet, and it is not open to the public. Entry roads are gated and/or guarded. No recreational activity is permitted at this site, nor would it be permitted during construction, operation, and closure of the NorthMet Project Proposed Action.

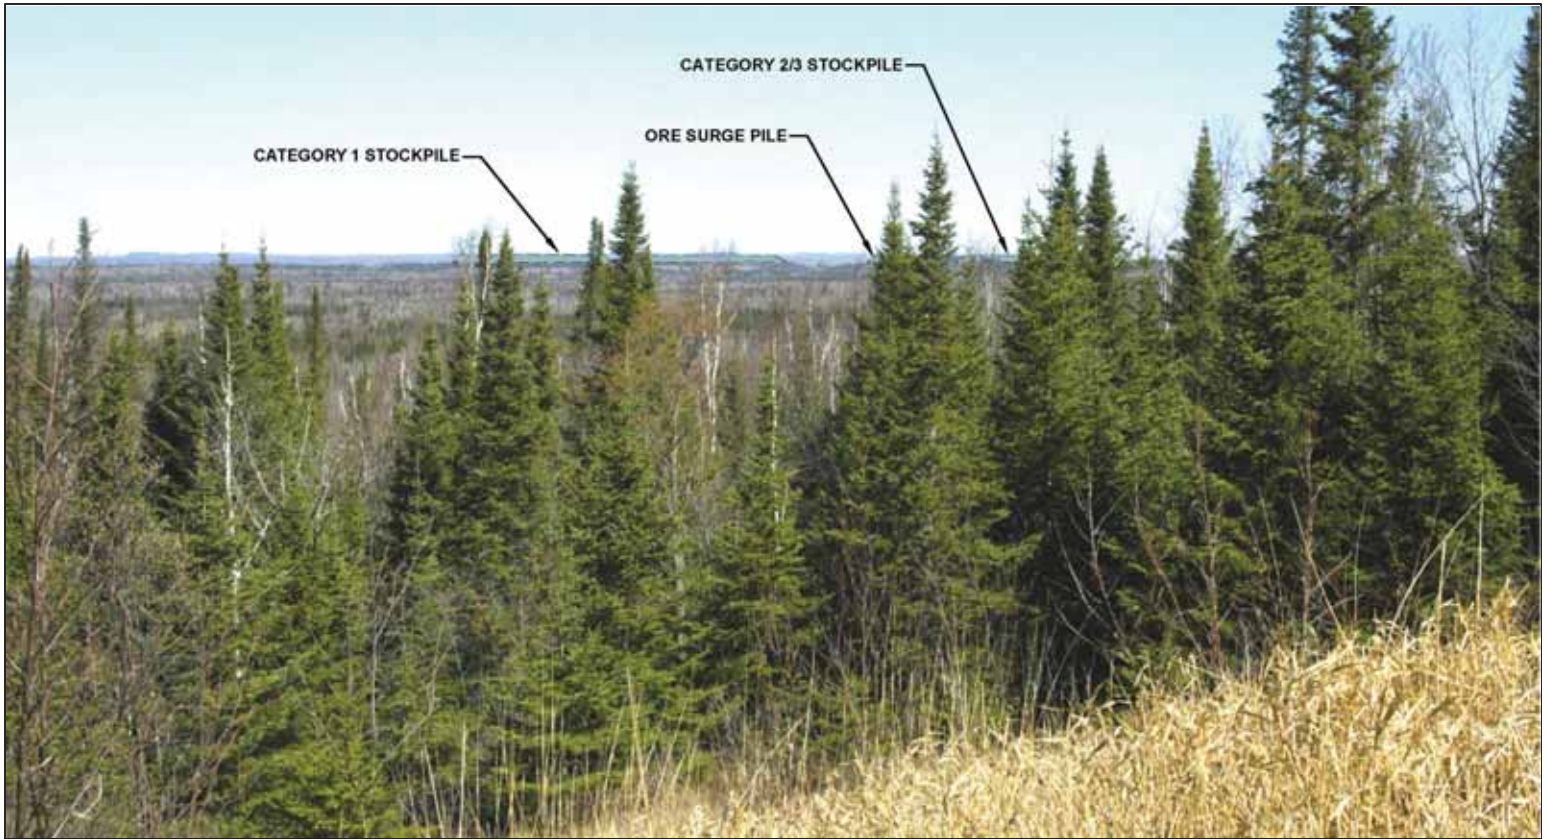

#### **5.2.11.2.2 Visual Resources**

At the Mine Site, the maximum height of the waste rock stockpiles would range from approximately 1,840 ft amsl (Category 1 Stockpile and Category 4 Stockpile) to 1,770 ft amsl (Category 2/3 Stockpile), or a maximum stockpile elevation of 180 to 240 ft above ground surface (PolyMet 2015a). The Giants Range rises sharply to the north of the Mine Site, blocking views of the mine, stockpiles, and safety lights (used when the stockpiles are active) from receptors to the north and west, including the BWCAW.

The Mine Site would be in operation 24 hours per day; therefore, nighttime safety lighting of the active stockpiles would potentially contribute to a localized “glow” effect that could be visible in the night sky. Light sources at the Mine Site would be similar to light levels at other mining projects across the Iron Range. For example, most of the lighting at the Mine Site would be directed downward, such as at the digging area in the case of the shovels and loaders, at the driving surface in the case of the haul trucks and locomotives, and at the dumping area at the stockpiles and the rail transfer hopper. The area around the blasthole drills would be illuminated so the drill can maneuver around the pattern. PolyMet does not propose any further specific mitigation measures with respect to light effects (Kevin Pylka, Pers. Comm., July 25, 2012).

The upland forest surrounding the Mine Site to the east, south, and west would shield ground-level views of the Mine Site (including mine, stockpiles, and associated facilities) in those areas. These forest stands are a mix of coniferous and deciduous forests upwards of 60 ft in height and would provide year-round screening within several miles of the Mine Site (except, perhaps, from portions of the Superior National Forest that are very close to the southern boundary of the Transportation and Utility Corridor).

Viewers at elevated vistas to the south would have clearer views of the Mine Site. Figure 5.2.11-1 simulates the profile of the maximum extent of stockpiles (the largest visible component of the Mine Site) from the Skibo Vista Overlook on the Superior National Forest Scenic Byway, approximately 12 miles south-southwest of the Mine Site. Given the 180- to 240-ft height of the stockpiles, a portion of these would be visible above the treeline. The stockpiles would not project above Giants Range or alter the silhouette of the skyline.

This document is a working document.  
 This document may change over time  
 as a result of new information, further  
 deliberation, or other factors not yet  
 known to the Co-lead Agencies.

**Figure 5.2.11-1**

 NorthMet Mining Project and Land Exchange PFEIS  
 Minnesota

-Page Intentionally Left Blank-

DRAFT

Visual conditions would vary throughout the course of the mine's life. Initially, stockpiles would be less visible until heights exceed the surrounding treeline. The Category 2/3 Stockpile and Category 4 Stockpile would reach their maximum heights in year 11, after which they would be relocated into the East Pit. The Category 1 Stockpile would reach its maximum and permanent height in year 12 (excluding the cover material placed over the stockpile at mine closure). The height, shape, and coloring of the stockpiles would vary throughout the life of the mine; however, the coloring of the stockpiles would likely differ from the surrounding landscape, and would likely be more visible during winter months when screening from deciduous trees is at a minimum (although snow cover could tend to make the stockpiles look more like natural landforms). Viewers on elevated terrain to the east, north, or west of the Mine Site would generally have more limited views of the mine and stockpiles, although there could be sporadic direct views of the Mine Site, depending on exact location and vegetative screening.

Mining and associated industrial activities are long-established aspects of the Mesabi Iron Range landscape. The NorthMet Project Proposed Action would introduce visual elements to the landscape that are similar to other active mines in the region, such as the adjacent Northshore Mine. However, these visual disturbances would occur in an area that, as shown in Figure 5.2.11-1, is currently vegetated.

In addition to the new visible components of the Mine Site and Plant Site (see below), mine construction, operations, and closure would likely generate some visible diesel exhaust and fugitive dust emissions from mine vehicles. Construction and closure emissions would likely be difficult to discern from the Skibo Vista Overlook and other distant viewpoints (see Section 5.2.7 for more details on anticipated emissions). As with the mine facilities themselves, construction emissions would generally be difficult to see from closer viewpoints due to the screening effect of terrain and vegetation.

Evaluations of visual conditions are subjective, and are based in part on individual preferences. Many viewers consider any substantial disturbance of the existing landscape to be undesirable, but some viewers find industrial sites visually compelling. While much of northeast Minnesota's recreation and tourist economy is based on high-quality wildlife, wilderness, and vegetation, there are distinct mine-related tourism resources. The Low SIO of the federal lands associated with the Mine Site indicates that the Mine Site is an area where the USFS has determined that evidence of management activities may dominate the view.

Following the completion of the mining activities, the PolyMet reclamation plan would remove all buildings and facilities at the Mine Site, and would revegetate disturbed areas with an approved vegetation mix. The Category 1 Stockpile would remain in place, and would also be vegetated, to the degree possible. This structure would be noticeable above the treeline, especially in winter, as shown in Figure 5.2.11-1. However, other similar stockpiles are found throughout the region. Over time, this feature would take on the appearance of a vegetated hill, and would blend in with the overall landscape.

No substantial changes are anticipated to the visual character of the Plant Site during NorthMet Project Proposed Action operations. The NorthMet Project Proposed Action would use, update, and expand existing infrastructure at the former LTVSMC processing plant, including an expanded Tailings Basin, additional hydrometallurgical processing facilities, and refurbished mill buildings. Figure 5.2.11-2 shows the current view of the Plant Site from Skibo Overlook. New structures constructed as a result of the NorthMet Project Proposed Action would not be

visible from the overlook. During operations, steam plumes from the Plant Site would be visible under certain conditions, particularly from distant viewpoints such as Skibo Vista. To the degree that existing processing buildings are refurbished or removed (as appropriate), the NorthMet Project area would create the appearance of an active, maintained industrial site, rather than the current dilapidated appearance.

The Tailings Basin is visible to rural residences on County Road 358, located approximately 1 mile to the north of the Plant Site. The NorthMet Project Proposed Action would raise the elevation of Cells 1E and 2E to approximately the same elevation as the existing Cell 2W. The hydrometallurgical residue cells would raise the elevation on the southern portion of Cell 2W by about 40 ft. These changes would not be out of character with the existing Tailings Basin, although the low silhouette of the Tailings Basin on the southern horizon would be noticeably expanded.

Through the closure process, all buildings and facilities at the Plant Site would be removed. At-grade (or below-grade) slabs and foundations would remain and would be covered with surface overburden. Most structures would be removed within three years of the start of closure, except for water treatment facilities necessary to maintain post-closure water quality standards. The Plant Site would be revegetated and seeded to promote a self-sustaining community of regionally-appropriate vegetation. As a result, the visual appearance of the Plant Site during and following closure would evolve rapidly from the operations-phase industrial character to a vegetated area that progressively becomes indistinguishable from adjacent vegetated areas.

### **5.2.11.3 NorthMet Project No Action Alternative**

#### **5.2.11.3.1 Recreation**

Under the NorthMet Project No Action Alternative, the NorthMet Project Proposed Action would not be developed. The Mine Site would remain unchanged, and the USFS would continue to retain surface rights to the federal lands that comprise portions of the Mine Site. Given other private ownership (e.g., the Transportation and Utility Corridor), the federal lands would remain generally inaccessible to the public. There would be no direct or indirect effects on recreational activities at the Mine Site or the region's surrounding recreational resources. Under the NorthMet Project No Action Alternative, the NorthMet Project Proposed Action would not be developed, and the Plant Site would remain off-limits to the public for recreation or other uses.

#### **5.2.11.3.2 Visual Resources**

Under the NorthMet Project No Action Alternative, the NorthMet Project Proposed Action would not be developed, and would retain the Low SIO assigned by USFS. The Mine Site would remain unchanged, and there would be no effects on visual resources at the Mine Site. Under the NorthMet Project No Action Alternative, the NorthMet Project Proposed Action would not be developed. The former LTVSMC process facility would be reclaimed, including building removal, in accordance with a separate closure plan. Reclamation activities could create a short-term disruption of the visual landscape, while long-term effects would be to reduce the developed nature of the site sooner than under the NorthMet Project Proposed Action.

## 1 **5.2.12 Wilderness and Other Special Designation Areas**

2 Designations such as Wilderness or RNAs emphasize higher restrictions on human activity and  
3 access, while other designations, such as historic landmarks or scenic byways, emphasize  
4 management that seeks to enhance public enjoyment of certain spaces. Evaluation of the effects  
5 on each type of designation considered how each set of characteristics or management objectives  
6 would be changed by the NorthMet Project Proposed Action or the project alternatives. Potential  
7 effects could occur due to mining activity or due to changes in other human activity resulting  
8 from mining activity. No specific issues related to wilderness or special designations area were  
9 identified during public scoping. As discussed in Section 4.2.12, for the purposes of this analysis,  
10 the term “wilderness” is defined by the Wilderness Act of 1964 (Public Law 88-577) (16 USC §  
11 1131-1136). In its planning, management, and monitoring, the USFS identifies four  
12 characteristics of wilderness, as defined in the Wilderness Act: Untrammeled, Undeveloped,  
13 Natural, and Solitude or a Primitive and Unconfined Type of Recreation.

### 14 **Summary**

15 The NorthMet Project Proposed Action would have no direct effects on wilderness or special  
16 designation areas. Air quality and water quality in these areas would be virtually unchanged from  
17 existing conditions; distance from activities associated with the NorthMet Project Proposed  
18 Action would leave ambient noise levels also unchanged. The absence of these direct effects  
19 means that there would be no indirect effects on wildlife, vegetation, or aquatic species. There  
20 could be a minimal effect on the Skibo Vista Scenic Overlook along the Superior National Forest  
21 Scenic Byway, and therefore an associated indirect effect on recreation.

### 22 **5.2.12.1 Methodology and Evaluation Criteria**

23 This section uses data presented in Section 4.2.12 for all wilderness or special designation areas  
24 (including state parks) within a 25-mile radius of the NorthMet Project area. While no direct  
25 effects on wilderness character are anticipated due to changes in air quality, water quality or  
26 noise, recreation opportunities could be indirectly affected because of a small change in visual  
27 character.

28 For land that is or would be controlled by the USFS, the recreation evaluation criteria of the ROS  
29 system were used to determine indirect project effects (see Section 5.2.11.1.1).

### 30 **5.2.12.2 NorthMet Project Proposed Action**

#### 31 **5.2.12.2.1 Federally Managed Areas**

32 Table 5.2.12-1 lists the federally managed wilderness and other special designation areas within  
33 or adjacent to the NorthMet Project area and indicates significant features that would have the  
34 most bearing on the potential effects of the NorthMet Project Proposed Action. Isle Royale  
35 National Park is outside of the study area for evaluation of Wilderness and Other Special  
36 Designation; however, the visibility analyses in Section 5.2.7.2.2 do include Isle Royale National  
37 Park.

38 **Table 5.2.12-1 Federally Managed Wilderness and Other Special Designation Areas located**  
 39 **within or Adjacent to the NorthMet Project Area**

| <b>Special Designation Area</b>       | <b>Distance (miles) to the NorthMet Project Area</b> | <b>Significant Feature</b>        |
|---------------------------------------|------------------------------------------------------|-----------------------------------|
| Boundary Waters Canoe Area Wilderness | 25                                                   | Laurentian Divide                 |
| Voyageurs National Park               | 50                                                   | Laurentian Divide                 |
| <b>Research Natural Areas</b>         |                                                      |                                   |
| Big Lake-Seven Beavers cRNA           | 12                                                   | Watershed, topography, vegetation |
| Keeley Creek RNA                      | 25                                                   | Watershed, topography, vegetation |
| Dragon Lake cRNA                      | 25                                                   | Watershed, topography, vegetation |
| <b>Unique Biological Areas</b>        |                                                      |                                   |
| Little Isabella River UBA             | 25                                                   | Watershed, topography, vegetation |
| Harris Lake National Natural Landmark | 20                                                   | Watershed, topography, vegetation |
| <b>National Historic Landmark</b>     |                                                      |                                   |
| Soudan Iron Mine                      | 18                                                   | Topography, vegetation            |
| <b>National Recreation Trail</b>      |                                                      |                                   |
| Taconite State Trail                  | 15-17                                                | Topography, vegetation            |

40 The table shows that all of the federally managed areas would be well-removed from activities  
 41 related to the NorthMet Project Proposed Action, and generally would be screened by  
 42 intervening topography and vegetation.

43 Effects from the NorthMet Project Proposed Action associated with Class I Increment, visibility,  
 44 and sulfur dioxide effects on flora and fauna would be all well below their respective  
 45 significance levels in all Class I areas, including the BWCAW and Voyageurs National Park. In  
 46 addition, all sulfur dioxide and sulfur deposition relating to terrestrial and aquatic settings would  
 47 be well below “green light” significance levels in these areas. Total nitrogen deposition effects  
 48 approach their significance levels at the BWCAW (see Section 5.2.7.2.2).

49 Due to the presence of the Laurentian Divide, there would be no direct effects on waters of the  
 50 BWCAW or Voyageurs National Park. The NorthMet Project area is in the Lake Superior Basin,  
 51 while these two Class I areas are to the northeast of the Laurentian Divide where streams and  
 52 rivers flow to the Hudson Bay Basin.

53 As described in Section 5.2.8, daytime noise standards for sensitive receptors would not be  
 54 reached beyond 0.8 mile from the Mine Site and 0.5 mile from the Plant Site. The nighttime  
 55 noise standards would not be exceeded beyond 2.3 miles from the Mine Site and 1.5 miles from  
 56 the Plant Site. The BWCAW and Voyageurs National Park, as well as the rest of the specially  
 57 designated areas within 25 miles of the NorthMet Project area are all located at distances much  
 58 greater than these ranges and so would not be expected to be directly affected by NorthMet  
 59 Project Proposed Action-related noise. Nighttime views from the BWCAW toward the NorthMet  
 60 Project area and nearby towns are such that light from the NorthMet Project Proposed Action  
 61 would be indistinguishable from other sources of illumination.

62 The RNAs, cRNAs, and UBAs are also in watersheds not affected by the NorthMet Project  
 63 Proposed Action so there would be no direct or indirect effects on surface water or groundwater  
 64 in these areas. Topography and vegetation again screen these areas from view of the NorthMet  
 65 Project Proposed Action-related activities so there are no direct effects on visual resources or  
 66 indirect effects on recreation.

67 By virtue of distance, as well as topography and vegetation, the Taconite State Trail would  
 68 experience neither direct nor indirect effects from the NorthMet Project Proposed Action.

69 By virtue of distance, topography, watershed, or vegetation, none of the four characteristics of  
 70 Wilderness defined above (Untrammelled, Undeveloped, Natural, and Solitude or a Primitive and  
 71 Unconfined Type of Recreation) would be affected by the NorthMet Project Proposed Action.

72 **5.2.12.2.2 State-Managed Areas**

73 Table 5.2.12-2 shows that all of the state-managed wilderness and other special designation areas  
 74 would be well-removed from activities related to the NorthMet Project Proposed Action and  
 75 generally would be screened by intervening topography and vegetation.

76 **Table 5.2.12-2 State-Managed Wilderness and Other Special Designation Areas located**  
 77 **within or Adjacent to the NorthMet Project Area**

| Special Designation Area              | Distance (miles) to the NorthMet Project Area | Significant Feature               |
|---------------------------------------|-----------------------------------------------|-----------------------------------|
| Boundary Waters Canoe Area Wilderness | 25                                            | Laurentian Divide                 |
| State Parks                           |                                               |                                   |
| Soudan Underground Mine State Park    | 18                                            | Watershed, topography, vegetation |
| Lake Vermilion State Park             | 16                                            | Watershed, topography, vegetation |
| Iron Range Off-Highway State Park     | 11                                            | Watershed, topography, vegetation |
| Bear Head Lake State Park             | 17                                            | Watershed, topography, vegetation |
| National Historic Landmark            |                                               |                                   |
| Soudan Iron Mine                      | 18                                            | Topography, vegetation            |
| National Scenic Byway                 |                                               |                                   |
| Superior National Forest Scenic Byway | 9                                             | Topography, vegetation            |

78 All of the state parks have been shown to be in areas where predicted concentrations would be  
 79 below secondary air standards that are designed to protect public welfare, including decreased  
 80 visibility and damage to animals, crops, and vegetation. None of the state parks are within  
 81 watersheds potentially affected by the NorthMet Project Proposed Action, so there would be  
 82 neither direct effects on water quality nor indirect effects on aquatic species or wetlands.

83 Topography and vegetation screen the parks from view of the activities within NorthMet Project  
 84 area, so there would be no direct effects on visual resources and no indirect effects on recreation.

85 The Superior National Forest Scenic Byway is at a distance where it would be unaffected by  
 86 NorthMet Project Proposed Action-related noise. Similar to other specially designated resources,  
 87 there would be no direct or indirect effects due to air quality or water quality (i.e., visibility of  
 88 waters potentially affected by the NorthMet Project Proposed Action). Most of the Byway is  
 89 screened from view of the NorthMet Project Proposed Action by topography and vegetation.  
 90 However, from Skibo Vista Scenic Overlook, which is approximately 12 miles south-southwest  
 91 of the Mine Site, a portion of the stockpiles would be visible above the treeline. This direct effect  
 92 would also mean a potentially small indirect effect on recreation.

93 By virtue of distance, topography, watershed, or vegetation, none of the four characteristics of  
 94 Wilderness defined above (Untrammelled, Undeveloped, Natural, and Solitude or a Primitive and  
 95 Unconfined Type of Recreation) would be affected by the NorthMet Project Proposed Action.

96 **5.2.12.3 NorthMet Project No Action Alternative**

97 Under the NorthMet Project No Action Alternative, the NorthMet Project Proposed Action  
98 would not be developed. The NorthMet Project No Action Alternative presents no anticipated  
99 effect on the BWCAW, Voyageurs National Park, established and candidate RNAs, UBAs,  
100 National Historic Landmarks, the Superior National Forest Scenic Byway, and a National  
101 Recreation Trail, as the Mine Site and portions of the federal lands would continue to be  
102 managed in the same way they have been.

DRAFT

1 **5.2.13 Hazardous Materials**

2 Issues relating to the presence of hazardous materials or waste may include the accidental release  
3 of these materials during transportation, storage, handling, and/or use at the NorthMet Project  
4 area and any resulting potential effects on the environment. Environmental resources that could  
5 potentially be affected by hazardous materials and hazardous waste if they are accidentally  
6 released include: air, water, soil, and ecological resources. The APE therefore corresponds to the  
7 areas defined for each specific resource.

8 The NorthMet Project Proposed Action would use, or generate as waste, the following hazardous  
9 materials (Barr 2007d; Kevin Pylka, PolyMet, Pers. Comm., October 19, 2011; Kevin Pylka,  
10 PolyMet, Pers. Comm., May 11, 2012):

- 11 • Fuels, equipment maintenance products, and solvents – diesel fuel, gasoline, oils, grease,  
12 lubricants, anti-freeze, solvents, and lead-acid batteries used for equipment operation and  
13 maintenance;
- 14 • Plant reagents – sodium hydrosulfide, sodium hydroxide, acids, flocculants, and antiscalants  
15 used in processing plant applications;
- 16 • Mine Site WWTF chemicals – calcium hydroxide (hydrated lime), sodium metasilicate,  
17 ferric chloride, sodium hydroxide, polymer flocculent, carbon dioxide liquid, citric acid, and  
18 sodium hypochlorite;
- 19 • Plant Site WWTP chemicals – potassium permanganate, antiscalant, carbon dioxide liquid,  
20 and calcium hydroxide (hydrated lime);
- 21 • Blasting agents – ANFO, emulsions, emulsion blends (a blend of ANFO and emulsion),  
22 blasting caps, initiators and fuses, and other high explosives used in blasting; and
- 23 • Other materials – assay chemicals, and other by-products characterized as hazardous waste.

24 The MPCA has determined that the hydrometallurgical residue is not hazardous by legal  
25 definition under RCRA. Mishandling of hazardous materials or wastes could result in spills,  
26 accidental release, or discharge into the environment, which could cause effects on workers,  
27 waters of the state, or the general public. Mitigation measures to prevent releases in  
28 transportation, storage, and handling or use of these materials are described in several hazardous  
29 material management plans necessary to comply with various regulatory requirements for the  
30 NorthMet Project Proposed Action. The following sections present the methodology and criteria  
31 used to estimate the risks to the public and environment from the use of hazardous materials and  
32 the generation of hazardous waste during the construction, operation, and closure phases of the  
33 NorthMet Project Proposed Action. The presentation is broken down into the major activities of  
34 transportation, storage, and handling and use.

35 **Summary**

36 Materials defined as hazardous are a routine part of mining and ore processing. Their handling,  
37 storage, and disposal are regulated by a number of state and federal laws. Adherence to these  
38 would limit the potential for off-site effects on only the transport of large quantities of hazardous  
39 materials. Transport routes have been defined that limit the potential for effects on population  
40 centers and sensitive resources. Given overall Project design and operational commitments, there

41 would be no significant adverse effects from the proposed use or generation of hazardous wastes  
42 by the NorthMet Project Proposed Action.

### 43 **5.2.13.1 Evaluation Criteria**

44 Several criteria are generally used in federal and State of Minnesota regulations and statutes to  
45 define the effects from an accidental spill, release, or discharge of contaminants or hazardous  
46 material or waste to the environment. The basic principle of these criteria is the protection of  
47 people and the environment. Based on this principle, the NorthMet Project Proposed Action  
48 would have an environmental effect if the following were to occur:

- 49 • A spill, release, or discharge of any hazardous material or hazardous waste during  
50 transportation that, if not recovered in a timely manner, could cause pollution of waters of the  
51 state, or other harm to the environment or to the public;
- 52 • A spill, release, or discharge of any hazardous material or hazardous waste during handling  
53 or use, which could cause pollution of waters of the state, or other harm to the environment  
54 or to the public;
- 55 • Hazardous emissions from handling of any hazardous materials or hazardous waste that have  
56 the potential to cause harm to the public or the environment; and
- 57 • A spill, release, or discharge from on-site storage facilities exceeding the volumes of the  
58 primary and secondary containment structures, and which could not be recovered in a timely  
59 manner, and thus pollute waters of the state or cause other harm to the environment or to the  
60 public.

### 61 **5.2.13.2 NorthMet Project Proposed Action**

62 Federal and State of Minnesota regulations establish management and reporting requirements for  
63 hazardous materials. Based on current design, applicable administrative rules and statutes  
64 include the following:

- 65 • *Minnesota Statute* 115.061 – Duty to Notify and Avoid Water Pollution (*Minnesota Statutes*,  
66 chapter 115, Water Pollution Control; Sanitary Districts);
- 67 • USEPA 40 CFR 302 – Designation, Reportable Quantities, and Notification, Section 6 –  
68 Notification Requirements (USEPA 40 CFR 300–399, Superfund; Emergency Planning;  
69 Community Right-to-Know Programs);
- 70 • USEPA 40 CFR 355 – Emergency Planning and Notification, Subpart C – Emergency  
71 Release Notification (USEPA 40 CFR 300–399, Superfund; Emergency Planning;  
72 Community Right-to-Know Programs);
- 73 • USEPA 40 CFR 355–372 – EPCRA (USEPA 40 CFR 300–399, Superfund; Emergency  
74 Planning; Community Right-to-Know Programs);
- 75 • USEPA 40 CFR 112 – Oil Pollution Prevention (USEPA 40 CFR 100–149, Water  
76 Programs);
- 77 • USEPA 40 CFR 68 – Chemical Accident Prevention Provisions (USEPA 40 CFR 70–99, Air  
78 Programs II);

- 79 • USEPA Clean Air Act, Section 112(b) – Hazardous Air Pollutants (42 USC chapter 85, Air  
80 Pollution Prevention and Control);
- 81 • OSHA 29 CFR 1910.120 – Hazardous Waste Operations and Emergency Response (OSHA  
82 29 CFR 1900–1910);
- 83 • DOT 49 CFR 100–180 – Hazardous Materials Transportation (Hazardous Materials  
84 Transportation 49 CFR 100–180, Chapter I, Pipeline and Hazardous Materials Safety  
85 Administration, DOT);
- 86 • MSHA Rule 30 CFR Part 47 Hazard Communication (Mine Safety Administration 30 CFR  
87 1–199);
- 88 • *Minnesota Statutes*, Chapter 115 and Chapters 115A–115E – Water Pollution Control,  
89 through Oil and Hazardous Substance Discharge Preparedness (*Minnesota Statutes*, chapter  
90 115, Water Pollution Control; Sanitary Districts);
- 91 • *Minnesota Rules*, Chapter 7151 – Aboveground Storage of Liquid Substances (*Minnesota  
92 Rules*, MPCA, chapter 7151);
- 93 • *Minnesota Rules*, Chapters 7045–7048 – Hazardous Waste (*Minnesota Rules*, MPCA,  
94 chapter 7045–7048);
- 95 • *Minnesota Rules*, Chapters 7507 and 7513 – Hazardous Materials (*Minnesota Rules*, MPCA,  
96 chapter 7507–7513);
- 97 • *Minnesota Rules*, Chapter 7035 – Solid Waste (*Minnesota Rules*, MPCA, chapter 7035); and
- 98 • *Minnesota Rules*, Chapter 6132 – Nonferrous Metallic Mineral Mining (*Minnesota Rules*,  
99 Department of Natural Resources, chapter 6132).

100 A list of the larger quantity hazardous materials transported, stored, handled, recycled, or  
101 disposed, and their classifications, that would be associated with the NorthMet Project Proposed  
102 Action construction, operation, and closure is provided in Table 5.2.13-1. The estimated delivery  
103 frequency, volumes, and annual use of these materials are also listed in Table 5.2.13-1.

104 The MPCA reviewed hydrometallurgical residue pilot-testing and analysis data provided by  
105 PolyMet and has established the following statements (Email from Richard Clark [MPCA] to  
106 Lisa Fay [DNR], October 24, 2014):

- 107 1. TCLP testing results of pilot test residues in 2005 and 2009 did not meet the thresholds to be  
108 regulated as a RCRA hazardous waste.
- 109 2. Elimination of the bulk hydrometallurgical mode from the NorthMet Project Proposed  
110 Action since the DEIS would not materially affect the chemical composition of residue  
111 stored in the Hydrometallurgical Residue Facility, and 2005 and 2009 testing results will be  
112 representative of the residue stored in the Hydrometallurgical Residue Facility if the current  
113 Project is approved.
- 114 3. New residue resulting from future hydrometallurgical pilot-testing and/or Phase 2 of the  
115 NorthMet Project Proposed Action should be tested to verify that the residue remains under  
116 RCRA hazardous waste thresholds.

117 **Table 5.2.13-1 Hazardous Materials used during Construction, Operation, and Closure Phases of the NorthMet Project Proposed**  
 118 **Action**

| Material                         | Classifications & Precautions**                                                                                                | Environmental Concern                                                                                                                                                                                   | Storage Capacity                                                                                                           | Deliveries<br>(Estimated Frequency)                         |                             | Annual Use<br>(Est.)                                                                                                               |

| ANFO                             | Explosive 1.1D or 1.5D: Irritant to skin and eyes. May cause nausea if ingested and irritation to nose and throat if ingested. | Harmful to aquatic life at low concentrations.                                                                                                                                                          | No on-site storage. Vendor provided on a daily basis.                                                                      | Vendor/truck                                                | 883,333 lbs/month           | 10,600,000 lbs/year                                                                                                                |
| Booster (solid - cord sensitive) | Explosive 1.1D: Eye irritant. Skin irritant. Inhalation of dust may cause irritation, sneezing or coughing.                    | May cause elevated nitrate levels in water and could affect aquatic animals.                                                                                                                            | No on-site storage. Vendor provided on a daily basis.                                                                      | Vendor/truck                                                | 1,555/month                 | 18,650/year                                                                                                                        |
| Emulsion                         | Explosive 1.5D: Eye irritant. May be harmful if ingested. Inhalation may cause dizziness, nausea, or intestinal upset.         | May cause elevated nitrate levels in water and could affect aquatic animals.                                                                                                                            | No on-site storage. Vendor provided on a daily basis.                                                                      | Vendor/truck                                                | 387,500 lbs/month           | 4,650,000 lbs/year                                                                                                                 |
| Diesel fuel                      | Flammable: Continued exposure to vapors can irritate eyes and lungs. Potentially fatal if ingested.                            | Any spill or release may cause adsorption to sediment and soil and may cause a visible sheen or deposit of a sludge or emulsion if released to surface waters creating a hazard for plants and animals. | <u>Mine:</u><br>3 - 12,000 gal<br>or<br>2 - 20,000 gal<br><u>Locomotives:</u><br>15,000 gal<br><u>Plant:</u><br>12,000 gal | Tanker truck (volume/<br>tanker truck =<br>5,500-9,000 gal) | 74 tanker truck loads/month | <u>Mine:</u><br>5,910,000 gal/year<br><u>Plant:</u><br>Uncertain, but relatively minor<br><u>Locomotives:</u><br>473,040 gal/year  |
| Grease (385 lbs/55-gallon drum)  | Mild skin irritant, ingestion may cause discomfort.                                                                            | Spill or release may cause adsorption to sediment and soil and may cause a visible sheen or deposit of a sludge or emulsion if released to surface waters creating a hazard for plants and animals.     | Existing bulk storage at Area 1 and Area 2 Shops.                                                                          | 55-gal drums                                                | <1 truck/month              | <u>Mine:</u><br>Unknown<br><u>Plant:</u><br>Uncertain, but relatively minor<br><u>Locomotives:</u><br>16 lb/year – each locomotive |

|                                                       |                                                                                                                    |                                                                                                                                                                |                                   | Means                                            | Approximate Rate   |                   |
| Lime                                                  | Eye and skin irritant; harmful if swallowed. Avoid breathing vapor or dust.                                        | Possibly hazardous in the short term. Degradation products are not likely; however, long-term degradation products may arise.                                  | Bulk - lime silo                  | Freight truck (20 – 25 t/truck)                  | 15 loads/month     | 5,181 t/year      |
| Magnesium hydroxide                                   | Harmful if swallowed; eye, skin, and respiratory irritant.                                                         | Possibly hazardous in the short term. Degradation products are not likely; however, long-term degradation products may arise.                                  | Storage tank                      | Bulk rail car (65 – 104 t/rail car)              | 3 tank cars/month  | 3,674 t/year      |
| Grinding metals (metal alloy grinding rods and balls) | Harmful if swallowed; eye and respiratory irritant, if fine particles.                                             | Airborne particulates may cause some harm to environment dependent on concentrations.                                                                          | None required                     | Bulk rail car (100 t/rail car)                   | 13 rail cars/month | 15,600 t/year     |
| Flotation activators (copper sulfate)                 | Harmful if swallowed; eye and respiratory irritant.                                                                | Toxic to fish and plants if released into waters.                                                                                                              | 9,200-gal activator storage tank  | Reuse from Oxidation Autoclave                   | Not applicable     | 650 t/year        |
| Ferric chloride (35%)                                 | Very hazardous if ingested; corrosive to eyes and skin; respiratory irritant.                                      | Mutagen; harmful to fish and invertebrates; reproductive effects, low potential for bio-accumulation; no information regarding environmental fate or toxicity. | 6,000- and 1,000-gal storage tank | Tanker truck (typically <3,000 gal/tanker truck) | 1,200 gal/month    | 14,400 gal/year   |
| Potassium permanganate                                | Eye and skin irritant; respiratory irritant.                                                                       | Mutagen; ecological information not available.                                                                                                                 | Bulk (dry)                        | Freight truck                                    | 1,300 lbs/month    | 16,000 lbs/year   |
| Liquid carbon dioxide                                 | Gas is an asphyxiant; prolonged skin or eye contact to gas, liquid or solid (crystals) may cause severe frostbite. | No adverse effects; carbon dioxide does not contain Class I or II ozone depleting chemicals.                                                                   | Bulk (liquefied gas)              | Tanker (cylinder) truck                          | 105 t/month        | 1250 t/year       |

119 Note: t = short tons; equal to 2,000 lbs.

120 The United Nations hazard classification system for classifying explosive materials and explosive components is recognized internationally and is used universally by the United  
121 States Department of Defense, United States Department of Energy (USDOE) contractors, and the DOT. UN numbers however, are different from the hazard class and division  
122 designations used by the DOT.  
123 Hazard Classification 1.1D and 1.5D: 1.1 is a Hazard Class division for Class 1 (Explosives) and is defined as a Mass Detonation Hazard. It is expected that if one item in a  
124 container or pallet inadvertently detonates, the explosion will sympathetically detonate the surrounding items. The explosion could propagate to all or the majority of the items

125 stored together, causing a mass detonation. There will also be fragments from the item's casing and/or structures in the blast area. Hazard Class division 1.5 is an Explosive  
126 substance, very insensitive (with a mass explosion hazard).  
127 The "D" is the Class 1 Compatibility Group defined as the secondary detonating explosive substance or black powder or article containing a secondary detonating explosive  
128 substance, in each case without means of initiation and without a propelling charge, or article containing a primary explosive substance and containing two or more effective  
129 protective features (UNO 2012).  
130 \*\*Precautions are described as indicated by NIOSH (2012), or those described in chemical-specific Material Safety Data Sheets (MSDSs) (Montana Refining Company 2011),  
131 (Dow 2009), (EDS 2009a), (CSCC 2005), (EDS 2009b), (Praxair Technology 2009b), (Flottec 2009), (Martin Marietta Materials 2007), (Western Lime Corporation 2009),  
132 (AluChem 2010), (Old Bridge Chemicals 1999), (H-Valley Chemical 2006), (ClearTech Industries 2010), and (Praxair Technology 2009a).  
133 Material, Storage Capacity, Delivery Means, Delivery Approximate Rate, and Annual Use Estimate (Kevin Pylka, PolyMet, Pers. Comm., October 19, 2011), (Kevin Pylka,  
134 PolyMet, Pers. Comm., May 11, 2012)).

DRAFT

135 **5.2.13.2.1 Transportation**

136 All hazardous materials would be transported by commercial carriers in accordance with state  
137 and federal hazardous material shipping requirements. Such carriers would be licensed and  
138 inspected by the Minnesota DOT. Tanker trucks would possess a Certificate of Compliance  
139 issued by the Minnesota Motor Vehicle Division. These permits, licenses, and certificates would  
140 be the responsibility of the carrier. Federal regulations (49 CFR) require that all shipments of  
141 hazardous materials be properly identified and placarded. Shipping documents must be  
142 accessible and include MSDSs that describe the hazardous material, immediate health hazards,  
143 fire and explosion risks, immediate precautions, fire-fighting information, procedures for  
144 handling leaks or spills, first aid measures, and emergency response telephone numbers.

145 Hazardous waste would also be transported from the Mine Site and Plant Site for proper  
146 disposal. Transportation of these wastes would require compliance with state and federal  
147 regulations that include requirements for hazardous waste manifests with the shipments, labeling,  
148 and/or use of placards, and emergency information. PolyMet employees would be trained to  
149 manage all wastes in accordance with their specific job duties. Transportation of hazardous waste  
150 would be conducted by vendors also licensed and trained to manage hazardous waste.

151 As identified in Table 5.2.13-1, trucks would be used to transport a variety of hazardous  
152 materials to the Mine Site and Plant Site. Shipments of hazardous materials would originate from  
153 a number of locations. The risk of accidental truck spills was evaluated using two representative  
154 hazardous materials, diesel fuel and PAX, due to the relatively large number of deliveries and  
155 health risks associated with these materials (Rhyne 1994). Approximately 74 tanker truck loads  
156 of diesel fuel and 5 truckloads of PAX would be delivered monthly. These quantities would  
157 amount to approximately 17,800 and 1,200 shipments of diesel fuel and PAX, respectively,  
158 based on 20 years of estimated mine life.

159 For this evaluation, materials were assumed to be shipped from Duluth. These materials would  
160 be transported approximately 60 miles along State Highway 53 (four-lane divided highway) from  
161 Duluth to Eveleth, and then approximately 20 miles along State Highways 37 and 135 (two-lane  
162 highways) from Eveleth to the North Gate access road to the site. This route would take the  
163 materials through the towns of Duluth, Twig, Independence, Canyon, Cotton, Central Lakes,  
164 Eveleth, Gilbert, Biwabik, and Pineville and across the Cloquet, Whiteface, St Louis, and  
165 Embarrass rivers and Paleface Creek. These state highways already provide transportation routes  
166 for freight that includes hazardous materials and waste. St. Louis County Emergency Services  
167 are available for response to incidents associated with hazardous materials due to the current  
168 transport of these materials from existing businesses that use hazardous materials or generate  
169 hazardous waste within their operations. Emergency response services vary from medical rescue  
170 and ambulance services to fire-fighting and local HazMat-trained response teams stationed in  
171 various cities or districts along the defined transportation route. The locations of emergency  
172 response services are identified in multiple sectors within the county as defined by the St. Louis  
173 County Hazard Mitigation Plan prepared by the St. Louis County Emergency Management  
174 division of the St Louis County Sheriff's Office (St. Louis County 2013). The County HazMat  
175 Response Team is stationed in Duluth.

176 The effect of an accidental release would depend on the location in relation to population, local  
177 activities, the quantity released, environmental factors, and the nature of the released material.  
178 The probability of an accidental release of the representative hazardous materials described  
179 above during transportation was calculated using the Federal Highway Administration truck  
180 accident statistics model (Rhyne 1994) as presented in Table 5.2.13-2. The definition of  
181 hazardous materials, per the Minnesota Hazardous Materials and Uniform HazMat Registration  
182 Program is, “a substance or material capable of posing unreasonable risk to health, safety, and  
183 property when transported in commerce, as determined by the US Secretary of Transportation.”  
184 According to these statistics, the average rate of truck accidents for transport along a rural  
185 interstate highway, such as State Highway 53, is 0.64 per million miles traveled. For rural two-  
186 lane highways, such as State Highways 37 and 135, the average truck accident rate is 2.19  
187 accidents per million miles traveled.

DRAFT

188 **Table 5.2.13-2 Release Probability of Representative Materials Transported during Construction, Operation, and Closure Phases**  
 189 **of the NorthMet Project Proposed Action**

| Material Transported | Rural State/Interstate Highway (four lane) |                       |                                          |                                |                                              |                             | Rural State Highway (two lane) |                       |                                          |                                |                                              |                             |                                                               |

190 Source: Federal Highway Administration truck accident statistics model (Rhyne 1994).

191 The probability of a release or spill was based on accident statistics for liquid tankers carrying  
192 hazardous materials. The Federal Highway Administration statistics indicate that on average,  
193 18.8 percent of the total accidents involving liquid tankers carrying hazardous materials resulted  
194 in a spill or release.

195 Using the accident and liquid tanker spill statistics, the evaluation indicates that the probability  
196 for an accidental release of liquids under truck transport during the life of the NorthMet Project  
197 Proposed Action is less than one spill accident for each of the representative materials  
198 considered. The release probability indicates there is a 1.8 percent probability of an accident  
199 resulting in a release of PAX, and a 27 percent probability of an accident resulting in a release of  
200 diesel fuel that could occur over the entire 20-year life of the NorthMet Project Proposed Action.  
201 The higher probability of a diesel fuel accident is due to the greater expected number of diesel  
202 fuel deliveries to the site.

203 The odds of a potential release of hazardous materials during a transportation accident would  
204 incrementally increase if the other shipments listed in Table 5.2.13-1 were included. An  
205 accidental release could range from a minor oil spill at the Mine Site and Plant Site, where  
206 cleanup equipment would be readily available, to a severe spill during transport involving a large  
207 release of diesel fuel or other hazardous material, where emergency cleanup equipment would  
208 not be readily available. Some of the chemicals could have immediate adverse effects on water  
209 quality and aquatic resources if a spill were to enter a surface water body. Considering the  
210 overall risk of an accident involving a spill, and the anticipated transport routes, the probability  
211 of a spill into a waterway would be moderate. An alternative transportation route, shorter by  
212 about 17 miles, was evaluated but rejected because of its close proximity to water bodies such as  
213 Wild Rice and Island lakes. The transportation route selected for this evaluation is longer, but is  
214 farther away from waterbodies, so in the event that an accidental spill or release of materials  
215 occurs, it could be managed in a more timely manner to reduce the likelihood of environmental  
216 harm. A shorter route could be used, but the probability of effect on a water body would be  
217 greater due to the proximity of the waterbodies.

218 A large-scale release of hazardous liquids delivered to the site by tanker truck (9,000-gallon  
219 capacity) or rail car (up to 13,000-gallon capacity)—such as diesel fuel, acid, or other hazardous  
220 materials—could have implications for public health and safety. The location of the release  
221 would again be the primary factor in determining potential effects. As indicated in Table  
222 5.2.13-2, the probability of a release anywhere along a proposed transportation route was  
223 calculated to be low. Review of the Hazmat Intelligence Portal of the U.S. DOT indicates that  
224 the likelihood of a bulk rail incident is 40 percent less than that of a highway incident (PHMSA  
225 2012b). The likelihood of a rail incident, when all incidents are included, is 82 percent less than  
226 that of a highway incident (PHMSA 2012a).

227 In addition to location, the potential harm presented by the material released is a factor in  
228 determining the effect of a release. A qualitative evaluation of the materials to be shipped  
229 indicates that the probability of causing harm is low for most materials. For example, though  
230 ANFO is an explosive, it will only detonate under specific conditions, such as when ignited with  
231 detonators, heat, or a sudden shock wave in a confined space. Caustic soda is corrosive and can  
232 be fatal if ingested or has prolonged contact with the skin; however, in a spill situation,  
233 emergency response would be undertaken to prevent or minimize exposure, such as restricting  
234 site access and immediate containment and removal. In the event of a release during transport,  
235 the commercial transportation company would be responsible for first response and cleanup.

236 Local and regional law enforcement, fire protection, and emergency planning agencies would  
237 also mobilize to secure the site and protect public safety.

238 In the event of an accident involving the release of hazardous material, 49 CFR requires that the  
239 carrier notify local emergency response personnel, the National Response Center (for discharge  
240 of reportable quantities of hazardous materials) (Hazardous Materials Transportation 49 CFR  
241 100–180, Chapter I, Pipeline And Hazardous Materials Safety Administration, DOT). Minnesota  
242 Statutes require notification of the Minnesota State Duty Officer (Minnesota Statutes, chapter  
243 115, Water Pollution Control). PolyMet and its hazardous material handlers and/or DOT-  
244 regulated contractors would be required to comply with these and similar regulatory  
245 requirements, which also stipulate emergency planning and response actions.

#### 246 **5.2.13.2.2 Storage**

247 The approximate capacities of hazardous material storage tanks that would be at the NorthMet  
248 Project area are listed in Table 5.2.13-1. Mobile tanker trucks may be used on site to fuel and  
249 maintain haul trucks, mobile equipment, and locomotives. The number of these trucks and their  
250 capacities would be based on NorthMet Project Proposed Action specifications. Tanks and  
251 vessels would be positioned on approved secondary containment with interior sumps to route  
252 spilled products or process solutions to lined collection areas. In addition, hazardous materials  
253 would be unloaded on an approved containment surface with sumps to route spills to lined  
254 collection areas. Some of the hazardous material storage tanks at the Mine Site would be double-  
255 walled for provision of secondary containment. Mine Site hazardous material storage tanks  
256 without double-walls and Plant Site hazardous material storage tanks would be designed to have  
257 secondary containment sufficient to hold at least 110 percent of the volume of the largest tank in  
258 the containment area. Waste materials such as used motor oil, hazardous waste, and spent  
259 hazardous materials would be managed by PolyMet employees while on-site, and shipped off-  
260 site for recycling or disposal using a DOT-licensed transporter. In addition, fire assay wastes—  
261 including cupels, crucibles, and slag—would be managed by PolyMet employees while on site  
262 and shipped off site for recycling or disposal at a licensed facility using a DOT-licensed  
263 transporter. Certain materials may be stored on-site for a period before shipment. These materials  
264 would be stored in compliance with safety storage requirements as dictated by state and federal  
265 requirements. The storage period would also comply with Minnesota and federal storage timeline  
266 stipulations. All stored wastes would be appropriately labeled and dated for timeline inspection  
267 purposes.

#### 268 **5.2.13.2.3 Handling and Use**

269 Over the life of the NorthMet Project Proposed Action, the probability of minor spills of oils and  
270 lubricants would be relatively high. Releases could occur during operations because of a poor  
271 connection of an oil or hydraulic line, or as the result of equipment failure. Effects of such minor  
272 spills could include contamination of surface water and soil; however, spills of this nature would  
273 likely be small, localized, and contained.

274 Some of these spills may be reportable. In Minnesota, spills or discharges of more than 5 gallons  
275 of petroleum products or any quantity of chemicals or materials, whether accidental or otherwise,  
276 are required by law to be reported to the Minnesota State Duty Officer at the MPCA, by the  
277 person with control of the spill, which, if not recovered, may cause pollution of waters of the  
278 state. The responsible NorthMet Project Proposed Action person is required to recover as rapidly

279 and thoroughly as possible such spilled material, and take immediate action as reasonably  
 280 possible to minimize or abate pollution of waters of the state (*Minnesota Statutes*, section  
 281 115.061, Duty to Notify and Avoid Water Pollution).

282 Emergency release notification requirements under EPCRA (USEPA 40 CFR, chapter 355) exist  
 283 in addition to the release notification requirements of the Comprehensive Environmental  
 284 Response, Compensation, and Liability Act (CERCLA) (USEPA 40 CFR, chapter 302). If the  
 285 NorthMet Project Proposed Action had a release of a CERCLA hazardous substance, it would be  
 286 required to comply with the notification requirements of EPCRA, and the release notification  
 287 requirements of CERCLA. If the reportable quantity of a substance were released within a 24-  
 288 hour period at the NorthMet Project area, and the substance was on the list of extremely  
 289 hazardous substances under EPCRA or the list of CERCLA hazardous substances (USEPA 40  
 290 CFR, chapter 302.4), then PolyMet would be subject to reporting requirements described in 40  
 291 CFR 355.60, 40 CFR 302, and the Emergency Notification Procedures in Minnesota as required  
 292 by Title III of the Superfund Amendments and Reauthorization Act (USEPA 40 CFR, chapters  
 293 300 to 399).

294 The requirements for storage of oils and lubricants, including the requirement for spill  
 295 prevention, control, and countermeasure (SPCC) planning are found in the Oil Pollution  
 296 Prevention Act (USEPA 40 CFR, chapter 112) and MN § 115E (Minnesota Statutes, chapter 115,  
 297 Water Pollution Control; Sanitary Districts). Applicable Minnesota Statutes include: Prevention  
 298 and Response Plans (Section 115E.04), Response Plans for Tank Facilities (Section 115E.045,  
 299 Subdivision 2), and Responses to Releases (Section 115C.03). A list of hazardous material  
 300 management and response plans is presented in Table 5.2.13-3.

301 **Table 5.2.13-3 Hazardous Material Management Plans**

| <b>Plans</b>                           | <b>Applicable Statute/Regulation</b>                                                                             | <b>Materials/Applications</b>                                                                                                                                      |

302

303 The threshold quantity, as defined in 40 CFR 112, for triggering the requirement for  
304 development of a SPCC plan is 1,320 gallons of petroleum products in bulk container storage  
305 greater than 55 gallons. Since the NorthMet Project area would have more than 1,320 but less  
306 than 1,000,000 gallons of oil storage, an SPCC plan would be required under 40 CFR 112. The  
307 primary goal of an SPCC plan is to develop strategies to prevent oil spills from reaching  
308 Minnesota and United States waters. An SPCC plan is thus specific to each facility, providing  
309 persons responsible for planning emergency response site-specific information such as a  
310 description of facilities, storage information, preventative measures, response action, equipment,  
311 and contact information. An SPCC plan must also provide information for routine facility  
312 inspections.

313 To reduce the likelihood of incidental spills of petroleum products, a preliminary SPCC plan has  
314 been prepared for the NorthMet Project Proposed Action. The plan identifies potential  
315 emergencies that may arise during operations or an activity within the NorthMet Project area.  
316 The plan establishes a framework to respond effectively to the identified potential emergencies.

317 The final SPCC plan would include procedures, methods, equipment, and other requirements to  
318 prevent discharges of oil from facilities, and to contain such discharges, should they occur. The  
319 SPCC plan would also contain a detailed, facility-specific description of how the operations  
320 comply with the requirements of the Oil Pollution Prevention regulation (USEPA 40 CFR, Part  
321 112). The SPCC plan would address measures such as secondary containment, facility drainage,  
322 dikes and barriers, sump and collection systems, retention ponds, curbing, tank corrosion  
323 protection systems, liquid level devices, and emergency shut-off or release alarms. The final  
324 SPCC plan must be certified by a Professional Engineer that in their professional judgment the  
325 following are true:

- 326 • The SPCC plan is adequate for the facility;
- 327 • Technical standards have been considered;
- 328 • Inspections and tests are adequate for the facility; and
- 329 • The SPCC plan has been prepared in accordance with good engineering practices, including  
330 consideration of applicable industry practice.

331 A final SPCC plan is not possible for the NorthMet Project Proposed Action until construction  
332 has been completed. However, PolyMet has prepared a preliminary SPCC plan that is compliant  
333 with 40 CFR 112 requirements.

334 The policies and procedures set forth in the SPCC plan, inclusive of PolyMet's Standard  
335 Operating Procedure for Storage Tank Management, would be prepared to comply with  
336 *Minnesota Rules*, Chapter 7151, Aboveground Storage of Liquid Materials.

337 The preliminary SPCC plan would be finalized and certified by a Professional Engineer, as  
338 required, after petroleum storage and handling facilities have been constructed. Based on current  
339 planning information, the final SPCC plan would need to address at least the following areas or  
340 activities involving petroleum and other oils:

- 341 • A truck fueling station;
- 342 • Remote fueling activities (i.e., at the equipment operating location);
- 343 • ASTs;

- 344 • Large-quantity oil-filled equipment;  
345 • Locomotive fueling (at Area 2); and  
346 • A gasoline fueling station (at the main gate).

347 The fueling station would consist of an enclosed building for fueling, including floor drain  
348 sumps and holding tanks for collection of spills. The holding tanks would be cleaned out, as  
349 needed, by a contractor with appropriate certification or license, and the waste would be  
350 transported to a recycling, treatment, or disposal facility. One fueling station would typically be  
351 provided to fuel all mobile equipment with rubber tires (trucks, dumps, front end loaders, dozers,  
352 etc.). This equipment also may be fueled in place by remote fuel tankers. Remote fueling  
353 typically would be conducted for equipment located within the mine pits and at material  
354 stockpiles (e.g., excavators, dozers, and other tracked equipment). Portable spill clean-up kits  
355 would be available at the fueling stations and on the fuel tankers. Standard operating procedures,  
356 including spill response plans, would be prepared and associated training would be conducted for  
357 fueling operations. Equipment would be attended during fueling operations. When possible,  
358 remote fueling would not be performed near sensitive areas, where, if a release were to occur,  
359 surface water could be affected. At final design stage, an updated or final version of the current  
360 SPCC plan would be prepared for the NorthMet Project Proposed Action facilities, to address  
361 specific spill response, cleanup, release notifications, etc. For oil-filled equipment, an appropriate  
362 containment system would be constructed so that discharge from a primary containment system  
363 would not escape the containment system before cleanup occurs. Alternatively, facility  
364 procedures and a contingency plan would be established that define inspections and/or a  
365 monitoring program to detect equipment requiring service or failure, and/or discharge. ASTs  
366 would be located at the truck fueling station where fuel storage would meet secondary  
367 containment standards. The tanks would have a containment dike with membrane, or a concrete  
368 enclosure to contain leaks or spills. As previously indicated, double-walled ASTs would not  
369 require secondary containment.

370 The SPCC documents, along with manufacturer MSDSs, would be available in all areas where  
371 hazardous materials were expected to be used or produced, and at all areas of fuel and lube-oil  
372 storage.

#### 373 **5.2.13.2.4 Emergency Planning and Community Right-to-Know**

374 Management of hazardous materials at the NorthMet Project area would be governed by a  
375 number of interrelated federal, state, and local regulations, as listed in the first part of this  
376 Hazardous Materials Section. The following discusses federal and Minnesota state actions under  
377 EPCRA, including its emergency response-planning activities, Hazardous Chemical Inventory  
378 Reporting (Tier II) requirements, and Toxics Release Inventory (TRI) reporting requirements.  
379 Minnesota's hazardous materials regulations are codified in the *Minnesota Rules*, chapters 7507  
380 and 7513, and in *Minnesota Statutes*, chapter 299K.

381 As required by EPCRA, Minnesota has established the Minnesota Emergency Response  
382 Commission (ERC), an agency within the Minnesota Department of Public Safety, Division of  
383 Homeland Security and Emergency Management. The Minnesota ERC coordinates information  
384 specific to hazardous materials at facilities around the state so that local emergency officials are  
385 able to prepare for emergencies. The Minnesota ERC serves as the repository for the EPCRA  
386 hazardous chemical inventory reports (Tier II reports). Along with the listing of hazardous

387 materials identified on Table 5.2.13-1, PolyMet would prepare and submit Tier II Emergency  
388 and Hazardous Chemical Inventory Report Forms for sodium hydroxide, hydrochloric acid,  
389 sodium hydroxide, sulfuric acid, and SO<sub>2</sub>, and would be subject to reporting additional hazardous  
390 materials or chemicals maintained on-site in quantities greater than the Tier II reporting  
391 thresholds.

392 The Minnesota ERC also collects data from facilities reporting under the federal TRI report  
393 program mandated by SARA Title III, Section 313. The NorthMet Project Proposed Action  
394 would be subject to TRI reporting based on the quantities of sulfuric acid and SO<sub>2</sub> to be  
395 maintained at the NorthMet Project area and could include others depending on actual quantities.

396 Under the federal Pollution Prevention Act of 1990, facilities subject to TRI reporting must also  
397 provide information on the pollution prevention and recycling activities associated with the  
398 reported toxic chemicals. The NorthMet Project Proposed Action would be subject to  
399 Minnesota's Toxic Pollution Prevention Act (Minnesota Statutes, section 115D.07), and PolyMet  
400 would have to prepare a TPPP. The TPPP would describe the facility's processes and operations,  
401 and set objectives for the handling, storage, and disposal or recycling of hazardous materials and  
402 toxic chemicals to eliminate or reduce at the source, the use, generation, or release of toxic  
403 pollutants, hazardous substances, materials, and hazardous wastes.

404 Under the federal CAA Amendments of 1990 Section 112(r), the NorthMet Project Proposed  
405 Action would be subject to the Accidental Release Prevention/Risk Management Plan rule, based  
406 on the projected use of hydrochloric acid and other flammable and toxic substances (42 USC,  
407 chapter 85, Air Pollution Prevention and Control). PolyMet would be required to develop a Risk  
408 Management Program that would include:

- 409 • Hazard assessment and potential effects of an accidental release, accident history, and  
410 evaluation of worst-case and accidental release scenarios;
- 411 • Prevention program including safety precautions, maintenance, monitoring, and training  
412 measures; and
- 413 • Emergency response program detailing emergency health care, training, and procedures for  
414 informing the public and response agencies should an accident occur.

415 The hazardous material management plans include procedures for evacuating personnel,  
416 maintaining safety, cleanup, neutralization activities, emergency contacts, internal and external  
417 notifications to regulatory authorities, and incident documentation. Proper implementation of the  
418 SPCC plan, TPPP, Hazard Communications, Emergency Response Plan, Spill Response Plans,  
419 and the Risk Management Program would minimize the incidents and effects associated with  
420 potential releases of hazardous materials.

421 If present, other hazardous or potentially hazardous materials or wastes would be characterized  
422 and managed per the hazardous materials management plans described in Table 5.2.13-3 above,  
423 and, if applicable, would adhere to the requirements defined in *Minnesota Rules*, chapter 7045,  
424 Hazardous Waste.

425 **5.2.13.3 Potential Mitigation Measures**

426 Mitigation of a hazardous material release would follow the principle of prevention,  
427 minimization, and treatment. Prevention would be achieved when any hazardous material was  
428 avoided, where possible, by replacing it with a substitute material that was not hazardous. To the  
429 extent possible, this has been done; where not possible, precautions to be defined in the TPPP  
430 would be taken to properly manage hazardous materials or substances, and keep the potential  
431 risk of exposure to a minimum. Accidentally released hazardous material would be treated  
432 quickly in accordance with the described plans.

433 In addition, mitigation processes or procedure definitions would be included in the following:

- 434 • Hazardous communication materials, through communications and training programs;
- 435 • Overfill protection procedures;
- 436 • Provision for secondary containment;
- 437 • Establishment of leak detection systems;
- 438 • Preventative inspection and maintenance procedures; and
- 439 • Emergency response plan.

440 These measures would be designed to ensure that accidental releases were prevented or  
441 minimized, and when they did occur, were responded to quickly and properly.

442 Monitoring activities proposed for prevention of incidental releases, mitigation, or quick removal  
443 of the effects, if hazardous materials were released, include the following:

- 444 • Regular inspection and testing of storage containers and facilities;
- 445 • Inspection of vessels for leaks, drips, or loss content of containers;
- 446 • Verification of locks, emergency valves, and other safety devices, protective equipment, and  
447 floors;
- 448 • Regular checks on the operability of emergency systems;
- 449 • Periodic awareness training for employees;
- 450 • Maintaining MSDSs at visible locations for easy access at all times; and
- 451 • Regular monitoring of surface water and groundwater quality.

452 Monitoring and inspection would be an integral part of the hazardous material management  
453 processes at the NorthMet Project area.

454 Given current Project design and operational commitments, this analysis did not identify  
455 significant adverse effects from proposed hazardous materials use or hazardous waste generation  
456 by the NorthMet Project Proposed Action. Therefore, no additional mitigation measures are  
457 proposed.

458 **5.2.13.4 NorthMet Project No Action Alternative**

459 The NorthMet Project No Action Alternative has no risk of environmental effect since no  
460 hazardous materials would be used, and no hazardous waste would be generated under this  
461 alternative.

DRAFT

1 **5.2.14 Geotechnical Stability**

2 The geotechnical stability of the proposed large-scale material storage facilities for the NorthMet  
3 Project Proposed Action is addressed in this section. These facilities are the waste rock  
4 stockpiles that would be created at the Mine Site; the Tailings Basin, which would be constructed  
5 on top of the existing LTVSMC Tailings Basin; and the Hydrometallurgical Residue Facility,  
6 which would be constructed at the existing LTVSMC Emergency Basin.

7 This section provides a summary of the required design criteria and the methodology and results  
8 of the iterative modeling and design process, as well as an overview of the proposed monitoring  
9 and mitigation plans.

10 **Summary**

11 Designs of the waste rock stockpiles, Tailings Basin, and Hydrometallurgical Residue Facility  
12 have been developed and shown by PolyMet, through an iterative design and modeling process,  
13 to meet the minimum Factors of Safety and water quality criteria (see Section 5.2.2) acceptable  
14 to the Co-lead Agencies. The slope stability and liner integrity of these facilities would be  
15 monitored throughout operations and long-term closure. This approach would allow for  
16 identification of a need to implement adaptive mitigation measures as a contingency to improve  
17 performance should the facilities perform differently from their design.

18 **5.2.14.1 Methodology and Evaluation Criteria**

19 The direct environmental consequences of the proposed large-scale waste material storage  
20 facilities, including the disturbance footprint and impacts to water, are discussed under the  
21 respective environmental factors in Chapter 5.0. This section addresses the slope stability and  
22 liner integrity of the proposed facilities.

23 If incorrectly designed, constructed, and/or managed, or from other unforeseen circumstances,  
24 waste material storage facilities have the potential to increase hydrologic and/or water quality  
25 effects and may become unstable, potentially leading to slope or dam failure (and/or other  
26 environmental impacts to downstream areas).

27 The large-scale waste material storage facilities proposed for the NorthMet Project Proposed  
28 Action would require compliance with MDNR, nonferrous mining, and dam safety rules, as well  
29 as the MPCA NPDES/SDS Permit. The Dam Safety permit requires that design and safety  
30 criteria be met to reduce the risk of potential failure.

31 The design of geotechnical structures is typically developed using an iterative design and  
32 modeling approach where the design is amended until modeling results meet the required  
33 minimum design criteria, including Factors of Safety and other requirements for permitting.  
34 Factor of Safety is used to describe the ratio of resisting forces to driving forces along a potential  
35 failure surface, whereby a Factor of Safety of 1.0 represents equilibrium between the estimated  
36 resisting shear strength to the applied shearing load along a specific plane of potential  
37 movement. Systems are often designed to a Factor of Safety above 1.0 to allow for unexpected  
38 loading conditions, unexpected operating conditions, and variations in estimated material  
39 properties.

40 The specific design and minimum required Factor of Safety criteria for the proposed large-scale  
41 waste materials storage facilities and the methodology applied to develop the designs of the

42 proposed facilities in order to meet these criteria are discussed for each facility in the respective  
43 sections below. Technical analysis was performed by PolyMet and reviewed by the Co-lead  
44 Agencies.

45 The potential effects of hypothetical failure scenarios have not been assessed in this FEIS, as the  
46 risk of failure is mitigated through application of design and safety requirements including  
47 adaptive management procedures.

## 48 **5.2.14.2 NorthMet Project Proposed Action**

### 49 **5.2.14.2.1 Waste Rock Stockpiles**

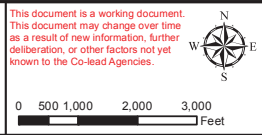

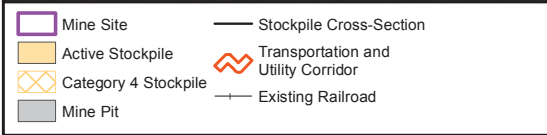

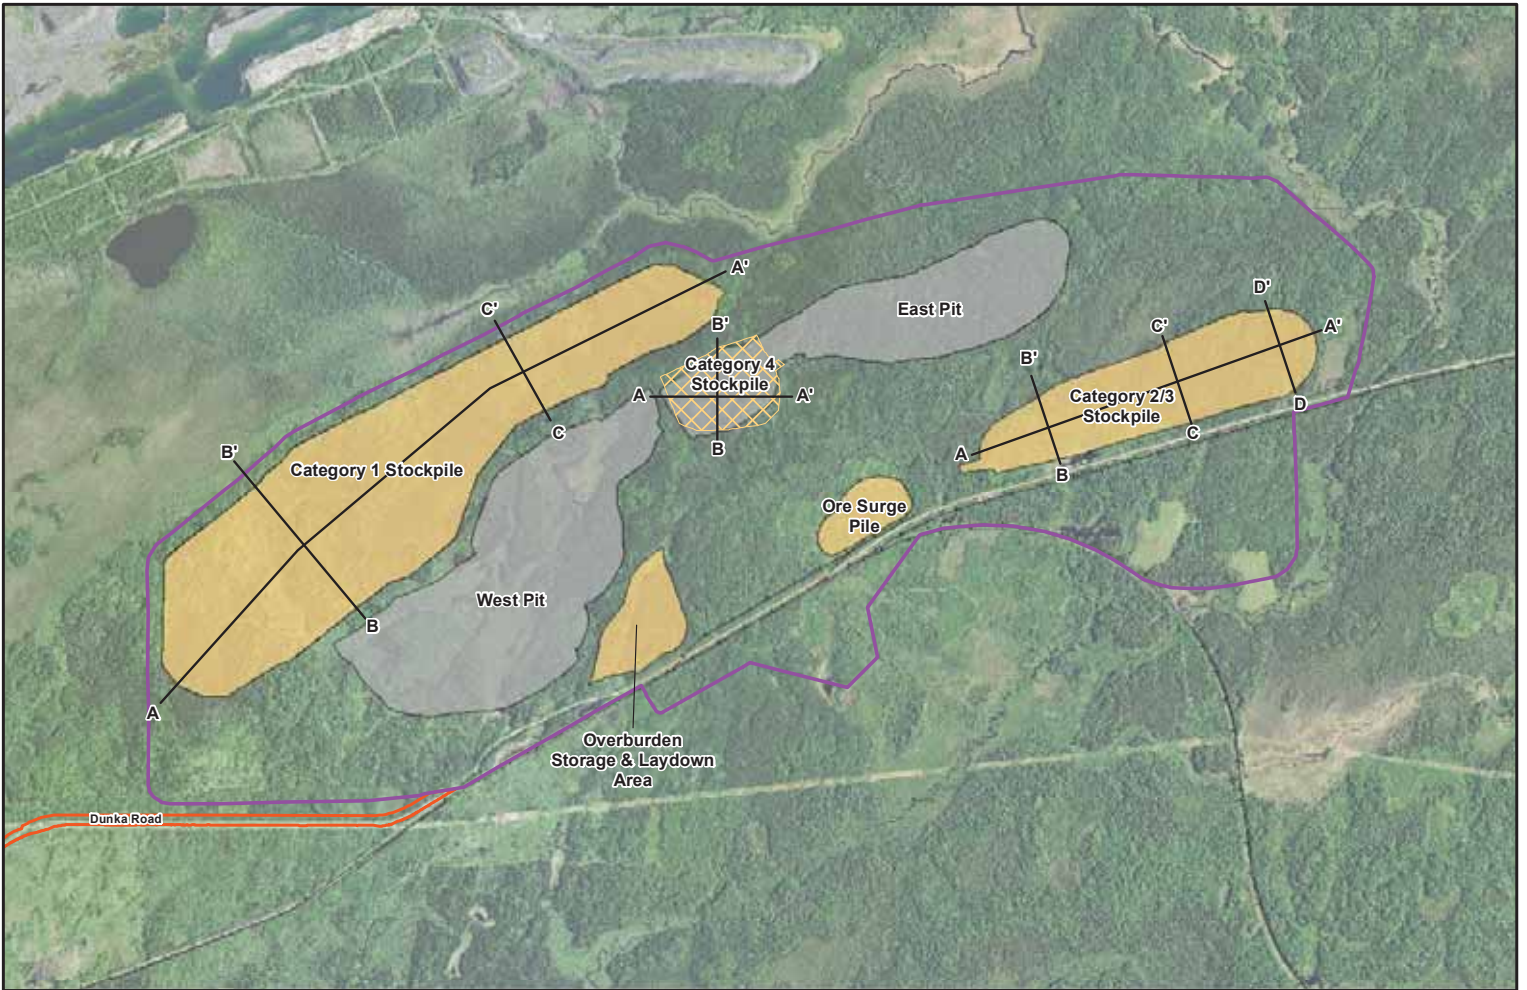

50 The proposed large scale waste material storage facilities at the Mine Site are:

- 51 • A permanent waste rock stockpile for Category 1 waste rock encompassed by a surface water  
52 and groundwater containment system and with an engineered geomembrane cover system at  
53 closure, and
- 54 • Temporary, lined stockpiles for Category 4 waste rock, combined Category 2/3 waste rock,  
55 and an Ore Surge Pile.

56 In addition to the stockpiles above, PolyMet would also prepare an Overburden Storage and  
57 Laydown Area that would be used for temporarily stockpiling overburden prior to its use.

58 PolyMet expects that the NorthMet Project Proposed Action would produce approximately 308  
59 million tons of waste rock over the life of mine. Waste rock would be categorized and managed  
60 based on its potential to oxidize. The least reactive, Category 1, waste rock would be placed into  
61 a permanent stockpile, while Category 2/3 waste rock and Category 4 waste rock would be  
62 stored in temporary stockpiles before being placed as backfill into the East Pit after year 11 of  
63 operations. The location of the stockpiles is shown in Figure 5.2.14-1. The total weight of waste  
64 rock stored in a permanent stockpile (Category 1 Stockpile) would be approximately 168 million  
65 tons (see Section 3.2.2.1.7).

66 The data inputs, evaluation methodology, results, and design and operating requirements for the  
67 stockpiles were reported in Geotechnical Data Package Volume 3 (PolyMet 2014p) and Rock  
68 and Overburden Management Plan (PolyMet 2015h) and reviewed by the Co-lead Agencies.  
69 Additional geotechnical investigations are required to gain a better understanding of the liner  
70 interface frictional values (for the composite liners that would be used at the proposed facility),  
71 as well as the geotechnical material properties of the foundation soils in the wetland areas and  
72 stockpile geotechnical material properties prior to construction of the stockpiles. PolyMet has  
73 committed to undertake further investigations as necessary.

**Figure 5.2.14-1**  
**Mine Site Plan - Year 11**  
 NorthMet Mining Project and Land Exchange PFEIS  
 Minnesota  
 June 2015

-Page Intentionally Left Blank-

DRAFT

76 **Design Criteria**

77 Waste rock stockpiles must be designed to comply with *Minnesota Rule* 6132.2400 (stockpile  
78 slopes are required to meet *Minnesota Rule* 6132.2400 Subp. 2. B. and stockpile foundations are  
79 required to meet *Minnesota Rule* 6132.2400, Subpart 2. A. (1)). These are design requirements  
80 that have been established to attain acceptable slope stability Factors of Safety for global stability  
81 and acceptable foundation deformations, the latter of which relates to the capability of the  
82 composite geomembrane liner system to withstand the strain anticipated due to differential  
83 settlement that may occur in the stockpile foundation materials.

84 The NorthMet Geotechnical Modeling Work Plan (PolyMet 2015l, Attachment A) requires  
85 PolyMet to perform stockpile subgrade settlement analysis to predict magnitude of deformation  
86 and resulting strain in the stockpile geomembrane liners for comparison to allowable strain in the  
87 proposed liner system. Allowable strains are material-specific and would be determined from  
88 manufacturers specifications for the materials selected for the stockpile liners.

89 **Methodology**

90 In order to demonstrate that the design of the stockpiles would meet the geotechnical  
91 requirements, PolyMet completed the following:

- 92 • Collected existing conditions data needed to support foundation design (refer to Section  
93 4.2.14);
- 94 • Configured stockpile slopes to meet or exceed the minimum dimensional requirements  
95 established by *Minnesota Rules* 6132.2400;
- 96 • Conducted a stockpile subgrade settlement analysis to predict the magnitude of deformation  
97 and resulting strain in the stockpile liners for comparison to allowable strain in the liner  
98 system;
- 99 • Completed slope stability analyses using RocScience's limit equilibrium program SLIDE;  
100 and
- 101 • Developed the stockpile design and operating requirements necessary to maintain required  
102 slope stability Factors of Safety and liner performance.

103 **Design**

104 The design of the stockpiles would need to conform to *Minnesota Rule* 6132.2400. Various  
105 design specifications have been established and used for the stockpile analysis (PolyMet 2014p).  
106 The following is a summary of the design characteristics applied and considered in geotechnical  
107 evaluation.

108 ***Preconstruction Design Considerations for Stability and Water Management***

109 Additional geotechnical investigation such as soil borings, test trenches, and geotechnical  
110 laboratory tests of on-site materials are required at the locations of the proposed stockpiles to  
111 verify the geotechnical information currently available. Examples of information that the  
112 additional investigation would yield include: confirmation of the classification of native soils,  
113 identification of depths to bedrock and groundwater, identification and delineation of on-site  
114 borrow sources, and procurement of additional material samples of waste rock and overburden

115 soils for laboratory testing. Information would be used to modify stockpile and foundation design  
116 and confirm the design assumptions and earthwork balance computations. The additional  
117 investigations would take place before stockpile construction but cannot be undertaken until the  
118 land exchange has been completed, appropriate permitting has been received, and dewatering of  
119 the wetland areas has been performed. As noted above, before construction, the sites would be  
120 dewatered and stockpile foundations would be established on soils identified through permitting,  
121 that the MDNR agree to be suitable for structural support; unsuitable soils on the stockpile's  
122 perimeter would be removed and replaced with structural fill for stability purposes.

123 The Category 1 Stockpile would be a permanent, unlined facility. A drainage system would be  
124 installed around the stockpile, prior to waste rock placement to capture ground and surface water  
125 flows that may extrude from the stockpile.

126 The temporary Category 2/3 and 4 Stockpiles would include a composite geomembrane liner  
127 systems comprised of, from the bottom up, a foundation underdrain system, an impermeable  
128 composite liner barrier, and an overliner drainage layer. The composite liner systems are designed to  
129 perform on a level commensurate with the level of environmental risk expected by the waste rock  
130 classification type. The composite liner system for each temporary stockpile consists of a minimum  
131 of one foot of compacted soil overlain by an 80-millimeter thick Linear Low Density Polyethylene  
132 (LLDPE) geomembrane liner and a minimum of two ft of granular drainage material. The liners  
133 would utilize gravity drainage to a series of collection sumps, and an overliner drainage layer  
134 would be constructed to reduce the potential for leaks due to puncturing of the geomembrane by  
135 the waste rock. For angular overliner materials, a geomembrane liner load integrity test would be  
136 conducted during the additional investigation work mentioned above to support specification of the  
137 acceptable geomembrane thickness and polymer type.

138 Additional information on water containment and management is provided in Section 3.2.2.1.8.

### 139 ***Stockpile Design and Construction***

- 140 • Stockpile design geometry used for analysis is as follows: minimum width at the top of  
141 stockpile: approximately 150 ft or as controlled by the minimum safe turning radius for  
142 operating mine haulage trucks
- 143 • Perimeter access road for light truck traffic (plus allowance for berms): 20 ft
- 144 • Nominal angle of repose slopes: 1.4H:1V (horizontal:vertical) (assumed)
- 145 • Maximum slope for stockpile foundation excavation: 2H:1V
- 146 • Grading considerations at closure:
  - 147 – For the Category 1 Stockpile: 3.75H:1V regraded interbench slopes for the geomembrane  
148 cover
  - 149 – Regrading is not necessary for Categories 2/3 and 4 stockpiles or the Ore Surge Pile as  
150 these are temporary stockpiles
- 151 • Height of first lift (over geomembrane, where located): 15 ft
- 152 • Height of second lift (over geomembrane, where located): 25 ft
- 153 • Nominal lift height (after initial two lifts over geomembrane and where no geomembrane is  
154 located): 40 ft

- 155 • Maximum stockpile heights and interbench slope configurations considered for stability  
156 analyses are:
- 157 – 160 ft at interbench slope angles of 1.4H:1V and 2.5H:1V
- 158 – 200 ft at interbench slope angle of 3H:1V
- 159 – 240 ft at interbench slope angle of 3.7H:1V

160 Stockpile liner systems and foundation designs used for analysis are as follows:

- 161 • Number of development phases: to be determined in permitting
- 162 • Minimum grade for foundation underdrains: 0.5 percent
- 163 • Minimum grade for drainage collection overliner: 0.5 percent
- 164 • Liner system design, including piping and underliner and overliner collection points
- 165 • Liner system geomembrane: 80-millimeter linear low density polyethylene (LLDPE)

166 Cross sections of the proposed stockpiles are shown in Figure 5.2.14-2 and Figure 5.2.14-3.

167 The stability model (SLIDE) assumed a geomembrane liner interface friction angle (i.e., the  
168 strength that the geomembrane possesses for resisting sliding against the adjacent earthen  
169 material) of 19 degrees, meeting the criteria of 15.7 degrees or greater.. Further geotechnical  
170 investigation and laboratory testing is required to verify the liner interface shear strength values  
171 as placed against potential borrow materials comprising the underliner material, as well as the  
172 shear strength parameters for the foundation and stockpile materials prior to construction. To  
173 mitigate associated uncertainty, PolyMet has committed to removing all unsuitable foundation  
174 soils from beneath lined stockpiles and replace them (where required) with structural fill to meet  
175 strength and grade requirements (PolyMet 2015h). PolyMet has also committed to undertaking  
176 further geotechnical investigations prior to the construction of the stockpiles to define the  
177 foundation management needs.

178 Temporary stockpiles at the Overburden Storage and Laydown Area have not been included in  
179 stability analysis given their temporary nature and relatively small size.

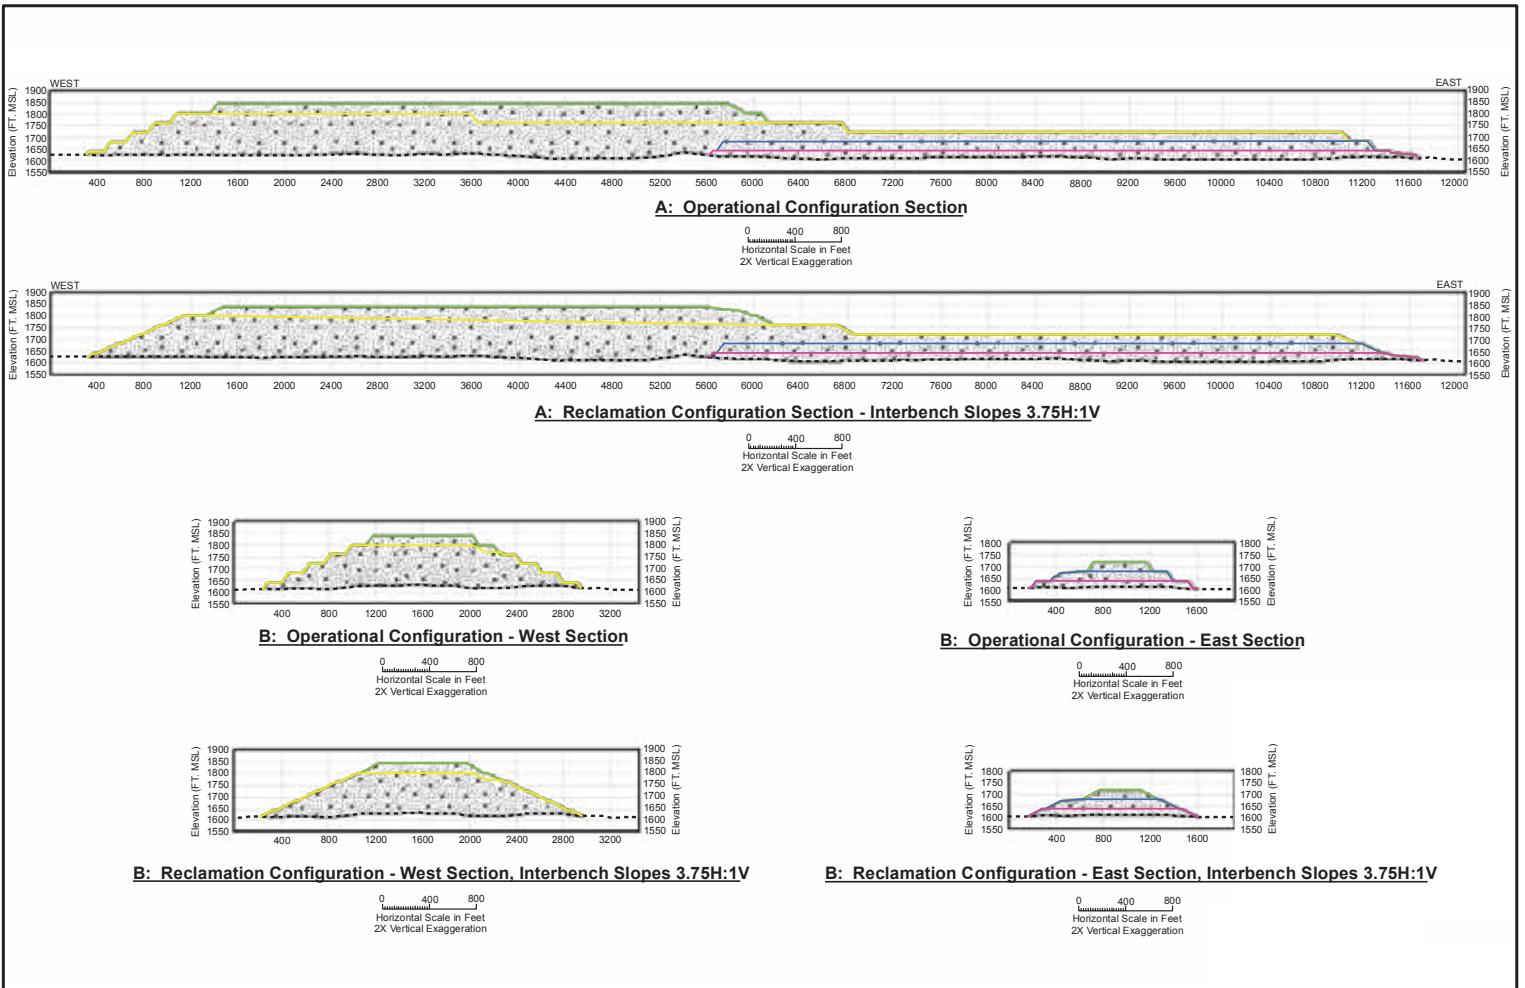

### 180 ***Closure of the Stockpiles***

181 The Category 1 Stockpile would be a permanent feature that would be progressively reclaimed,  
182 starting in mine year 14, with an engineered geomembrane cover system. Reclaimed  
183 configurations are described in the section above and in the stability modeling results below. The  
184 cover would include an engineered geomembrane system that would be vegetated to meet the  
185 requirements of *Minnesota Rules*, part 6132.2200, subpart 2, item B. A subgrade layer would be  
186 placed over the Category 1 Stockpile to provide a uniform layer upon which to construct the  
187 cover system. The cover would be designed to promote runoff with reduced erosion potential. To  
188 provide an adequate base for sloping of cover materials, Category 1 Stockpile side slopes would  
189 be re-shaped to no steeper than a horizontal-to-vertical ratio of 3.75H:1V, with the cover system  
190 placed on top of the re-shaped waste rock. The outermost layer would consist of local till soils  
191 (also known as “overburden” per *Minnesota Rules*, part 6132.0100, subpart 32) adequate for  
192 native vegetation growth. To provide further erosion control, catch benches at least 30 ft in width  
193 would remain on the stockpile. Long-term maintenance of the Category 1 Stockpile would

194 include repairing erosion and removal of woody species and trees from the stockpile cover  
195 system to mitigate against the potential for deep root systems puncturing the underlying  
196 geomembrane. Additional information on reclamation is provided in Section 3.2.2.1.10 and an  
197 overview of monitoring and maintenance actions for stability is provided below.

198 The Category 2/3 and 4 stockpiles and Ore Surge Pile would be temporary and would be  
199 backfilled into the East Pit following year 11. The footprint of the temporary stockpiles would be  
200 reclaimed to wetlands or other native habitats where practical.

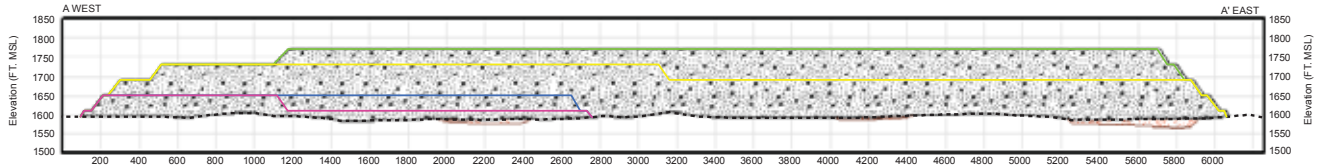

DRAFT

207 **Modeling Results**

208 The results reported in Geotechnical Data Package Volume 3 indicate that the proposed design of  
209 the stockpiles would meet the required Factors of Safety (PolyMet 2014p). The geotechnical  
210 evaluation is summarized below.

211 ***Stability***

212 PolyMet undertook a stability analysis of the design cross sections developed to represent the  
213 following typical conditions at different phases of stockpile development:

- 214 • Temporary Category 2/3 Stockpile, Category 4 Stockpile, and Ore Surge Pile
- 215 1. Initial operational configuration (single lift of waste rock placed in two stages).
- 216 2. Operational configuration at proposed final buildout (excludes the Ore Surge Pile, which  
217 would fluctuate).
- 218 • Permanent Category 1 Stockpile
- 219 1. Initial operational configuration (a single lift of waste rock with a maximum height of  
220 40 ft placed at the angle of repose).
- 221 2. Operational configuration at proposed final buildout prior to reclamation (assume four  
222 lifts of waste rock).
- 223 3. Reclaimed configuration, interbench slopes regraded to 2.5H:1V.
- 224 4. Reclaimed configuration, interbench slopes regraded to 3H:1V.
- 225 5. Reclaimed configuration, interbench slopes regraded to 3.75H:1V.
- 226 6. Assuming a liner interface (i.e., overliner material/LLDPE geomembrane liner/soil liner)  
227 friction angle of 19 degrees.

228 Results indicated that all sections analyzed met the minimum required Factors of Safety.

229 Estimated liner strains resulting from foundation settlement are less than 1 percent; well below  
230 the 30 percent maximum strain allowed in the LLDPE geomembrane proposed for the  
231 geomembrane barrier layer component of the basal liner system for the Category 2/3 Stockpile,  
232 Category 4 Stockpile, and the Ore Surge Pile.

233 **Proposed Monitoring, Maintenance, and Mitigation**

234 A Construction Quality Assurance Plan would be developed by PolyMet for the stockpile  
235 construction prior to permitting. The objective of the plan would be to assure that the  
236 construction of the soil and geosynthetic components would be in compliance with the project  
237 specifications and to demonstrate that the regulatory requirements for the construction would be  
238 achieved. The plan also would provide the means for resolution of problems that may occur  
239 during construction. The Construction Quality Assurance Plan would be independent of the  
240 quality control programs to be followed by the manufacturers, installers, and the contractor.

241 A Rock and Overburden Management Plan (PolyMet 2015h) has been prepared by PolyMet that  
242 includes a description of the operating plans, monitoring procedures, and adaptive management  
243 approaches for the stockpiles.

244 The stockpile quantities would be monitored throughout the life of the mine and the stockpile  
245 heights and footprints would be monitored to verify that they are constructed as designed.  
246 Monitoring and maintenance of the Category 1 Stockpile would also continue through the post-  
247 closure period until the MDNR determines that the cover is stable. An annual compliance report  
248 would be developed each year for submittal to the MDNR to comply with the Permit to Mine  
249 requirements.

250 Information gained through ongoing monitoring would also be used to advise adaptive waste  
251 management requirements should the capacity of the Category 2/3 Stockpile, the Category 4  
252 Stockpile, and/or the East Pit be insufficient for the mined volume of Category 2/3 and Category  
253 4 waste rock generated by mining. Adaptive waste rock management could include expansion of  
254 the waste rock stockpiles. While moving all of the Category 1 waste rock into the West Pit as  
255 backfill was eliminated as a potential alternative (refer to Section 3.2.3.4.2), it may be possible to  
256 dispose of some excess waste rock or saturated overburden in the West Pit in areas where mining  
257 has ceased, if necessary as an adaptive measure.

258 Each year, an operating plan and annual report would be completed, as required for the Permit to  
259 Mine, to keep the Rock and Overburden Management Plan (PolyMet 2015h) current and to track  
260 changes in the mine plan, rock type schedule, and characterization of the material. Modifications  
261 to the Rock and Overburden Management Plan based on changes to the material characterization  
262 would be completed, as necessary.

#### 263 **5.2.14.2.2 Tailings Basin**

264 Tailings from the beneficiation process would be disposed of in a Tailings Basin, constructed on  
265 top of Cell 1E and Cell 2E of the existing LTVSMC Tailings Basin. Figure 5.2.14-4 depicts the  
266 Tailings Basin at its proposed final elevation (year 20).

267 The data inputs, modeling methodology, results, and design and operating requirements for the  
268 Tailings Basin were reported in Geotechnical Data Package Volume 1 (PolyMet 2015l) and  
269 Flotation Tailings Management Plan (PolyMet 2015n), which were reviewed by the Co-lead  
270 Agencies. The information provided in the data package informs the permitting process and is  
271 summarized below.

#### 272 **Design Criteria**

273 In Minnesota, dams must be constructed in accordance with applicable requirements of  
274 *Minnesota Rules* 6115.0300 through 6115.0520. In addition, under the NorthMet Geotechnical  
275 Modeling Work Plan (PolyMet 2015l, Attachment A), the Co-lead Agencies require that the  
276 critical cross section of the Tailings Basin is demonstrated to meet or exceed the following  
277 minimum Factors of Safety as required for various loading scenarios:

- 278 • Factor of Safety greater than or equal to 1.5 for effective stress conditions using parameters  
279 that reflect long-term, drained strength conditions.
- 280 • Factor of Safety greater than or equal to 1.3 for short-term, undrained strength conditions for  
281 soils that are not prone to static liquefaction using undrained strength conditions.
- 282 • Liquefaction analysis of potentially liquefiable materials in undrained strength conditions  
283 including:
  - 284 – Liquefaction triggering analysis Factor of Safety greater than or equal to 1.1;

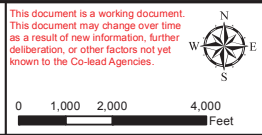

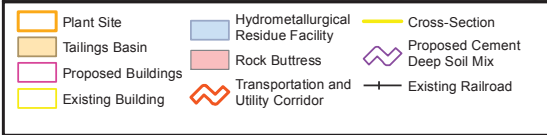

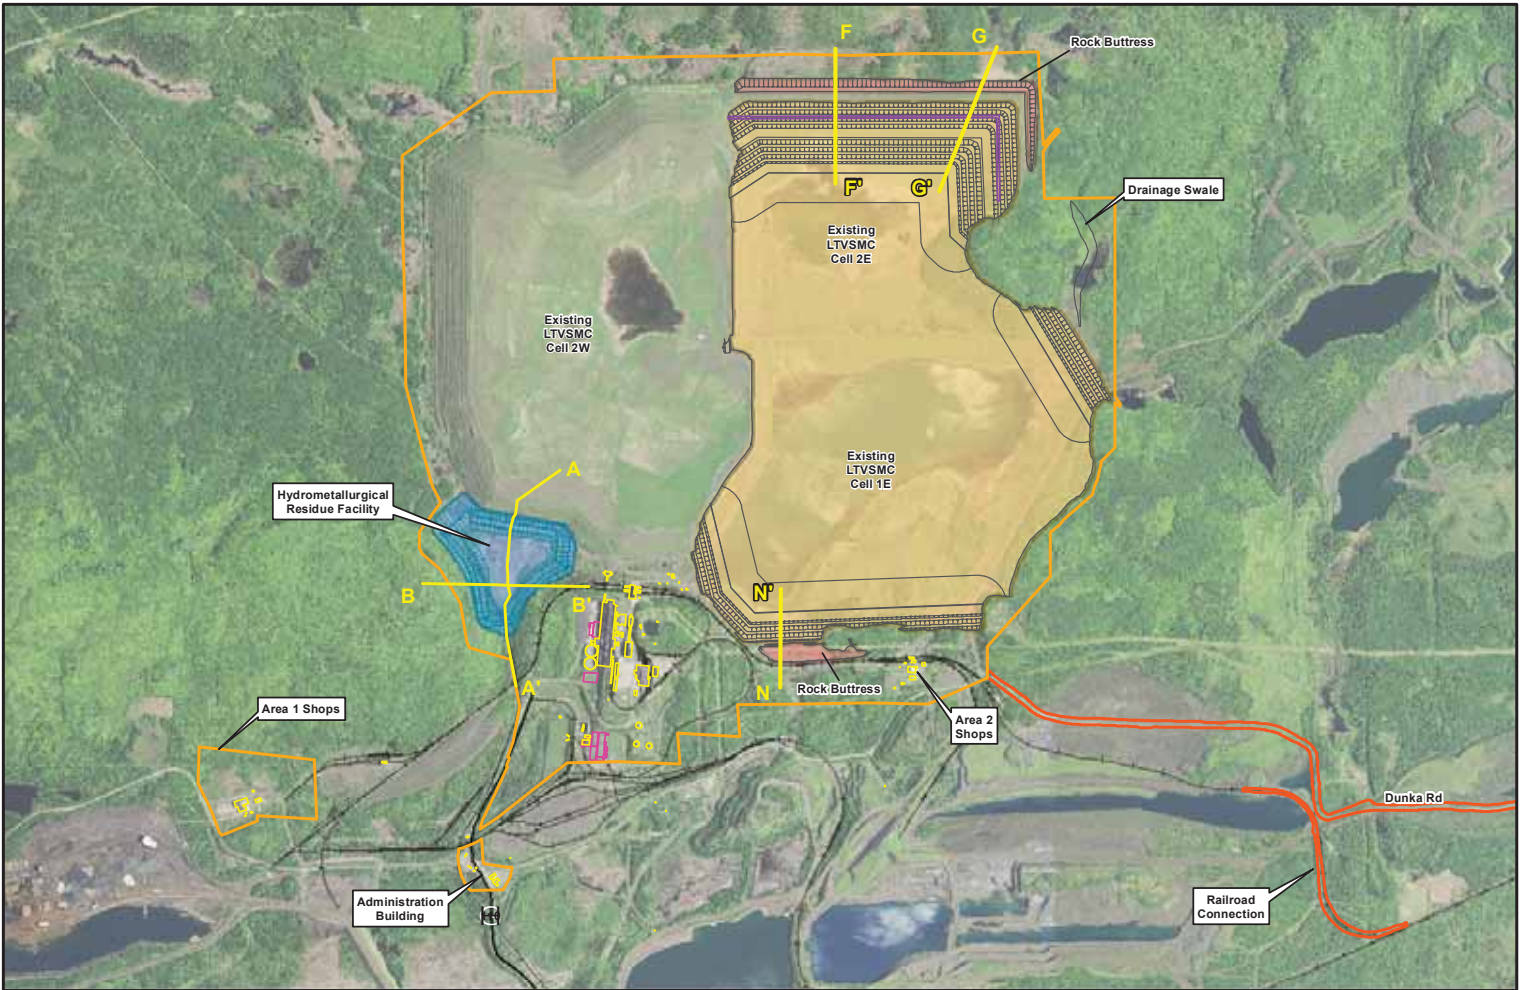

- 285       – Seismic liquefaction triggering analysis (i.e., induced by design earthquake event) Factor  
286       of Safety greater than or equal to 1.2 (or, the Co-lead Agencies may accept a Factor of  
287       Safety between 1.2 and 1.0 if the results of deformation modeling are also deemed  
288       acceptable by the Co-lead Agencies); and
- 289       – Liquefied scenario (assumes all saturated contractive materials have liquefied) Factor of  
290       Safety greater than or equal to 1.10.

291   These minimum Factors of Safety were selected with consideration for:

- 292   • The proposed construction of the Tailings Basin on top of the existing LTVSMC Tailings  
293    Basin and the known geotechnical conditions and material characteristics of the existing  
294    facility;
- 295   • The expected characteristics of the NorthMet Project tailings and construction materials and  
296    methods, including long-term wet closure; and
- 297   • Similar industry standards and other large tailings dams in Minnesota.

DRAFT

301 **Methodology**

302 In order to demonstrate that the design of the Tailings Basin would meet the respective  
303 geotechnical requirements, PolyMet, in accordance with the NorthMet Geotechnical Modeling  
304 Work Plan (PolyMet 2015I, Attachment A) took the following steps:

- 305 1. Gathered existing conditions data (i.e., existing basin topography, stratigraphy, soil and  
306 tailings strength and hydraulic characteristics [see Section 4.2.14], characteristics of  
307 NorthMet tailings based on material produced during the pilot-plant processing, and other  
308 data as needed to support geotechnical modeling and Tailings Basin design).
- 309 2. Developed Tailings Basin cross sections (i.e., geometry and stratigraphy for existing and  
310 planned conditions) for the Tailings Basin for seepage and stability modeling.
- 311 3. Developed seepage and stability models using Geo-Slope International, Inc. modeling  
312 software (i.e., SLOPE/W, SEEP/W and SIGMA/W as necessary) for various construction  
313 and loading scenarios (such as various dam crest and pond surface elevations during  
314 construction and closure).
- 315 4. Established the geotechnical design data for model input including identification of hydraulic  
316 and strength parameters and the triggering potential for static and seismic events of the  
317 various tailings material types.
- 318 5. Performed modeling and results interpretation.
- 319 6. Refined the design and operating requirements necessary until modeling showed that the  
320 required slope stability Factors of Safety are achieved for the critical slope cross section.

321 **Design**

322 Various design specifications have been established and used for Tailings Basin geotechnical  
323 analysis (PolyMet 2015I). The following is a summary of the design characteristics applied and  
324 considered in modeling.

325 ***Preconstruction Design Considerations for Stability and Water Management***

326 Before placement of NorthMet tailings, coarse tailings sourced from the existing LTVSMC  
327 Tailings Basin would be used to construct a drainage layer to maintain a lowered phreatic surface  
328 within the new dam. A lower phreatic surface would help to prevent saturation of the dam  
329 embankments. Additional modeling would be conducted to ascertain if this drainage layer needs  
330 to be continuous along the length of the dam, or if narrow segments of foundation material  
331 would prove to be sufficiently effective.

332 Rock buttresses would be placed at the northern toe of the existing Cell 2E starter dam, and at  
333 the south end of Cell 1E near the railroad fill to provide resistance to the driving forces created  
334 by the dam raises. The location of the proposed rock buttress is shown in Figure 5.2.14-4. Peat  
335 would be removed from below the rock buttress footprint before placement, so that the rock can  
336 be founded on the firmer till and bedrock. Buttress material would likely consist of waste rock  
337 sourced from the LTVSMC Area 5 Stockpile (assumed to have the same geochemical properties  
338 as Category 1 waste rock for water impact modeling purposes).

339 Installation of CDSM columns would also be used along the northern and northeastern sides of  
340 Cell 2E to enhance the shear strength of the existing LTVSMC fine tailings, slimes, and peat

341 layers by mixing in situ soil with cement or other suitable stabilizing agent. The location of one  
342 proposed CDSM option is shown in plan view on Figure 5.2.14-5. A potential arrangement of  
343 CDSM that may be applied at the Tailings Basin is shown in Figure 5.2.14-5.

344 As described in Section 3.2.2.3.10, the Tailings Basin design includes a containment system and  
345 a storm water management system that would encompass the northern, western and eastern sides  
346 of the Tailings Basin. Storm water runoff is not expected to cause significant erosion to the  
347 dams. However, if erosion were to occur, more robust erosion control measures would be  
348 implemented. A drainage swale would be added to redirect runoff storm waters falling outside of  
349 the dams. These design features would not affect the stability of the dams (PolyMet 2015l).  
350 Precipitation that falls within the Tailings Basin would be contained by a freeboard that has been  
351 designed based on the predicted bounce from a PMP event (PolyMet 2015n). Overflow would be  
352 prevented by pumping excess pond water to the WWTP. In the rare event that freeboard within  
353 the Tailings Basin, and pumping of excess water to the WWTP, is not sufficient to contain all  
354 storm water, water would be directed to an emergency overflow spillway.

355 A seismic hazard assessment and subsequent liquefaction analysis was undertaken for the  
356 Tailings Basin. Results indicated that a significant earthquake is unlikely in Minnesota, and a  
357 seismic design event with a peak ground acceleration of 0.024g (2,475 year return period) is not  
358 likely to trigger liquefaction in the Tailings Basin materials. Seismic deformation was also  
359 considered and the effect of settlement resulting from a design earthquake event would not affect  
360 the stability or pond containment of the Tailings Basin.

### 361 ***NorthMet Tailings Basin Design and Construction***

362 The Tailings Basin would be constructed using the upstream method, whereby NorthMet dam  
363 embankments would be constructed using preferentially borrowed LTVSMC tailings on top of  
364 the existing LTVSMC tailings embankment and on the spigotted tailings adjacent to the  
365 perimeter embankment. NorthMet bulk tailings would be discharged into the new basin by  
366 perimeter spigots and a pond barge pump. New dam embankments (using LTVSMC Bulk  
367 tailings) would be raised in stages on top of the existing LTVSMC tailings impoundment, and  
368 the new tailings are deposited upstream of the dam into the basin from spigots at the dam's edge.  
369 Tailings would also be discharged subaqueously in the basin via a barge.

370 The Tailings Basin incorporates construction of new dam embankments over the existing  
371 LTVSMC Tailings Basin Cells 1E and 2E. The design process is an iterative approach whereby  
372 various combinations of stabilization factors including slope angle, lift heights, intermediate  
373 slope bench width, drainage layers beneath the proposed NorthMet tailings, CDSM, and  
374 supporting rock buttresses were modeled to identify a design that would achieve the following:

- 375 • Provide safe permanent storage of tailings generated over the proposed 20-year operating life  
376 of the NorthMet Project Proposed Action and maintain stability post-closure;
- 377 • Efficiently and effectively recover process water from the surface of the Tailings Basin  
378 during operation, and contain groundwater and surface water seepage during operation and  
379 over the long term (refer to Section 5.2.2 for more information on water management);
- 380 • Accommodate the planned wet cover system at closure; and
- 381 • Meet project regulatory requirements (including Factors of Safety).

382 As shown in Figure 5.2.14-6, Figure 5.2.14-7, and Figure 5.2.14-8 the proposed design consists  
383 of eight lifts with a proposed final crest elevation (selected on the basis of tailings storage  
384 capacity requirements) modeled as 1,732 ft amsl. This would be an additional 150 ft on top of  
385 the existing LTVSMC Tailings Basin Cell 2E. This proposed elevation is similar to the elevation  
386 of the existing north dam of Cell 2W, which is at a designed final elevation of 1,735 ft amsl. A  
387 schematic cross section of the Tailings Basin is shown in Section 3.2.2.3.5.

388 The proposed dams would be constructed from mechanically placed and compacted “bulk  
389 tailings” taken from the existing LTVSMC Tailings Basin as needed to produce the desired dam  
390 lift height and geometry. LTVSMC “bulk tailings” are currently defined as a mixture of tailings  
391 from the existing LTVSMC Tailings Basin. The exterior face of the dams would be augmented  
392 with a bentonite layer to limit oxygen and rain water infiltration into the Tailings Basin.

393 The individual lifts would have a slope of 4.5H:1V, which, including setbacks, would provide for  
394 an overall slope of approximately 8.6H:1V. Each lift would be 20 ft high, with the exception of  
395 the final lift, Lift 8, which would be 10 ft in height. There is a 60-ft bench on top of each lift,  
396 with an additional 200-ft setback on top of Lift 4, and a 625-ft beach extending from the interior  
397 crest of dam to the edge of the Tailings Basin pond.

#### 398 ***Closure of the Tailings Basin***

399 As dams are constructed, exterior slopes would be covered with bentonite and vegetated. Upon  
400 reaching the final proposed dam elevation (after 20 years of operation), the Tailings Basin would  
401 be closed in accordance with *Minnesota Rules* 6132.3200 and would also include the following:

- 402 • Bentonite augmentation of the pond area bottom to reduce infiltration to a sufficient degree  
403 to maintain desired pond water elevations at closure;
- 404 • Slight slope grading of the interior portions for effective storm water routing into the pond  
405 area;
- 406 • Bentonite augmentation of the exposed embankments and beach areas; and
- 407 • Mulching and planting/seeding of native vegetation of upland areas (plants would be selected  
408 and monitored to limit root growth from penetrating bentonite).

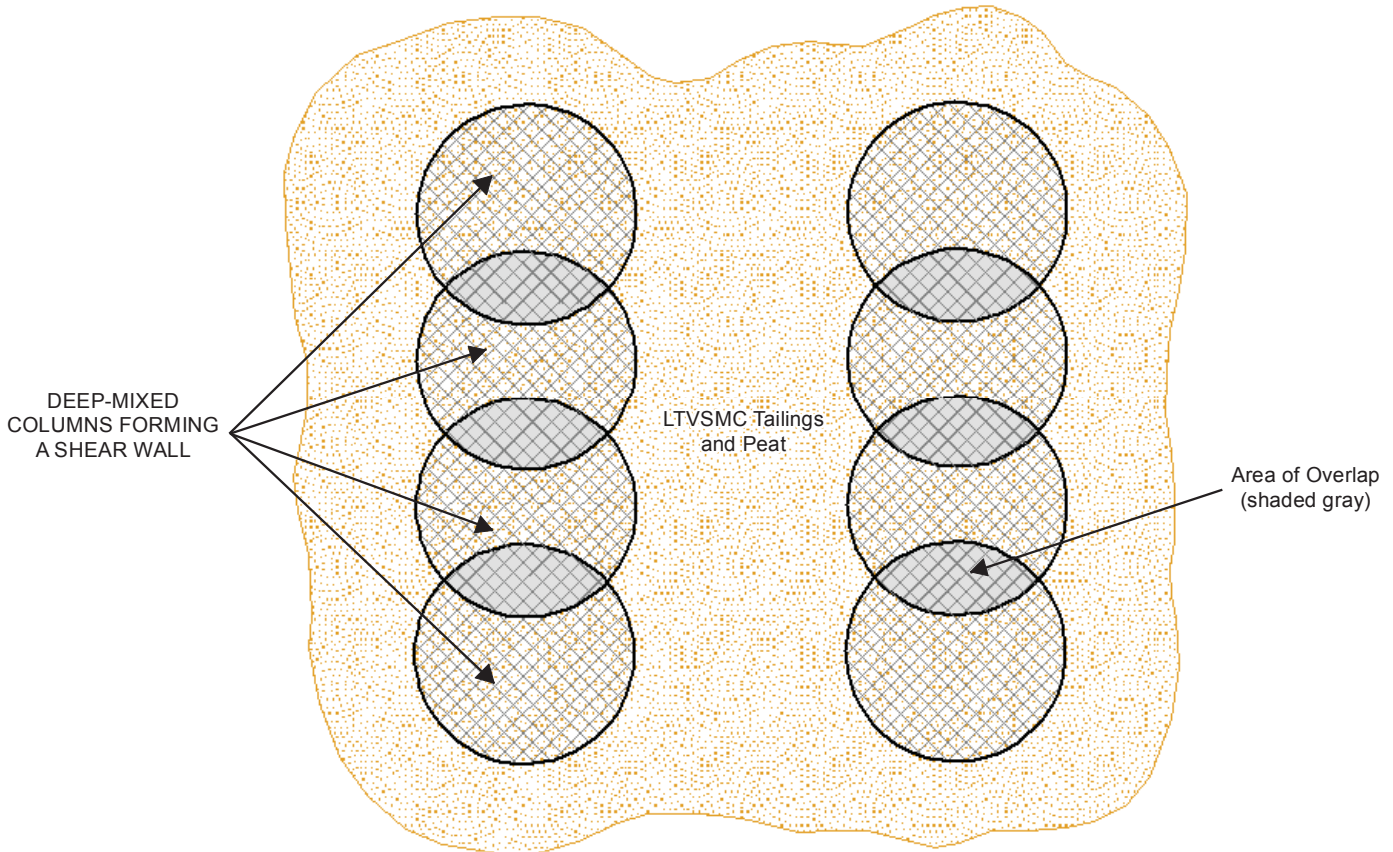

409 Monitoring and maintenance measures that would be applied post closure are further addressed  
410 below and additional details on closure are provided in Section 3.2.2.3.12.

423 **Identification of the Critical Cross Section**

424 Geotechnical conditions along the length of existing LTVSMC Tailings Basin dams have  
425 varying layers of coarse tailings, fine tailings, and slimes. Cross Section F, which intersects the  
426 northern dam of Cell 2E, as shown in Figure 5.2.14-4, was selected to represent the critical cross  
427 section for stability analysis purposes as it is the maximum section based on height as measured  
428 from the downstream toe to the proposed final crest, some layers of the weaker fine tailings and  
429 slimes extend close to the dam, and the original starter dam lower existing tailings is underlain  
430 by peat. Material types identified from borings in the existing LTVSMC Tailings Basin along  
431 Cross Section F are shown in Figure 4.2.14-3. Figure 5.2.14-6 shows the proposed design of the  
432 NorthMet Project Proposed Action Tailings Basin along Cross Section F at its full extent.

433 Cross Section F was analyzed in a sequential manner consisting of the development of the dam  
434 cross section stratigraphy for analyses, application of the material strength and permeability  
435 characteristics, and modeling of seepage conditions at the dam cross section, followed by  
436 stability analyses.

437 Cross Section F also was evaluated with the Tailings Basin at the proposed final crest height to  
438 determine whether liquefaction would be triggered in the contractive materials, based on certain  
439 triggers prescribed in the NorthMet Geotechnical Modeling Work Plan (PolyMet 2015I,  
440 Attachment A).

441 In addition to Cross Section F, Cross Section G and N were selected to represent separate, non-  
442 critical sections of the Tailings Basin. These cross sections are shown in plan view on Figure  
443 5.2.14-4. Figures 5.2.14-7 and 5.2.14-8 show the proposed design of the NorthMet Project  
444 Proposed Action Tailings Basin along Cross Sections G and N at their full extent respectively.  
445 Stability modeling was also performed for these cross sections as described below.

446 **Modeling Results**

447 The results reported in Geotechnical Data Package Volume 1 indicate that the proposed design of  
448 the Tailings Basin would meet all respective Factors of Safety as required (PolyMet 2015I). The  
449 modeling undertaken and results obtained are summarized below. Subsequent to Geotechnical  
450 Data Package Volume 1, PolyMet evaluated the effect that the Tailings Basin groundwater  
451 containment system would have on stability. Results indicated that the groundwater containment  
452 system would not impact the stability of the Tailings Basin or the Factor of Safety results for  
453 Cross Sections F, G, and N determined in Geotechnical Data Package Volume 1 and provided  
454 below (PolyMet 2015I). All minimum Factors of Safety correspond to Cross-Section F,  
455 confirming that it is the critical cross-section given the analyses performed.

456 Technical documents have been reviewed by the Co-lead Agencies and these results would be  
457 further verified before the completion of permitting.

458 **Slope Stability**

459 The predicted Factor of Safety values for Cross Sections F, G and N at various stages of  
460 development of the Tailings Basin are summarized in Table 5.2.14-1. The geometry and physical  
461 changes to the embankments (such as CDSM) were incorporated into the design so that all  
462 computed slope stability Factors of Safety met or exceeded the Factors of Safety required by the  
463 NorthMet Geotechnical Modeling Work Plan (PolyMet 2015I, Attachment A).

464 **Table 5.2.14-1 Summary of Stability Modeling Results**

| Cross-Section Location                           | Cross-Section F |      |             | Cross- Section G |      |             | Cross-Section N |      |             |

466 USSA = Undrained Strength Stability Analysis

467 ESSA = Effective Strength Stability Analysis

468 Liq = Liquefied conditions

469 Yield = point of elastic deformation

470

471 **Liquefaction**

472 The potential for liquefaction, where a triggering event changes the stress state of the material  
473 such that it loses a significant amount of its strength, was assessed under different scenarios,  
474 including rapid loading and construction, ineffective underdrain resulting in increased saturation,

475 and erosion events. Results shown in Table 5.2.14-1 indicate that the design under these  
476 conditions meets the minimum Factor of Safety for Cross Sections F, G, and N.

477 A scenario for potential liquefaction was evaluated whereby all contractive, saturated soils were  
478 modeled with their liquefied shear strengths. Table 5.2.14-1 shows that if the contractive,  
479 saturated soils were to liquefy at the end of operations, or 20, 200, or 2,000 years after  
480 operations, the design would meet the minimum Factors of Safety deemed acceptable by the Co-  
481 lead Agencies.

482 Potential for seismic activity was also analyzed and assessed. Results indicated that there is a  
483 very low likelihood of liquefaction as a result of seismic events.

484  
485  
486

### 487 ***Long-Term Closure Stability Conditions***

488 While it is normally preferable from a stability perspective to allow tailings facilities to drain  
489 following closure, the NorthMet Project Proposed Action involves maintaining a pond on top of  
490 the Tailings Basin for water quality management purposes.

491 The Tailings Basin would be covered with a bentonite-amended surface on the exterior face of  
492 the NorthMet Project dam lifts (amended during construction). After the Tailings Basin has been  
493 filled to its maximum height, the dam would be prepared for reclamation by amending the 625-ft  
494 beach of tailings and the bottom of the pond with bentonite. A closure overflow channel would  
495 be constructed to drain excess water from the Tailings Basin pond in order to maintain  
496 appropriate freeboard and beach lengths.

497 Modeling was undertaken to predict the long-term stability of the Tailings Basin. As shown in  
498 Table 5.2.14-1, the long-term closure slope stability Factors of Safety are above the minimum  
499 value required under the Work Plan.

### 500 ***Proposed Monitoring***

501 Geotechnical investigations would be performed on the Tailings Basin during construction and  
502 operations to confirm that the construction and performance of the dam meet design criteria.  
503 Results may inform adaptive design changes to ensure stability criteria would be met as  
504 construction progresses. This approach is typical for large earthen structures that are developed  
505 incrementally over long periods of time.

506 A Flotation Tailings Management Plan (PolyMet 2015n) has been prepared by PolyMet that  
507 includes a description of the operating plans, monitoring procedures, and adaptive management  
508 approaches for the Tailings Basin. Monitoring activities include construction material sampling,  
509 geotechnical instrumentation, geotechnical investigations, and systematic dam safety inspections.

510 Existing and proposed geotechnical instrumentation would measure actual tailings dam  
511 performance by monitoring stability, seepage, and deformation. Monitoring instrumentation  
512 relevant to geotechnical stability would include:

- 513 • **Piezometers** to facilitate monitoring of the pore water pressure within the Tailings Basin and  
514 perimeter dams (the phreatic surface has a significant effect on slope stability), which would  
515 be compared to modeled phreatic surface.

- 516 • **Inclinometers** to facilitate monitoring of the movement of the Tailings Basin dams.
- 517 • **Survey monitoring points** to facilitate the monitoring of horizontal and vertical deformation  
518 (including settlement) of the Tailings Basin dams.
- 519 Geotechnical investigations and systematic dam safety inspections would include:
- 520 • Staff observation of the condition of the dam and the reporting of any conditions that indicate  
521 a departure from the design specifications.
- 522 • Weekly/daily routine dam inspections by staff to observe the conditions and performance of  
523 the Tailings Basin dams and associated facilities so that any changes to dam conditions could  
524 be identified and promptly addressed. These would supplement more detailed Dam Safety  
525 Inspections (below).
- 526 • Regulator Dam Safety Inspections to evaluate, on a regular basis, the current and past  
527 performance of the Tailings Basin dams and to observe potential deficiencies in their  
528 condition, performance, and/or operation.
- 529 • Semi-annual Dam Safety Inspections undertaken by an independent Minnesota-registered  
530 consulting engineer retained specifically for dam safety expertise.
- 531 • Inspection after unusual events to monitor and report observations.
- 532 • Routine Dam Safety Reviews every 5 years by a qualified geotechnical engineer registered in  
533 the State of Minnesota. The review would ascertain that the dam has an adequate margin of  
534 safety, based on the current Dam Safety Permit, current engineering practice, and updated  
535 operations and design input data. A Dam Safety Review may also be carried out to address a  
536 specific problem.
- 537 Annual reports on the conditions of the Tailings Basin are required under the MDNR Dam  
538 Safety Permit and Permit to Mine. Monitoring and maintenance would continue post closure in  
539 accordance with permit requirements.

540 **Proposed Maintenance and Mitigation**

541 Typical maintenance of the facility would include repairing eroded surfaces and repair and/or  
542 replacement of damaged monitoring and operational infrastructure. The majority of the non-  
543 mechanical maintenance work at the Tailings Basin would be carried out on an as-required basis,  
544 rather than on a scheduled basis because it is driven by weather events rather than hours of  
545 operation.

546 Where monitoring or model updates indicate that the Factor of Safety for the Tailings Basin may  
547 no longer meet design criteria, appropriate modifications to the Tailings Basin would be  
548 considered, modeled, and, if necessary, undertaken. Modifications could include but are not  
549 limited to: modification of bench widths between lifts of the dam, modification of lift heights,  
550 and modification of slope angles. Other modifications could include increasing the size of the  
551 rock buttress, improving the performance of underdrains, and increasing mid-slope setbacks.

552 A Contingency Action Plan has been prepared as part of the Flotation Tailings Management Plan  
553 (PolyMet 2015n). The plan provides guidance to on-site personnel and emergency responders in  
554 the case of unplanned occurrences at the Tailings Basin. The plan defines three levels of  
555 hazardous and emergency conditions response:

- 556 1. Level 1 is defined as unusual conditions that do not warrant an emergency response but  
557 require prompt investigation and resolution.
- 558 2. Level 2 is defined as conditions that represent a potential emergency, if sustained or allowed  
559 to progress, but no emergency situation is imminent. The first action in the event of a Level 2  
560 emergency condition is to discuss and define a response plan.
- 561 3. Level 3 is defined by either imminent failure of the Tailings Basin or a significant component  
562 thereof. The first actions in the event of any Level 3 condition are to check all persons who  
563 could potentially be affected are safe, initiate the appropriate chain of communications, and  
564 immediately undertake appropriate response actions.

565 Long-term maintenance tasks at the Tailings Basin would include:

- 566 • Annual inspection of vegetation on the exterior dam faces and interior beaches, with erosion  
567 repaired and vegetation reseeded in accordance with requirements of plans as needed until  
568 released from these activities by the MDNR;
- 569 • Snow removal from the dam crest to allow access during winter months;
- 570 • Reconstruction of eroded dam crest, slope or toe;
- 571 • Mulching for fugitive dust control in accordance with requirements of plans; and
- 572 • Repair and/or replacement of damaged instrumentation and monitoring.

### 573 **5.2.14.2.3 Hydrometallurgical Residue Facility**

574 As shown in Figure 5.2.14-4, hydrometallurgical residue would be disposed of in a new  
575 Hydrometallurgical Residue Facility that would be located at the site of the existing LTVSMC  
576 Emergency Basin, adjacent to the southern extent of existing LTVSMC Tailings Basin Cell 2W.

577 The data inputs, modeling methodology, results, and design and operating requirements for the  
578 Hydrometallurgical Residue Facility were reported in Geotechnical Data Package Volume 2  
579 (PolyMet 2014c) and reviewed by the Co-lead Agencies. The information provided in the data  
580 package informs the permitting process and is summarized below.

#### 581 **Design Criteria**

582 The design of the Hydrometallurgical Residue Facility must meet the applicable requirements of  
583 *Minnesota Rules* 6115.0300 through 6115.0520 and the requirements of the NorthMet  
584 Geotechnical Modeling Work Plan (PolyMet 2015l, Attachment A) which include the following:

- 585 • The ability of the most sensitive slope cross section to meet a global slope stability Factor of  
586 Safety of 1.5;
- 587 • The ability of the composite liner system to comply with infinite slope stability Factor of  
588 Safety of 1.5, and
- 589 • The capability of the composite liner system to withstand the longitudinal strain anticipated  
590 due to differential settlement that may occur in the facility foundation materials.

591 **Methodology**

592 PolyMet took the steps listed below in order to demonstrate that the design of the  
593 Hydrometallurgical Residue Facility would meet the respective geotechnical requirements and  
594 would be in accordance with the NorthMet Geotechnical Modeling Work Plan (PolyMet 2015I,  
595 Attachment A):

- 596 1. Gathered existing conditions data (i.e., facility foundation material stratigraphy and strength  
597 data, hydrogeological data, characteristics of NorthMet Project Proposed Action residues  
598 based on those produced during the pilot-plant processing, and other data as needed to  
599 support geotechnical modeling of the Hydrometallurgical Residue Facility) (see Section  
600 4.2.14).
- 601 2. Developed residue facility layout and cross sections (i.e., geometry and stratigraphy for  
602 existing and planned conditions) for proposed residue facility stability and deformation  
603 modeling.
- 604 3. Developed seepage and stability models using Geo-Slope International, Inc. modeling  
605 software (i.e., SLOPE/W, SEEP/W and SIGMA/W as necessary) for maximum facility dam  
606 height with minimum and maximum pond elevation, and post-closure – cover effective with  
607 minimum pond elevation.
- 608 4. Established the geotechnical design data for model input including identification of strength  
609 parameters and the triggering potential for static and seismic events.
- 610 5. Ran the models to determine Factors of Safety, and the potential for slope failure and  
611 deformation of the foundation and liner.
- 612 6. Refined the design and operating requirements necessary to maintain required slope stability  
613 Factors of Safety and deformation requirements for the critical slope cross section.

614 **Design**

615 Various design specifications have been established and used for the Hydrometallurgical Residue  
616 Facility geotechnical analysis (PolyMet 2014c). The following is a summary of the design  
617 characteristics applied and considered in modeling.

618 ***Preconstruction Design Considerations for Stability and Water Management***

619 The proposed Hydrometallurgical Residue Facility would be located on top of the existing  
620 LTVSMC Emergency Basin, and would include a double liner and leakage collection system. To  
621 prevent stress deformation and strain on the liner system, the emergency tailings would be  
622 consolidated by applying a preload fill material on top of the emergency tailings to achieve the  
623 required consolidated conditions prior to construction of the Hydrometallurgical Residue  
624 Facility.

625 To achieve this, PolyMet would perform the following tasks:

- 626 1. Install a granular drainage layer at the existing LTVSMC Emergency Basin, as needed to  
627 facilitate wick drain installation and operation;
- 628 2. Install wick drains (if required); and

629 3. Place, monitor, and remove a preload fill in the existing LTVSMC Emergency Basin to pre-  
630 consolidate existing material, thereby reducing future anticipated settlements to mitigate the  
631 potential future strains.

632 In addition to consolidation of the existing LTVSMC emergency tailings, a railroad grade would  
633 also be abandoned and removed to facilitate construction.

634 Seeps have been observed along the southern edge of the LTVSMC Tailings Basin Cell 2W.  
635 These seeps have diminished since the termination of the LTVSMC operations and are expected  
636 to remain minimal as Cell 2W is not proposed for use as part of the NorthMet Project Proposed  
637 Action. The design of the Hydrometallurgical Residue Facility includes a collection drain that  
638 would collect water from the seep below the proposed constructed embankment and liner  
639 systems to transmit the collected seep to the exterior of the facility. This seepage collection  
640 system would consist of a layer of free draining soil which would reduce the potential for  
641 phreatic build-up below the liner.

642 The double liner and collection system would be installed with the following components, listed  
643 in order from top to bottom:

- 644 1. Upper geomembrane;
- 645 2. Geocomposite (geonet) (for leakage collection and recovery);
- 646 3. Lower geomembrane; and
- 647 4. Geosynthetic clay liner.

648 PolyMet initiated laboratory testing to consider the chemical compatibility of the potential  
649 geosynthetic liner to be used with leakage from residue (PolyMet 2014r). Results indicated that a  
650 polymer-treated geosynthetic liner should be used that is manufactured specifically in  
651 anticipation of the chemical characteristics of the liquid and the pore water that would be  
652 contained within the facility. The hydraulic conductivity of the leakage collection system is not  
653 expected to degrade over time. Typical liner performance assumes a 500 year service life of the  
654 geomembrane, therefore, hydraulic conductivity of the liner is not expected to degrade over that  
655 time. Specific attributes would be determined during the geosynthetic clay layer development to  
656 achieve the desired performance before final installation.

657 As noted in Section 4.2.14.3.4, the Minnesota Geological Survey has inferred but not confirmed  
658 the presence of a north-south trending fault that would underlie the proposed Hydrometallurgical  
659 Residue Facility. The potential presence of faults within the footprint of the Hydrometallurgical  
660 Residue Facility is not anticipated to have a negative impact on the storage of residue within the  
661 double lined facility. A probabilistic seismic hazard analysis was done for the  
662 Hydrometallurgical Residue Facility. Results indicated that a severe earthquake is highly  
663 unlikely in Minnesota, and any seismically induced forces would not likely affect the stability of  
664 the Hydrometallurgical Residue Facility.

### 665 ***Hydrometallurgical Residue Facility Design and Construction***

666 The Hydrometallurgical Residue Facility has been designed as a single cell structure with a  
667 design capacity of 6,400,000 cubic yards. The perimeter would have an irregular shape  
668 consisting of the north dam (a portion of the existing southern LTVSMC Tailings Basin Cell 2W  
669 dam), natural high ground, and new dams (see Figure 5.2.14-4). New dams would be located

670 beyond the extent of the LTVSMC Emergency Basin and founded on existing silty sand, gravel  
671 glacial till, and Giants Range granite.

672 The maximum height of the proposed dams is approximately 85 ft, with a crest elevation of  
673 1,650 ft amsl and an additional 3-ft minimum freeboard (14-ft maximum freeboard at a residue  
674 surface slope of 0.5 percent). The exterior, downstream face of the dam would be constructed at  
675 a slope of 4H:1V) The interior of the Hydrometallurgical Residue Facility would be sloped at  
676 4H:1V and 30-ft horizontal benches would be placed at elevations of 1,600 and 1,630 ft amsl.

677 The dams would be constructed using downstream construction methods that involve  
678 constructing a smaller starter dam first and then raising the dam upward and outward over the  
679 downstream shell of the dam as additional capacity is needed. Construction material would be  
680 sourced from natural soil and quarried bedrock between the high ground and south dam. Some  
681 LTVSMC coarse tailings may also be utilized for dam construction. While the material is placed,  
682 it would be compacted to the design density.

683 Materials placed in thin, well-compacted lifts, such as those proposed for the Hydrometallurgical  
684 Residue Facility embankment fill, are understood to be sufficiently dense so that liquefaction is  
685 not anticipated under the various loading conditions, including the design earthquake event with  
686 a peak ground acceleration of 0.024g (2,475 year return period). Although liquefaction of the  
687 hydrometallurgical residue (within the basin) may occur, the embankment dam is sufficiently  
688 designed so that containment would not be lost. Therefore, the integrity of the facility would not  
689 be impacted by the loss of strength associated with potential residue liquefaction.

#### 690 ***Closure of the Hydrometallurgical Residue Facility***

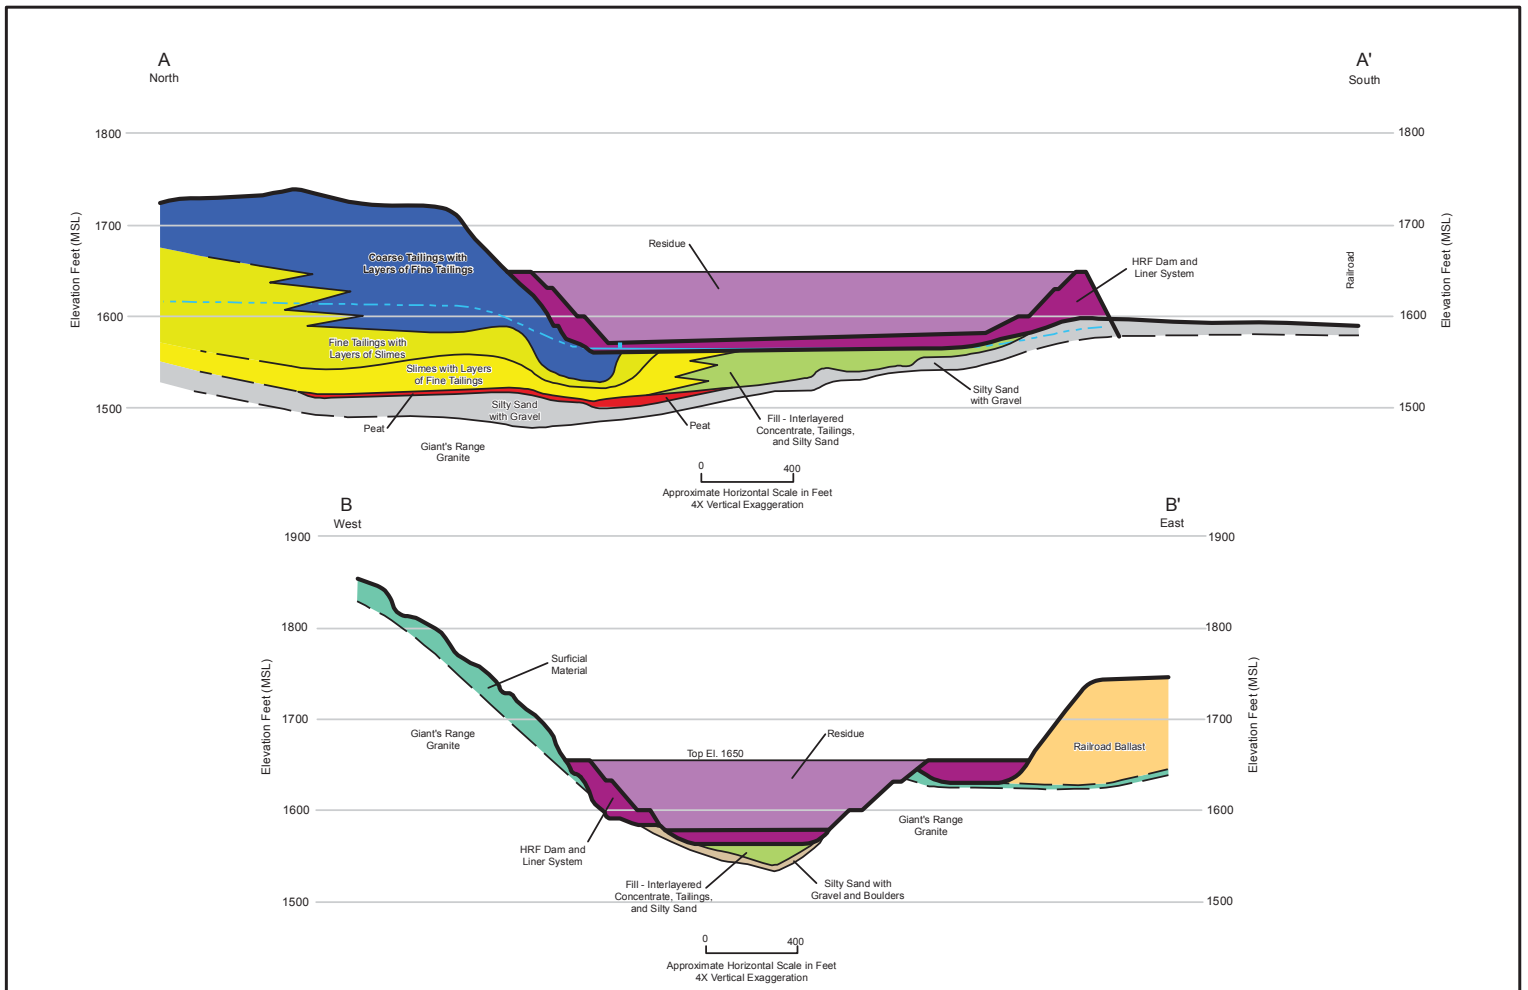

691 Reclamation of the Hydrometallurgical Residue Facility would include removal of ponded water,  
692 removal of pore water from the residue, construction of the cover system, and establishment of  
693 vegetation and surface water runoff controls.

694 Turf and final cover would be inspected and maintained by mowing once per year or as needed,  
695 fertilizing when visual inspection indicates poor vegetation growth, and implementing repairs.  
696 Additional information relating to closure of the Hydrometallurgical Residue Facility is provided  
697 in Section 3.2.2.3.12.

#### 698 ***Identification of the Design Cross Section***

699 Cross Section A, depicted in Figure 5.2.14-4, has been identified as the design cross section. It  
700 approximates the base of a former ravine, beginning south of the future south dam and  
701 terminating near the crest of the Hydrometallurgical Residue Facility north dam. It is considered  
702 as the design cross section, as it incorporates the thickest sections of LTVSMC slimes. Fine  
703 tailings and slimes in the Emergency Basin are the thickest at approximately 50 ft located 280 ft  
704 away from the toe of the south dam of Cell 2W. A cross section of the Hydrometallurgical  
705 Residue Facility at its maximum extent along cross sections A and B is shown in Figure  
706 5.2.14-9.

707 The global slope stability discussed below was assessed along Cross Section A.

- Coarse Tailings with Layers of Fine Tailings
- Fine Tailings with Layers of Slimes
- Slimes with Layers of Fine Tailings
- Peat
- Railroad Ballast
- Residue
- Silty Sand with Gravel
- Silty Sand with Gravel and Boulders
- HRF Dam and Liner System
- Surficial Material

This document is a working document. This document may change over time as a result of new information, further deliberation, or other factors not yet known to the Co-lead Agencies.

DRAFT

710 ***Modeling Results***

711 The results reported in Geotechnical Data Package Volume 2 indicate that the proposed design of  
712 the Hydrometallurgical Residue Facility would meet all respective Factors of Safety as required  
713 (PolyMet 2014c). The modeling undertaken and results are summarized below.

714 ***Stress Deformation and Strain in the Liner System***

715 A preload would be placed on the existing LTVSMC Emergency Basin to consolidate the  
716 foundation materials before construction of the Hydrometallurgical Residue Facility. Wick  
717 drains may be used to help accelerate the consolidation time by increasing the effective hydraulic  
718 conductivity of the tailings due to decrease in flow path length. Some portion of this load would  
719 be removed before construction, and the remaining material would be graded to provide  
720 sufficient drainage slope and provide a suitable foundation material for the facility. The material  
721 would rebound a small amount after the preload is removed. The aggregate settlement at a  
722 representative location within the Emergency Basin, considering the maximum anticipated  
723 tailings thickness in the foundation, is computed to be 3.9 ft. The material at this location is  
724 modeled to consolidate an additional 1.4 ft by the end of operations of the Hydrometallurgical  
725 Residue Facility.

726 Residue consolidation within the basin is modeled as beginning after the cessation of residue  
727 discharge to the Hydrometallurgical Residue Facility. Over time, the rate of consolidation would  
728 decrease with the greatest amount of consolidation occurring before pore-water pressure reaches  
729 hydrostatic equilibrium (approximately 10 years following closure). Total settlement in areas  
730 with the greatest depth of residue is estimated to be on the order of 9.6 ft. As the depth of residue  
731 decreases near the edge of the Hydrometallurgical Residue Facility, less settlement would occur.  
732 The resulting deformed surface of the Hydrometallurgical Residue Facility would be concave  
733 with the greatest deformation in areas of greatest residue thickness.

734 Strain in the Hydrometallurgical Residue Facility liner system would result from differential  
735 settlement in the facility foundation between points along the liner. The maximum strain in the  
736 liner system is estimated to be 0.20 percent. This value is well within acceptable limits of most  
737 geosynthetics, which range from 1 to 19 percent.

738 ***Global Slope Stability***

739 Analysis of the new dams (i.e., those not supported by the existing LTVSMC Tailings Basin or  
740 natural topography) at their greatest height (at year 20) resulted in a computed Factor of Safety  
741 for the ESSA of 2.32, which is greater than the required minimum of 1.5. Because the friction  
742 angle for the dam fill material (approximately 30 degrees) is greater than the proposed dam  
743 downstream slope angle (18 degrees), significant surficial slope failures are not expected.

744 Liquefaction analysis was not applicable and not performed because the material proposed in the  
745 constructed dams would be well-compacted and the Hydrometallurgical Residue Facility liner  
746 system would limit leakage through the dams. Therefore, the embankment is not anticipated to  
747 be saturated during and after operations.

748 ***Infinite Slope Stability***

749 The components of the double liner system are designed to act as hydraulic barriers to leakage;  
750 not as structural members of the dam system. Therefore, the liner layers must not be allowed to

751 slide relative to one another. Evaluation of this potential for sliding was performed using infinite  
 752 slope stability analyses. The minimum infinite slope stability Factor of Safety for all  
 753 Hydrometallurgical Residue Facility liner system components is 1.5.

754 The interior slope angle for the Hydrometallurgical Residue Facility and the geosynthetic  
 755 materials of the liner that would directly contact the underlying soils used for dam construction  
 756 must be selected to produce a stable liner system—a system that would not slide down-slope  
 757 during operations. In addition, each successive layer of the liner system must have an adequate  
 758 interface-friction angle with the adjacent layer to prevent down-slope movement of any layer of  
 759 the liner system. Infinite slope stability for the liner system layer interface configurations  
 760 currently expected is shown in Table 5.2.14-2. Computed Factors of Safety shown in Table  
 761 5.2.14-2 are based on commonly reported interface friction angles between the materials  
 762 anticipated to be used for the Hydrometallurgical Residue Facility liner. Any variation from the  
 763 anticipated material types warrants project-specific interface shear testing to confirm that the  
 764 friction angles are equal to or greater than those used in this analysis.

765 Shear failure in the geosynthetic clay/geomembrane liner systems would occur at the interface  
 766 with the lowest peak shear strength. On the basis of the interface friction angles used in the  
 767 analysis, the design proposed for the Hydrometallurgical Residue Facility achieves a computed  
 768 Factor of Safety of 2.94.

769 **Table 5.2.14-2 Infinite Slope Stability Analysis Results for the Hydrometallurgical Residue**  
 770 **Facility**

| Interface Number | Material Types                                       | Slope Angle, (deg) | Predicted friction Angle, (deg) | Minimum required Factor of Safety | Predicted Factor of Safety |
|------------------|------------------------------------------------------|--------------------|---------------------------------|-----------------------------------|----------------------------|
| 4                | Textured Geomembrane above Geocomposite Drainage Net | 15.95              | 28                              | 1.5                               | 1.86                       |
| 3                | Geocomposite Drainage Net above Textured Geomembrane | 15.95              | 28                              | 1.5                               | 1.86                       |
| 2                | Textured Geomembrane above Geosynthetic Clay Liner   | 15.95              | 28                              | 1.5                               | 1.86                       |
| 1                | Geosynthetic Clay Liner above Granular Soil          | 15.95              | 24                              | 1.5                               | 1.56                       |

771 **Proposed Monitoring, Maintenance, and Mitigation**

772 A Hydrometallurgical Residue Management Plan (PolyMet 2014r) prepared by PolyMet includes  
 773 a description of the operating plans, monitoring procedures, and adaptive management  
 774 approaches for the Hydrometallurgical Residue Facility.

775 Monitoring and maintenance for the Hydrometallurgical Residue Facility would be similar to  
 776 that discussed for the Tailings Basin at the end of Section 5.2.14.2.2 above.

777 Construction quality control and assurance would occur throughout construction of the  
 778 Hydrometallurgical Residue Facility, beginning with regulatory agency review and approval of the  
 779 construction quality control and assurance plan. A Construction Quality Assurance Manual template  
 780 for the installation of the soil and geosynthetic components of liner and cover systems has been

781 drafted to addresses QA/QC procedures for earthwork, geomembrane and geosynthetic clay liner  
782 installation, and piping components of the HRF double liner and leakage collection system, drainage  
783 collection system, and cover system (PolyMet 2014r). Upon completion of construction, a  
784 construction documentation report would be prepared to document that construction of the  
785 Hydrometallurgical Residue Facility was completed in conformance with regulatory agency permit  
786 requirements.

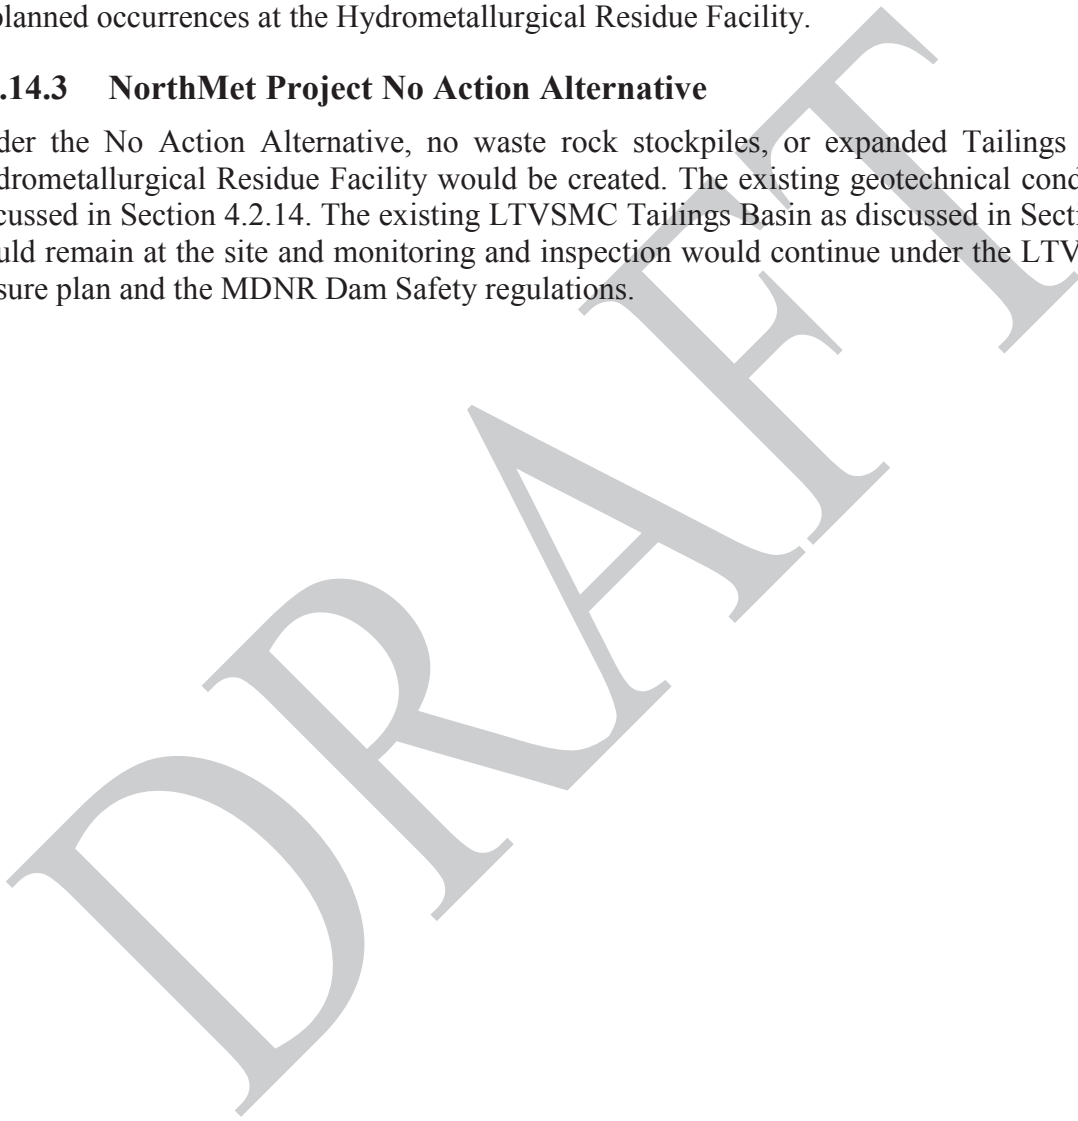

787 A Contingency Action Plan has been prepared as part of the Residue Management Plan (PolyMet  
788 2014r). The plan provides guidance to on-site personnel and emergency responders in the case of  
789 unplanned occurrences at the Hydrometallurgical Residue Facility.

### 790 **5.2.14.3 NorthMet Project No Action Alternative**

791 Under the No Action Alternative, no waste rock stockpiles, or expanded Tailings Basin, or  
792 Hydrometallurgical Residue Facility would be created. The existing geotechnical conditions are  
793 discussed in Section 4.2.14. The existing LTVSMC Tailings Basin as discussed in Section 4.2.14  
794 would remain at the site and monitoring and inspection would continue under the LTVSMC site  
795 closure plan and the MDNR Dam Safety regulations.

796

797

DRAFT

## 1 **5.3 LANDEXCHANGE**

### 2 **5.3.1 Land Use**

3 The Land Exchange Proposed Action represents a transfer of surface rights of 6,495.4 acres from  
4 the Superior National Forest to PolyMet to eliminate the conflict between federal surface and  
5 private mineral estate. This action would remove those acres from Superior National Forest  
6 management and public use. The Land Exchange Proposed Action would remove these acres,  
7 which are part of the 1854 Ceded Territory, from lands available to the Bands to exercise  
8 reserved 1854 Treaty rights. Given the existing lack of overland public access and the current  
9 and historic use of the federal lands for mineral exploration (see Section 4.2.9), the Land  
10 Exchange Proposed Action represents little to no change in the actual level of recent or current  
11 use of the federal lands. At the same time, the Land Exchange Proposed Action brings as many  
12 as 7,075.0 acres of private land into the public domain, making it available for the Bands to  
13 exercise 1854 Treaty rights (see Section 4.3.9).

14 When compared with the Land Exchange No Action Alternative, the Land Exchange Proposed  
15 Action and the Land Exchange Alternative B would provide a slight improvement in key  
16 indicators described in Section 5.3.1.1. The Land Exchange Proposed Action provides for more  
17 of an improvement in overall indicators than under the Land Exchange Alternative B. The Land  
18 Exchange Proposed Action and the Land Exchange Alternative B are both compatible with  
19 adjacent zoning and management area designations.

20 There is no current legacy contamination on the non-federal parcels. Past legacy contamination  
21 concerns are discussed in Section 4.3.1.

#### 22 **5.3.1.1 Methodology and Evaluation Criteria**

23 The area of analysis for land use effects from the Land Exchange Proposed Action included the  
24 federal and non-federal tracts, as well as properties abutting the tracts, which provide the basis  
25 for determining compatibility of land uses on the federal and non-federal parcels. The temporal  
26 analysis is based on the time of change in ownership. Management areas and subsequent land  
27 uses would be established at the time of the ownership change.

28 The analysis of the land use resources affected by the Land Exchange Proposed Action was  
29 guided by evaluation criteria that were developed by the USFS and the other Co-lead Agencies.  
30 The following impact indicators identify anticipated outcomes of the Land Exchange Proposed  
31 Action alternatives being considered for the NorthMet Project Proposed Action:

- 32 • Net change in the number of acres controlled by the USFS on the Superior National Forest;
- 33 • Net change in the length of the boundary around USFS-controlled land in the Superior  
34 National Forest (including internal boundaries around private in-holdings) to be managed  
35 under each of the proposed alternatives;
- 36 • Net change in the level of land fragmentation, expressed as a ratio of linear boundary-to-area  
37 (linear miles per acre) of the USFS-controlled portions of the Superior National Forest under  
38 each of the proposed alternatives;

- 39 • The degree of access to lands owned by the USFS in the Superior National Forest, as  
40 determined through the identification of public access points via road or trail;
- 41 • Degree of compatibility between USFS management areas and zoning or land use  
42 designations (in the absence of zoning) of adjacent areas;
- 43 • Potential for mineral development within the parcels, assessed by the USFS based on mineral  
44 ownership, the type of mineral, and the precedent/history for exploitation of this mineral  
45 within Minnesota; and
- 46 • Quality of title within each of the parcels being considered. Quality was evaluated by the  
47 USFS according to outstanding encumbrances on the parcels considered for each of the Land  
48 Exchange Proposed Action alternatives, including mineral ownership and development  
49 potential.
- 50 Quantitative criteria, such as boundary length and land area, were calculated using GIS.  
51 Evaluations of mineral development potential were conducted by third party professional  
52 geologists (Barr 2011c). The risk of conflict between mineral interests and USFS surface  
53 management and quality of title were assessed by a USFS Forest Realty Specialist.

#### 54 **5.3.1.2 Land Exchange Proposed Action**

##### 55 **5.3.1.2.1 Forest Available for Public Access and Use**

56 Through the Land Exchange Proposed Action, 6,495.4 acres of federal lands in the Superior  
57 National Forest would be transferred to PolyMet in exchange for up to approximately 7,075.0  
58 acres of non-federal lands presently in private ownership. This would result in a net increase of  
59 up to 579.6 acres for the Superior National Forest.

60 All of the non-federal lands are within the 1854 Ceded Territory and would thus be subject to  
61 Treaty rights reserved by the Bands as a result of the Land Exchange Proposed Action. This  
62 would result in a net increase of up to 579.6 acres of publicly owned land in the 1854 Ceded  
63 Territory. Table 5.3.1-1 shows the Management Area designations that the USFS would apply to  
64 the non-federal lands under the Land Exchange.

65

66 **Table 5.3.1-1 Management Area Allocations under the Land Exchange Proposed Action**

| Tract                                      | Acreage by Management Area <sup>1</sup> |                                |                         | cRNA <sup>5</sup> | Total <sup>6</sup> |
|--------------------------------------------|-----------------------------------------|--------------------------------|-------------------------|-------------------|--------------------|
|                                            | General Forest                          | General Forest-Longer Rotation | Riparian Emphasis Areas |                   |                    |
| <b>Federal Lands<sup>2</sup></b>           | 355.3                                   | 6,140.1                        | 0.0                     | 0.0               | 6,495.4            |
| <b>Non-federal Lands<sup>3</sup></b>       |                                         |                                |                         |                   |                    |
| Tract 1                                    | 4,619.3                                 | 0.0                            | 0.0                     | 306.9             | 4,926.2            |
| Tract 2                                    | 0.0                                     | 161.0                          | 220.9                   | 0.0               | 381.9              |
| Tract 3                                    | 1,450.0                                 | 125.8                          | 0.0                     | 0.0               | 1,575.8            |
| Tract 4                                    | 0.0                                     | 160.2                          | 0.0                     | 0.0               | 160.2              |
| Tract 5                                    | 0.0                                     | 30.8                           | 0.0                     | 0.0               | 30.8               |

| <b>Net Increase/(Decrease)<sup>4</sup></b> | 5,714.0                                 | (5,662.3)                      | 220.9                   | 306.9             | 579.6              |

67 <sup>1</sup> See definitions of USFS Management Areas in Section 4.2.3.  
 68 <sup>2</sup> Source: USFS 2011a.  
 69 <sup>3</sup> Source: USFS 2011b.  
 70 <sup>4</sup> Calculated as (non-federal) minus (federal).  
 71 <sup>5</sup> Candidate Research Natural Area (see Section 4.2.3).  
 72 <sup>6</sup> Totals may not match overall NorthMet Project area acreages due to rounding.

73 The 6,495.4 acres of federal lands are not accessible for public use via land (see Section 4.2.11),  
 74 while substantial portions of the non-federal lands do have public access via public roads or  
 75 hiking trails. This distinction is a factor in evaluating land use effects, because public access  
 76 defines the degree to which the lands in question can actually be used—either by the public for  
 77 recreational purposes, by forestry interests for economic purposes, or for research and  
 78 conservation purposes (in the case of Riparian Emphasis and cRNA management areas, defined  
 79 in Section 4.3.1). Tract 1 has direct public access via existing county roads (see Figure 5.3.1-1),  
 80 and Tract 4 has public access via other roads (see Figure 5.3.1-2). Tracts 2 and 3 have no direct  
 81 public access (see Figure 5.3.1-1). When considered collectively, public access to, and therefore  
 82 use of the Superior National Forest, would be increased under the Land Exchange Proposed  
 83 Action.

84 Table 5.3.1-2 shows the effect of the Land Exchange Proposed Action on the total acreage within  
 85 the Superior National Forest that is controlled by the USFS, the boundary of the USFS-  
 86 controlled land (see Section 5.3.1.2.2), and the fragmentation ratio (see Section 5.3.1.2.3). The  
 87 Land Exchange Proposed Action would increase the federal estate by adding a net of 385.1 acres  
 88 to the 2,171,603.9 acres of USFS-controlled land within the Superior National Forest.

89 **Table 5.3.1-2 Superior National Forest Boundary, Acreage, and Fragmentation under the**  
 90 **Land Exchange Proposed Action**

|--------------------------------------------------------|------------------------------------------------------------|-------------------------------|------------------------------------------|
|                                                        |                                                            | Predicted Value               | Net Increase/<br>(Decrease) <sup>1</sup> |
| Acreage in Superior National Forest controlled by USFS | 2,171,603.9                                                | 2,171,989.0                   | 385.1                                    |
| Boundary length (linear miles)                         | 10,054.8                                                   | 10,021.6                      | (33.2)                                   |
| Fragmentation (linear miles per acre)                  | 0.005                                                      | 0.005                         | 0.00                                     |

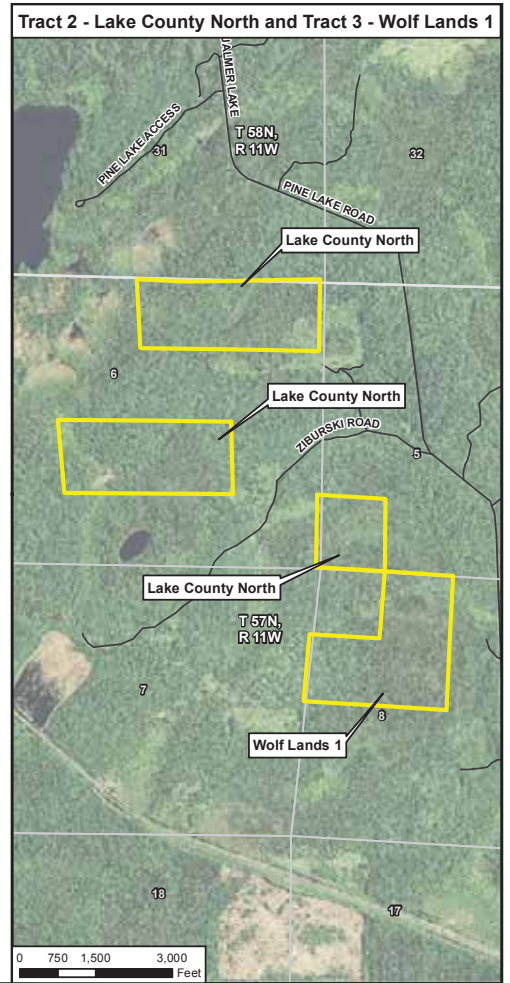

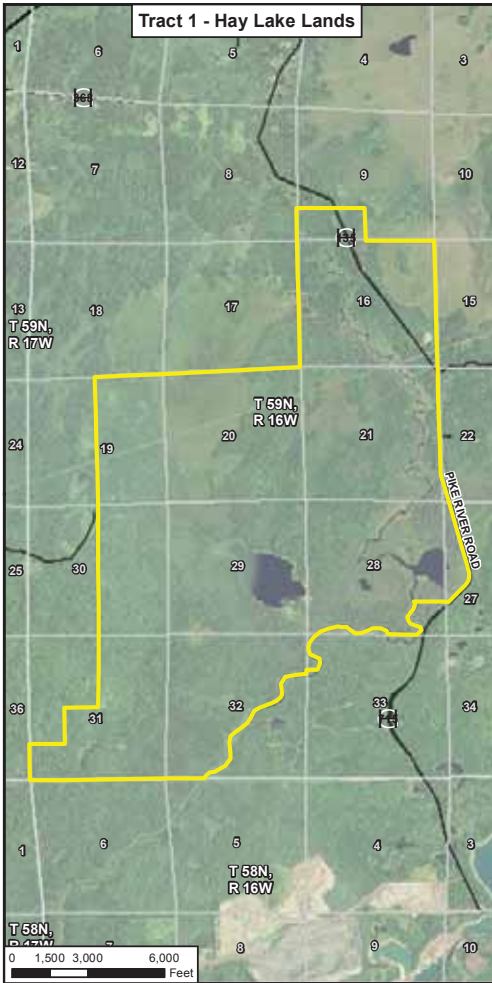

91 <sup>1</sup> Totals differ from acreage reported in Section 5.3.1.2.1 (579.6 acres) due to inconsistencies in GIS data and because Mud Lake  
 92 (30.5 acres) would continue to be managed by the MDNR.

93 **5.3.1.2.2 Boundary Managed**

94 A reduced boundary length is more desirable for the USFS, because it reduces the difficulty of  
 95 accessing and managing the forest. The Land Exchange Proposed Action would result in a  
 96 33.2-linear mile net reduction of the perimeter around the USFS-controlled portions of the  
 97 Superior National Forest (see Table 5.3.1-2).

98 **5.3.1.2.3 Forest Fragmentation**

99 The underlying assumption regarding land fragmentation of USFS-controlled portions of the  
 100 Superior National Forest is that a lower ratio of boundary to area is more desirable, because it  
 101 reduces the difficulty of accessing and managing the forest in addition to increasing the forest's  
 102 overall quality and function. All of the non-federal parcels are contiguous with National Forest  
 103 System lands, thus decreasing the ratio of boundary to area. This reduction would be marginal in  
 104 magnitude, and the Land Exchange Proposed Action would not alter the existing ratio of  
 105 fragmentation in the Superior National Forest of approximately 0.005 linear mile of boundary  
 106 per acre of USFS-controlled Superior National Forest land (see Table 5.3.1-2).

111 **5.3.1.2.4 Zoning Compatibility**

112 Management area designations establish USFS policy for public use of National Forest System  
113 lands (e.g., recreation, scenic resources, and facilities). Section 4.3.1 provides definitions of the  
114 intended uses of the management area designations that apply to the federal and non-federal  
115 tracts, as well as surrounding areas within the Superior National Forest.

116 Zoning in areas adjacent to the non-federal lands outside of the Superior National Forest and  
117 compatibility with the management area designations of non-federal lands are summarized  
118 below:

- 119 • Zoning on privately owned (“non-forest”) lands adjacent to Tract 1 is split among multiple  
120 zoning districts that collectively provide for residential development, wild rice production,  
121 timber, and hunting (St. Louis County 2011). With the exception of residential development  
122 and timber, these uses are generally compatible with the proposed General Forest  
123 Management Area designation of Tract 1. Recreational uses such as personal-use riding and  
124 hunting would be consistent with the cRNA designation. Non-forest lands to the east and  
125 south of Tract 1 are in the Multiple-Use Non-Shoreland (MUNS-4) district (St. Louis County  
126 2011), which is generally compatible with the General Forest and cRNA management areas.
- 127 • Non-forest lands adjacent to Tracts 2 and 3 are in the Forest-Recreation district, as defined by  
128 the Lake County Zoning Ordinance (Nelson, Pers. Comm., October 10, 2011). This is  
129 compatible with the proposed General Forest, General Forest – Longer Rotation, and  
130 Riparian Emphasis Area Management Area designations.
- 131 • Non-forest lands adjacent to Tract 4 to the west and southeast are within the St. Louis County  
132 FAM-1 zoning district, which emphasizes forestry, agricultural, and recreational uses  
133 (St. Louis County 2011). These uses are generally compatible with the proposed General  
134 Forest – Longer Rotation Management Area designation.
- 135 • Privately owned lands adjacent to Tract 5 to the north and southeast are within Cook  
136 County’s Recreational Development zoning district (Cook County 2011), which is generally  
137 compatible with the proposed General Forest – Longer Rotation Management Area.

138 Overall, the management area designations of the non-federal lands are compatible with  
139 surrounding zoning. The Land Exchange Proposed Action would be compatible with the USFS  
140 Management Areas and zoning/land use designations of adjacent lands.

141 **5.3.1.2.5 Mineral Development Potential and Quality of Title**

142 The Land Exchange Proposed Action would remove from the Superior National Forest 6,495.4  
143 acres of land with privately held, minable mineral development potential and USFS-held surface  
144 rights, in exchange for up to 7,075.0 acres of non-federal land with a low mineral development  
145 potential. As described in Section 3.3, the Land Exchange would eliminate conflict between  
146 mineral estate and surface rights on the federal lands by transferring the federal surface to the  
147 holder of the private mineral rights, fulfilling the USFS’s purpose and need.

148 Table 5.3.1-3 summarizes the risk of conflict between mineral potential and the USFS surface  
149 management objectives on each of the non-federal parcels, as well as the overall quality of title  
150 to the land.

151 **Table 5.3.1-3 Mineral Interests and Quality of Title for Non-Federal Lands**

| Tract/Parcel         | Risk of Conflict Between Mineral Interests and USFS Surface Management <sup>1</sup> | Quality of Title <sup>2,3</sup> |
|----------------------|-------------------------------------------------------------------------------------|---------------------------------|
| 1: Hay Lake          | Moderate                                                                            | Moderate                        |
| 2: Lake County North | Low                                                                                 | Moderate                        |
| 2: Lake County South | Low                                                                                 | Moderate                        |
| 3: WolfLands 1       | Low                                                                                 | Moderate                        |
| 3: WolfLands 2       | Low                                                                                 | Moderate                        |
| 3: WolfLands 3       | Low                                                                                 | Moderate                        |
| 3: WolfLands 4       | Low                                                                                 | Moderate                        |
| 4: Hunting Club      | Low                                                                                 | High                            |
| 5: McFarland Lake    | Low                                                                                 | Moderate                        |

152 Source: USFS 2011c.

153 <sup>1</sup> Low is the best and high is the worst, as defined in USFS 2011c and Barr 2011c.

154 <sup>2</sup> Condition of title represents review as of December 21, 2011 -- may be revised per specialist investigation or advice of USDA,  
 155 Office of General Counsel.

156 <sup>3</sup> High is the best and poor is the worst, as defined in USFS 2011c.

157 The risk of conflict determination in Table 5.3.1-3 expresses the degree to which “split estate”  
 158 conditions could complicate achievement of USFS management goals and objectives. Split estate  
 159 refers to situations where private ownership of mineral rights would occur on land whose surface  
 160 is owned by the Superior National Forest after the Land Exchange Proposed Action. This  
 161 concern notwithstanding, the USFS allows exploration, development, and production of mineral  
 162 resources on National Forest System lands under conditions where the activities “are conducted  
 163 in an environmentally sound manner so that they may contribute to economic growth and  
 164 national defense” (USFS 2004b).

165 The “moderate” risk of conflict on Tract 1 reflects the presence of potential surficial aggregate  
 166 resources in the far northeastern corner of the tract. There are also some potential surficial  
 167 aggregate resources near Greenwood Lake in Tract 3, but development of these resources is  
 168 constrained due to the presence of wetlands, which may limit or prohibit access (Barr 2011c).  
 169 For all other tracts, the risk of conflict is low due to the low potential for mineral development.

170 The quality of title determination assesses existing uncertainties in surface ownership, title  
 171 insurance, or other encumbrances that may be transferred to the USFS in the event of the Land  
 172 Exchange moving forward, as well as the risk of conflict defined above. Details of the quality of  
 173 title determination are presented below by tract (USFS 2011c):

- 174 • Tract 1: Moderate, due to the presence of surficial aggregate resources in the northeastern  
 175 portion of the site and certain title encumbrances that may be cured by endorsements in the  
 176 final title insurance policy.
- 177 • Tract 2: Moderate, due to the presence of privately held mineral exploitation rights. This  
 178 potential is constrained by the low potential presence of subsurface mineral resources and the  
 179 absence of surficial deposits.
- 180 • Tract 3: Moderate, due to the presence of privately held mineral exploitation rights on  
 181 portions of all Tract 3 parcels and the presence of private timber rights for one parcel. Mining  
 182 potential is constrained by the low potential presence of subsurface mineral resources, the  
 183 absence of surficial deposits, and the presence of wetlands that may make mineral  
 184 exploitation difficult.

- 185 • Tract 4: High, because the mineral estate was never severed from this parcel.
- 186 • Tract 5: Moderate, due to the potential for privately held mineral exploitation rights. This
- 187 potential is constrained by the low potential presence of subsurface mineral resources and the
- 188 absence of surficial deposits.

189 By comparison, the risk of conflict between mineral and surface rights on the federal lands is

190 high due to the presence of privately owned mineral rights and economically developable

191 minerals and USFS surface ownership. The Land Exchange Proposed Action would reduce this

192 risk by exchanging the high-risk federal lands for predominantly low-risk non-federal lands. The

193 risk of conflict on the non-federal lands may be reduced and title quality further improved

194 through subsequent arrangements with holders of mineral rights on the non-federal lands or

195 affirmative title insurance coverage. Thus, the overall effect of the Land Exchange Proposed

196 Action improves the quality of title and reduces the complexity of title to the federal and non-

197 federal lands.

### 198 **5.3.1.3 Land Exchange Alternative B**

#### 199 **5.3.1.3.1 Forest Available for Public Access and Use**

200 Under the Land Exchange Alternative B, 4,752.6 acres of federal lands would be transferred to

201 private ownership in exchange for up to approximately 4,926.3 acres of land (Tract 1 only), as

202 determined by appraisals. This land is currently in private ownership, resulting in a net increase

203 of approximately 173.6 acres for the Superior National Forest. The federal lands transferred out

204 of the Superior National Forest in this scenario have poor public access (see Section 4.3.11). The

205 smaller federal parcel would leave an isolated island of federal lands to the west of the Mine Site.

206 These federal lands would be difficult to access because the railroad and road are private

207 property. Access points managed by the USFS to the isolated area are limited. The non-federal

208 tract has relatively good public access. Land Exchange Alternative B would result in a net

209 increase of 173.6 acres for the Superior National Forest. All of Tract 1 is within the 1854 Ceded

210 Territory and would thus be available for exercise of 1854 Treaty rights reserved by the Bands.

211 Table 5.3.1-4 shows the Management Area designations that the USFS would apply to Tract 1

212 under Land Exchange Alternative B.

213

214 **Table 5.3.1-4 Management Area Allocations under Land Exchange Alternative B**

| Tract                                      | Acreage by Management Area <sup>1</sup> |                                    |                            | cRNA <sup>5</sup> | Total <sup>6</sup> |
|--------------------------------------------|-----------------------------------------|------------------------------------|----------------------------|-------------------|--------------------|
|                                            | General Forest                          | General Forest-<br>Longer Rotation | Riparian<br>Emphasis Areas |                   |                    |

|-----------------------------------------------------------|-----------------------------------------------------------|-----------------------------|-----------------------------------------|
|                                                           |                                                           | Predicted Value             | Net<br>Increase/(Decrease) <sup>1</sup> |
| Acreage in Superior National Forest<br>controlled by USFS | 2,171,603.9                                               | 2,171,642.6                 | 38.7                                    |
| Boundary length (linear miles)                            | 10,054.8                                                  | 10,046.2                    | (8.6)                                   |
| Fragmentation (linear miles per acre)                     | 0.005                                                     | 0.005                       | 0.00                                    |

228 <sup>1</sup> Totals differ from acreage reported in Table 5.3.1-4 (173.6 acres) due to inconsistencies in GIS data and because Mud Lake  
 229 (30.5 acres) would continue to be managed by the MDNR.

230 **5.3.1.3.2 Boundary Managed**

231 The Land Exchange Alternative B would result in an 8.6-mile net reduction of the perimeter  
 232 around the USFS-controlled portions of the Superior National Forest (see Table 5.3.1-5).

233 **5.3.1.3.3 Forest Fragmentation**

234 The Land Exchange Alternative B would not change the fragmentation ratio in USFS-controlled  
 235 portions of the Superior National Forest (see Table 5.3.1-5).

236 **5.3.1.3.4 Zoning Compatibility**

237 Under the Land Exchange Alternative B, the forest lands that would become isolated under this  
 238 alternative to the west of the smaller federal parcel would remain within the Superior National  
 239 Forest, and would retain their General Forest – Longer Rotation Management Area designation.

240 This management area is compatible with nearby mining activity. There is no existing public  
241 access to this portion of the Superior National Forest, and it is reasonable to expect that  
242 permission of the private landowner to access the land would be restricted, for health and safety  
243 reasons, for the anticipated life of the mine.

244 The proposed management area designation for Tract 1 under the Land Exchange Alternative B  
245 would be the same as in the Land Exchange Proposed Action (see Section 5.3.1.2.4). The Land  
246 Exchange Alternative B would be compatible with the USFS management areas and zoning/land  
247 use designations of adjacent lands.

#### 248 **5.3.1.3.5 Mineral Development Potential and Quality of Title**

249 The Land Exchange Alternative B would remove 4,752.6 acres of forest lands with proven  
250 mineral development potential from the Superior National Forest, in return for up to 4,926.3  
251 acres with moderate mineral development potential, except for potential surficial aggregate  
252 resources in the far northeastern corner of Tract 1 (Barr 2011c). The risk of conflict and quality  
253 of title for the Land Exchange Alternative B is the same as for Tract 1 in the Land Exchange  
254 Proposed Action (see Table 5.3.1-3).

255 As with the Land Exchange Proposed Action, the Land Exchange Alternative B would result in a  
256 reduced risk of conflict and improved quality of title. The Land Exchange Alternative B would  
257 result in relinquishing the federal parcel with severed, private mineral rights and known,  
258 economically developable minerals and acquiring parcels with low to moderate risk of conflict  
259 and moderate to high title quality. The risk of conflict and title quality may be further improved  
260 through subsequent arrangements with holders of mineral rights on the non-federal lands or  
261 affirmative title insurance coverage. Thus, the Land Exchange Alternative B would also benefit  
262 efforts to manage the Superior National Forest, although to a lesser degree than the Land  
263 Exchange Proposed Action.

264 Mineral rights to the Mine Site are held by PolyMet, while surface rights are held by USFS,  
265 creating a conflict between surface and mineral rights. As described in Section 3.3, the USFS's  
266 Purpose and Need is to resolve the conflict between surface and mineral rights (see Section  
267 5.3.1).

268 The Land Exchange Alternative B would be consistent with this Purpose and Need, as well as  
269 existing land use designations surrounding the Mine Site. Therefore, the Land Exchange  
270 Alternative B would have no adverse effect on land use at the Mine Site. Effects on recreational  
271 and natural resource use at the Mine Site are addressed in other sections of this chapter.

#### 272 **5.3.1.4 Land Exchange No Action Alternative**

273 The Land Exchange No Action Alternative represents no change to current land use on the  
274 federal and non-federal lands. There would be no change in the amount of forest boundary  
275 managed, level of forest fragmentation, or acres available for public access and use.

276 Under the Land Exchange No Action Alternative, interest in development of mineral potential on  
277 the federal lands could continue, and would be compatible with relevant local zoning ordinances  
278 and planning designations. The Land Exchange No Action Alternative is also compatible with  
279 the General Forest and General Forest – Longer Rotation Management Area classifications.  
280 However, the mineral rights would remain severed from federal ownership. The potential

281 conflict between mineral interests and USFS surface management of the federal parcel would  
282 remain.

283 The presence of a privately owned road (Dunka Road) and rail on the southern border of the  
284 federal lands would continue to limit public access to and use of the federal lands, as envisioned  
285 by the management area designations.

DRAFT

1 **5.3.2 Water Resources**

2 This section describes the potential effects and compares the resource value of the Land  
3 Exchange Proposed Action on water resources of the federal and non-federal lands to be  
4 exchanged, as well as for Land Exchange Alternative B and the Land Exchange No Action  
5 Alternative. The effects on the federal and non-federal lands are discussed together to facilitate  
6 comparison between the water resources of the lands exchanged. The total yield and quality of  
7 surface and groundwater currently leaving the non-federal tracts and flowing into the federal  
8 estate would not be altered by any of the Land Exchange alternatives. Under the Land Exchange  
9 Proposed Action and alternatives, the Superior National Forest would retain its ongoing  
10 responsibility for managing water resources on USFS lands in accordance with the Forest Plan.  
11 Table 5.3.2-1 shows the effects of the Land Exchange Proposed Action and Land Exchange  
12 alternatives on acreage of surface water and wild rice beds.

13 Under the Land Exchange Proposed Action, a net increase of 95.2 acres of MDNR-designated  
14 public water lakes (2.1 miles of shoreline) and 4.6 miles of public water streams would be added  
15 to the federal estate. By comparison, under Land Exchange Alternative B, a net increase of 116.8  
16 acres of public water lakes (2.6 miles of shoreline) and 3.6 miles of public water streams would  
17 be added to the federal estate. One difference is that, under the Land Exchange Proposed Action,  
18 all of Mud Lake (30.5 acres) would be exchanged for the private lands, while under Land  
19 Exchange Alternative B only about 8.9 acres of Mud Lake would be included in the land  
20 exchange.

21 Both the Land Exchange Proposed Action and Land Exchange Alternative B would result in a  
22 net increase of wild rice beds to the federal estate. The federal lands do not contain any known  
23 wild rice beds, but Hay Lake Lands (Tract 1) contain known wild rice beds (approximately 126  
24 acres). No wild rice beds would be affected as a result of the Land Exchange Proposed Action or  
25 Land Exchange Alternative B as no activities are proposed on the non-federal lands and the  
26 proposed mining activities would not affect these lands. Furthermore, though the Land Exchange  
27 Proposed Action would result in an increase in wild rice stands within the federal estate  
28 boundaries, there would be no change to the wild rice harvest opportunities for the public due to  
29 the Land Exchange Proposed Action or the Land Exchange Alternative B.

30 **Table 5.3.2-1 Net Change in Surface Water and Wild Rice Beds to the Federal Estate under**  
 31 **the Land Exchange Proposed Action and Alternatives**

| Alternative                            | Net Increase/(Decrease) of Water Resources |                                                  |                                    |                                        |
|----------------------------------------|--------------------------------------------|--------------------------------------------------|------------------------------------|----------------------------------------|
|                                        | Public Water<br>Lakes<br>(acres)           | Public Water<br>Lakes<br>(miles of<br>shoreline) | Public Water<br>Streams<br>(miles) | Wild Rice Beds<br>(acres) <sup>1</sup> |
| Land Exchange Proposed<br>Action       | 95.2                                       | 2.1                                              | 4.6                                | >125.7 <sup>(2)</sup>                  |
| Land Exchange<br>Alternative B         | 116.8                                      | 2.6                                              | 3.6                                | >125.7 <sup>(2)</sup>                  |
| Land Exchange No Action<br>Alternative | 0                                          | 0                                                | 0                                  | 0                                      |

32 <sup>1</sup> Wild rice beds within the Land Exchange Proposed Action and the Land Exchange Alternative B boundaries are currently, and  
 33 would continue to be, located in MDNR-designated public waters.

34 <sup>2</sup> Excludes area of wild rice beds in Pike River. Presence of wild rice in the Pike River, which runs through Rice Lake, was  
 35 noted in Barr's surveys (2011a; 2012a; 2013l), but the area of rice was not calculated.

36 There is limited groundwater or surface water quality data available for the non-federal tracts,  
 37 with the exception of sulfate data for the Hay Lake Lands. There are, however, no known  
 38 reasons to suspect surface water or groundwater contamination of any of the tracts from human  
 39 activities. In general, water quality is expected to reflect natural conditions as similar to that  
 40 found from MPCA regional studies (see Section 4.3.2.2.3).

### 41 5.3.2.1 Methodology and Evaluation Criteria

42 The area of analysis for water resource effects of the Land Exchange alternatives included the  
 43 federal and non-federal tracts proposed for the exchange.

44 Since the Land Exchange Proposed Action would not actually result in any direct effects, as  
 45 there are no construction or other activities proposed that would affect water resources, this  
 46 assessment focuses on a comparison of the net change in the quantity and quality of water  
 47 resources between the federal and non-federal tracts involved in the exchange.

#### 48 5.3.2.1.1 Groundwater Evaluation Criteria

49 Groundwater resource evaluation criteria for the Land Exchange Proposed Action include a  
 50 qualitative assessment of potential for groundwater contamination of the non-federal properties  
 51 using MDNR and MPCA groundwater quality data.

#### 52 5.3.2.1.2 Surface Water and Wild Rice Evaluation Criteria

53 Surface water evaluation criteria for the Land Exchange Proposed Action include a comparison  
 54 of the length of public water streams/rivers, public water lake acreage, and shoreline length  
 55 between the federal and non-federal lands. This was used to determine the net change in quantity  
 56 of waterbodies. In addition, a qualitative assessment of surface water quality was conducted  
 57 taking into consideration available water quality data, aerial photographs, and GIS information.

58 Wild rice evaluation criteria include a comparison in the amount of known or potential wild rice  
 59 beds between federal and non-federal lands. This was used to determine the potential change in

60 acres of wild rice on the federal estate. Information that was used in the analysis of wild rice  
61 beds included available field data, aerial photographs, and GIS layers.

### 62 **5.3.2.2 Land Exchange Proposed Action**

63 The Land Exchange Proposed Action would involve the transfer of 6,495.4 acres of federal lands  
64 from public to private ownership, and up to 7,075.0 acres of private land to public ownership  
65 (see Figure 3.3-1).

#### 66 **5.3.2.2.1 Groundwater**

67 The Land Exchange Proposed Action would not directly result in a change in groundwater  
68 quantity or quality presently at the non-federal tracts. Evaluation of existing hydrogeologic data  
69 did not suggest the potential for groundwater contamination from human activity from any of the  
70 tracts. Therefore, there does not appear to be any substantive difference in the quality of  
71 groundwater resources between the federal and non-federal tracts.

#### 72 **5.3.2.2.2 Surface Water and Wild Rice**

73 The Land Exchange Proposed Action would not directly result in a change in surface water  
74 quantity or quality at the non-federal tracts. There would be a net increase to the federal estate of  
75 4.6 miles of public water streams and 95.2 acres of public water lakes (including 2.1 miles of  
76 additional shoreline).

77 No wild rice stands are known to occur on the federal lands, and suitable habitat is limited. The  
78 non-federal lands that contain wild rice beds would not be affected as a result of the Land  
79 Exchange Proposed Action or Land Exchange Alternative B, because no activities are proposed  
80 on these lands and the proposed mining activities would not affect these lands. As noted in the  
81 FEIS, the Land Exchange Proposed Action would result in a net increase of 125.7 acres of wild  
82 rice beds to the federal estate. FEIS Sections 5.3.2 and 5.3.4 clarify that, although the Land  
83 Exchange would result in an increase in wild rice stands within the federal estate boundaries,  
84 there would be no change to the existing public access to Tract 1 wild rice stands via the Pike  
85 River. Consequently, there would be no increase in wild rice harvest opportunities for the public.

86 Table 5.3.2-2 summarizes the federal and non-federal surface water resources and shows the net  
87 changes in these resources to the federal estate that would result from the Land Exchange  
88 Proposed Action. The Hay Lake lands (Tract 1) account for the majority of the net gain in  
89 surface water and wild rice beds to the federal estate from all the non-federal lands.

90 **Table 5.3.2-2 Net Change in Surface Water and Wild Rice Beds to the Federal Estate under**  
 91 **the Land Exchange Proposed Action**

|                                | Surface Water Resource           |                                                  |                                    |                                        |
|--------------------------------|----------------------------------|--------------------------------------------------|------------------------------------|----------------------------------------|
|                                | Public Water<br>Lakes<br>(acres) | Public Water<br>Lakes<br>(miles of<br>shoreline) | Public Water<br>Streams<br>(miles) | Wild Rice Beds<br>(acres) <sup>1</sup> |
| <b>Lands Conveyed</b>          |                                  |                                                  |                                    |                                        |
| Federal Lands                  | 30.5                             | 0.9                                              | 4.5                                | 0.0                                    |
| <b>Lands Acquired</b>          |                                  |                                                  |                                    |                                        |
| Tract 1 – Hay Lake             | 125.7                            | 2.8                                              | 8.1                                | >125.7 <sup>(2)</sup>                  |
| Tract 2 – Lake County          | 0.0                              | 0.0                                              | 0.0                                | 0.0                                    |
| Tract 3 – Wolf Lands           | 0.0                              | 0.0                                              | 1.0                                | 0.0                                    |
| Tract 4 – Hunting Club         | 0.0                              | 0.0                                              | 0.0                                | 0.0                                    |
| Tract 5 – McFarland Lake       | 0.0                              | 0.2                                              | 0.0                                | 0.0                                    |
| Subtotal: Non-federal<br>Lands | 125.7                            | 3.0                                              | 9.1                                | >125.7 <sup>(2)</sup>                  |
| <b>Net Increase/(Decrease)</b> | <b>95.2</b>                      | <b>2.1</b>                                       | <b>4.6</b>                         | <b>&gt;125.7<sup>(2)</sup></b>         |

92 <sup>1</sup> Wild rice beds within the Land Exchange Proposed Action boundaries are currently, and would continue to be, in MDNR-  
 93 designated public waters.

94 <sup>2</sup> Excludes area of wild rice beds in Pike River.

95 **5.3.2.3 Land Exchange Alternative B**

96 Under the Land Exchange Alternative B, 4,752.6 acres of federal lands would be transferred  
 97 from public to private ownership, and 4,926.3 acres of land from private to public ownership, for  
 98 a net increase in 173.7 acres in the federal estate (see Figure 3.3-2).

99 **5.3.2.3.1 Groundwater**

100 The Land Exchange Alternative B would not directly result in a change in groundwater quantity  
 101 or quality at the non-federal tracts. Evaluation of existing hydrogeologic data did not suggest the  
 102 potential for groundwater contamination from human activity from any of the tracts. Therefore,  
 103 there does not appear to be any substantive difference in the quality of groundwater resources  
 104 between the federal and non-federal tracts.

105 **5.3.2.3.2 Surface Water and Wild Rice**

106 The Land Exchange Alternative B would not directly result in a change in surface water quantity  
 107 or quality at the non-federal tracts. There would be a net increase to the federal estate of about  
 108 3.6 miles of public water streams, under Land Exchange Alternative B. There would also be a  
 109 net increase of about 116.8 acres of public water lake area (including 2.6 miles of shoreline) and  
 110 at least 125.7 acres of wild rice beds contained within the federal estate under the Land  
 111 Exchange Alternative B.

112 No wild rice stands are known to occur on the smaller federal parcel, and suitable habitat is  
 113 limited. The non-federal lands that contain wild rice beds would not be affected as a result of the  
 114 Land Exchange Proposed Action or Land Exchange Alternative B, because no activities are  
 115 proposed on these lands and the proposed mining activities would not affect these lands. As  
 116 noted in the FEIS, the Land Exchange Alternative B would result in a net increase of 125.7 acres

117 of wild rice beds to the federal estate. FEIS Sections 5.3.2 and 5.3.4 clarify that, although the  
 118 Land Exchange would result in an increase in wild rice stands within the federal estate  
 119 boundaries, there would be no change to the existing public access to Tract 1 wild rice stands via  
 120 the Pike River. Consequently, there would be no increase in wild rice harvest opportunities for  
 121 the public.

122 Table 5.3.2-3 summarizes the federal and non-federal surface water resources and shows the net  
 123 changes in these resources to the federal estate that would result from the Land Exchange  
 124 Alternative B.

125 **Table 5.3.2-3 Net Change in Surface Water and Wild Rice Beds to the Federal Estate under**  
 126 **Land Exchange Alternative B**

|                                | Surface Water Resource           |                                               |                                    |                                        |
|--------------------------------|----------------------------------|-----------------------------------------------|------------------------------------|----------------------------------------|
|                                | Public Water<br>Lakes<br>(acres) | Public Water<br>Lakes<br>(miles of shoreline) | Public Water<br>Streams<br>(miles) | Wild Rice Beds<br>(acres) <sup>1</sup> |
| <b>Lands Conveyed</b>          |                                  |                                               |                                    |                                        |
| Federal Lands                  | 8.9                              | 0.2                                           | 4.5                                | 0.0                                    |
| <b>Lands Acquired</b>          |                                  |                                               |                                    |                                        |
| Tract 1                        | 125.7                            | 2.8                                           | 8.1                                | >125.7 <sup>(2)</sup>                  |
| <b>Net Increase/(Decrease)</b> | <b>116.8</b>                     | <b>2.6</b>                                    | <b>3.6</b>                         | <b>&gt;125.7<sup>(2)</sup></b>         |

127 <sup>1</sup> Wild rice beds within the Land Exchange Alternative B boundaries are currently, and would continue to be, in MDNR-  
 128 designated public waters.  
 129 <sup>2</sup> Excludes area of wild rice beds in Pike River.

130 **5.3.2.4 Land Exchange No Action Alternative**

131 Under the Land Exchange No Action Alternative, the Land Exchange Proposed Action would  
 132 not take place and would result in no changes in existing water resources under federal  
 133 ownership. The Superior National Forest would have an ongoing responsibility for managing  
 134 water resources on the federal lands in accordance with the Forest Plan. The Land Exchange No  
 135 Action Alternative would not change the USFS responsibility for managing water resources.

DRAFT

1 **5.3.3 Wetlands**

2 This section describes the potential environmental consequences of the Land Exchange Proposed  
3 Action on wetland resources that occur on the federal and non-federal lands. In this section,  
4 effects on the federal and non-federal lands are discussed together, to facilitate calculation of net  
5 changes to wetland resources. Under the Land Exchange Proposed Action and alternatives, the  
6 Superior National Forest would retain its ongoing responsibility for managing wetland resources  
7 on Forest Service lands in accordance with the Forest Plan.

8 Overall, the Land Exchange Proposed Action would result in an increase to the federal estate of  
9 wetland acreage by up to 505.5 acres through the acquisition of up to 7,075.0 acres of non-  
10 federal lands in exchange for 6,495.4 acres of federal land, and thus would be in conformity with  
11 EO 11990 (see Table 5.3.3-1). The Land Exchange Proposed Action would result in a net  
12 increase to the federal estate of 376.2 acres of mapped floodplain area, but would result in a  
13 decrease of 1,602.2 acres of unmapped floodplain area, for a net decrease of 1,226.0 acres of  
14 overall floodplain area (see Table 5.3.3-1). There would be no decrease in the amount of mapped  
15 floodplain or increase in the flood damage potential associated with the Land Exchange  
16 Proposed Action. The effects on the ecological function of the floodplain wetlands would be  
17 mitigated through the Section 404 Permit and the proposed mitigation described in Section 5.2.3.  
18 The Land Exchange Proposed Action would also increase the wetlands within the federal estate.  
19 The Land Exchange Proposed Action would be in conformance with EO 11988 (USFS 2004d  
20 [FSH 5409.13 § 33.43c]). The Land Exchange Proposed Action would result in an increase of  
21 coniferous swamp, hardwood swamp, open water, shallow marsh, and shrub swamp wetland  
22 resources to the federal estate, but would result in a decrease of coniferous bog, open bog, and  
23 sedge/wet meadows wetland resources to the federal estate (see Table 5.3.3-2). In addition, the  
24 Land Exchange Proposed Action would result in an increase in waterway acreage and frontage to  
25 the federal estate (see Table 5.3.3-3).

26 Due to the reduced land area involved, Land Exchange Alternative B would result in a lesser  
27 degree of wetlands, floodplains, and other water resources exchanged to the federal estate as the  
28 proposed Land Exchange Proposed Action. Overall, Land Exchange Alternative B would  
29 increase wetland areas to the federal estate by 69.9 acres (see Table 5.3.3-1) through the  
30 acquisition of up to 4,926.3 acres of the non-federal lands in exchange for 4,752.6 acres of  
31 federal land, and would thus be in conformity with EO 11990. The Land Exchange Alternative B  
32 would result in a net increase to the federal estate of 376.2 acres of mapped floodplain area, but  
33 would result in a decrease of 1,237.9 acres of unmapped floodplain area, for a net decrease of  
34 861.7 acres of overall floodplain area (see Table 5.3.3-1). There would be no decrease in the  
35 amount of mapped floodplain or increase in the flood damage potential associated with the Land  
36 Exchange Alternative B. The effects on the ecological function of the floodplain wetlands would  
37 be mitigated through the Section 404 Permit and the proposed mitigation described in Section  
38 4.2.3. The Land Exchange Alternative B would also increase the wetlands within the federal  
39 estate. The Land Exchange Alternative B would be in conformance with EO 11988 (USFS  
40 2004d [FSH 5409.13 § 33.43c]). Land Exchange Alternative B would result in an increase of  
41 coniferous swamp, open water, shallow marsh, and shrub swamp wetland resources to the federal  
42 estate but would result in a decrease to coniferous bog, hardwood swamp, open bog, and  
43 sedge/wet meadows wetland resources to the federal estate (see Table 5.3.3-2). In addition, Land

44 Exchange Alternative B would result in an increase of waterway acreage and frontage to the  
45 federal estate (see Table 5.3.3-3).

46 **Table 5.3.3-1 Net Increase or Decrease of Wetland and Floodplain Acres on the Federal**  
47 **Estate from the Land Exchange Proposed Action and Alternatives**

| Alternative                   | Increase (or Decrease) of Wetland and Floodplain Acres |                                    |
|-------------------------------|--------------------------------------------------------|------------------------------------|
|                               | Wetlands (Acres)                                       | Floodplains <sup>1,2</sup> (Acres) |
| Land Exchange Proposed Action | 505.5                                                  | (1,226.0)                          |
| Land Exchange Alternative B   | 69.9                                                   | (861.7)                            |

48 <sup>1</sup> The federal floodplain area is a 500-year (0.2%) probability floodplain.

49 <sup>2</sup> Includes an increase of 376.2 acres of mapped floodplains to the federal estate.

50 **Table 5.3.3-2 Net Increase or Decrease of Wetland Resource Types on the Federal Estate**  
51 **from the Land Exchange Proposed Action and Alternatives**

| Alternative                   | Increase (or Decrease) of Wetland Resource Types (Acres) |                               |            |                             |          |                                                      |                  |                            |                                                     |
|-------------------------------|----------------------------------------------------------|-------------------------------|------------|-----------------------------|----------|------------------------------------------------------|------------------|----------------------------|-----------------------------------------------------|
|                               | Coniferous Bog                                           | Coniferous Swamp <sup>1</sup> | Deep Marsh | Hardwood Swamp <sup>2</sup> | Open Bog | Open Water (includes shallow, open water, and lakes) | Sedge/Wet Meadow | Shallow Marsh <sup>3</sup> | Shrub Swamp (includes alder thicket and shrub-carr) |
| Land Exchange Proposed Action | (1,961.4)                                                | 1,954.6                       | 0.0        | 36.9                        | (202.4)  | 151.7                                                | (35.7)           | 20.5                       | 541.3                                               |
| Land Exchange Alternative B   | (1,677.0)                                                | 1,477.8                       | 0.0        | (5.7)                       | (172.9)  | 168.0                                                | (34.9)           | 3.2                        | 311.4                                               |

52 <sup>1</sup> Coniferous bogs on the non-federal lands were grouped with coniferous swamps during field data collection.

53 <sup>2</sup> Hardwood swamps on the non-federal lands may contain coniferous tree species.

54 <sup>3</sup> Shallow marsh areas on the non-federal lands may contain deep marshes.

55 **Table 5.3.3-3 Net Increase or Decrease of Frontage of Waterways on the Federal Estate**  
56 **from the Land Exchange Proposed Action and Alternatives**

| Alternative                   | Increase (or Decrease) of Frontage of Waterways |               |                              |                    |                      |                               |
|-------------------------------|-------------------------------------------------|---------------|------------------------------|--------------------|----------------------|-------------------------------|
|                               | Lake                                            |               |                              | River/Stream/Creek |                      |                               |
|                               | Acres                                           | Frontage (ft) | Length of Lake Frontage/Acre | Miles              | Frontage (linear ft) | Length of River Frontage/Acre |
| Land Exchange Proposed Action | 99.1                                            | 12,864.0      | 34.9                         | 3.8                | 27,456.0             | 34.0                          |
| Land Exchange Alternative B   | 120.7                                           | 15,224.0      | 3.2                          | 2.8                | 16,896.0             | 3.5                           |

57 Source: Data from Section 4.3.3.

58 Based on a qualitative assessment, the Land Exchange Proposed Action and Land Exchange  
59 Alternative B would appear to result in an increase to the federal estate of wetlands rated as high  
60 for vegetation diversity/integrity, wetland water quality, fish habitat, and amphibian habitat.  
61 Land Exchange Alternative B would also appear to result in an increase to the federal estate of

62 wetlands rated as high for hydrology and wildlife habitat. The Land Exchange Proposed Action  
63 would result in an increase to the federal estate of moderate and low rated wetlands for  
64 amphibian habitat, as where Land Exchange Alternative B would also result in an increase to the  
65 federal estate of wetlands rated low for amphibian habitat. The Land Exchange Proposed Action  
66 would have similarly rated hydrology, flood attenuation, downstream water quality, wildlife  
67 habitat, and aesthetics/education/cultural functions. Land Exchange Alternative B would result in  
68 a decrease to the federal estate of wetlands rated high and moderate for flood attenuation and  
69 downstream water quality and would not result in a change to aesthetics/education/cultural  
70 functions.

### 71 **5.3.3.1 Methodology and Evaluation Criteria**

72 The potential effect that the Land Exchange Proposed Action and alternatives would have on  
73 wetland resources was evaluated using two types of criteria: 1) criteria assessing conformity to  
74 EOs 11990 and 11988, which requires a wetland acre-for-acre analysis and a floodplain acre-for-  
75 acre analysis of the federal estate, and 2) criteria used in an analysis of wetlands and floodplain  
76 habitat, as well as other water resource indicators.

77 As previously discussed, to satisfy the requirements of EOs 11990 and 11988, the USFS policy  
78 is to use the following three conditions (USFS 2004d [FSH 5409.13 § 33.43c]): 1) the value of  
79 the wetlands or floodplains for properties received and conveyed is equal (balancing test) and the  
80 land exchange is in the public interest; 2) reservations or restrictions are retained on the  
81 unbalanced portion of the wetlands and floodplains on the federal lands when the land exchange  
82 is in the public interest but does not meet the balancing test; and 3) the federal property is  
83 removed from the exchange proposal when the conditions described in the preceding paragraphs  
84 1 or 2 cannot be met.

85 In addition to evaluating wetlands in accordance with the two EOs, analysis of the Land  
86 Exchange included information on wetland community types as well as ecological floodplains.

87 To evaluate conformity to the EOs, the following evaluation criteria were used:

- 88 • Comparative difference in acres of wetland between the federal and non-federal parcels; and
- 89 • Comparative difference in acres of floodplain between the federal and non-federal parcels.

90 Other wetland resources indicators that were used are the following:

- 91 • Comparative difference in acres of wetland types between the federal and non-federal  
92 parcels;
- 93 • A MnRAM assessment of wetland function and value;
- 94 • Change in flood damage potential on the parcels and to the surrounding parcels;
- 95 • A MnRAM assessment of floodplain assets; and
- 96 • Comparative difference of length of streams, rivers, and lake frontage between the federal  
97 and non-federal parcels.

98 The spatial area of analysis for wetland resource effects from the Land Exchange Proposed  
99 Action and alternatives included the federal and non-federal tracts proposed for the exchange,

100 while the temporal area of analysis assessed was the point in time at which the change in  
 101 ownership would occur.

102 The analysis of the wetland resources affected by the Land Exchange Proposed Action and  
 103 alternatives was guided by evaluation criteria that were developed by the USFS and other Co-  
 104 lead Agencies, which included a comparison of wetland resource acreages, wetland resources  
 105 types, wetland function and values, floodplain acreages, and other water resources acreages. GIS  
 106 data and field observations were used and then compared over an area of analysis that included  
 107 the federal and non-federal lands.

108 **5.3.3.1.1 Wetlands**

109 The federal lands contain 4,164.4 acres of wetlands (see Table 5.3.3-4). By comparison, the five  
 110 non-federal land tracts contain 4,669.9 acres of wetlands. The Land Exchange Proposed Action  
 111 would result in a net increase of up to 505.5 acres of wetlands to the federal estate if all five  
 112 tracts are exchanged (see Table 5.3.3-4). The Land Exchange Proposed Action would increase  
 113 wetland acreage to the federal estate by up to 505.5 acres through the acquisition of up to 7,075.0  
 114 acres of non-federal lands in exchange for 6,495.4 acres of federal land, and thus would be in  
 115 conformity with EO 11990.

116 **Table 5.3.3-4 Wetland and Floodplain Acres for the Land Exchange Proposed Action**

| Parcel                      | Acres of Wetlands | Acres of Floodplains     |
|-----------------------------|-------------------|--------------------------|
| <b>Lands Conveyed</b>       |                   |                          |
| Federal Lands               | 4,164.4           | 1,889.4 <sup>(1)</sup>   |
| <b>Lands Acquired</b>       |                   |                          |
| Tract 1                     | 2,930.8           | 551.2                    |
| Tract 2                     | Lake County North | 209.3                    |
|                             | Lake County South | 73.6                     |
| Tract 3                     | Wolf Lands 1      | 90.4                     |
|                             | Wolf Lands 2      | 706.2                    |
|                             | Wolf Lands 3      | 233.2                    |
|                             | Wolf Lands 4      | 362.8                    |
| Tract 4                     | 63.6              | 0.0                      |
| Tract 5                     | 0.0               | 0.0                      |
| Subtotal: Non-federal lands | 4,669.9           | 633.4                    |
| <b>Net Change</b>           |                   |                          |
| Net Increase/(Decrease)     | 505.5             | (1,226.0) <sup>(2)</sup> |

117 <sup>1</sup> The federal floodplain area is a 500-year (0.2%) probability floodplain.

118 <sup>2</sup> Includes an increase of 376.2 acres of mapped floodplains to the federal estate.

119 As part of the increase in total wetland acreage, the Land Exchange Proposed Action would  
 120 result in a net increase to the federal estate of the following wetland resource types (see Table  
 121 5.3.3-5): coniferous swamp (1,954.6 acres), hardwood swamp (36.9 acres), open water (151.7  
 122 acres), shallow marsh (20.5 acres), and shrub swamp (541.3 acres). However, the Land  
 123 Exchange Proposed Action would result in a net decrease to the federal estate of the following  
 124 wetland resource types: coniferous bog (1,961.4 acres), open bog (202.4 acres), and sedge/wet  
 125 meadow (35.7 acres).

126 **Table 5.3.3-5 Wetland Resource Types for the Land Exchange Proposed Action**

| Parcel                      | Acres of Wetland Resource Types |                               |            |                             |          |                                                      |                  |                            |                                                     |

| Net Increase/(Decrease)     | (1,961.4)                       | 1,954.6                       | 0.0        | 36.9                        | (202.4)  | 151.7                                                | (35.7)           | 20.5                       | 541.3                                               |

127 <sup>1</sup> Coniferous bogs on the non-federal lands were grouped with coniferous swamps during field data collection.  
 128 <sup>2</sup> Hardwood swamps on the non-federal lands may contain coniferous tree species.  
 129 <sup>3</sup> Shallow marsh areas on the non-federal lands may contain deep marshes.

130 **5.3.3.1.2 Wetland Functional Assessment**

131 Based on a qualitative assessment, the Land Exchange Proposed Action would appear to result in  
132 an increase to the federal estate of the following high rated wetland functions: vegetation  
133 diversity/integrity, wetland water quality, fish habitat, and amphibian habitat. The Land  
134 Exchange Proposed Action would result in an increase to the federal estate of moderate- and  
135 low-rated wetlands for amphibian habitat. The Land Exchange Proposed Action would have  
136 similarly rated hydrology, flood attenuation, downstream water quality, wildlife habitat, and  
137 aesthetics/education/cultural functions.

138 **5.3.3.1.3 Floodplains**

139 There are no mapped floodplains within the federal lands as described in Section 4.3.3. The Land  
140 Exchange Proposed Action would result in a net increase to the federal estate of 376.2 acres of  
141 mapped floodplain area, but would result in a decrease of 1,602.2 acres of unmapped floodplain  
142 area, for a net decrease of 1,226.0 acres of overall floodplain area (see Table 5.3.3-4). There  
143 would be no decrease in the amount of mapped floodplain or increase in the flood damage  
144 potential associated with the Land Exchange Proposed Action. The effects on the ecological  
145 function of the floodplain wetlands would be mitigated through the Section 404 Permit and the  
146 proposed mitigation described in Section 4.2.3. The Land Exchange Proposed Action would also  
147 increase the wetlands within the federal estate. The Land Exchange Proposed Action would be in  
148 conformance with EO 11988 (USFS 2004d [FSH 5409.13 § 33.43c]).

149 **5.3.3.1.4 Frontage of Waterways**

150 The Land Exchange Proposed Action would result in a net increase of other water resources to  
151 the federal estate (see Table 5.3.3-6). A net increase of 99.1 acres of lake and 3.8 miles of rivers  
152 would be added to the federal estate from the Land Exchange Proposed Action. These increases  
153 would result in additional frontage of lakes and rivers to the federal estate.

154 **Table 5.3.3-6 Frontage of Waterways for the Land Exchange Proposed Action**

| Parcel                      | Acres        | Lake          |                              | Rivers/Creeks/Streams |                      |                               |      |

155 Source: Data from Section 4.3.3.

156 **5.3.3.2 Land Exchange Alternative B**

157 **5.3.3.2.1 Wetlands**

158 The smaller federal parcel contains 2,860.9 acres of wetlands (see Table 5.3.3-7). By  
 159 comparison, the non-federal lands contain 2,930.8 acres of wetlands. The Land Exchange  
 160 Alternative B would result in a net increase of 69.9 acres of wetlands to the federal estate. The  
 161 Land Exchange Alternative B would increase wetland areas to the federal estate by 69.9 acres  
 162 through the acquisition of up to 4,926.3 acres of the non-federal lands in exchange for 4,752.6  
 163 acres of federal land, and would thus be in conformity with EO 11990.

164 **Table 5.3.3-7 Wetland and Floodplain Acres for Land Exchange Alternative B**

|                         | Acres of Wetlands | Acres of Floodplains |

| <b>Lands Conveyed</b>   |                   |                      |
| Smaller Federal Parcel  | 2,860.9           | 1,412.9 <sup>1</sup> |
| <b>Lands Acquired</b>   |                   |                      |
| Tract 1                 | 2,930.8           | 551.2                |
| <b>Net Change</b>       |                   |                      |
| Net Increase/(Decrease) | 69.9              | (861.7) <sup>2</sup> |

165 <sup>1</sup> The federal floodplain area is a 500-year (0.2%) probability floodplain.

166 <sup>2</sup> Includes an increase of 376.2 acres of mapped floodplains to the federal estate.

167 As part of the increase in wetland acreage, Land Exchange Alternative B would result in a net  
168 increase to the federal estate of the following wetland resource types (see Table 5.3.3-8):  
169 coniferous swamp (1,477.8 acres), open water (168.0 acres), shallow marsh (3.2), and shrub  
170 swamp (311.4 acres). However, the Land Exchange Alternative B would result in a net decrease  
171 to the federal estate of the following wetland resource types: coniferous bog (1,677.0 acres),  
172 hardwood swamp (5.7 acres), open bog (172.9 acres), and sedge/wet meadow (34.9 acres).

DRAFT

173 **Table 5.3.3-8 Wetland Resource Types for Land Exchange Alternative B**

| Parcel                  | Acres of Wetland Resource Types |                               |            |                             |          |                                                      |                  |                            |                                                     |

| Tract 1                 | 0.0                             | 1,953.9                       | 0.0        | 8.0                         | 2.1      | 176.6                                                | 0.0              | 84.1                       | 706.1                                               |
| <b>Net Change</b>       |                                 |                               |            |                             |          |                                                      |                  |                            |                                                     |
| Net Increase/(Decrease) | (1,677.0)                       | 1,477.8                       | 0.0        | (5.7)                       | (172.9)  | 168.0                                                | (34.9)           | 3.2                        | 311.4                                               |

174 <sup>1</sup> Coniferous bogs on the non-federal lands were grouped with coniferous swamps during field data collection.  
 175 <sup>2</sup> Hardwood swamps on the non-federal lands may contain coniferous tree species.  
 176 <sup>3</sup> Shallow marsh areas on the non-federal lands may contain deep marshes.

177 **5.3.3.2.2 Wetland Functional Assessment**

178 The Land Exchange Alternative B would result in an increase to the federal estate of wetlands  
 179 rated as high for vegetation diversity/integrity, hydrology, wetland water quality, wildlife habitat,  
 180 fish habitat, and amphibian habitat. There would be a decrease to the federal estate of wetlands  
 181 rated high and moderate for flood attenuation and downstream water quality. The Land  
 182 Exchange Alternative B would also result in an increase to the federal estate of wetlands rated  
 183 low for amphibian habitat. The Land Exchange Alternative B would not result in a change to  
 184 aesthetics/education/cultural functions to the federal estate.

185 **5.3.3.2.3 Floodplains**

186 There are no mapped floodplains within the federal lands as described in Section 4.3.3. The Land  
 187 Exchange Alternative B would result in a net increase to the federal estate of 376.2 acres of  
 188 mapped floodplain area and 1,237.9 acres of unmapped floodplain area, for a net decrease of  
 189 861.7 acres of overall floodplain area (see Table 5.3.3-7). There would be no decrease in the  
 190 amount of mapped floodplain or increase in the flood damage potential associated with the Land  
 191 Exchange Alternative B. The effects on the ecological function of the floodplain wetlands would  
 192 be mitigated through the Section 404 Permit and the proposed mitigation described in Section  
 193 4.2.3. The Land Exchange Alternative B would also increase the wetlands within the federal  
 194 estate. The Land Exchange Alternative B would be in conformance with EO 11988 (USFS  
 195 2004d [FSH 5409.13 § 33.43c]).

196 **5.3.3.2.4 Frontage of Waterways**

197 The Land Exchange Alternative B would result in a net increase of other water resources to the  
 198 federal estate (see Table 5.3.3-9). A net increase of 120.7 acres of lake and 2.8 miles of rivers  
 199 would be added to the federal estate from the Land Exchange Alternative B. These increases  
 200 would result in additional frontage of lakes and rivers to the federal estate.

201 **Table 5.3.3-9 Frontage of Waterways for Land Exchange Alternative B**

| Parcel                  | Acres | Lake          |                              | Rivers/Creeks/Streams |                      |                               |
|-------------------------|-------|---------------|------------------------------|-----------------------|----------------------|-------------------------------|
|                         |       | Frontage (ft) | Length of Lake Frontage/Acre | Miles                 | Frontage (linear ft) | Length of River Frontage/Acre |
| <b>Lands Conveyed</b>   |       |               |                              |                       |                      |                               |
| Smaller Federal Parcel  | 8.9   | 1,200.0       | 0.3                          | 5.3                   | 55,968.0             | 11.8                          |

| Net Increase/(Decrease) | 120.7 | 15,224.0      | 3.2                          | 2.8                   | 16,896.0             | 3.5                           |

202 Source: Data from Section 4.3.3.

203 **5.3.3.3 Land Exchange No Action Alternative**

204 Under the Land Exchange No Action Alternative, the Superior National Forest would have an  
 205 ongoing responsibility for managing wetland resources, floodplains, and surface waters on the  
 206 federal lands in accordance with the Forest Plan. The Land Exchange No Action Alternative  
 207 would not change USFS's responsibility for managing wetland resources, floodplains, and  
 208 surface waters and would result in no further effects on these resources.

### 5.3.4 Vegetation

This section provides an evaluation of the effects of the Land Exchange Proposed Action on vegetation, including comparisons of MDNR GAP land cover types, native plant community types, MBS Sites of Biodiversity Significance, MIH types, age classes, threatened and endangered plant species, and biodiversity between the federal and non-federal lands. Table 5.3.4-1 provides a summary of these data on a net increase or decrease basis to the federal estate.

When comparing the total acres of the federal and non-federal lands, the federal estate would have an increase of 579.6 acres of MDNR GAP land cover types (see Table 5.3.4-1) as a result of the Land Exchange Proposed Action. The shrublands (1,199.4 acres) would increase the most and the upland conifer forests (919.5 acres) would decrease the most (see Table 5.3.4-2). There would be an acreage increase of upland forest (MIH 1) with lesser amounts of lowland black spruce-tamarack forest (MIH 9) and aquatic habitat (MIH 14), but a decrease of upland conifer forest (MIH 5) to the federal estate (see Table 5.3.4-1). There would be an increase to the federal estate of immature forest stands with lesser amounts of young stands, but a decrease in mature forest stands.

There would be a decrease to the federal estate of up to approximately 6,025.8 acres of MBS Sites of High Biodiversity Significance and an increase of up to 767.9 acres of MBS Sites of Moderate Biodiversity Significance under the Land Exchange Proposed Action (see Table 5.3.4-1). There would be a decrease to the federal estate of three native plant communities that are “imperiled,” “imperiled-vulnerable,” or “vulnerable,” as well as others that are ranked as “apparently secure” or “widespread and secure,” in exchange for one native plant community that is ranked as “vulnerable” and two that are ranked as “apparently secure.” There would be a decrease to the federal estate of up to 2,016.6 acres in the Jack Pine-Black Spruce landscape ecosystem, and an increase of up to 994.7 acres in the Lowland Conifer landscape ecosystem and 558.7 acres in the Mesic Red and White Pine landscape ecosystem. Additionally, the USFS would increase representation in the Dry-Mesic Red and White Pine, Mesic Birch-Aspen-Spruce-Fir, Lowland Hardwood, and Sugar Maple landscape ecosystems. Overall, there would be an increase to the federal estate of 625.2 acres of landscape ecosystems as a result of the Land Exchange Proposed Action.

There would be a decrease to the federal estate of 12 populations of 10 state-listed ETSC plant species on the federal lands in exchange for three populations of three known state-listed ETSC plant species on the non-federal lands. Though the 10 state-listed plant species on the federal lands are not known to occur on the non-federal lands, the Land Exchange Proposed Action would result in an increase to the federal estate of most habitats important to them. Drawing from the MIH exchange, RFSS plants associated with upland forest (MIH 1), lowland black spruce-tamarack forest (MIH 9), and aquatic habitat (MIH 14) could potentially exist on or spread to the habitats on the non-federal parcels. There would also be a gain of Rove Formation cliff microhabitats to the federal estate, which are important for a variety of RFSS plants in the Superior National Forest.

Rulemaking was conducted with the intent to update the list of ETSC species (*Minnesota Rules*, parts 6134.0100 to 6134.0400), with new listings becoming effective on August 19, 2013 (MDNR 2013h). This FEIS considers any new listings, or changes in the previous listings, associated with the updated list. The FEIS also considers any federal listing changes.

44 A Biological Evaluation has been prepared that contains further information about RFSS. The  
45 Biological Evaluation is included in Appendix D and is posted on the USFS website  
46 (<http://www.fs.usda.gov/goto/superior/northmet>). The organization of the methodologies and  
47 discussion in the Biological Evaluation may be different from the FEIS. The document also  
48 contains determinations of effect for the species discussed.

49

#### 52 **5.3.4.1 Methodology and Evaluation Criteria**

53 The vegetation assessment area for the Land Exchange Proposed Action would involve 6,495.4  
54 acres of federal lands transferred from public to private ownership, and up to 7,075.0 acres of  
55 land transferred from private to public ownership. The spatial and temporal area of analysis for  
56 vegetation as part of the Land Exchange Proposed Action included direct and indirect effects  
57 resulting from the change in ownership of the federal and non-federal lands, including the extent  
58 of landscape ecosystems as defined in the Forest Plan or the extent of similar landscape  
59 ecosystems on the abutting forest lands.

60 An evaluation was conducted to determine the potential effect that the Land Exchange Proposed  
61 Action would have on the following vegetation resources:

- 62 • The quality and quantity of forest resources/lands (change in forest types and age classes);
- 63 • Change in state-listed ETSC plant species and RFSS plants (individuals, habitat, and/or  
64 populations);
- 65 • Change in biodiversity or overall vegetation and habitat; and
- 66 • The introduction and spread of invasive non-native species.

67 The analysis of the vegetation resources affected by the Land Exchange Proposed Action was  
68 guided by evaluation criteria that were developed by the USFS and other Co-lead Agencies,  
69 which included a comparison of the MDNR GAP land cover types, native plant communities,  
70 MBS Sites of Biodiversity Significance, MIH types (MIH 1, 5, 9, and 14, as well as lowland  
71 shrublands, lowland emergent wetlands, and upland grass), age classes (young, immature, and  
72 mature), large mature forest patches, landscape ecosystems, management areas, threatened and  
73 endangered plant species, RFSS plants, and invasive non-native plant species. GIS data for these  
74 categories were gathered to the extent possible, and then compared over an area of analysis that  
75 included the federal and non-federal lands, and also the surrounding landscape ecosystems of the  
76 Superior National Forest or ecological subsections. MIH types and age classes have also been  
77 compared within the context of landscape ecosystems to reveal how many acres of each MIH  
78 and age class would be increased or decreased on the federal estate by the Land Exchange  
79 Proposed Action within each landscape ecosystem. MIH type and age class data for the non-  
80 federal lands were interpreted from field survey maps, aerial maps, surrounding federal MIH  
81 data, topographic maps, and USFS review. These were then compared to the federal lands MIH  
82 data to determine MIH type and age class increases or decreases of acreage to the federal estate.  
83 Additionally, all of the data types mentioned have been compared to summarize the vegetative  
84 biodiversity of the federal and non-federal lands.

#### 85 **5.3.4.2 Land Exchange Proposed Action**

##### 86 **5.3.4.2.1 Cover Types**

87 Cover types consist of several categories of classification, including MDNR GAP land cover  
88 types, USFS management areas, USFS ELTs, and USFS MIH types.

89 **Habitat Types**

90 The Land Exchange Proposed Action would result in an increase to the federal estate of up to  
 91 579.6 acres of MDNR GAP land cover designations, with the greatest increase in shrubland  
 92 acreage of 1,199.4 acres and the greatest decrease in upland conifer forest of 919.5 acres (see  
 93 Table 5.3.4-2). The decrease of upland conifer forest is contrary to a goal of the 2004 Forest  
 94 Plan. The Forest Plan calls for an increase in the acreage of red, white, and jack pine habitats  
 95 (and a decrease in the acreage of aspen vegetation communities). In addition, the Land Exchange  
 96 Proposed Action would support other Forest Plan goals to maintain acreage of lowland  
 97 deciduous habitats and non-forested wetlands. The Land Exchange Proposed Action would result  
 98 in a small increase to the federal estate of lowland deciduous forests, an increase in aquatic  
 99 habitats, and a large increase of shrublands.

100 **Table 5.3.4-2 Net Increase or Decrease to the Federal Estate of MDNR GAP Land Cover**  
 101 **Types under the Land Exchange Proposed Action**

| Cover Types                           | Federal Land Acres | Non-federal Land Acres | Net Increase/ (Decrease) Acres |
|---------------------------------------|--------------------|------------------------|--------------------------------|
| Shrubland                             | 645.6              | 1,845.0                | 1,199.4                        |
| Aquatic environments                  | 60.1               | 266.6                  | 206.5                          |
| Upland deciduous forest               | 1,091.8            | 1,232.9                | 141.1                          |
| Upland conifer-deciduous mixed forest | 20.9               | 50.4                   | 29.5                           |
| Cropland/grassland                    | 6.2                | 31.7                   | 25.5                           |
| Lowland deciduous forest              | 9.5                | 28.6                   | 19.1                           |
| Lowland coniferous forest             | 2,978.6            | 2,920.5                | (58.1)                         |
| Disturbed                             | 63.8               | 0.0                    | (63.8)                         |
| Upland coniferous forest              | 1,618.9            | 699.4                  | (919.5)                        |
| Total <sup>1</sup>                    | 6,495.4            | 7,075.0                | 579.6                          |

102 Source: MDNR 2006b.

103 <sup>1</sup> Total acres may be more or less than presented due to rounding.

104 **Culturally Important Plants**

105 The Land Exchange Proposed Action would result in additional wild rice beds on the federal  
 106 estate by the acquisition of Tract 1. Tract 1 contains Little Rice Lake, which supports a  
 107 continuous population of wild rice. Wild rice also grows along the Pike River south of Little  
 108 Rice Lake and in isolated populations on Hay Lake. Section 4.3.4.2.5 provides further discussion  
 109 of wild rice on Tract 1. Wild rice does not currently grow within the proposed federal land  
 110 boundaries. Though the Land Exchange would result in an increase in wild rice beds within the  
 111 federal estate boundaries, there is existing public access to Tract 1 wild rice beds via the Pike  
 112 River. Consequently, there would be no change in wild rice harvest opportunities for the public.  
 113 A carry-down boat launching access point is located on Tract 1, which may provide private  
 114 access for wild rice harvesting on the Tract 1 lands.

115 Natural resources culturally important to the Bands are discussed in Section 4.2.9.3.3.

116 **Minnesota Biological Survey**

117 The Land Exchange Proposed Action would result in a decrease to the federal estate of 6,142.7  
 118 acres of MBS Sites of High Biodiversity Significance in the Laurentian Uplands subsection, and

119 an increase of 116.9 acres of MBS Sites of High Biodiversity Significance in the North Shore  
120 Highlands subsection. Furthermore, the Land Exchange Proposed Action would result in an  
121 increase to the federal estate of 767.6 acres of MBS Sites of Moderate Biodiversity Significance  
122 in the Laurentian Uplands subsection.

123 Native plant community rankings are largely unavailable for the non-federal lands, with the  
124 exception of Lake County South, which has one site ranked as “vulnerable” and others ranked as  
125 “apparently secure.” Section 4.3.4.2.6 provides further discussion of native plant community  
126 types on the Lake County South parcel. The Land Exchange Proposed Action would result in a  
127 decrease to the federal estate of three native plant communities on the federal lands that are  
128 ranked as “imperiled” to “vulnerable” in the state. A native plant community increase or  
129 decrease comparison cannot be accurately made since rankings are unavailable for much of the  
130 non-federal lands.

### 131 **Management Areas**

132 In conjunction with landscape ecosystem objectives, the USFS has developed desired future  
133 conditions and objectives, based on management areas, which describe what is desired socially  
134 and economically (USFS 2004b). The majority of the non-federal lands (86 percent) would be  
135 allocated to the General Forest Management Area upon completion of the Land Exchange  
136 Proposed Action. This management area provides a wide variety of goods, uses, and services,  
137 including wood products, scenic quality, recreation opportunities, and habitat types (USFS  
138 2004b). The remaining non-federal lands would be allocated to the General Forest – Longer  
139 Rotation Management Area (7 percent), Potential/cRNA (4 percent), and Riparian Areas  
140 Management Area (3 percent). Section 5.3.1 provides a discussion of management area  
141 allocations on the non-federal lands for the Land Exchange Proposed Action.

142 Through the acquisition of Tract 1, the Land Exchange Proposed Action would result in a gain of  
143 a large contiguous block of land and lakeshore/river frontage. The majority of this tract (94  
144 percent) would be allocated to the General Forest Management Area, with the balance allocated  
145 as a cRNA (6 percent). Two cRNA lands abut Tract 1 (USFS 2011b) and, upon completion of  
146 the Land Exchange Proposed Action, these two cRNA lands would be extended onto the parcel.  
147 The Pike Mountain cRNA is located at the southwestern corner of Tract 1. Approximately 135  
148 acres of Tract 1 are proposed to be added to the Pike Mountain cRNA because it is an extension  
149 of the northern hardwood uplands with a high sugar maple component. The Loka Lake cRNA is  
150 located at the northeastern corner of Tract 1. Approximately 172 acres of the parcel are proposed  
151 to be added to the Loka Lake cRNA because it is an extension of the high-quality lowland black  
152 spruce and tamarack swamp.

153 The Land Exchange Proposed Action would result in Tract 2 being allocated as Riparian Areas  
154 (83 percent) and General Forest – Longer Rotation Management Area (17 percent) (USFS  
155 2011b). The Riparian Emphasis Area Management Area provides protection to diverse age  
156 classes, but generally for older-growth forest stands along sensitive riparian areas.

157 The majority of Tract 3 would be allocated to the General Forest Management Area (92 percent),  
158 with the remaining 8 percent allocated to the General Forest – Longer Rotation Management  
159 Area (USFS 2011b).

160 All of Tracts 4 and 5 would be allocated to the General Forest – Longer Rotation Management  
161 Area (USFS 2011b). Obtaining Tract 5 would result in a gain of lakeshore property.

162 Overall, there would be a large increase to the federal estate in the General Forest Management  
 163 Area (5,714.1 acres) and smaller increases in the cRNA (306.9 acres) and Riparian Areas (220.9  
 164 acres) Management Areas as a result of the Land Exchange Proposed Action (see Table 5.3.4-3).  
 165 There would be a decrease to the federal estate of 5,662.3 acres of the General Forest – Longer  
 166 Rotation Management Area. The lands to be acquired as part of the Land Exchange Proposed  
 167 Action would be managed in accordance with Forest Plan standards and guidelines. Section 5.3.1  
 168 describes the management areas in detail.

169 **Table 5.3.4-3 Net Increase or Decrease to the Federal Estate of Management Areas under**  
 170 **the Land Exchange Proposed Action**

| Category                         | Federal Lands |    | Non-federal Lands |    | Net Increase/<br>(Decrease) |
|----------------------------------|---------------|----|-------------------|----|-----------------------------|
|                                  | Acres         | %  | Acres             | %  | Acres                       |
| General Forest                   | 355.3         | 5  | 6,069.4           | 86 | 5,714.1                     |
| General Forest – Longer Rotation | 6,140.2       | 95 | 477.8             | 7  | (5,662.3)                   |
| Potential/cRNAs                  | 0.0           | 0  | 306.9             | 4  | 306.9                       |
| Riparian Areas                   | 0.0           | 0  | 220.9             | 3  | 220.9                       |

171 Source: USFS 2011j.

172 **Ecological Land Types**

173 The Land Exchange Proposed Action would result in an increase to the federal estate of seven  
 174 ELTs, including ELT 3, 4, 10, 11, 14, 17, and 18. Five of these ELTs are upland soils and two  
 175 are lowland soils. The USFS would not lose representation of any ELTs currently on the federal  
 176 lands, based on available data.

177 **Management Indicator Habitats**

178 The Land Exchange Proposed Action would result in an increase to the federal estate of upland  
 179 forest (MIH 1; 1,364.5 acres), lowland black spruce-tamarack forest (MIH 9; 248.3 acres), and  
 180 aquatic habitat (MIH 14; 226.7 acres), and a decrease of upland conifer forest (MIH 5; 1,172.5  
 181 acres) (see Table 5.3.4-4). The Land Exchange Proposed Action would also result in a decrease  
 182 to the federal estate of lowland shrub habitat (160.1 acres), but an increase in lowland emergent  
 183 (200.2 acres) and upland grass (43.3 acres) habitat types. While not considered MIH types, these  
 184 are important habitats for several wildlife species. The fact that aquatic habitat (MIH 14) is not  
 185 mapped on the federal lands results in an apparent increase to the federal estate in these  
 186 categories, even though this habitat type does occur on the federal lands.

187 The Land Exchange Proposed Action would result in an increase to the federal estate of 2,507.6  
 188 acres of young and immature forest stands. However, it would result in a decrease to the federal  
 189 estate of 2,029.6 acres of mature forest types. The Land Exchange Proposed Action would not  
 190 result in a change to the federal estate of large patches (stands over 300 acres) of mature upland  
 191 forests (MIH 13), as none exist on the federal lands (USFS 2012c) and the patches of mature  
 192 forest on the non-federal lands are not part of the USFS Patch layer.

193

194 **Table 5.3.4-4 Net Increase or Decrease to the Federal Estate of MIH Types and Age**  
 195 **Classes under the Land Exchange Proposed Action**

| Category                                     | Federal Land Acres <sup>2</sup> | Non-federal Land Acres <sup>1,2</sup> | Net Increase/ (Decrease) Acres |
|----------------------------------------------|---------------------------------|---------------------------------------|--------------------------------|
| <b>MIH Types</b>                             |                                 |                                       |                                |
| MIH 1 (Upland Forest)                        | 1,330.0                         | 2,694.5                               | 1,364.5                        |
| MIH 5 (Upland Conifer Forest)                | 1,252.4                         | 79.9                                  | (1,172.5)                      |
| MIH 9 (Lowland Black Spruce-tamarack Forest) | 3,060.2                         | 3,308.5                               | 248.3                          |

196 Source: USFS 2010b.

197 <sup>1</sup> According to non-federal lands cover type table (see Table 4.3.4-3).

198 <sup>2</sup> Total acres may be more or less than presented due to rounding.

199 **Landscape Ecosystems**

200 The Land Exchange Proposed Action would result in a decrease to the federal estate of 2,016.6  
 201 acres of the Jack Pine-Black Spruce landscape ecosystem (0.65 percent decrease), but there  
 202 would be an increase of 994.7 acres in the Lowland Conifer landscape ecosystem (0.08 percent  
 203 increase) and 558.7 acres of the Mesic Red and White Pine landscape ecosystem (0.73 percent  
 204 increase). The Superior National Forest, as part of the Land Exchange Proposed Action, would  
 205 have increased representation in the Dry-Mesic Red and White Pine landscape ecosystem (682.9  
 206 acres; 0.11 percent increase), Mesic Birch-Aspen-Spruce-Fir landscape ecosystem (302.2 acres;  
 207 0.04 percent increase), Lowland Hardwood landscape ecosystem (66.5 acres; 0.01 percent  
 208 increase), and the Sugar Maple landscape ecosystem (36.7 acres; 0.04 percent increase), and  
 209 there would be an overall increase to the federal estate of 625.1 acres.

210 Within the Superior National Forest, the USFS tracks acreage of MIH types and age classes  
 211 within each landscape ecosystem to better manage them within the broader ecological context.  
 212 As a result of the Land Exchange Proposed Action, there would be an increase to the federal  
 213 estate in acreage of MIH types and age classes within some landscape ecosystems and a decrease  
 214 in others (see Table 5.3.4-5). The greatest percentage increase to the federal estate in MIH  
 215 acreage within a landscape ecosystem is lowland black spruce-tamarack forest (MIH 9) in the  
 216 Mesic Birch-Aspen-Spruce-Fir landscape ecosystem, while the greatest decrease is upland  
 217 conifer forest (MIH 5) in the Jack Pine-Black Spruce landscape ecosystem. The greatest  
 218 percentage increase to the federal estate in age class acreage within a landscape ecosystem is the  
 219 immature age class in the Lowland Conifer landscape ecosystem, while the greatest decrease is  
 220 the immature and mature age classes in the Jack Pine-Black Spruce landscape ecosystem.  
 221 Overall, the Lowland Conifer landscape ecosystem would have the highest acreage increase to  
 222 the federal estate in MIH types and age classes, while the Jack Pine-Black Spruce landscape  
 223 ecosystem would have the highest acreage decrease in MIH types and age classes.

224 **Table 5.3.4-5 Net Increase or Decrease to the Federal Estate of MIH Types and Age**

|                                      | Mature             | Acres <sup>1</sup>      | 129.2     | (1,079.0)  | (1,559.6) | 22.5    | 181.6   | 247.1    | 8.9   |
|                                      |                    | % <sup>2</sup>          | 1         | (4)        | (2)       | 1       | 1       | 1        | 6     |

227 Source: USFS 2010b; USFS 2011g.

228 <sup>1</sup> Total acres may be more or less than presented due to rounding.

229 <sup>2</sup> Percentage of acres increased or decreased on the federal estate within the entire landscape ecosystem.

230 <sup>3</sup> MIH 14 is not tracked on the federal lands; thus, percentage is NA (not applicable).

231 **5.3.4.2.2 Invasive Non-native Plants**

232 The Land Exchange Proposed Action would result in a reduction of occurrences of invasive non-  
 233 native species on the federal lands, but an increase to the federal estate of similar occurrences of  
 234 invasive non-native species on Tracts 1, 2, and 3, including common tansy, orange hawkweed,  
 235 ox-eye daisy, and thistles. Tracts 4 and 5 would not have an increase of any occurrences of  
 236 invasive non-native species.

237 **5.3.4.2.3 Threatened and Endangered Plant Species**

238 **Endangered, Threatened, and Special Concern Plant Species**

239 There are fewer occurrences of state-listed ETSC plant species on the non-federal lands (one  
240 species on Tract 1 and two species on Tract 5) than on the federal lands (10 species), so the  
241 USFS would have fewer populations as a result of the Land Exchange Proposed Action (see  
242 Table 5.3.4-6). The three species gained in the exchange are *Carex ormostachya*, *Woodsia*  
243 *scopulina*, and *Saxifraga paniculata*. Sections 4.3.4.2.5 and 4.3.4.2.9 provide a discussion of  
244 these species. There are no federally listed plant species in St. Louis, Lake, or Cook counties  
245 (USFWS 2012). Rulemaking was conducted with the intent to update the list of ETSC species  
246 (*Minnesota Rules*, parts 6134.0100 to 6134.0400), with new listings becoming effective on  
247 August 19, 2013 (MDNR 2013h). This FEIS considers any new listings, or changes in the  
248 previous listings, associated with the updated list.

249 Though the 10 known state-listed ETSC plant species on the federal lands are not known to  
250 occur on the non-federal lands, the Land Exchange Proposed Action would result in an increase  
251 to the federal estate of most habitats important to them. The Land Exchange Proposed Action  
252 would result in additional grassland habitat, which *Botrychium campestre* and *Botrychium*  
253 *pallidum* occupy. The Land Exchange Proposed Action would also result in an increase to the  
254 federal estate of upland deciduous and mixed forest habitats, used by *Botrychium pallidum*,  
255 *Botrychium rugulosum*, and *Botrychium simplex*. There would be an increase to the federal estate  
256 of aquatic habitats (open water or wetlands) for *Caltha natans*, *Eleocharis nitida*, *Juncus stygius*  
257 var. *americanus*, and *Torreyochloa pallida*. According to the MIH analysis, the Land Exchange  
258 Proposed Action would result in an increase to the federal estate of lowland black spruce or  
259 tamarack habitats, which could mean more habitats for *Platanthera clavellata*, *Pyrola minor*, and  
260 *Ranunculus lapponicus*.

261 **Table 5.3.4-6 Increase or Decrease to the Federal Estate of State-listed ETSC Plant**  
 262 **Populations under the Land Exchange Proposed Action**

| Plant Species (State Status/<br>Global Status <sup>1</sup> ) | Federal Lands<br>Populations        |                                   | Non-federal Lands<br>Populations    |                                   | Net Species<br>Increase/<br>(Decrease) |
|--------------------------------------------------------------|-------------------------------------|-----------------------------------|-------------------------------------|-----------------------------------|----------------------------------------|

263 Source: MDNR 2014d.

264 <sup>1</sup> The state status is E – Endangered; T – Threatened; and SC – Species of Special Concern. The global ranks range from G1 to  
 265 G5. A lower global ranking (e.g., G3) indicates a species at higher global risk than higher ranking (e.g., G5) (NatureServe  
 266 2014b).

267 <sup>2</sup> Populations are interpreted from MDNR NHIS data using Element Occurrence; this differs from the DEIS, which used  
 268 colonies as the population estimate.

269 <sup>3</sup> Data included here were provided by the Division of Ecological Resources, MDNR, and were current as of August 5, 2014.  
 270 These data are not based on an exhaustive inventory of the state. The lack of data for any geographic area shall not be  
 271 construed to mean that no significant features are present.

272 **Regional Foresters Sensitive Species**

273 The USFS RFSS data layer indicates there are no RFSS plants on the federal lands. However,  
 274 several state-listed ETSC plant species that occur on the federal lands are also listed as RFSS  
 275 plants, including *Botrychium pallidum*, *Botrychium rugulosum*, *Botrychium simplex*, *Caltha*  
 276 *natans*, *Eleocharis nitida*, *Juncus stygius* var. *americanus*, and *Pyrola minor*. The USFS would  
 277 have a decrease to the federal estate in these RFSS plant species as a result of the Land Exchange  
 278 Proposed Action. *Saxifraga paniculata* is a state-listed ETSC plant species that is also listed as a  
 279 RFSS plant on the Tract 5 lands. The USFS would gain this RFSS plant species under the Land  
 280 Exchange Proposed Action.

281 As with the NorthMet Project Proposed Action, the Land Exchange Proposed Action would not  
 282 affect 20 RFSS plants on the Superior National Forest. In addition, the Land Exchange Proposed  
 283 Action may affect individuals, but would not be likely to cause a trend to federal listing or loss of  
 284 viability for the remaining 38 RFSS plants on the Superior National Forest. Please see the  
 285 Biological Evaluation listed on the USFS website (<http://www.fs.usda.gov/goto/superior/northmet>)  
 286 for more information about effects to RFSS plants.

287 There would be the greatest increase to the federal estate in acres of lowland black spruce-  
288 tamarack forest (MIH 9; see Table 5.3.4-4) as a result of the Land Exchange Proposed Action,  
289 which means there is the highest chance to gain the RFSS plants listed under that category in  
290 Table 4.2.4-5, as long as the suitable habitats exist on the non-federal lands. There would be  
291 smaller acreage increases of both upland forest (MIH 1) and aquatic habitat (MIH 14), meaning  
292 the RFSS plants in those categories could also be gained. The largest acreage decrease to the  
293 federal estate would be upland conifer forest (MIH 5). There are no RFSS plants specifically  
294 listed under upland conifer forest (MIH 5); however, it is likely that some RFSS plants that  
295 occupy upland forest (MIH 1) habitats would also occupy upland conifer forest (MIH 5) habitats  
296 and the USFS could therefore have a decrease to the federal estate in RFSS plant species that  
297 prefer coniferous upland habitats. There would also be a gain of Rove Formation cliff  
298 microhabitats, which are important for a variety of RFSS plants in the Superior National Forest.

#### 299 **5.3.4.2.4 Biodiversity**

300 Biodiversity is described in the Forest Plan as the “variety of life and its ecological processes ...  
301 [as well as] ecosystems, which comprise both the communities of organisms within particular  
302 habitats, and the physical conditions under which they live” (USFS 2004b). Biodiversity is  
303 important to consider for managing natural communities in a sustainable and ecological manner.  
304 Several data sources mentioned above and in Section 4.2.4 were compared on an increase or  
305 decrease basis to the federal estate to measure or estimate the biodiversity of both the federal and  
306 non-federal lands.

307 The federal land contains a high level of biodiversity because the majority of the parcel has been  
308 classified for inclusion in two Sites of High Biodiversity Significance. Additionally, several  
309 different native plant communities exist on it, as do 10 state-listed ETSC plant species. Because  
310 the non-federal lands have not been fully studied yet, they contain less biodiversity classification  
311 since they lack MBS Sites of High Biodiversity Significance and native plant communities.  
312 Table 5.3.4-1 provides a summary of the various data used to estimate biodiversity.

313 In summary, the non-federal lands contain 116.9 acres of MBS Sites of High Biodiversity  
314 Significance in the North Shore Highlands subsection and 767.9 acres of MBS Sites of Moderate  
315 Biodiversity Significance in the Laurentian Uplands subsection. The Land Exchange Proposed  
316 Action would result in a decrease to the federal estate of 6,142.7 acres of MBS Sites of High  
317 Biodiversity Significance in the Laurentian Uplands subsection, and an increase of 116.9 acres of  
318 MBS Sites of High Biodiversity Significance in the North Shore Highlands subsection.  
319 Furthermore, the Land Exchange Proposed Action would result in an increase to the federal  
320 estate of 767.6 acres of MBS Sites of Moderate Biodiversity Significance in the Laurentian  
321 Uplands subsection. Overall, there would be a decrease to the federal estate of 6,025.8 acres of  
322 MBS Sites of High Biodiversity Significance and an increase of 767.6 acres of MBS Sites of  
323 Moderate Biodiversity Significance under the Land Exchange Proposed Action. However,  
324 several of the non-federal lands have preliminary classifications of Sites as Moderate, High, or  
325 Outstanding Biodiversity Significance, which, if approved by the MDNR MBS program, would  
326 help balance the exchange.

327 Native plant community rankings are largely unavailable for the non-federal lands, with the  
328 exception of Lake County South, which has one site ranked as “vulnerable” and others ranked as  
329 “apparently secure.” Section 4.3.4.2.6 provides further discussion of native plant community  
330 types on the Lake County South parcel. The Land Exchange Proposed Action would result in a

331 decrease to the federal estate of three native plant communities on the federal lands that are  
332 ranked as “imperiled” to “vulnerable” in the state. A native plant community increase or  
333 decrease comparison cannot be accurately made since rankings are unavailable for much of the  
334 non-federal lands.

335 ***Endangered, Threatened, and Special Concern Plant Species***

336 As previously stated, the federal lands support 10 known state-listed ETSC plant species, while  
337 the non-federal lands currently support three known state-listed ETSC plant species. This would  
338 be a decrease to the federal estate in known state-listed species as a result of the Land Exchange  
339 Proposed Action.

340 **5.3.4.3 Land Exchange Alternative B**

341 **5.3.4.3.1 Cover Types**

342 The effects of Land Exchange Alternative B would be comparable to those from the Land  
343 Exchange Proposed Action, although to a lesser extent. A smaller portion of the federal lands  
344 (approximately 4,752.6 acres) would be transferred into private ownership for the non-federal  
345 Tract 1 lands (approximately 4,926.3 acres), which would be conveyed into USFS ownership.  
346 Under this alternative, the USFS would retain a smaller federal parcel located on the  
347 northwestern and western sides of the current federal lands, which would create additional linear  
348 boundaries for the USFS to maintain (see Section 5.3.1).

349 ***Habitat Types***

350 This alternative would result in an overall increase to the federal estate of 173.6 acres of MDNR  
351 GAP land cover types. As under the Land Exchange Proposed Action, the greatest increase to the  
352 federal estate would be shrubland acreage (1,227.7 acres), and upland conifer forest would have  
353 the greatest acreage decrease (928.8 acres), as shown in Table 5.3.4-7 below.

354 **Table 5.3.4-7 Net Increase or Decrease to the Federal Estate of MDNR GAP Land Cover**  
 355 **Types under Land Exchange Alternative B**

| Cover Types                              | Alternative B:                  |                            | Net Increase/<br>(Decrease) Acres |
|------------------------------------------|---------------------------------|----------------------------|-----------------------------------|
|                                          | Smaller Federal<br>Parcel Acres | Tract 1 Acres <sup>1</sup> |                                   |
| Shrubland                                | 436.9                           | 1,664.6                    | 1,227.7                           |
| Aquatic environments                     | 26.3                            | 251.1                      | 224.8                             |
| Upland deciduous forest                  | 804.7                           | 999.9                      | 195.2                             |
| Cropland/grassland                       | 2.2                             | 31.7                       | 29.5                              |
| Lowland deciduous forest                 | 4.7                             | 17.4                       | 12.7                              |
| Upland conifer-deciduous mixed<br>forest | 17.8                            | 0.0                        | (17.8)                            |
| Disturbed                                | 29.1                            | 0.0                        | (29.1)                            |
| Lowland coniferous forest                | 2,064.8                         | 1,524.2                    | (540.6)                           |
| Upland coniferous forest                 | 1,366.1                         | 437.3                      | (928.8)                           |
| Total <sup>2</sup>                       | 4,752.6                         | 4,926.2                    | 173.6                             |

356 Source: MDNR 2006b.

357 <sup>1</sup> According to Tract 1 land cover type table (see Table 4.3.4-11).

358 <sup>2</sup> Total acres may be more or less than presented due to rounding.

359 **Culturally Important Plants**

360 As with the Land Exchange Proposed Action, Land Exchange Alternative B would result in  
 361 additional wild rice beds on the federal estate from the acquisition of Tract 1, but would not  
 362 result in a change in harvesting opportunities for the public. Section 5.3.4.2 provides additional  
 363 information on wild rice.

364 As with the Land Exchange Proposed Action, see Section 4.2.9.3.3 for a discussion of natural  
 365 resources culturally important to the Bands.

366 **Minnesota Biological Survey**

367 Land Exchange Alternative B would result in a decrease to the federal estate of 4,573.1 acres of  
 368 MBS Sites of High Biodiversity Significance and a decrease of 0.3 acre of MBS Sites of  
 369 Moderate Biodiversity Significance within the Laurentian Uplands subsection (see Table  
 370 5.3.4-1). Portions of the west end of One Hundred Mile Swamp would remain in federal  
 371 ownership. Furthermore, Land Exchange Alternative B would result in removal from the  
 372 Superior National Forest of three native plant communities that are ranked as “imperiled” to  
 373 “vulnerable” in the state. As previously discussed, Tract 1 does not contain any MBS Sites of  
 374 Biodiversity Significance or native plant communities, so, unlike the Land Exchange Proposed  
 375 Action, the federal estate would not have an increase of either MBS sites or native plant  
 376 communities under this alternative.

377 **Management Areas**

378 Lands included as part of Land Exchange Alternative B are currently managed under the General  
 379 Forest – Longer Rotation Management Area (93 percent) and the General Forest Management  
 380 Area (7 percent) (see Table 5.3.4-8). The majority of Tract 1 (94 percent) would be allocated to  
 381 the General Forest Management Area upon completion of Land Exchange Alternative B, and the

382 remaining area would be managed under the cRNA Management Area (6 percent). Land  
 383 Exchange Alternative B would be comparable to the Land Exchange Proposed Action in that  
 384 cRNA lands would be increased on the federal estate, but Riparian Areas would not be. Section  
 385 5.3.1 describes the management areas in detail.

386 **Table 5.3.4-8 Net Increase or Decrease to the Federal Estate of Management Areas under**  
 387 **Land Exchange Alternative B**

| Category                                   | Alternative B:<br>Smaller Federal<br>Parcel |    |         |    | Net Increase/<br>(Decrease)<br>Acres |
|--------------------------------------------|---------------------------------------------|----|---------|----|--------------------------------------|
|                                            |                                             |    | Tract 1 |    |                                      |
|                                            | Acres                                       | %  | Acres   | %  |                                      |
| General Forest                             | 355.3                                       | 7  | 4,619.3 | 94 | 4,264.0                              |
| General Forest - Longer Rotation           | 4,397.3                                     | 93 | 0.0     | 0  | (4,397.3)                            |
| Potential/candidate Research Natural Areas | 0.0                                         | 0  | 306.9   | 6  | 306.9                                |

388 Source: USFS 2011j.

389 **Ecological Land Types**

390 Land Exchange Alternative B would result in a decrease to the federal estate of five ELTs,  
 391 including ELT 1, 2, 6, 13, and 16, which are currently located on the proposed smaller federal  
 392 parcel. The ELTs are unavailable for Tract 1, and so a comparison cannot be made.

393 **Management Indicator Habitats**

394 Land Exchange Alternative B would result in an increase to the federal estate in upland forest  
 395 (MIH 1; 1,411.8 acres) and aquatic habitat (MIH 14; 206.2 acres); however, there would be a  
 396 decrease of upland conifer forest (MIH 5; 1,084.6 acres) and lowland black spruce-tamarack  
 397 forest (MIH 9; 261.1 acres) (see Table 5.3.4-9). Though not considered MIH types, there would  
 398 be a decrease to the federal estate of lowland shrubland habitat (272.1 acres) and an increase of  
 399 lowland emergent wetlands (249.6 acres). Similar to the Land Exchange Proposed Action, the  
 400 aquatic habitat (MIH 14) type is not fully mapped on lands that are part of Land Exchange  
 401 Alternative B, resulting in an apparent increase to the federal estate in this category; however,  
 402 this habitat type does occur on these lands.

403 There would be a large increase to the federal estate of immature forest stands (1,933.9 acres)  
 404 with lesser amounts of young stands (262.7 acres), corresponding to a decrease of mature forest  
 405 stands (2,114.5 acres). Land Exchange Alternative B would not result in a change to the federal  
 406 estate of large patches (stands over 300 acres) of mature upland forest, as none exist on the  
 407 Alternative B: Smaller Federal Parcel lands (USFS 2012c) and patch data does not exist for the  
 408 Tract 1 lands.

409 **Table 5.3.4-9 Net Increase or Decrease to the Federal Estate of MIH Types and Age**  
 410 **Classes under Land Exchange Alternative B**

| <b>Category</b>                              | <b>Alternative B:<br/>Smaller Federal<br/>Parcel Acres<sup>2</sup></b> | <b>Tract 1 Acres<sup>1,2</sup></b> | <b>Net Increase/<br/>(Decrease) Acres</b> |

| Young                                        | 271.1                                                                  | 533.8                              | 262.7                                     |
| Immature                                     | 1,325.9                                                                | 3,259.8                            | 1,933.9                                   |
| Mature                                       | 2,574.7                                                                | 460.2                              | (2,114.5)                                 |

411 Source: USFS 2010b.

412 <sup>1</sup> According to Tract 1 lands MIH table (see Table 4.3.4-3).

413 <sup>2</sup> Total acres may be more or less than presented due to rounding.

414 **Landscape Ecosystems**

415 Land Exchange Alternative B would result in a decrease to the federal estate of 1,411.6 acres of  
 416 the Jack Pine-Black Spruce landscape ecosystem (0.46 percent decrease), but result in an  
 417 increase of 486.2 acres of the Lowland Conifer landscape ecosystem (0.04 percent increase).  
 418 Furthermore, there would be an increase in representation in the Dry-Mesic Red and White Pine  
 419 landscape ecosystem (589.2 acres; 0.10 percent increase), Mesic Red and White Pine landscape  
 420 ecosystem (528.0 acres; 0.69 percent increase), and the Mesic Birch-Aspen-Spruce-Fir landscape  
 421 ecosystem (0.9 acres; less than 0.01 percent increase), and an overall increase to the federal  
 422 estate of 192.7 acres.

423 Similar to the Land Exchange Proposed Action, Land Exchange Alternative B would result in an  
 424 increase to the federal estate in acreage of MIH types and age classes within various landscape  
 425 ecosystems, and a decrease in acreage in others (see Table 5.3.4-10). The greatest percentage  
 426 increase to the federal estate in MIH acreage within a landscape ecosystem is upland forest (MIH  
 427 1) in the Lowland Conifer and Dry-Mesic Red and White Pine landscape ecosystems, while the  
 428 greatest decrease is upland conifer forest (MIH 5) in the Jack Pine-Black Spruce landscape  
 429 ecosystem. The largest percentage increase to the federal estate in age class acreage within a  
 430 landscape ecosystem is the immature age class in the Lowland Conifer landscape ecosystem,  
 431 while the largest decrease is in the immature age class in the Jack Pine-Black Spruce landscape  
 432 ecosystem and the mature age classes within the Jack Pine-Black Spruce and Lowland Conifer  
 433 landscape ecosystems. Overall, the Dry-Mesic Red and White Pine landscape ecosystem would  
 434 have the highest acreage increase to the federal estate of MIH types and age classes and the Jack  
 435 Pine-Black Spruce landscape ecosystem would have the highest acreage decrease of MIH types  
 436 and age classes.

|                                      |                    | % <sup>2</sup>          | 14                                    | (1)                           | 4                  | 0                   | 0                                  | 0                        | 0              |
|                                      | Immature           | Acres <sup>1</sup>      | 148.5                                 | (528.7)                       | 2,014.3            | 0.0                 | 0.9                                | 298.9                    | 0.0            |
|                                      |                    | % <sup>2</sup>          | 1                                     | (3)                           | 26                 | 0                   | 0                                  | 1                        | 0              |
|                                      | Mature             | Acres <sup>1</sup>      | 92.1                                  | (726.1)                       | (1,709.8)          | 0.0                 | 0.0                                | 217.1                    | 0.0            |
|                                      |                    | % <sup>2</sup>          | 1                                     | (3)                           | (3)                | 0                   | 0                                  | 1                        | 0              |

440 Source: USFS 2010b; USFS 2011g.

441 <sup>1</sup> Total acres may be more or less than presented due to rounding.

442 <sup>2</sup> Percentage of acres increased or decreased on the federal estate within the entire landscape ecosystem.

443 <sup>3</sup> MIH 14 is not tracked on the federal lands; thus, percentage is NA.

#### 444 5.3.4.3.2 Invasive Non-native Plants

445 Land Exchange Alternative B would result in a reduction of occurrences of invasive non-native  
 446 species on the smaller federal parcel, but in an increase to the federal estate of similar  
 447 occurrences of invasive non-native species on Tract 1, including common tansy, orange  
 448 hawkweed, and ox-eye daisy.

#### 449 5.3.4.3.3 Threatened and Endangered Plant Species

##### 450 Endangered, Threatened, and Special Concern Plant Species

451 Under Land Exchange Alternative B, a smaller portion of the federal lands would be exchanged  
 452 for Tract 1. The same 10 ETSC plant species would be exchanged as for the Land Exchange  
 453 Proposed Action, but fewer colonies would be exchanged. There is one known state-listed ETSC  
 454 plant species located on Tract 1 (*Carex ormostachya*). Overall, 12 populations of 10 different

455 species on the smaller federal parcel would be exchanged for one population of one species on  
 456 Tract 1 (see Table 5.3.4-11). Rulemaking was conducted with the intent to update the list of  
 457 ETSC species (*Minnesota Rules*, parts 6134.0100 to 6134.0400), with new listings becoming  
 458 effective on August 19, 2013 (MDNR 2013h). This FEIS considers any new listings, or changes  
 459 in the previous listings, associated with the updated list.

460 **Table 5.3.4-11 Increase or Decrease to the Federal Estate of State-listed ETSC Plant**  
 461 **Populations under Land Exchange Alternative B**

| Plant Species (State Status/<br>Global Status <sup>1</sup> ) | Alternative B: Smaller<br>Federal Parcel Populations |                                      | Tract 1<br>Populations              |                                   | Net Species<br>Increase/<br>(Decrease) |
|--------------------------------------------------------------|------------------------------------------------------|--------------------------------------|-------------------------------------|-----------------------------------|----------------------------------------|
|                                                              | Total<br>Populations <sup>2,3</sup>                  | Total<br>Individuals <sup>3, 4</sup> | Total<br>Populations <sup>2,3</sup> | Total<br>Individuals <sup>3</sup> |                                        |
| <i>Botrychium pallidum</i> (SC/G3)                           | 1                                                    | 2                                    | 0                                   | NA                                | (1)                                    |
| <i>Botrychium rugulosum</i> (SC/G3)                          | 1                                                    | 4                                    | 0                                   | NA                                | (1)                                    |
| <i>Botrychium simplex</i> (SC/G5)                            | 3                                                    | 905                                  | 0                                   | NA                                | (1)                                    |
| <i>Caltha natans</i> (E/G5)                                  | 1                                                    | 29                                   | 0                                   | NA                                | (1)                                    |
| <i>Eleocharis nitida</i> (SC/G4)                             | 1                                                    | ~486 ft <sup>2</sup>                 | 0                                   | NA                                | (1)                                    |
| <i>Juncus stygius</i> var. <i>americanus</i><br>(SC/G5)      | 1                                                    | 1                                    | 0                                   | NA                                | (1)                                    |
| <i>Platanthera clavellata</i> (SC/G5)                        | 1                                                    | 3                                    | 0                                   | NA                                | (1)                                    |
| <i>Pyrola minor</i> (SC/G5)                                  | 1                                                    | 10                                   | 0                                   | NA                                | (1)                                    |
| <i>Ranunculus lapponicus</i> (SC/G5)                         | 1                                                    | ~919 ft <sup>2</sup>                 | 0                                   | NA                                | (1)                                    |
| <i>Torreyochloa pallida</i> (SC/G5)                          | 1                                                    | ~25 ft <sup>2</sup>                  | 0                                   | NA                                | (1)                                    |
| <i>Carex ormostachya</i> (SC/G4)                             | 0                                                    | NA                                   | 1                                   | >20                               | 1                                      |
| <b>Total</b>                                                 | <b>12</b>                                            | <b>NA</b>                            | <b>1</b>                            | <b>NA</b>                         | <b>(9)</b>                             |

462 Source: MDNR 2014d.

463 <sup>1</sup> The state status is E – Endangered; T – Threatened; and SC – Species of Special Concern. The global ranks range from G1 to  
 464 G5. A lower global ranking (e.g., G3) indicates a species at higher global risk than higher ranking (e.g., G5) (NatureServe  
 465 2014b).

466 <sup>2</sup> Populations are interpreted from MDNR NHIS data using Element Occurrence; this differs from the DEIS, which used  
 467 colonies as the population estimate.

468 <sup>3</sup> Data included here were provided by the Division of Ecological Resources, MDNR, and were current as of August 5, 2014. .  
 469 These data are not based on an exhaustive inventory of the state. The lack of data for any geographic area shall not be  
 470 construed to mean that no significant features are present. NA = Not Applicable.

471 <sup>4</sup> Where the number of individuals could not be determined without damaging the population, then patch size was used as a  
 472 representative abundance measure.

### 473 **Regional Foresters Sensitive Species**

474 The USFS RFSS data layer indicates there are no RFSS plants on the federal lands, which  
 475 includes the smaller federal parcel. However, several state-listed ETSC plant species occur on  
 476 the smaller federal parcel that are also RFSS plants, including *Botrychium pallidum*, *Botrychium*  
 477 *rugulosum*, *Botrychium simplex*, *Caltha natans*, *Eleocharis nitida*, *Juncus stygius* var.  
 478 *americanus*, and *Pyrola minor*.

479 As with the Land Exchange Proposed Action, the Land Exchange Alternative B would not affect  
 480 20 RFSS plants on the Superior National Forest. In addition, the Land Exchange Alternative B  
 481 may affect individuals, but would not be likely to cause a trend to federal listing or loss of  
 482 viability for the remaining 38 RFSS plants on the Superior National Forest. Please see the

483 Biological Evaluation listed on the USFS website (<http://www.fs.usda.gov/goto/superior/northmet>) for more information about effects to RFSS plants.  
484

485 There would be an increase to the federal estate in acres of upland forest (MIH 1) and aquatic  
486 habitat (MIH 14) as a result of Land Exchange Alternative B (see Table 5.3.4-9), which means  
487 there would be the greatest opportunity to gain the RFSS plants listed under those categories in  
488 Table 4.2.4-5. There would be a decrease to the federal estate in acreage of upland conifer forest  
489 (MIH 5) and lowland black spruce-tamarack forest (MIH 9), which means the RFSS plant  
490 species that prefer these habitat types and have suitable microhabitats may also be decreased on  
491 National Forest System lands.

#### 492 **5.3.4.3.4 Biodiversity**

493 The smaller federal parcel contains a high level of biodiversity because the majority of the parcel  
494 has been classified for inclusion in two MBS Sites of High Biodiversity Significance.  
495 Additionally, several different native plant communities exist on it, as well as 10 state-listed  
496 ETSC plant species. Because Tract 1 has not been fully studied, it is assumed to contain less  
497 biodiversity because it lacks MBS Sites of High Biodiversity Significance and native plant  
498 communities. However, inclusion of the preliminary Site of Outstanding Biodiversity  
499 Significance on Tract 1 would balance the exchange, if not make it more biodiverse than the  
500 smaller federal parcel. Table 5.3.4-1 provides a summary of the various data used to estimate  
501 biodiversity.

502 Land Exchange Alternative B would result in a decrease to the federal estate of 4,573.1 acres of  
503 MBS Sites of High Biodiversity Significance and a decrease of 0.3 acres of MBS Sites of  
504 Moderate Biodiversity Significance within the Laurentian Uplands subsection (see Table  
505 5.3.4-1). Portions of the west end of One Hundred Mile Swamp would remain in federal  
506 ownership.

507 Furthermore, Land Exchange Alternative B would result in removal from the Superior National  
508 Forest of three native plant community sites that are ranked as “imperiled” to “vulnerable” in the  
509 state. As previously discussed, Tract 1 does not contain any MBS Sites of Biodiversity  
510 Significance or native plant communities, so, unlike the Land Exchange Proposed Action, the  
511 federal estate would not have an increase of either MBS Sites or native plant communities under  
512 this alternative.

#### 513 **5.3.4.4 Land Exchange No Action Alternative**

514 Under the Land Exchange No Action Alternative, the Superior National Forest would have an  
515 ongoing responsibility for managing vegetation resources on the federal lands in accordance with  
516 the Forest Plan. The Land Exchange No Action Alternative would not change the USFS’s  
517 responsibility for managing vegetation resources and would result in no further effects on  
518 existing vegetation.

#### 519 **5.3.4.4.1 Cover Types**

520 Under the Land Exchange No Action Alternative, the current federal lands would remain in  
521 federal ownership and the lands would continue to be managed under the General Forest –  
522 Longer Rotation Management Area and the General Forest Management Area. Direct and  
523 indirect effects of the Land Exchange No Action Alternative on cover types would be

524 unchanged, as the management of these forests has occurred on site in the past. None of the  
525 federal lands currently have any vegetation management actions planned in the near future,  
526 regardless of whether the Land Exchange Proposed Action were to occur.

#### 527 **5.3.4.4.2 Invasive Non-native Plants**

528 Non-native species may still invade the federal lands as a result of logging, mineral exploration,  
529 vehicle traffic, and natural disturbances, but are likely to do so much more slowly than they  
530 would under the Land Exchange Proposed Action. The proximity of the federal lands to the  
531 already-disturbed Plant Site may put the federal lands at risk of eventual colonization by invasive  
532 non-native species.

#### 533 **5.3.4.4.3 Threatened and Endangered Plant Species**

534 Under the Land Exchange No Action Alternative, timber harvests are expected to continue to  
535 occur on the federal lands, though there are not any planned in the near future. Effects on ETSC  
536 plant species and RFSS plants, for different management techniques, are addressed in the Forest  
537 Plan (USFS 2004b). As discussed in the Biological Evaluation, the Land Exchange No Action  
538 Alternative would not have effects on RFSS species.

#### 539 **5.3.4.4.4 Biodiversity**

540 The Land Exchange No Action Alternative would not result in any change to biodiversity on the  
541 federal lands.

### 1 **5.3.5 Wildlife**

2 This section describes the environmental consequences of the Land Exchange to wildlife on the  
3 federal and non-federal lands. Effects from the change in federal ownership could be either  
4 beneficial or adverse, based on the change in species occurrences, habitat, and habitat  
5 connectivity on land that is under direct federal control. Effects due to the NorthMet Project  
6 Proposed Action are discussed in Section 5.2.5.

7 Rulemaking was conducted with the intent to update the list of ETSC species (*Minnesota Rules*,  
8 parts 6134.0100 to 6134.0400), with new listings becoming effective on August 19, 2013  
9 (MDNR 2013h). This FEIS considers any new listings, or changes in the previous listings,  
10 associated with the updated list.

11 A Biological Assessment that provides further information on federally listed species, and a  
12 Biological Evaluation that contains further information about RFSS have been prepared. The  
13 Biological Assessment and Biological Evaluation are included in Appendix D and are posted on  
14 the USFS website (<http://www.fs.usda.gov/goto/superior/northmet>). The Biological Assessment  
15 analyzes impacts to the Canada lynx, gray wolf, and northern long-eared bat. Land Exchange  
16 alternatives were analyzed in the Biological Assessment for the NorthMet Mining Project and  
17 Land Exchange. The organization of the methodologies and discussion in the Biological  
18 Assessment and Biological Evaluation may be different from the FEIS. Both documents also  
19 contain determinations of effect for the species discussed.

20 The Land Exchange Proposed Action would have mixed effects for the Canada lynx. It would  
21 result in an increase in suitable habitat for lynx and for snowshoe hare (prey species) on the  
22 federal estate (although the amount of unsuitable lynx habitat would also increase). It would also  
23 result in a decrease of denning habitat and a decrease to the federal estate within designated  
24 LAUs. Critical lynx habitat would not change regardless of ownership.

25 The Land Exchange Proposed Action would result in an increase in the number of occurrences  
26 and forage habitat availability for the gray wolf within the federal estate, but would result in a  
27 decrease in cover habitat. The Land Exchange Proposed Action would result in a net decrease of  
28 potential northern long-eared bat roosting habitat but an increase in foraging habitat within the  
29 federal estate.

30 Overall, the Land Exchange Proposed Action would result in an increase (to the federal estate) of  
31 the number of occurrences and habitat availability for two state-listed species of special concern,  
32 which include the Laurentian tiger beetle and the trumpeter swan (see Table 5.3.5-1). The Land  
33 Exchange Proposed Action is not expected to result in changes to the three additional state-listed  
34 and special concern species, which include the wood turtle, the eastern heather vole, and the  
35 yellow rail.

36 Under the Land Exchange Proposed Action, one additional state-listed species and 22 additional  
37 SGCN would be affected due to their presence on the federally held lands. The Land Exchange  
38 Proposed Action would result in an increase of up to 579.6 acres of habitat within the federal  
39 state in the Superior National Forest. While forested habitat would be decreased,  
40 shrubland/grassland and aquatic habitats would be increased as part of the Land Exchange  
41 Proposed Action. Under the Land Exchange Proposed Action, lands to be acquired would be

42 managed by the USFS in accordance with the current Forest Plan. No activities are planned on  
 43 these lands.

44 Under the Land Exchange Alternative B, one additional state-listed species but one less SGCN  
 45 would be affected because they occur within the federal estate. Forest habitat under federal  
 46 ownership would also decrease, though by a smaller amount than under the Land Exchange  
 47 Proposed Action. Similarly, the Land Exchange Alternative B would result in an increase of  
 48 173.6 acres of habitat to the federal estate, with a distribution of habitat similar to the Land  
 49 Exchange Proposed Action. As with the Land Exchange Proposed Action, lands acquired under  
 50 the Land Exchange Alternative B would be managed by the USFS in accordance with the current  
 51 Forest Plan. There are no activities planned on these lands.

52 As discussed in the Biological Evaluation, the USFS determined that the Land Exchange  
 53 Proposed Action and Land Exchange Alternative B may affect individuals but are not likely to  
 54 cause a trend to federal listing or loss of viability for 18 RFSS terrestrial wildlife species on the  
 55 Superior National Forest.

56 Under the Land Exchange No Action Alternative, no action would be taken. No lands would be  
 57 exchanged and no changes in wildlife species on the federal estate would be anticipated. As  
 58 discussed in the Biological Evaluation, the Land Exchange No Action Alternative would have no  
 59 effect on RFSS species.

60 **Table 5.3.5-1 Increase or Decrease of Special Status Wildlife Species on the Federal Estate**  
 61 **Resulting from the Land Exchange Proposed Action and Alternatives**

| Alternative                         | Increase or (Decrease) of Special Status Wildlife Species |                      |                                     |                                       |
|-------------------------------------|-----------------------------------------------------------|----------------------|-------------------------------------|---------------------------------------|

 67

### 68 5.3.5.1 Methodology and Evaluation Criteria

69 Evaluation was conducted to determine the potential effect that the Land Exchange Proposed  
 70 Action would have on wildlife on the federal estate species from the following:

- 71 • a change in federal and state-listed ETSC, SGCN, RFSS, and other wildlife species; and
- 72 • a change in habitat availability, prey species habitat availability, habitat connectivity, and  
 73 adjacent land use.

74 Analysis of wildlife species affected by the Land Exchange Proposed Action was guided by  
 75 evaluation criteria that were developed by the USFS and other Co-lead Agencies, which included  
 76 a comparison of the vegetation land cover and habitat types, forest age classes (young, immature,  
 77 and mature), large mature forest patches, road and trail densities, federal and state-listed ETSC,  
 78 SGCN, RFSS, and other wildlife species. GIS data and field observations for these categories  
 79 were gathered to the extent possible and then compared over an area of analysis that included the  
 80 federal and non-federal lands and LAU.

### 81 5.3.5.2 Land Exchange Proposed Action

#### 82 5.3.5.2.1 Federally Listed Species

##### 83 Canada Lynx

84 The federal lands of the Land Exchange Proposed Action include lynx habitat and habitat for  
 85 lynx prey species. Lynx habitat includes a wide variety of upland and lowland habitats and forest  
 86 types/ages, shrubland, and grasslands, but excludes aquatic environments and disturbed areas.  
 87 Preferred denning habitat is typically found in mature forest and is generally more dependent on  
 88 forest age classes, with trees older than saplings and with a dbh greater than 5 inches (immature  
 89 and mature age classes; see Table 4.3.4-3). Snowshoe hare are the primary prey species for the  
 90 Canada lynx, and hare habitat includes all types and age classes of forest and shrubland, but not  
 91 aquatic environments, disturbed areas, or grassland/croplands (see Table 5.3.5-3).

| Net Increase/(Decrease)              | (22.1)                                                   | (192.9)                                             | (51.6)                                                           | 195.7                                              |

95 Source: Tables 5.2.5-5, 4.3.4-3, and 4.3.4-8.

96 <sup>1</sup> Total acres may be more or less than presented due to rounding.

97 As shown in Table 5.3.5-3, the federal lands of the Land Exchange Proposed Action include  
 98 6,371.5 acres of suitable general habitat for lynx. The non-federal lands include a total of 6,808.4  
 99 acres of potentially suitable habitat, which is an increase of 436.9 acres. Aquatic environments  
 100 and disturbed areas are considered unsuitable habitat, along with lowlands with dead trees  
 101 (though this habitat was not specifically called out in habitat/cover data). The Land Exchange  
 102 Proposed Action would also result in an increase to the federal estate of 411.4 acres of hare  
 103 habitat. However, the Land Exchange Proposed Action would result in a decrease to the federal  
 104 estate of 29.1 acres of denning habitat and an increase of 126.9 acres of unsuitable lynx habitat.

105 Lynx may utilize snow packed trails and roads as travel corridors as they are energetically easier  
 106 to navigate, but they do not rely strictly on them. The federal lands do not contain any  
 107 established snow packed trails (such as snowmobile trails) but are crossed by 6.9 miles of road  
 108 surface. The non-federal lands are crossed by 0.03 mile of snow packed trail (snowmobile trail)  
 109 and 2.2 miles of roads. The Land Exchange Proposed Action would result in a decrease to the  
 110 federal estate of 4.7 miles of road and an increase to the federal estate of 0.03 mile of snow  
 111 packed trails available for lynx use (see Table 5.3.5-4).

114 Source: USFS 2011e.

115 Land ownership immediately adjacent to the federal lands is a mix of private, state, and federal.  
 116 The proximity of private lands and disturbance to the north and west may limit lynx passage and  
 117 utilization of habitat on the federal lands.

118 Overall, the land ownership patterns surrounding the non-federal lands are mixed. Federal land  
 119 proximity and, thus potential habitat connectivity, is marginal on Tract 1. Connectivity on the  
 120 other tracts is generally more favorable. Located in less developed areas of the Superior National  
 121 Forest, these tracts are generally bordered by federal, state, or county lands and are intended to  
 122 reduce fragmentation. As such, the Land Exchange Proposed Action is likely to result in  
 123 generally improved habitat connectivity overall.

124 Because all federal and non-federal lands are located within lynx critical habitat and would  
 125 remain so regardless of ownership, the Land Exchange Proposed Action would not result in a  
 126 change to lynx critical habitat to the federal estate. As previously discussed, LAU were identified  
 127 for purposes of analysis and development of conservation measures for lynx (USFS 2004b). The  
 128 federal lands are located within LAU 12 and the non-federal lands are located in LAU 4, 16, 21,  
 129 22, and 42. Tract 1 is not located within an LAU. The USFS indicated that no development or  
 130 activities are planned on the non-federal lands, which means that there would be no increase in  
 131 unsuitable habitat due to the Land Exchange Proposed Action (see Table 5.3.5-5). As such, the  
 132 percentage of currently unsuitable habitat in the overall LAU is not expected to change, nor  
 133 would it affect the Forest Plan condition that unsuitable habitat not exceed 30 percent of the  
 134 LAU (USFS 2013).

137 Source: Superior National Forest Monitoring and Evaluation Report (USFS 2009a)

138 <sup>1</sup> Total acres may be more or less than presented due to rounding.

139 The Land Exchange Proposed Action would have mixed effects for the Canada lynx. It would  
 140 result in an increase to the federal estate of overall suitable habitat for lynx and for snowshoe  
 141 hare (prey species) to the federal estate (although the amount of unsuitable lynx habitat would  
 142 also increase). It would also result in a decrease to the federal estate of denning habitat and a  
 143 decrease of federal lands within designated LAU. Critical lynx habitat would not change  
 144 regardless of ownership. Effects on the Canada lynx and its critical habitat are described in more  
 145 detail in the Biological Assessment.

146 **Gray Wolf**

147 The federal lands are likely part of a territory occupied by a single pack of wolves. The federal  
 148 lands are dominated by trees that range in age from immature to mature, which is adequate cover  
 149 habitat for wolves. Approximately 271 acres of young forest are present for forage opportunities  
 150 on the federal lands and 778 acres are present on the non-federal lands (see Table 4.3.4-3). There  
 151 are 5,393.4 acres of cover habitat on the federal lands and 5,364.3 acres on the non-federal lands  
 152 (see Table 5.3.5-6). Gray wolves or their sign were observed on Tracts 1, 2, 3, and 5.

153 **Table 5.3.5-6 Increase or Decrease in Gray Wolf Habitat on the Federal Estate Resulting**

| Tract 5 – McFarland Lake             | 0.0                    | 30.1                                |
| Net Increase/(Decrease)              | 507.1                  | (29.1)                              |
| <b>Land Exchange Alternative B</b>   |                        |                                     |
| Smaller Federal Parcel               | 271.1                  | 3,912.9                             |
| Tract 1 – Hay Lake                   | 533.8                  | 3,720.0                             |
| Net Increase/(Decrease)              | 262.7                  | (192.9)                             |

155 The amount of cover habitat is similar between the federal and non-federal lands, but the non-  
 156 federal lands include more potential forage habitat; therefore, the Land Exchange Proposed  
 157 Action would result in a very small decrease (29.1 acres) to the federal estate of cover habitat but  
 158 an increase to the federal estate of forage habitat (507.1) for the gray wolf. Overall, the Land  
 159 Exchange Proposed Action would result in an increase (to the federal estate) of the number of  
 160 occurrences and habitat availability for the gray wolf.

161 **Northern Long-Eared Bat**

162 Potential summer roosting and foraging habitat for the northern long-eared bat is present and  
 163 individuals have been observed on the federal lands, though no hibernacula have been observed.  
 164 Similarly, both forage and potential summer roosting habitat is present on the non-federal lands,  
 165 though no hibernacula have been observed. Bats were observed, though not identified to species,  
 166 on Tract 1 during field studies in 2009. The Land Exchange Proposed Action would result in a  
 167 net decrease of mature forest habitat to the federal estate, but an increase in grassland/ brushland,  
 168 which constitutes a decrease in potential bat roosting habitat but increase in foraging habitat  
 169 within the federal estate. Effects on the northern long-eared bat are described in more detail in  
 170 the Biological Assessment and Biological Evaluation.

171 **5.3.5.2.2 State-listed Species**

172

173 **Moose**

174 There is habitat present on the federal lands for the moose, and individuals and their sign have  
 175 been observed during surveys. Similarly, there is habitat present, and moose individuals or their  
 176 sign have been observed on Tracts 1, 2, and 3. The Land Exchange Proposed Action would result  
 177 in a decrease of mature mixed forest types on the federal estate, but an increase in moose

178 preferred habitats, including early successional forests, brushland, and aquatic environments. As  
179 moose or their sign have been observed on both the federal and non-federal lands, there would be  
180 neither an increase nor decrease in occurrences to the federal estate.

181 **Little Brown Bat**

182 Habitat for the little brown bat is present and individuals have been observed on the federal  
183 lands, though no hibernacula have been observed. Similarly, both forage and potential summer  
184 roosting habitat may be present on the non-federal lands, though no hibernacula have been  
185 observed. Bats were observed, though not identified to species, on Tract 1 during field studies in  
186 2009. The Land Exchange Proposed Action would result in a net decrease of mature forest  
187 habitat to the federal estate, but an increase in grassland/ brushland, which constitutes a decrease  
188 in potential bat roosting habitat but increase in foraging habitat within the federal estate.

189 **Eastern Pipistrelle**

190 Habitat for the eastern pipistrelle is present on the federal lands, but no hibernacula or  
191 individuals have been observed. Similarly, both forage and potential summer roosting habitat  
192 may be present on the non-federal lands, though no hibernacula have been observed. Bats were  
193 observed, though not identified to species, on Tract 1 during field studies in 2009. The Land  
194 Exchange Proposed Action would result in a net decrease of mature forest habitat to the federal  
195 estate, but an increase in grassland/ brushland, which constitutes a decrease in potential bat  
196 roosting habitat but increase in foraging habitat within the federal estate.

197 **Northern Goshawk**

198 The northern goshawk may be occasionally present since northern goshawk nests have been  
199 observed on the federal parcel. Northern goshawk individuals and nests have also been identified  
200 on Tract 1 since 2010, and an active northern goshawk territory (Pike Mountain 2 territory) has  
201 been identified and is being monitored by the MDNR. According to the MDNR NHIS database,  
202 there have also been northern goshawk observations within 10 miles of the non-federal lands  
203 (Tract 1, Tract 3, and Tract 4). More forested habitat for the species is present on the federal  
204 lands than the non-federal lands (see Table 5.3.5-2). As such, the Land Exchange Proposed  
205 Action would result in a decrease of forested habitat available for the northern goshawk on the  
206 federal estate.

207 **Boreal Owl**

208 Mature coniferous and deciduous forests are available as potential habitat for the boreal owl on  
209 the federal lands and non-federal lands. However, there would be a decrease of these forests to  
210 the federal estate under the Land Exchange Proposed Action (see Table 5.3.5-2). No boreal owls  
211 are known to occur on the non-federal lands, and one boreal owl was observed near the federal  
212 lands in 1988 to 1989. According to the MDNR NHIS database, there have been boreal owl  
213 observations within 10 miles of the non-federal lands (Tract 2, Tract 3, and Tract 5). It is  
214 unlikely boreal owls use either the federal or non-federal lands often.

215 **Wood Turtle**

216 The only known population of wood turtles near the federal lands is downstream from the Mine  
217 Site, along the southern border of the federal lands. Though there is no known suitable habitat for

218 wood turtles on the federal lands and no individuals are known to occur, wood turtles may use  
219 adjacent areas to the south of the federal lands. Similarly, no wood turtles or optimal wood turtle  
220 habitat was identified on the non-federal lands. According to the MDNR NHIS database, there  
221 have been wood turtle observations within 10 miles of the non-federal lands (Tract 1, Tract 2,  
222 and Tract 3).

223 Given that no wood turtles or wood turtle habitat were identified on either the federal or non-  
224 federal lands, the Land Exchange Proposed Action would not result in an increase or decrease of  
225 individuals, populations, or suitable habitat.

### 226 **Eastern Heather Vole**

227 The eastern heather vole has not been observed during field surveys or within 10 miles of the  
228 federal lands. Approximately 2,292 acres of potentially suitable habitat (upland coniferous forest,  
229 upland mixed forest, shrubland, and cropland/grassland) exists on the federal lands (see Table  
230 4.3.4-1), so the eastern heather vole could be present, but, if so, likely in very small numbers.  
231 The eastern heather vole was not identified on the non-federal lands by surveys or in the NHIS,  
232 but the non-federal lands contain 2,626.5 acres of habitat (see Table 4.3.4-10). According to the  
233 MDNR NHIS database, there have been eastern heather vole observations within 10 miles of the  
234 non-federal lands (Tract 3). As such, the Land Exchange Proposed Action would result in an  
235 increase to the federal estate of up to 334.9 acres of habitat.

### 236 **Yellow Rail**

237 The yellow rail was not found during surveys and was not reported in the NHIS database within  
238 10 miles of the federal lands. As previously mentioned, small, scattered areas of its preferred  
239 habitat are present on the federal lands (35.7 acres), but not the minimum nesting patch size (54  
240 acres) needed for the species (see Table 4.3.3-1). No yellow rails or yellow rail habitat were  
241 identified on the non-federal lands. The Land Exchange Proposed Action would not result in a  
242 net change to the species or habitat.

### 243 **Laurentian Tiger Beetle**

244 The lack of suitable habitat and any recorded observations for the Laurentian tiger beetle suggest  
245 that the species does not occur on the federal lands. However, the habitat for the Laurentian tiger  
246 beetle is present at Tract 1, in an area formerly used as a sand and gravel mine. No disturbance  
247 activities are currently planned on the non-federal lands, so this potential habitat would be  
248 preserved. According to the MDNR NHIS database, there have been Laurentian tiger beetles  
249 observed within 10 miles of the non-federal lands (Tract 4). As such, the Land Exchange  
250 Proposed Action would result in an increase of suitable habitat for this species.

### 251 **Taiga Alpine**

252 Lowland coniferous swamp is present on both the federal lands and non-federal lands, which is  
253 potential habitat for the taiga alpine. However, there would be a decrease to the federal estate of  
254 lowland coniferous swamp habitat under the Land Exchange Proposed Action. According to the  
255 MDNR NHIS database, there are no known occurrences of taiga alpine within 10 miles of the  
256 federal lands, and none were observed during surveys. There have been taiga alpine observations  
257 within 10 miles of the non-federal lands (Tract 2 and Tract 3). The Land Exchange Proposed

258 Action would result in a decrease in potential habitat for the species but unlikely result in a  
259 change in species occurrences.

260 **Freija's Grizzled Skipper**

261 Grassland and shrubland is present on both the federal lands and non-federal lands, which is  
262 potential habitat for the Freija's grizzled skipper. There would be an increase to the federal estate  
263 of grassland and shrubland habitats under the Land Exchange Proposed Action. According to the  
264 MDNR NHIS database, there are no known occurrences of Freija's grizzled skipper within 10  
265 miles of the federal lands, and none were observed during surveys. There have been Freija's  
266 grizzled skipper observations within 10 miles of the non-federal lands (Tract 2 and Tract 3). The  
267 Land Exchange Proposed Action would result in an increase in potential habitat for the species  
268 but unlikely result in a change in species occurrences.

269 **Nabokov's Blue**

270 Upper woodland habitat is present on both the federal lands and non-federal lands for the  
271 Nabokov's blue, though the larval host plant was not observed at either. There would be a  
272 decrease to the federal estate of upland woodland habitat under the Land Exchange Proposed  
273 Action. According to the MDNR NHIS database, there are no known occurrences within 10  
274 miles of the federal lands, and none were observed during surveys. There have been Nabokov's  
275 blue observations within 10 miles of the non-federal lands (Tract 2, Tract 3, and Tract 5). The  
276 larval host plant, dwarf bilberry, was noted to be locally moderate to common around the  
277 observation sites. The Land Exchange Proposed Action would result in a decrease in potential  
278 habitat for the species but unlikely result in a change in species occurrences.

279 **Quebec Emerald**

280 The Quebec emerald dragonfly can inhabit wet meadow/sedge meadow. Approximately 36 acres  
281 of this habitat type are present on the federal lands. There has only been one documented  
282 occurrence of this species in Minnesota (Lake County in 2006), and that occurrence was not on  
283 either the federal or non-federal lands. The non-federal lands do not contain any sedge/wet  
284 meadow wetlands. The Land Exchange Proposed Action would result in a decrease of potential  
285 habitat used by this species on the federal estate.

286 **Trumpeter Swan**

287 Trumpeter swans were observed on Tract 1 during surveys in 2009. A pair of adults with young  
288 was seen on Little Rice Lake. The species has not been observed on the federal lands. According  
289 to the MDNR NHIS database, there have been trumpeter swan observations within 10 miles of  
290 the non-federal lands (Tract 1, Tract 2, and Tract 3). Because the species has been observed on  
291 the non-federal lands and not on the federal lands, the Land Exchange Proposed Action would  
292 result in an increase of the occurrence of this listed species within the federal estate.

293 **5.3.5.2.3 Species of Greatest Conservation Need**

294 Sections 4.3.5.1.1 and 4.3.5.2 discuss the SGCN in the context of their habitat. The federal lands  
295 include a wide variety of habitat types, grouped into key habitat types and MIH types (see Table  
296 5.3.5-7).

297 Some acreage of some key habitat types, MIH types, and cover types within the federal estate  
 298 would increase through the Land Exchange Proposed Action, while others would decrease. The  
 299 key habitat types that would increase or decrease under the Land Exchange Proposed Action are  
 300 listed in Table 5.3.5-7. Species dependent on these habitat types are listed by ecological  
 301 subsection in Tables 4.3.5-1 through 4.3.5-5.

302 **Table 5.3.5-7 Increase or Decrease of Habitat Types on the Federal Estate Resulting from**  
 303 **the Land Exchange Proposed Action**

| Key Habitat Type and Management Indicator Habitat                | Federal Lands Acres | Non-Federal Lands <sup>1,2</sup> |                                   |                            |                                    |                                      | Net Increase or (Decrease) Acres |
|------------------------------------------------------------------|---------------------|----------------------------------|-----------------------------------|----------------------------|------------------------------------|--------------------------------------|----------------------------------|
|                                                                  |                     | Tract 1 – Hay Lake Lands Acres   | Tract 2 – Lake County Lands Acres | Tract 3 – Wolf Lands Acres | Tract 4 – Hunting Club Lands Acres | Tract 5 – McFarland Lake Lands Acres |                                  |
| Mature Upland Forest, Continuous Upland/Lowland Forest (MIH1-13) | 5,719.7             | 2,978.8                          | 337.2                             | 1,479.4                    | 105.7                              | 30.6                                 | (788.0)                          |
| Open Ground, Bare Soils (no MIH)                                 | 63.8                | 0.0                              | 0.0                               | 0.0                        | 0.0                                | 0.0                                  | (63.8)                           |
| Grassland and Brushland, Early Successional Forest (no MIH)      | 651.8               | 1,696.3                          | 38.9                              | 96.5                       | 45.0                               | 0.0                                  | 1,224.9                          |
| Aquatic Environments (MIH 14)                                    | 60.1                | 251.1                            | 5.8                               | 0.0                        | 9.6                                | 0.2                                  | 206.6                            |
| <b>Total</b>                                                     | <b>6,495.4</b>      | <b>4,926.2</b>                   | <b>381.9</b>                      | <b>1,575.9</b>             | <b>160.3</b>                       | <b>30.8</b>                          | <b>579.7</b>                     |

304 <sup>1</sup> According to non-federal land cover type summary tables (see Tables 4.3.4-1, 4.3.4-11, 4.3.4-13-20).  
 305 <sup>2</sup> Total acres may be more or less than presented due to rounding.

306 The Land Exchange Proposed Action would result in a decrease of 788.0 acres of forest habitat  
 307 and 63.8 acres of open ground/bare soil to the federal estate. In addition, the Land Exchange  
 308 Proposed Action would result in an increase of 1,224.9 acres of grassland/brushland and 206.6  
 309 acres of aquatic environment to the federal estate. Overall, the Land Exchange Proposed Action  
 310 would result in an increase of up to 579.7 acres of habitat to the federal estate, though there  
 311 would be a decrease of forest and open ground habitat. As such, forest-dependent species are  
 312 more likely to be affected through habitat decrease by the Land Exchange Proposed Action.  
 313 Grassland and brushland species (mostly bird species and one species of insect) would have  
 314 more habitat available under the Land Exchange Proposed Action, as would species dependent  
 315 on aquatic environments (bird species, reptile/amphibian species, and insect species). Overall,  
 316 the Land Exchange Proposed Action would result in an increase of SGCN habitat to the federal  
 317 estate.

318 **5.3.5.2.4 Regional Forester Sensitive Species**

319 A Biological Evaluation has been prepared that contains further information about RFSS. The  
 320 Biological Evaluation is included in Appendix D and is posted on the USFS website

321 (<http://www.fs.usda.gov/goto/superior/northmet>). Similar to the Biological Assessment, the  
322 organization of the methodologies and discussion in the Biological Evaluation may be different  
323 from the FEIS. The Biological Evaluation also contains determinations of effect for RFSS  
324 species.

325 The USFS determined that the Land Exchange Proposed Action and Land Exchange Alternative  
326 B may affect individuals but are not likely to cause a trend to federal listing or loss of viability  
327 for 18 RFSS terrestrial wildlife species on the Superior National Forest.

328 Of the 18 terrestrial RFSS on the 2011 list for the Superior National Forest, the gray wolf,  
329 eastern heather vole, northern long-eared bat, little brown bat, eastern pipistrelle, northern  
330 goshawk, boreal owl, wood turtle, taiga alpine, Freija's grizzled skipper, Nabokov's blue, and  
331 Quebec emerald dragonfly are discussed above as federally or state-listed species. Three  
332 additional RFSS (the olive-sided flycatcher, bay-breasted warbler, and Connecticut warbler) are  
333 included as SGCN and are also discussed above. The three remaining RFSS species are  
334 discussed below. Effects on the RFSS are described in more detail in the Biological Evaluation.  
335

### 336 **Bald Eagle**

337 As discussed in Section 5.2.5.2.2, eagles may utilize the area around the federal lands. The  
338 federal lands are located between the Embarrass and Partridge rivers, which eagles may use for  
339 foraging. Mud Lake may also be used for foraging. The nearest known nesting sites are more  
340 than 2 miles (5.8 miles south-southwest of the federal lands) from the federal lands and optimal  
341 habitat for nesting is not present. Eagles may utilize Mud Lake for nesting, though they tend to  
342 utilize larger lakes for nesting. Though optimal nesting and foraging habitat are not present in the  
343 federal lands, eagles may still utilize these areas.

344 Eagle habitat is present on several of the non-federal lands. Though they are smaller waterbodies  
345 than are optimal for eagles, Tract 1 includes the Pike River, Hay Lake, and Rice Lake. Tracts 2  
346 and 3 are located near large lakes such as Pine and Greenwood. Tract 5 borders McFarland Lake,  
347 which is connected to other lakes within the BWCAW. With the exception of Tract 1, these lands  
348 are also further from developed mining areas and disturbances are less likely than on the federal  
349 lands. Overall, the Land Exchange Proposed Action would result in an increase (to the federal  
350 estate) of the number of occurrences and habitat availability for the bald eagle.

### 351 **Great Gray Owl**

352 Though not observed during call surveys, the great gray owl may be occasionally present on the  
353 federal lands. Because owl calling surveys (ENSR 2005) found no great gray owls, populations  
354 in the area are likely small and/or occasional. No observations of great gray owls have been  
355 made on the non-federal lands. However, because the species utilizes forested habitat and the  
356 Land Exchange Proposed Action would result in a decrease of 788.0 acres of forested habitat, the  
357 Land Exchange Proposed Action would result in a decrease of this species' habitat on the federal  
358 estate.

### 359 **Three-Toed Woodpecker**

360 A three-toed woodpecker was identified on the federal lands during surveys in 2000 and was  
361 observed on the parcel again in 2007. Area populations are expected to be low, and these habitat

362 specialists require standing dead or dying trees where they can forage for bark beetles. The  
363 species has not been observed on the non-federal lands. As such, the Land Exchange Proposed  
364 Action would result in a decrease of this species' occurrence. Since the Land Exchange Proposed  
365 Action would result in a decrease of approximately 788.0 acres of forest, the Land Exchange  
366 Proposed Action would also result in a habitat decrease for this species on the federal estate.

367 Other factors, such as lower disturbance levels and increase of contiguous habitat, would  
368 potentially increase RFSS utilization of the non-federal lands. The federal lands contain two  
369 stands of contiguous forest habitat greater than 300 acres (340.6 acres and 1,352.3 acres) while  
370 the non-federal lands include one forest stand greater than 300 acres (598.2 acres – Tract 3, Wolf  
371 Lands 2). The Land Exchange Proposed Action would result in a net decrease of 1,094.7 acres of  
372 contiguous habitat stands greater than 300 acres to the federal estate.

### 373 **5.3.5.2.5 Other Wildlife Species**

374 Other regionally common wildlife species, such as ravens, grouse, beaver, wolves, black bear,  
375 white-tailed deer, fox, marten, and snowshoe hare, have been observed on both the federal and  
376 non-federal lands. Effects on wildlife species important to the Bands are discussed in Section  
377 5.2.9 on a connected ecosystems level. Similar to SGCN, habitat for some other species of  
378 wildlife would increase via the Land Exchange Proposed Action while habitat would decrease  
379 for others. As previously discussed, forested habitat would decrease via the Land Exchange  
380 Proposed Action, but grassland/shrubland habitat and aquatic habitat would increase. Grassland  
381 and brushland species would have more habitat available under the Land Exchange Proposed  
382 Action, as would species dependent on aquatic environments. The Land Exchange Proposed  
383 Action would result in 579.7 additional acres of wildlife habitat to the federal estate.

384 Game species such as white-tailed deer and black bear are of significant concern to the Bands.  
385 As mentioned above, forested habitat on the federal estate would decrease under the Land  
386 Exchange Proposed Action, but grassland and brushland and aquatic habitat would increase. The  
387 Land Exchange Proposed Action would result in increased hunting opportunities on the federal  
388 estate, as the non-federal lands would become available for use while the federal lands, which  
389 currently have limited access, would become private.

### 390 **5.3.5.3 Land Exchange Alternative B**

391 Under the Land Exchange Alternative B, a smaller federal parcel would be exchanged for only  
392 one non-federal parcel, Tract 1. The effects that would result from this alternative are similar to  
393 those of the Land Exchange Proposed Action.

#### 394 **5.3.5.3.1 Federally Listed Species**

##### 395 **Canada Lynx**

396 As shown in Table 5.3.5-3, the smaller federal parcel includes 4,697.2 acres of suitable general  
397 habitat for lynx. Tract 1 has a total of 4,675.1 acres of habitat potentially suitable for the Canada  
398 lynx, which would result in a decrease of 22.1 acres to the federal estate. The Land Exchange  
399 Alternative B would also result in a decrease of 192.9 acres of denning habitat. Snowshoe hare  
400 habitat would increase by 51.6 acres, but there would also be an increase of 195.7 acres of  
401 unsuitable lynx habitat to the federal estate under the Land Exchange Alternative B.

402 The smaller federal parcel does not contain any established snow packed trails (such as  
403 snowmobile trails) but is crossed by 6.9 miles of road surface. Tract 1 is crossed by 2.2 miles of  
404 roads and no established snow trails. Since lynx use snow packed trails and roads as travel  
405 corridors, the Land Exchange Alternative B would result in a decrease to the federal estate of 4.7  
406 miles of road use for lynx.

407 Land ownership under the Land Exchange Alternative B would be similar to the Land Exchange  
408 Proposed Action, but the smaller federal parcel would be bordered to the west by USFS-  
409 managed federal lands. Tract 1 is bordered by federal lands to the north, west, and partially east,  
410 but the area is generally surrounded by private lands and developed areas. Habitat connectivity to  
411 Tract 1 is marginal. The Land Exchange Alternative B is likely to result in limited habitat  
412 connectivity overall. Similar to the Land Exchange Proposed Action, the smaller federal parcel  
413 and non-federal lands are located within lynx critical habitat and would remain so regardless of  
414 ownership; the Land Exchange Alternative B would not result in a change to lynx critical habitat.  
415 As shown in Table 5.3.5-5, the Land Exchange Alternative B would result in the decrease of  
416 4,753 acres of land within an LAU because the federal parcel is within an LAU, but the Tract 1  
417 lands are not.

418 The Land Exchange Alternative B would have mixed habitat effects for the Canada lynx. It  
419 would result in a decrease of overall suitable habitat for lynx and denning habitat, but would  
420 result in an increase of suitable snowshoe hare habitat. It would also result in a decrease of  
421 federal lands within designated LAUs. Critical lynx habitat would not change regardless of  
422 ownership. As such, the Land Exchange Alternative B is not likely to have either a net increase  
423 or decrease on Canada lynx on the federal estate.

#### 424 **Gray Wolf**

425 Gray wolves have been observed on both the smaller federal parcel and on Tract 1.  
426 Approximately 271 acres of forage habitat is present on the smaller federal parcel (young age  
427 class, see Table 5.3.4-4) and 533.8 acres are present on Tract 1. There are 3,912.9 acres of cover  
428 habitat on the smaller federal parcel (immature and mature age classes) and 3,720.0 acres on  
429 Tract 1. This would result in an increase of 262.8 acres of forage habitat but also in a decrease of  
430 192.9 acres of cover habitat on the federal estate under Land Exchange Alternative B.

#### 431 **Northern Long-Eared Bat**

432 Potential summer roosting and foraging habitat for the northern long-eared bat is present and  
433 individuals have been observed on the smaller federal parcel, though no hibernacula have been  
434 observed. Bats were observed, though not identified to species, on Tract 1 during field studies in  
435 2009. The Land Exchange Alternative B would result in a net decrease of mature forest habitat to  
436 the federal estate, but an increase in grassland/brushland, which constitutes a decrease in  
437 potential summer roosting habitat but increase in foraging habitat within the federal estate.

### 438 **5.3.5.3.2 State-listed Species**

#### 439 **Moose**

440 There is habitat present on the Alternative B: Smaller Federal Parcel for the moose, and  
441 individuals and their sign have been observed during surveys. Similarly, there is habitat present  
442 and moose individuals or their sign have been observed, on Tracts 1, 2, and 3. There would not

443 be a change in species occurrences on the federal estate. The Land Exchange Alternative B  
444 would result in a decrease of mature mixed forest types, but an increase in preferred habitat  
445 types, including early successional forests, brushland, and aquatic environments.

446 **Little Brown Bat**

447 Habitat for the little brown bat is present and individuals have been observed on the Alternative  
448 B: Smaller Federal Parcel, though no hibernacula have been observed. Bats were observed,  
449 though not identified to species, on Tract 1 during field studies in 2009. The Land Exchange  
450 Alternative B would result in a net decrease of mature forest habitat to the federal estate, but an  
451 increase in grassland/brushland, which constitutes a decrease in potential bat roosting habitat but  
452 an increase in foraging habitat within the federal estate.

453 **Eastern Pipistrelle**

454 Habitat for the eastern pipistrelle is present on the Alternative B: Smaller Federal Parcel, though  
455 no hibernacula or individuals have been observed. Bats were observed, though not identified to  
456 species, on Tract 1 during field studies in 2009. The Land Exchange Alternative B would result  
457 in a net decrease of mature forest habitat to the federal estate, but an increase in  
458 grassland/brushland, which constitutes a decrease in potential bat roosting habitat but an increase  
459 in foraging habitat within the federal estate.

460 **Northern Goshawk**

461 The northern goshawk may be occasionally present on the Alternative B: Smaller Federal Parcel  
462 since a northern goshawk nest has been observed. Northern goshawk individuals and nests have  
463 also been identified on Tract 1, and according to the MDNR NHIS database, there have been  
464 northern goshawk observations within 10 miles of the non-federal lands (Tract 1). More forested  
465 habitat for the species is present on the smaller federal parcel than on Tract 1 (see Table 5.3.5-8).  
466 As such, the Land Exchange Alternative B would result in a decrease of forested habitat  
467 available for the northern goshawk on the federal estate.

468 **Boreal Owl**

469 The boreal owl was observed in proximity to the Alternative B: Smaller Federal Parcel in 1988  
470 to 1989, but has not been observed on the Tract 1 lands. The Land Exchange Alternative B  
471 would result in a decrease of coniferous or mixed forest habitats available for the boreal owl on  
472 the federal estate.

473 **Wood Turtle**

474 No wood turtles or optimal wood turtle habitat were identified on Tract 1 or the smaller federal  
475 parcel. According to the MDNR NHIS database, there have been wood turtles observed within  
476 10 miles of the non-federal lands (Tract 1). As such, the Land Exchange Alternative B would not  
477 result in an increase or decrease of habitat for the species on the federal estate.

478 **Eastern Heather Vole**

479 The eastern heather vole has not been observed during field surveys within 10 miles of the  
480 federal lands. There are 1,261.6 acres of potentially suitable habitat on the smaller federal parcel  
481 (see Table 4.3.4-6). Eastern heather voles were not identified on the non-federal lands by surveys

482 or in the NHIS, but Tract 1 contains 2,133.6 acres of habitat, which would result in an increase of  
483 872.0 acres of habitat for the eastern heather vole on the federal estate. As such, the Land  
484 Exchange Alternative B would result in an increase of habitat for this species.

485 **Yellow Rail**

486 The yellow rail was not found during surveys and was not reported in the NHIS database within  
487 10 miles of the federal lands. As previously mentioned, small, scattered areas of its preferred  
488 habitat are present on the federal lands (34.9 acres), but not the minimum nesting patch size (54  
489 acres) needed for the species. Similar to the Land Exchange Proposed Action, the Land Exchange  
490 Alternative B would not result in a net change to the species or its habitat on the federal estate.

491 **Laurentian Tiger Beetle**

492 Similar to the Land Exchange Proposed Action, the lack of suitable habitat and any recorded  
493 observations for the Laurentian tiger beetle suggest that the species does not occur on the smaller  
494 federal parcel. However, habitat for the Laurentian tiger beetle is present on Tract 1, in an area  
495 formerly used as a sand and gravel mine. No disturbance activities are currently planned on Tract  
496 1, so this potential habitat would be preserved. As such, the Land Exchange Alternative B,  
497 similar to the Land Exchange Proposed Action, would result in an increase of suitable habitat for  
498 the species on the federal estate.

499 **Taiga Alpine**

500 There is potential habitat present for the taiga alpine on both the Alternative B: Smaller Federal  
501 Parcel and Tract 1 lands. Under the Land Exchange Alternative B, there would be a decrease to  
502 the federal estate of lowland coniferous swamp habitat, and therefore a decrease in potential  
503 habitat for the species, but it is unlikely this would result in a change in species occurrences.

504 **Freija's Grizzled Skipper**

505 There is potential habitat present for the Freija's grizzled skipper on both the Alternative B:  
506 Smaller Federal Parcel and Tract 1 lands. Under the Land Exchange Alternative B, there would  
507 be an increase to the federal estate of grassland and shrubland habitats, and therefore an increase  
508 in potential habitat for the species, but it is unlikely this would result in a change in species  
509 occurrences.

510 **Nabokov's Blue**

511 There is potential habitat present for the Nabokov's blue on both the Alternative B: Smaller  
512 Federal Parcel and Tract 1 lands, though the larval host plant was not observed at either. Under  
513 the Land Exchange Alternative B there would be a decrease to the federal estate of upland  
514 woodland habitat and a decrease in potential habitat for the species; but it is unlikely this would  
515 result in a change in species occurrences.

516 **Quebec Emerald**

517 The Quebec emerald dragonfly has not been identified on the smaller federal parcel, as there has  
518 only been one documented occurrence of this species in Minnesota in Lake County in 2006  
519 (Minnesota Odonata Survey Project 2012). Tract 1 does not contain any sedge/wet meadow

520 wetlands, and so the Land Exchange Alternative B would result in a decrease of potential habitat  
 521 used by this species on the federal estate.

522 **Trumpeter Swan**

523 Trumpeter swans were observed on Tract 1 during surveys in 2009. A pair of adults with young  
 524 was seen on Little Rice Lake. The species has not been observed on the smaller federal parcel.  
 525 Similar to the Land Exchange Proposed Action, because the species has been observed on Tract  
 526 1 but not on the smaller federal parcel, the Land Exchange Alternative B would result in an  
 527 increase of the occurrence of this listed species within the federal estate.

528 **5.3.5.3.3 Species of Greatest Conservation Need**

529 Like the Land Exchange Proposed Action, the SGCN for the Land Exchange Alternative B are  
 530 discussed in the context of their habitat. The smaller federal parcel also includes a wide variety  
 531 of habitat types, grouped into key habitat types and MIH types (see Table 5.3.5-8).

532 Similar to the Land Exchange Proposed Action, the Land Exchange Alternative B would result  
 533 in a decrease of forest habitat (1,279.3 acres) and open ground/bare soil (29.1 acres) on the  
 534 federal estate. The Land Exchange Proposed Action, however, would result in an increase of  
 535 grassland/brushland (1,257.2 acres) and aquatic environments (224.8 acres) on the federal estate.  
 536 Overall, the Land Exchange Proposed Action would result in an increase of up to 173.6 acres of  
 537 habitat to the federal estate, though there would be a decrease of forest and open ground habitat.  
 538 As such, forest-dependent species are more likely to be affected through habitat decrease under  
 539 the Land Exchange Alternative B. Grassland and brushland species (mostly bird species and one  
 540 species of insect) would have more habitat available under the Land Exchange Alternative B, as  
 541 would species dependent on aquatic environments (bird species, reptile/amphibian species, and  
 542 insect species). Overall, the Land Exchange Alternative B would result in an increase of SGCN  
 543 habitat to the federal estate.

544 **Table 5.3.5-8 Increase or Decrease of Habitat Types on the Federal Estate Resulting from**  
 545 **Land Exchange Alternative B**

| Key Habitat Type and Management Indicator Habitat                | Smaller Federal Parcel (Acres) | Non-Federal Land Tract 1 (Acres) | Net Increase or (Decrease) (Acres) |
|------------------------------------------------------------------|--------------------------------|----------------------------------|------------------------------------|
| Mature Upland Forest, Continuous Upland/Lowland Forest (MIH1-13) | 4,258.1                        | 2,978.8                          | (1,279.3)                          |
| Open Ground, Bare Soils (no MIH)                                 | 29.1                           | 0.0                              | (29.1)                             |
| Grassland and Brushland, Early Successional Forest (no MIH)      | 439.1                          | 1,696.3                          | 1,257.2                            |
| Aquatic Environments (MIH 14)                                    | 26.3                           | 251.1                            | 224.8                              |
| <b>Total<sup>1</sup></b>                                         | <b>4,752.6</b>                 | <b>4,926.2</b>                   | <b>173.6</b>                       |

546 <sup>1</sup> Total acres may be more or less than presented due to rounding.

547 **5.3.5.3.4 Regional Forester Sensitive Species**

548 ***Bald Eagle***

549 As under the Land Exchange Proposed Action, the smaller federal parcel and surrounding areas  
550 may be utilized by bald eagles. Similar to the Land Exchange Proposed Action, the smaller  
551 federal parcel is also located between the Embarrass and Partridge rivers, which eagles may use  
552 for foraging. However, the smaller federal parcel excludes a portion of Mud Lake. The nearest  
553 known nesting sites are greater than 2 miles (5.8 miles south-southwest of the smaller federal  
554 parcel) from the federal lands and optimal habitat for nesting is not present.

555 Tract 1 contains waterbodies (Pike River, Hay Lake, and Rice Lake) and large trees, which  
556 eagles may use for nesting, though no nests have been observed. The nearest known eagle nest is  
557 approximately 4 miles southwest of the parcel.

558 ***Great Gray Owl***

559 Though not observed during call surveys, the great gray owl may be occasionally present on the  
560 smaller federal parcel, as an individual was observed along Dunka Road south of the Mine Site  
561 in 2009. No observations of great gray owls have been made on Tract 1. However, because the  
562 species utilizes forested habitat and the Land Exchange Alternative B would result in a decrease  
563 of 1,279.3 acres of forested habitat, the Land Exchange Alternative B would result in a decrease  
564 of this species' habitat on the federal estate.

565 ***Three-Toed Woodpecker***

566 Three-toed woodpeckers were observed on or near the smaller federal parcel in 2000 and again  
567 in 2007. Area populations are expected to be low, and the species has not been observed on Tract  
568 1. As such, the Land Exchange Alternative B would result in the decrease of this species'  
569 occurrence. Since the Land Exchange Alternative B would result in a decrease of 1,279.3 acres  
570 of forest, this would result in a habitat decrease for this species on the federal estate.

571 Other factors, such as lower disturbance levels and increase of contiguous habitat, would  
572 potentially increase RFSS utilization of Tract 1 lands. The smaller federal parcel contains two  
573 stands of contiguous forest habitat greater than 300 acres (340.6 and 926.1 acres) while there are  
574 no stands greater than 300 acres on Tract 1.

575 **5.3.5.3.5 Other Wildlife Species**

576 Similar to the Land Exchange Proposed Action, forested habitat within the federal estate would  
577 decrease under the Land Exchange Alternative B, but grassland/shrubland habitat and aquatic  
578 habitat would be increased. Grassland and brushland species would have more habitat available  
579 under the Land Exchange Alternative B, as would species dependent on aquatic environments.  
580 The Land Exchange Alternative B would result in 173.6 additional acres of wildlife habitat on  
581 the federal estate.

582 **5.3.5.4 Land Exchange No Action Alternative**

583 Under the Land Exchange No Action Alternative, the current federal lands would remain in  
584 federal ownership and would continue to be managed under the General Forest – Longer  
585 Rotation Management Area and the General Forest Management Area. Wildlife would be

586 directly affected by logging, mineral exploration, vehicle traffic, natural disturbances, and  
587 thinning activities, which would occur as planned by the USFS, and would be indirectly affected  
588 by changes in habitat caused by forest management. However, these activities would affect  
589 wildlife to a lesser degree than under the Land Exchange Proposed Action. Section 5.2.4.3.1  
590 provides further discussion of the effects on management of cover types and habitat on the  
591 federal lands. Under the Land Exchange No Action Alternative, the USFS has an ongoing  
592 responsibility for managing wildlife resources on Superior National Forest lands in accordance  
593 with the Forest Plan (USFS 2004b). The Land Exchange No Action Alternative would not  
594 change the Forest Service's responsibility for managing wildlife resources and would result in no  
595 change in anticipated effects on existing wildlife.

596 Under the Land Exchange No Action Alternative, the non-federal lands would not go into USFS  
597 ownership, and land use would be determined by the private land owners. Effects on wildlife  
598 species are difficult to predict given the uncertainty of future potential land use. Lands may be  
599 developed, resulting in potential effects on individuals and local populations, habitat decrease,  
600 and effects on wildlife travel corridors.

DRAFT

DRAFT

### 1 **5.3.6 Aquatic Species**

2 This section describes the environmental consequences of the Land Exchange alternatives on  
3 aquatic biota, using comparisons of the existing conditions presented in Sections 4.2.6 and 4.3.6  
4 to conditions after the Land Exchange alternatives in terms of net increase or decrease in aquatic  
5 biological resources for the federal and non-federal lands.

6 The Land Exchange Proposed Action would result in a net increase to the federal estate of  
7 surface waters (MIH 14), including 99.1 acres of lakes, 3.8 miles of rivers, and 8.1 miles of  
8 third-order streams. It would also result in a decrease to the federal estate of 0.3 miles of first-  
9 order streams and 4.0 miles of second-order streams. The Land Exchange Proposed Action  
10 would result in an increase in watershed riparian connectivity and aquatic connectivity for the  
11 federal estate. Based on available data, the Land Exchange Proposed Action would potentially  
12 result in an increase of nine additional fish species to the federal estate, while the  
13 macroinvertebrate assemblage would be similar. The Land Exchange Proposed Action could  
14 result in an increase to the federal estate of six new potential SGCN species, based on ecoregion  
15 data.

16 Land Exchange Alternative B would result in a net increase to the federal estate of surface waters  
17 (MIH 14), including 120.7 acres of lakes, 2.8 miles of rivers, and 8.1 miles of third-order  
18 streams. Additionally, it would result in a decrease to the federal estate of 1.3 miles of first-order  
19 streams and 4.0 miles of second-order streams, and an increase to the federal estate of. Land  
20 Exchange Alternative B would result in an increase in watershed riparian connectivity and  
21 aquatic connectivity for the federal estate. Based on available data, Land Exchange Alternative B  
22 would potentially result in a decrease to the federal estate of four fish species, while the  
23 macroinvertebrate assemblage would likely be similar. Land Exchange Alternative B would  
24 result in no net change of SGCN species, based on ecoregion data.

25 The Land Exchange No Action Alternative would not result in any increase or decrease of  
26 aquatic habitats or SGCN species to the federal estate.

27 Rulemaking was conducted with the intent to update the list of ETSC species (*Minnesota Rules*,  
28 parts 6134.0100 to 6134.0400), with new listings becoming effective on August 19, 2013  
29 (MDNR 2013h). The FEIS considers any new listings, or changes in the previous listings,  
30 associated with the updated list. The FEIS also considers any federal listing changes. A  
31 Biological Evaluation has been prepared that contains further information about RFSS species.  
32 The Biological Evaluation is included in Appendix D and is posted on the USFS website  
33 (<http://www.fs.usda.gov/goto/superior/northmet>).

#### 34 **5.3.6.1 Methodology and Evaluation Criteria**

35 The criteria used to describe the direct and indirect effects of the Land Exchange alternatives  
36 focused on the ecological integrity of the aquatic systems present at the federal lands and non-  
37 federal lands where physical, chemical, and biological characteristics that are important to biotic  
38 quality were considered. The spatial and temporal area of analysis for aquatic resources included  
39 the federal and non-federal lands that are proposed for the exchange based on current conditions.

40 The methodology used for analysis of the Land Exchange alternatives included review and  
41 evaluation of available literature, aerial photography review, and GIS analysis of all surface

42 waters and aquatic species habitat present within the Land Exchange areas. Both quantitative and  
43 qualitative analyses were used. The analysis of the aquatic resources affected by the Land  
44 Exchange alternatives was guided by evaluation criteria that were developed by the USFS and  
45 other Co-lead Agencies as follows:

- 46 • change in the amount of Superior National Forest MIHs (MIH 14 [aquatic habitat]) available  
47 for species on the federal and non-federal lands;
- 48 • changes in the length of stream segments;
- 49 • changes in the area of lake or deepwater wetland;
- 50 • qualitative determination of community habitat and ecological value;
- 51 • qualitative assessment of the aquatic connectivity (network created by streams, rivers, and  
52 lakes as they flow into one another) and the potential for barriers to fish passage; and
- 53 • net change in aquatic species.

### 54 **5.3.6.2 Land Exchange Proposed Action**

#### 55 **5.3.6.2.1 Surface Water Features (MIH 14)**

56 Comparing the footprints of the surface water features present within the federal and non-federal  
57 lands provides a direct assessment of the increase or decrease to the federal estate in aquatic  
58 environments that support aquatic biota and associated habitats. This comparison was made by  
59 analyzing the linear shoreline frontage and frontage index of the surface water features within the  
60 federal and non-federal lands, where the frontage index indicates the linear ft of lake and  
61 shoreline frontage per acre of land.

62 The Land Exchange Proposed Action would result in a net increase of surface water resources to  
63 the federal estate (see Table 5.3.6-1). A net increase of 99.1 acres of lake and 3.8 miles of rivers  
64 would be added to the federal estate from the Land Exchange Proposed Action. For both lakes  
65 and streams, the frontage index would increase substantially by 34.0 shoreline/acre units as a  
66 result of the exchange.

67 **Table 5.3.6-1 Federal and Non-federal Land Surface Water Comparisons**

| Parcel                   | Lake  |               |                                 | Rivers/Creeks/Streams |                                   |                                              |
|--------------------------|-------|---------------|---------------------------------|-----------------------|-----------------------------------|----------------------------------------------|
|                          | Acres | Frontage (ft) | Frontage Index (shoreline/acre) | Miles                 | Frontage (linear ft) <sup>1</sup> | Frontage Index (shoreline/acre) <sup>2</sup> |
| <b>Lands Conveyed</b>    |       |               |                                 |                       |                                   |                                              |
| Federal Lands            | 30.5  | 4,550.0       | 0.7                             | 5.3                   | 55,968.0                          | 8.6                                          |
| <b>Lands Acquired</b>    |       |               |                                 |                       |                                   |                                              |

| Net Increase/(Decrease)  | 99.1  | 12,864.0      | 34.9                            | 3.8                   | 27,456.0                          | 34.0                                         |

68 Note: Surface water shoreline distance calculated by GIS analysis.

69 <sup>1</sup> Includes shoreline distance on both sides of streams.

70 <sup>2</sup> Frontage Index calculated by dividing total acres of parcel by total shoreline within parcel.

71

72 **5.3.6.2.2 Differences of Strahler Stream Orders and Habitat**

73 For the purposes of this FEIS, the Strahler Order (USEPA 2011a) is used to describe the  
 74 hierarchical ordering of streams, where a first-order stream describes a headwater type stream  
 75 with no branching. Where two first-order streams meet, they become larger second-order streams  
 76 and where two second-order streams meet, they become larger third-order streams, etc. A  
 77 quantitative comparison of the Strahler Stream Order indicates the Land Exchange Proposed  
 78 Action would result in a decrease of 0.3 miles of first-order headwater streams and 4.0 miles of  
 79 second-order streams, and an increase in 8.1 miles of third-order streams to the federal estate  
 80 (see Table 5.3.6-2).

81 The net increase of third-order streams and decrease in second-order streams would likely add  
 82 more habitat diversity to the Superior National Forest since, generally, stream habitat diversity  
 83 increases with higher-order streams. No significant habitat changes would likely occur associated  
 84 with the slight decreases in first-order, headwater streams acquired as a result of the Land  
 85 Exchange Proposed Action; however, the net reduction to the Superior National Forest of 0.3  
 86 mile of first order streams may result in slightly less habitat available for headwater stream  
 87 dependent species.

88 **Table 5.3.6-2 Increase or Decrease of Stream Orders from the Land Exchange Proposed**  
 89 **Action**

| Parcel (Stream)                                | Stream Distance (miles) |                       |                       |
|------------------------------------------------|-------------------------|-----------------------|-----------------------|
|                                                | 1 <sup>st</sup> Order   | 2 <sup>nd</sup> Order | 3 <sup>rd</sup> Order |
| <b>Lands Conveyed</b>                          |                         |                       |                       |
| Federal Lands (Yelp Creek and Partridge River) | 1.3                     | 4.0                   | 0.0                   |

| <b>Net Increase/(Decrease)</b>                 | <b>(0.3)</b>            | <b>(4.0)</b>          | <b>8.1</b>            |

90 Note: Surface water shoreline distance calculated by GIS analysis.

91 **5.3.6.2.3 Watershed Level Riparian and Aquatic Connectivity**

92 **Riparian Connectivity**

93 Intact riparian areas are an important factor contributing to diverse and productive aquatic  
 94 ecosystems and function to maintain available water quality and physical habitat. The streams  
 95 present on the federal and non-federal lands (Partridge River, Pike River, and Coyote Creek) are  
 96 each part of a network of streams, creeks, and rivers that makes up a larger watershed. The  
 97 connections between these surface water features are affected by the vegetated, undisturbed  
 98 riparian edges bordering these water bodies. A comparison of the watersheds using the RCI is  
 99 presented in Table 5.3.6-3. The index was developed from GIS analysis of vegetative cover  
 100 along riparian areas where agriculture and land development have affected natural riparian  
 101 vegetative cover.

102 The Land Exchange Proposed Action would result in a slight increase in watershed riparian  
 103 connectivity, which indicates that the streams on both the federal and non-federal lands are  
 104 located within watersheds with existing high-quality riparian connectivity.

105 **Table 5.3.6-3 Watershed Riparian Connectivity Index Comparison**

| Surface Water                              | Tract                  | Watershed              | Percent Agriculture in Riparian Zone | Percent Development in Riparian Zone | RCI Score <sup>1</sup> |
|--------------------------------------------|------------------------|------------------------|--------------------------------------|--------------------------------------|------------------------|
| <b>Lands Conveyed</b>                      |                        |                        |                                      |                                      |                        |
| Partridge River/Yelp Creek                 | Federal Lands          | St. Louis              | 0                                    | 5                                    | 95                     |
| <b>Lands Acquired</b>                      |                        |                        |                                      |                                      |                        |
| Pike River                                 | 1 - Hay Lake           | Vermillion             | 0                                    | 1                                    | 99                     |
| Coyote Creek                               | 3 - Wolf Lands 3 and 4 | Rainy River-Headwaters | 0                                    | 0                                    | 100                    |
| <b>Net Increase/(Decrease)<sup>2</sup></b> |                        |                        | 0                                    | (4)                                  | 4.5                    |

106 Adopted from MDNR 2015a.

107 <sup>1</sup> RCI score calculated with MDNR formula using Percent Agriculture and Percent Development in Riparian Zone; scale is from  
108 0 to 100 where 100 indicates excellent riparian conductivity.

109 <sup>2</sup> Non-federal lands RCI score averaged to determine net increase/decrease.

110 **Aquatic Connectivity**

111 Structures within streams, such as dams, bridges, and culverts reduce the longitudinal and lateral  
112 connectivity of the watershed. These structures can degrade the aquatic habitat in the watershed  
113 by slowing stream flow, increasing sedimentation, incising stream channels, changing the depth,  
114 and disconnecting portions of streams from the floodplain. The ACI was developed from GIS  
115 analysis of number of structures per stream mile for each watershed, and the watershed ACI  
116 scores were used to provide a comparison of each watershed.

117 The Land Exchange Proposed Action would result in the Superior National Forest acquiring  
118 streams located in watersheds with better aquatic connectivity values (see Table 5.3.6-4).

119 **Table 5.3.6-4 Watershed Aquatic Connectivity Index Comparison**

| Surface Water                              | Tract                  | Watershed              | Aquatic: Bridges and Culverts (miles stream/# structures) | Aquatic: Dams (miles stream/# structures) | ACI Score <sup>1</sup> |
|--------------------------------------------|------------------------|------------------------|-----------------------------------------------------------|-------------------------------------------|------------------------|
| <b>Lands Conveyed</b>                      |                        |                        |                                                           |                                           |                        |
| Partridge River/Yelp Creek                 | Federal Lands          | St. Louis              | 15                                                        | 6                                         | 11                     |
| <b>Lands Acquired</b>                      |                        |                        |                                                           |                                           |                        |
| Pike River                                 | 1 - Hay Lake           | Vermillion             | 41                                                        | 11                                        | 26                     |
| Coyote Creek                               | 3 - Wolf Lands 3 and 4 | Rainy River-Headwaters | 89                                                        | 19                                        | 54                     |
| <b>Net Increase/(Decrease)<sup>2</sup></b> |                        |                        | 50                                                        | 9                                         | 29                     |

120 Adopted from MDNR 2015b.

121 <sup>1</sup> ACI score calculated by dividing total miles of streams and ditches per watershed by total number of culverts, bridges, and  
122 dams; scale is from 0 to 100 where 100 indicates free flowing streams (no structures) and 0 indicates one structure for every 20  
123 miles of flowing water.

124 <sup>2</sup> Non-federal lands averaged to determine net increase/decrease.

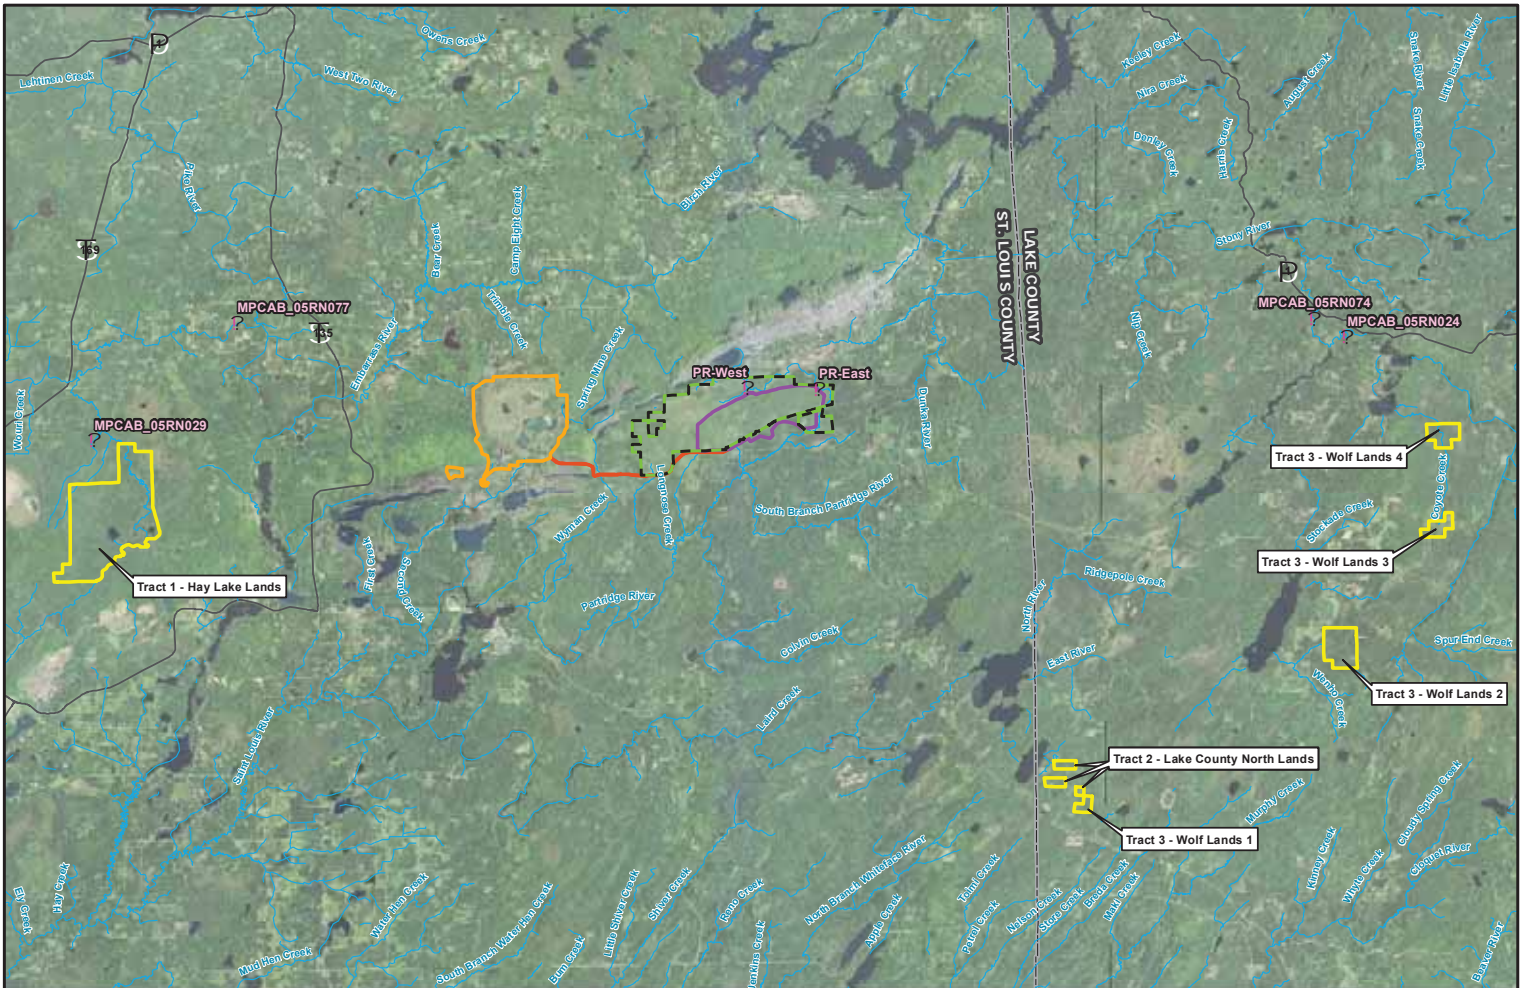

126 **5.3.6.2.4 Aquatic Species Assemblages**

127 A complete quantitative comparison of the net increase or decrease of aquatic species cannot be  
128 made for the purposes of the Land Exchange Proposed Action due to the absence of complete  
129 baseline information. Only the federal lands had aquatic biota and habitat sampling sites within  
130 the parcel boundaries. A qualitative comparison can be made for species located at the two sites  
131 within the federal parcels and the four sites near the non-federal parcels (see Section 4.2.6). The  
132 exception to this statement includes the differences between the Coyote Creek headwater stream  
133 habitat and the Stony River sampling sites chosen to qualitatively represent Tract 3, which are  
134 summarized below.

135 **Fish Assemblages**

136 Two survey sites were analyzed within the vicinity of the federal lands while four survey sites  
137 were analyzed among the non-federal lands (in the vicinity of Pike River and Coyote Creek; see  
138 Figure 5.3.6-1). The federal lands and the survey sites within the vicinity of the non-federal lands  
139 had 11 species in common (see Table 5.3.6-5). The Land Exchange Proposed Action would  
140 result in a potential increase to the federal estate of 12 additional species, including two  
141 pollution-intolerant species and two pollution-tolerant species (see Tables 5.3.6-5 and 5.3.6-7).  
142 There would be a potential decrease to the federal estate of one different pollution-intolerant  
143 species and one different pollution-tolerant species. Given the fact that the survey sites used for  
144 non-federal lands may not be representative, it is possible that some species are more or less  
145 prevalent than is noted here.

146 The fish assemblages located at each survey site indicate that the Land Exchange Proposed  
147 Action potentially would result in minimal change to the fish assemblages for the streams the  
148 Superior National Forest would acquire. Additionally, the dominant fish species present at each  
149 site (see Table 5.3.6-6) indicate that the stream characteristics were consistent with slower  
150 moving, glide pool features with the exception of the segment on the Stony River where the  
151 MCAB\_05RN024 survey site was located. Longnose dace dominate the fish community at the  
152 site, which indicate riffle-run habitats are likely present as described in Section 4.2.6. Note that  
153 Coyote Creek, within Tract 3, likely exhibits first order, headwater stream characteristics and if  
154 riffle-run habitat is present there, it would likely be smaller and support a less diverse fish  
155 community than the Stony River sampling site.

160 <sup>1</sup> Rapid Bioassessment Protocols for Use in Streams and Wadeable Rivers: Periphyton, Benthic Macroinvertebrates, and Fish -  
 161 Second Edition EPA 841-B-99-002 (USEPA 2012b).

162 **Table 5.3.6-6 Dominant Fish Species Present at Study Sites**

| Attributes       | Federal Land (within parcel) |                        | Non-federal Land (study areas within vicinity of Tract 1) |               | Non-federal Land (study areas within vicinity of Tract 3- Wolf Lands 3 and 4) |                  |
|------------------|------------------------------|------------------------|-----------------------------------------------------------|---------------|-------------------------------------------------------------------------------|------------------|
|                  | PR-west                      | PR-east                | MPCAB-05RN029                                             | MPCAB-05RN077 | MPCAB-05RN024                                                                 | MPCAB-05RN074    |
| Study site       | PR-west                      | PR-east                | MPCAB-05RN029                                             | MPCAB-05RN077 | MPCAB-05RN024                                                                 | MPCAB-05RN074    |
| Dominant Species | Brook stickleback            | Northern redbelly dace | White sucker                                              | White sucker  | Longnose dace                                                                 | Blacknose shiner |

163 Adopted from Barr 2011b and MPCA 2011c.

164 **Table 5.3.6-7 Increase or Decrease of Stream Fish Assemblage for the Land Exchange**  
 165 **Proposed Action**

| Combined Studies Within, or Within Vicinity of, Surface Water | Tract                        | Total Species (#)               | Pollution-Intolerant Species (#) | Pollution-Tolerant Species (#) |
|---------------------------------------------------------------|------------------------------|---------------------------------|----------------------------------|--------------------------------|
| <b>Lands Conveyed</b>                                         |                              |                                 |                                  |                                |
| Partridge River                                               | Federal Lands                | 15                              | 3                                | 4                              |
| <b>Lands Acquired</b>                                         |                              |                                 |                                  |                                |
| Pike River                                                    | Tract 1                      | 11                              | 0                                | 4                              |
| Coyote Creek                                                  | Tract 3 - Wolf Lands 3 and 4 | 18                              | 4                                | 4                              |
| Total Non-Federal Lands                                       |                              | 21 <sup>1</sup>                 | 4                                | 5 <sup>2</sup>                 |
| <b>Net Increase/(Decrease)</b>                                |                              | 12 species<br>(4) other species | 1                                | 1                              |

166 Adopted from Section 4.3.6.

167 <sup>1</sup> Species would overlap between Tract 1 and Tract 3; thus, 21 species are distinct number of species for combined non-federal  
 168 lands.

169 <sup>2</sup> Does not equal sum of non-federal lands since some species overlap or vary between Tract 1 and Tract 3.

170 **Benthic Macroinvertebrate Assemblages**

171 Macroinvertebrate baseline surveys completed within and in the vicinity of the federal lands  
 172 ranked macroinvertebrate assemblages as fair within the second-order stretches of the Partridge  
 173 River, as indicated by the HBI (see Table 5.3.6-8). The first-, third-, and fourth-order segments  
 174 of the streams within the vicinity of the non-federal lands indicated macroinvertebrate  
 175 assemblages ranging from good to fair. A qualitative comparison using the attributes of HBI,  
 176 stream order, total families (diversity), and percent pollution-tolerant organisms indicate that the  
 177 macroinvertebrate assemblages likely would remain the same under the Land Exchange  
 178 Proposed Action. This qualitative comparison assumes the habitat and associated  
 179 macroinvertebrate assemblages are similar in the stream segments within the non-federal lands  
 180 boundaries including the third-order segment of the Pike River on Tract 1 and the first-order  
 181 segments of Coyote Creek within Tract 3 (see Figure 5.3.6-1).

182 **Table 5.3.6-8 Stream Macroinvertebrate Assemblage Comparisons for the Land Exchange**  
 183 **Proposed Action**

| Attributes                 | Federal Parcel (within parcel) |         | Non-federal Land (study areas within vicinity of Tract 1) |               | Non-federal Land (study areas within vicinity of Tract 3- Wolf Lands 3 and 4) |               |

| Percent pollution-tolerant | 8                              | 18      | 3                                                         | 5             | 10                                                                            | 26            |

184 Adopted from Barr 2011b and MPCA 2011c.

185 **5.3.6.2.5 Aquatic Species of Greatest Conservation Need**

186 The MDNR and USFS have developed the ECS for ecological mapping and landscape  
 187 classification (MDNR 2011a), which defines uniform ecological features within a mapped area.  
 188 The federal and non-federal lands are located in the Northern Superior Uplands Section of the  
 189 Laurentian Mixed Forest Province. These lands are further divided into several subsections. The  
 190 federal lands include the Laurentian and Nashwauk Uplands subsections while the non-federal  
 191 lands include these two subsections and the Border Lakes subsection.

192 As discussed in Section 4.2.6.1.4, SGCN aquatic species are associated with these ecological  
 193 subsections based on occurrence and habitat considerations. Using the approach of comparing  
 194 SGCN species by subsection association only, the Land Exchange Proposed Action could result  
 195 in an increase of six new potential SGCN species (see Table 5.3.6-9). Of these, the spoonhead  
 196 sculpin, lake chub, and longear sunfish have the highest potential to be found near the shoreline  
 197 habitat of Tract 5 (within the Border Lakes subsection).

198 Regardless of the potential indicated by subsection association, no SGCN species were identified  
 199 within the boundaries of the federal or non-federal lands during field surveys. While habitat is
