The SDEIS does not mention testing, mitigation, or monitoring procedures or duration of these activities for the transfer of pollutants and contaminants. Transfer could occur through fractures, surface water, aquifers, soils, or watersheds, among other vectors.

Thematic Response

PolyMet has developed an Adaptive Water Management Plan (AWMP) (PolyMet 2015d, as cited in the FEIS) that includes adaptive engineering controls and contingency mitigation measures. Additionally, the NorthMet Project Proposed Action includes a water quality and quantity monitoring plan that would be finalized in permitting and updated as required. Overviews of the water monitoring plans at the Mine Site and Plant Site, with PolyMet recommended monitoring locations and frequencies, are presented in Tables 5.2.2-52 and 5.2.2-53. The specifics of monitoring—including specific locations, frequencies, and parameters—would be finalized during the NPDES/SDS permitting process. Monitoring and maintenance activities would continue for as long as needed to ensure permit water quality requirements are met.

Theme WR 091

Theme Statement

Calibration of the Mine Site MODFLOW model to erroneously low Partridge River baseflow targets leads to underestimates of areal recharge and surficial deposit hydraulic conductivity and may result in incorrect groundwater flowpaths. Use of incorrect baseflow calibration targets invalidates the MODFLOW results. The model must be recalibrated to the correct baseflow values. The FEIS should also include a baseflow sensitivity analysis. The Myers MODFLOW model considers higher Partridge River baseflow, which leads to results that are different from the SDEIS model. The FEIS should discuss and explain the discrepancies between the two models.

Thematic Response

The estimates for groundwater baseflow derived from the surficial aquifer applied in the SDEIS and FEIS are based on best available information (see the response to theme WR 003). Thus, the MODFLOW inputs related to groundwater baseflow did not change significantly in the FEIS (except for general recalibrations based on new water level and water quality data). It should be noted that an independent flow/transport model developed by Myers uses higher rates of surficial recharge and Partridge River groundwater baseflow than the Mine Site MODFLOW model. The revised Mine Site MODFLOW model is well-calibrated and sufficiently accurate for impacts evaluation, and that the Myers model is calibrated to Partridge River groundwater baseflows that are too high.

Attachment B of the Mine Site Water Modeling Data package (PolyMet 2015m, as cited in the FEIS) has been updated to provide a complete description of the Mine Site MODFLOW model. The attachment no longer references earlier documents to provide basic information about the model, but instead provides directly the justifications for the layers, boundary conditions, material properties, and areal recharge. Calibration targets are also fully described in Attachment B. The model has been recalibrated using all head data through 2013 and groundwater baseflows used in the SDEIS (and carried forward into the FEIS). The surficial- and bedrock-aquifer flowpaths used to estimate solute transport in Mine Site groundwater are consistent with the calibrated MODFLOW model.

To address comments on the relationship between groundwater baseflow and the impact assessment, a sensitivity analysis was conducted for the Mine Site to evaluate if predicted NorthMet Project Proposed Action impacts are sensitive to groundwater baseflow values. The sensitivity analysis considered the relationship of various model inputs to groundwater baseflow including hydraulic conductivity, recharge, and surface runoff chemical concentrations. The results of the sensitivity analysis are reported in FEIS Section 5.2.2.3.2.

Theme WR 092

Theme Statement

With regard to surficial deposits, the Mine Site MODFLOW model uses erroneously low hydraulic conductivity (due to the baseflow issue) and at the Plant Site does not consider the known presence of buried stream channels that likely have higher hydraulic conductivity. Table 4.2.2-5 should present all test results rather than ranges.

Thematic Response

The SDEIS groundwater baseflow values developed for the Partridge River are reasonable best estimates and are retained in the FEIS. Because the FEIS Mine Site MODFLOW model is calibrated to the SDEIS/FEIS groundwater baseflows, the calibrated recharge rates and hydraulic conductivities of surficial deposits are also appropriate best estimates. See FEIS Sections 5.2.2.2.1 and 5.2.2.3.2 for more information.

The Mine Site model and the Plant Site model explicitly consider buried stream channels by including a rendering of bedrock topography based on a compilation of bedrock topographic data. It is acknowledged that buried stream channels could exist in surficial deposits at the Mine Site, but given that the average thickness of surficial deposits is only 5 to 10 meters, it is unlikely that buried channels (if any) would have materials much higher in permeability than adjacent materials. Variation in the hydraulic conductivity of surficial deposits is accounted for by the probabilistic approach used in the GoldSim model, where hydraulic conductivity is input as a probability distribution rather than as a fixed, deterministic value.

Based on a pre-construction topographic map of the Tailings Basin area and an interpreted map for the top of bedrock, the thickness of surficial deposits varies below the Tailings Basin and this may reflect the presence of buried stream channels. This aspect has been incorporated into the FEIS model.

Theme WR 093

Theme Statement

The Plant Site MODFLOW model needs to be corrected and rerun. In particular, the model incorrectly treats the embankment outer surfaces as no-flow boundaries; where there are no drain cells or modeled wetlands, the model incorrectly treats ground surface adjacent to the embankment toes as no-flow boundaries. Both of these assumptions are theoretically incorrect for an unconfined groundwater system. The incorrect use of no-flow boundaries artificially shows a lack of surface seepage, rather than allowing the model to determine if surface seepage would occur. There are insufficient drain cells placed at the toes of the Tailings Basin perimeter to provide a credible evaluation of where seepage may or may not occur during and after operations. The placement of a small number of drain cells biases the model to allow surface seepage only at pre-determined locations and to underestimate total surface seepage. The model does not explicitly incorporate the groundwater capture system or the adjacent treated-water discharge pipe that are components of the Project Description. There are insufficient drain or river cells to simulate the known wetland areas. The FEIS should disclose where the model

predicts upwelling of groundwater into wetlands and other surface water features. The FEIS should disclose capture system design details so modeling assumptions can be assessed.

Thematic Response

In response to these issues, the Plant Site MODFLOW model was modified and recalibrated as follows: 1) Updated areal distribution of surficial deposits and bedrock outcrops, 2) established surficial deposits below and adjacent to the East Embankment, 3) used drain or river cells along the East Embankment to allow surface seepage of tailings water, 4) incorporated the hydrologic effects of the future swale to drain surface water from the East Embankment area, 5) recalibrated model material properties and boundary conditions using all available site data through 2013 (this is mostly new hydraulic head information), and 6) expanded the use river and drain cells to provide a more accurate representation of wetlands outside the Tailings Basin.

As a result of these changes, the FEIS Plant Site MODFLOW model no longer has a no-flow boundary condition at the toe of the East Embankment, and river and/or drain cells in surficial deposits are in place to allow the potential for surface seepage along the embankment toes (Reference: Attachment A, Plant Site Water Modeling Data Package—PolyMet 2015j, as cited in the FEIS). The model was checked to ensure that hydraulic heads in the tailings and adjacent surficial deposits were not well above ground surface. In the FEIS Plant Site MODFLOW model, storage coefficients for the surficial deposits and bedrock outcrops were assigned and/or calibrated to be more in line with literature values for these types of materials.

As discussed in the responses to themes WR 018, WR 019, WR 020, and WR 022, the assumed capture efficiencies of the groundwater containment systems are justified and supported by modeling. FEIS Section 5.2.2 appropriately summarizes the methodology and results of the water impact analysis. Full technical details on modeling including the assumptions made with regards to the capture system design are provided in the Water Modeling Data Packages for the Mine Site and Plant Site (PolyMet 2015m and 2015j, respectively, both as cited in the FEIS).

Theme WR 094

Theme Statement

The Plant Site MODFLOW model used an incorrect and outdated Tailings Basin design and footprint.

Thematic Response

The Tailings Basin design and footprint used in the FEIS Plant Site MODFLOW model was updated from the version used in the SDEIS to address the theme.

Theme WR 095

Theme Statement

The Plant Site MODFLOW model applies unreasonable storage coefficients and/or specific yields to surficial deposits and bedrock outcrops. The supporting documents mislead the reader into thinking that that the storage parameters were fully determined by calibration.

Thematic Response

In the FEIS Plant Site MODFLOW model, storage coefficients for the surficial deposits and bedrock outcrops were assigned and/or calibrated to be more in line with literature values for these types of materials.

Theme WR 096

Theme Statement

The Plant Site MODFLOW model uses the hydraulic conductivity rates for surficial deposits that are much greater than values used in the GoldSim and Seep-W models, and greater than values indicated by field testing. The FEIS should provide an explanation for these discrepancies. The hydraulic conductivity of surficial deposits should be reduced to more reasonable levels, or a justification provided for the higher values used. Inappropriate no-flow boundary conditions used in the model lead to unrealistic calibrated hydraulic conductivity values for the surficial deposits. The model does not consider the hydraulic effects of known buried channels that exist in surficial deposits below the Tailings Basin.

Thematic Response

The Co-lead Agencies acknowledge that the calibrated hydraulic conductivity of surficial deposits in the FEIS Plant Site MODFLOW model (approximately 70 feet per day) is greater than the hydraulic conductivities of surficial deposits used in the FEIS Plant Site GoldSim model (lognormal distribution with mean of 13 feet per day and standard deviation of 5.2 feet per day).

The GoldSim hydraulic conductivity distribution is based on the results of field tests and calculations showing that the values are reasonable given recharge, saturated thickness, and hydraulic gradients between the Tailings Basin and the Partridge River. It is the Co-lead Agencies' opinion that the hydraulic conductivity distribution used in the GoldSim model is reasonable given the purpose of the model, which is to evaluate groundwater flow and transport in flowpaths to the Embarrass River.

The main purpose of the MODFLOW model is to evaluate the distribution of tailings water flow from the interior of the Tailings Basin to the toes and this is an entirely different focus and area of interest from the GoldSim model. The hydraulic conductivity in the FEIS Plant Site MODFLOW model is a calibrated value that achieves a reasonable model match to measured hydraulic heads below the Tailings Basin and estimated leakage rates from the Tailings Basin ponds. For the purpose of the MODFLOW model, the higher calibrated hydraulic conductivity of surficial deposits allows that model to function in a more credible manner.

It is the Co-lead Agencies' position that the different surficial deposit hydraulic conductivities used in the Plant Site GoldSim model and Plant Site MODFLOW model allow each model to function more appropriately for its intended purpose. To force the hydraulic conductivities of the two models to be similar would be artificial and would detract from each model's ability to fulfill its purpose. Accordingly, the Co-lead Agencies recognize the difference between the two models, but do not recommend that the values be changed.

The extensive no-flow boundary condition used in the SDEIS Plant Site MODFLOW model has been corrected in the FEIS model by assigning a greater distribution of drain and river cells along the perimeter of the Tailings Basin. This is where significant wetlands are observed between the Tailings Basin and the Embarrass River. Drain and river cells allow the potential for groundwater discharge to ground surface, which is prevented by "no-flow" cells in MODFLOW.

Based on a pre-construction topographic map of the Tailings Basin area and an interpreted map for the top of bedrock, the thickness of surficial deposits varies below the Tailings Basin and this may reflect the presence of buried stream channels. This aspect has been incorporated into the FEIS model.

Theme WR 097

Theme Statement

At some locations in the Plant Site MODFLOW model, the predicted hydraulic heads are well above ground surface, which is not possible for unconfined groundwater conditions.

Thematic Response

The FEIS Plant Site MODFLOW model has been modified using different boundary conditions (drain and river cells) and calibrated with new hydraulic conductivities so that predicted hydraulic heads are below or just slightly above ground surface, but not well above ground surface as was the case in portions of the SDEIS model.

Theme WR 098

Theme Statement

In the Plant Site MODFLOW model, the areal distribution of surficial deposits and bedrock outcrops is inconsistent with geologic information. Use of the RS13 (Barr 2007a) areal distribution map is incorrect and should be replaced with the revised RS13b (2008c, as cited in the FEIS) distribution map.

Thematic Response

In the FEIS Plant Site MODFLOW model, storage coefficients for the surficial deposits and bedrock outcrops were assigned and/or calibrated to be more in line with literature values for these types of materials.

Theme WR 099

Theme Statement

The Plant Site MODFLOW model does not consider the presence of bedrock below the surficial deposits (as is the case in the Mine Site MODFLOW model). Except for outcrop areas, deeper bedrock is incorrectly assumed to be impermeable and excluded from model. The model does not consider known faults and fractures in bedrock. MODFLOW does not consider the effect of low pH water on bedrock hydraulic conductivity or capture system. In contrast to the SDEIS model, the Myers MODFLOW model does include deeper bedrock and assigns this material reasonable hydraulic conductivity values. The Myers model shows that groundwater flow in bedrock cannot be ignored. The FEIS should address the discrepancies between these models.

Thematic Response

The Co-lead Agencies acknowledge that the calibrated hydraulic conductivity of surficial deposits in the FEIS Plant Site MODFLOW model (approximately 70 feet per day) is greater than the hydraulic conductivities of surficial deposits used in the FEIS Plant Site GoldSim model (lognormal distribution with mean of 13 feet per day and standard deviation of 5.2 feet per day).

The GoldSim hydraulic conductivity distribution is based on the results of field tests and calculations showing that the values are reasonable given recharge, saturated thickness, and hydraulic gradients between the Tailings Basin and the Partridge River. It is the Co-lead Agencies' opinion that the hydraulic conductivity distribution used in the GoldSim model is reasonable given the purpose of the model, which is to evaluate groundwater flow and transport in flowpaths to the Embarrass River.

The main purpose of the MODFLOW model is to evaluate the distribution of tailings water flow from the interior of the Tailings Basin to the toes and this is an entirely different focus and area of interest from the GoldSim model. The hydraulic conductivity in the FEIS Plant Site MODFLOW model is a calibrated value that achieves a reasonable model match to measured hydraulic heads below the Tailings Basin and estimated leakage rates from the Tailings Basin ponds. For the purpose of the MODFLOW model, the higher calibrated hydraulic conductivity of surficial deposits allows that model to function in a more credible manner.

It is the Co-lead Agencies' position that the different surficial deposit hydraulic conductivities used in the Plant Site GoldSim model and Plant Site MODFLOW model allow each model to function more appropriately for its intended purpose. To force the hydraulic conductivities of the two models to be similar would be artificial and would detract from each model's ability to fulfill its purpose. Accordingly, the Co-lead Agencies recognize the difference between the two models, but do not recommend that the values be changed.

The extensive no-flow boundary condition used in the SDEIS Plant Site MODFLOW model has been corrected in the FEIS model by assigning a greater distribution of drain and river cells along the perimeter of the Tailings Basin. This is where significant wetlands are observed between the Tailings Basin and the Embarrass River. Drain and river cells allow the potential for groundwater discharge to ground surface, which is prevented by "no-flow" cells in MODFLOW.

Based on a pre-construction topographic map of the Tailings Basin area and an interpreted map for the top of bedrock, the thickness of surficial deposits varies below the Tailings Basin and this

may reflect the presence of buried stream channels. This aspect has been incorporated into the FEIS model.

MODFLOW is a groundwater hydraulics model and does not specifically consider water chemistry. Site characterization studies and water quality modeling do not predict that low pH groundwater would be generated by the Tailings Basin. As a consequence, the possible effects of low pH groundwater on hydraulic conductivity of surficial deposits or bedrock are not considered in the FEIS.

Theme WR 100

Theme Statement

The Plant Site MODFLOW model needs to include the groundwater capture system and adjacent treated-water discharge pipe on the north and west sides of the Tailings Basin. A groundwater capture system on the east side of the Tailings Basin is also required.

Thematic Response

The FEIS Plant Site MODFLOW model has been modified using different boundary conditions (drain and river cells) and calibrated with new hydraulic conductivities so that predicted hydraulic heads are below or just slightly above ground surface, but not well above ground surface as was the case in portions of the SDEIS model.

Theme WR 101

Theme Statement

The Plant Site MODFLOW model does not include a south groundwater flowpath and does not allow for potential surface seepage along most of the south side of the Tailings Basin.

Thematic Response

Local topography influences the behavior of seepage at the southern end of the Tailings Basin. It is expected that seepage at this part of the facility emerges as surface seepage within a short distance of the Tailings Basin toe rather than being transported via subsurface flow. The effectiveness of the recent improvements to the existing seepage management system, which include a dam, are currently being assessed by Cliffs Erie and PolyMet through water quality monitoring downstream of the existing system. PolyMet has committed to collecting essentially all of the seepage from the Tailings Basin in this area (Plant Site Water Management Plan, Section 4.1.3 [PolyMet 2015i, as cited in the FEIS]), and would implement additional improvements to the seepage management system if necessary. Potential measures that could bring the capture efficiency of the seepage management system to 100 percent include improvements to the existing in-stream dam such as lining the upstream dam face with bentonite and injecting grout into the dam. If seepage were observed to bypass the existing dam, a second structure could be constructed approximately 500 feet downstream of the existing system, in an area where the Second Creek headwaters valley is more constricted and any remaining subsurface seepage would have surfaced. This potential second structure could be constructed as an earthen dam with a clay or concrete cutoff wall (extending to bedrock if necessary) in order to achieve 100 percent capture of the Tailings Basin surface seepage. Based on PolyMet's

commitment to collect essentially all seepage to the south, the proposed South Surface Seepage Management System is assumed for the GoldSim modeling to capture 100 percent of the surface water and that there is no groundwater flow or seepage.

Theme WR 102

Theme Statement

At the east embankment of the Tailings Basin, the Plant Site MODFLOW model uses incorrect no-flow boundary conditions that prevent any possibility of surface seepage. The incorrect assumed distribution of surficial deposits also prevents the model from potentially showing significant eastward groundwater flow away from the Tailing Basin. The model should be revised to include the correct distribution of surficial deposits and to apply drain cells along the toe of the east embankment, which is the theoretically correct boundary condition for an unconfined groundwater system. The model materials and boundary conditions used in the MODFLOW model should be consistent with the hydrogeologic conceptual model for the east embankment area, including the Spring Mine Lake and Spring Mine Creek.

Thematic Response

The Plant Site MODFLOW model was modified for the FEIS to better represent natural and NorthMet Project Proposed Action-related conditions. These include: 1) more accurate representation of surficial deposits and bedrock outcrops around the perimeter of the Tailings Basin, 2) more extensive distribution of drain and/or river cells to provide for potential surface seepage and distribution of wetlands, 3) more appropriate storage coefficients, and 4) steady-state and transient calibrations using new data extending through the end of 2013. Many of the improvements pertained to the East Embankment area of the Tailings Basin, where it is acknowledged that tailings water seepage would be likely to occur and model changes were made to simulate this seepage more accurately. These changes in response to the theme improve the SDEIS MODFLOW model that limited tailings seepage on the east side of the Tailings Basin.

Theme WR 103

Theme Statement

The groundwater flow trajectories predicted by the Plant Site MODFLOW model are not accurately transferred to the GoldSim model to create flowpaths. The areal recharge used in the model is too low, which might lead to incorrect flowpaths. The model does not demonstrate that groundwater would not migrate into other watersheds.

Thematic Response

The Plant Site MODFLOW model was modified for the FEIS to better represent natural and NorthMet Project Proposed Action-related conditions. These modifications include: 1) more accurate representation of surficial deposits and bedrock outcrops around the perimeter of the Tailings Basin, 2) more extensive distribution of drain and/or river cells to provide for potential surface seepage and distribution of wetlands, 3) more appropriate storage coefficients, and 4) steady-state and transient calibrations using new data extending through the end of 2013. Many

of the improvements pertained to the East Embankment area of the Tailings Basin, where it is the acknowledged that tailings water seepage would be likely to occur and model changes were made to simulate this seepage more accurately. These changes correct deficiencies in the SDEIS MODFLOW model that limited tailings seepage on the eastern side of the Tailings Basin. With these modifications, the FEIS MODFLOW model provides reliable groundwater flow directions away from the Tailings Basin to the north, northwest, and west. Note that on eastern side of the Tailings Basin, current groundwater flows are from east to west -- i.e., toward and not away from the Tailings Basin.

The Plant Site GoldSim model uses one-dimensional flow/transport to simulate the migration of affected groundwater away from the Tailings Basin in the northern, northwestern, and western directions. For these analyses to be accurate, flow/transport parameters from the MODFLOW model were transferred to each GoldSim flowpath including average linear flow direction and hydraulic gradient. Saturated thickness, hydraulic conductivity, and porosity values used in the GoldSim flowpaths were based on field data and generic information, not the MODFLOW model. Recharge in the GoldSim flowpaths was based on Embarrass River baseflow analysis and not on the MODFLOW model.

The main purpose of the Plant Site MODFLOW model was to evaluate groundwater flows beneath the Tailings Basin and groundwater flows away from the Basin in the northern, northwestern, western, and eastern directions. The model was generally local to the Tailings Basin area and was not intended to evaluate the potential for groundwater flows outside the Embarrass River watershed.

Theme WR 104

Theme Statement

The Plant Site MODFLOW model does not account for known buried stream channels, with potentially higher hydraulic conductivity, below the Tailings Basin.

Thematic Response

The thickness of surficial deposits at the Plant Site is interpreted to vary below and adjacent to the Tailings Basin. The interpretation relies upon: 1) a preconstruction topographic map of the area, 2) a 2014 geotechnical investigation conducted along the Tailings Basin perimeter, and 3) an interpreted map for the top of the underlying bedrock. This allows for the model to at least partially reflect the presence of buried stream channels. The interpreted variable thickness of surficial deposits is incorporated into the Plant Site MODFLOW model. This is of interest because surficial deposit thickness affects transmissivity such that enhanced groundwater flow occurs in portions of the model having thicker surficial deposits. See FEIS Section 5.2.2.2.1 for more information.

Theme WR 105

Theme Statement

The Plant Site MODFLOW model should be re-run to address numerous general issues. Two critical issues are that all known wetlands and seepage areas are not modeled, and drain/river cells are based on current wetlands and seeps and do not account for future conditions. In addition, the SDEIS does not adequately explain the general model setup. The model does not conform to the known hydrogeology, is not adequately calibrated to steady-state and transient heads, predicts incorrect baseflows to the Embarrass River, and does not adequately show all groundwater flowpaths. The site hydrogeology is not sufficiently understood to develop a reliable model, and the model is therefore not sufficiently accurate for effects evaluation. The model should be probabilistic. Based on the model results, the FEIS should describe mounding below the Tailings Basin, present estimates of leakage from the unlined tailings into the surficial and bedrock groundwater systems, and provide estimates of groundwater discharge into wetlands upstream of surface water evaluation locations. The results of the Myers MODFLOW model are different from the SDEIS model. The FEIS should explain the discrepancies between the two models.

Thematic Response

The Plant Site MODFLOW model was modified for the FEIS to better represent natural and NorthMet Project Proposed Action-related conditions. These include: 1) more accurate representation of surficial deposits and bedrock outcrops around the perimeter of the Tailings Basin, 2) more extensive distribution of drain and/or river cells to provide for potential surface seepage and distribution of wetlands, 3) more appropriate storage coefficients, and 4) steady-state and transient calibrations using new data extending through the end of 2013. Many of the improvements pertained to the East Embankment area of the Tailings Basin, where it is acknowledged that tailings water seepage would be likely to occur and model changes were made to simulate this seepage more accurately. These changes correct deficiencies in the SDEIS MODFLOW model that limited tailings seepage on the east side of the Tailings Basin. With the modifications described above, the FEIS MODFLOW model has provided reliable flow directions in this area.

See the response to theme WR 003.

Rather than conduct probabilistic flow modeling, a detailed sensitivity analysis of baseflow was conducted to evaluate if impacts to groundwater and surface water are sensitive to baseflow values used in the water quality (GoldSim) models. The sensitivity analysis fully considered the relationship of various model inputs to baseflow including hydraulic conductivity, recharge, and surface runoff chemical concentrations.

It is also acknowledged that the Myers model provides some results that are different from the FEIS Plant Site MODFLOW model. A major difference is that the Myers model considers higher groundwater baseflows in the Embarrass River and this leads to higher hydraulic conductivities and recharge at the Plant Site. As stated in other theme responses, the FEIS groundwater baseflows for the Embarrass River are reasonable and represent a better estimate than what is assumed in the Myers model. In addition, the Myers model does not use concentration caps so that chemical concentrations and mass loading associated with tailings is unrealistically high.

Due to these differences, it is thought the Myers model unrealistically overestimates NorthMet Project Proposed Action-related flow and chemical impacts at the Plant Site.

Theme WR 106

Theme Statement

The water modeling (XP-SWMM, MODFLOW, and GoldSim) in the SDEIS does not incorporate known hydrology, is not calibrated to correct baseflows and heads, and gives different results from Myers MODFLOW model; therefore, it is not sufficiently accurate for evaluation of effects. The modeling needs to be redone and should use probabilistic methodology. Most of the available data was used in calibrating the model and thus is not usable to validate it.

Thematic Response

The inputs and assumptions of the water models used to predict the potential effects of the NorthMet Project Proposed Action have been subject to rigorous review over the course of the EIS. The Myers model was independently developed and its conclusions have been considered in the development of the FEIS.

It is acknowledged that the Myers model provides some results that are different from the FEIS Plant Site MODFLOW model. A major difference is that the Myers model considers higher groundwater baseflows in the Embarrass River and this leads to higher hydraulic conductivities and recharge at the Plant Site. As stated in other theme responses, FEIS groundwater baseflows for the Embarrass River are reasonable and represent a better estimate than what is assumed in the Myers model. In addition, the Myers model does not use concentration caps so that chemical concentrations and mass loading associated with tailings is unrealistic.

See the response to theme WR091.

Development of the site models used all available data for calibration in accordance with accepted industry practice. Validations would be performed as new data become available.

The models used for FEIS development are complete and sufficiently accurate for impact evaluation. There is no need to redo any of the FEIS models. Probabilistic analyses are performed by the GoldSim models and are not needed in the MODFLOW models.

Theme WR 107

Theme Statement

For the Mine Site, the FEIS should acknowledge that the NorthMet Project Proposed Action would increase chemical loading of contaminants, including fibers to groundwater and surface water compared to current existing conditions. Water quality standards would not be met.

Thematic Response

The FEIS reports that the NorthMet Project Proposed Action facilities would release solutes and cause an increase in loading of some solutes to surface water and groundwater relative to the continuation of existing conditions; See FEIS Section 5.2.2.3 for more detail and consideration

of these results with respect to water quality evaluation criteria. Estimates for mass loading from the Plant Site tailings facility are presented in the Water Modeling Data Package Vol 2 - Plant Site, Attachment G (PolyMet 2015j, as cited in the FEIS).

There is no technical reason to believe that groundwater affected by the Tailings Basin would have unacceptably high concentrations of fibers. The generally fine-grained nature of tailings materials would effectively filter suspended solids including fibers.

Based on modeling results, the Co-lead Agencies conclude that water quality evaluation criteria would be met. Evaluation criteria can be found in Section 5.2.2.

Theme WR 108

Theme Statement

For the Plant Site, the FEIS should acknowledge that the NorthMet Project Proposed Action would increase chemical loading of contaminants including fibers to groundwater and surface water compared to current existing conditions, as well as to no-action conditions that properly account for future mitigations associated with the Cliffs Erie Consent Decree.

Thematic Response

The Co-lead Agencies acknowledge in FEIS Section 5.2.2.3.3 that concentrations of some parameters at some evaluation location would increase at the P90 level as result of the NorthMet Project Proposed Action in comparison to the continuation of existing conditions modeling scenario. See response to theme ALT014.

There is no technical reason to believe that groundwater affected by the Tailings Basin would have unacceptably high concentrations of fibers. The generally fine-grained nature of tailings materials would effectively filter suspended solids including fibers.

Theme WR 109

Theme Statement

At some compliance locations, the NorthMet Project Proposed Action would cause exceedances or increase the chemical concentrations of constituents that already exceed water quality standards such as mercury. Thus, the FEIS should evaluate whether or not the NorthMet Project Proposed Action would comply with Minnesota nondegradation rules. Metals are toxic to aquatic life and would threaten public health.

Thematic Response

The evaluation and decision of whether or not the NorthMet Project Proposed Action could discharge into surface waters where water quality standards are exceeded is a permit decision.

The FEIS reports that the NorthMet Project Proposed Action facilities would release solutes and cause an increase in loading and concentrations of some solutes to surface water and groundwater relative to the continuation of existing conditions at some evaluation locations. See FEIS Section 5.2.2.3 for more detail and consideration of these results with respect to water quality evaluation criteria. The FEIS identifies potential impacts on water resources and

measures available to anticipate and control these same impacts. Potential effects on aquatic resources are addressed in FEIS Section 5.2.6. Public health considerations are summarized in FEIS Section 7.3.4. See Theme WR 173 and Theme WR 177 responses.

Theme WR 110

Theme Statement

The SDEIS uses the wrong criteria used for assessing water quality effects, and underestimates effects by using criteria that are not risk-based; thus, factors of safety are not appropriate. P90 is an unacceptable level of significance. The FEIS should use P99.

Thematic Response

Evaluation criteria are based on applicable water quality standards. Evaluation criteria can be found in Section 5.2.2. Where a waterbody is classified as Domestic Consumption (1B) or for groundwater, USEPA primary drinking water standards apply. The USEPA primary drinking water standards set mandatory maximum contaminant levels for drinking water to protect the public from consuming water that presents a risk to human health.

As described in FEIS Section 5.2.2.2.3, the P90 threshold is deemed appropriate for the EIS and has been adopted for other mining NEPA documents where probabilistic modeling was used (e.g., Idaho Cobalt Project—USFS 2009b, as cited in the FEIS). The use of the P90 criterion for determining whether or not evaluation criteria are being met is not equivalent to how WQBELs would be developed for NPDES permitting. Appropriate WQBELs would be derived based on water quality standards and implemented in the permit. Discharges would be evaluated during the NPDES permitting stage and WQBELs applied according to 40 CFR 122.44(d).

Theme WR 111

Theme Statement

NorthMet Project Proposed Action discharges would put at risk and potentially degrade water quality far beyond the mine, including Colby Lake, the BWCAW, St. Louis River, Lake Superior, Superior National Forest, the entire State of Minnesota, the Great Lakes, and Atlantic Ocean. No level of risk to these resources is acceptable. More analysis is necessary. Increased federal scrutiny is needed. Mining has already impacted the St. Louis River and efforts have been made to clean it up.

Thematic Response

As addressed in FEIS Section 5.2.2, the NorthMet Project Proposed Action would have the potential to affect groundwater and surface water hydrology and quality in both the Partridge River and Embarrass River watersheds. These two rivers are both tributaries to the St. Louis River and within the Lake Superior Basin. FEIS Section 6.2.2 identifies that the NorthMet Project Proposed Action is not considered to have the potential for cumulative effects on hydrology and water quality in the St. Louis River or Lake Superior.

The BWCAW and the Rainy Lake Watershed is located on the opposite side of the Laurentian Divide (the major watershed divide between the Rainy River Watershed and Lake Superior

Basin) from the NorthMet Project Proposed Action, and as such surface water and surficial groundwater would not be impacted by it; therefore, this is not included in the FEIS.

If it is predicted that water via bedrock would flow north from the Mine Site, mitigation would be implemented to prevent this from occurring. See FEIS Sections 5.2.2.3.5 and 5.2.2.3.6.

Theme WR 112

Theme Statement

The SDEIS does not adequately evaluate the water quality effects of drying up or inundating thousands of acres of wetlands, nor the water quality effects of dredging and filling wetlands or water discharges to wetlands that are likely to result in violations of wetland water quality standards.

Thematic Response

The hydrology of the wetlands outside the Tailings Basin containment system would be maintained within an established range through flow augmentation so that wetlands would not experience substantial inundation or desiccation. Wetland hydrology is a complex mix of precipitation, surface runoff, and, in some cases, groundwater. The indirect effects analyses performed for the EIS were not performed to characterize impacts but were done to inform where monitoring should take place for those areas that were identified as having a potential for indirect wetland effects. The Co-lead Agencies agree that multiple factors can affect whether a wetland would experience indirect effects due to a project. The direct and potential indirect effects from the NorthMet Project Proposed Action, as well as the proposed monitoring and mitigation, are described in detail in FEIS Section 5.2.3.

Theme WR 113

Theme Statement

The SDEIS does not adequately evaluate the water quality and fisheries effects of acid generation.

Thematic Response

The FEIS considers the release of acidity from proposed NorthMet facilities in that leachate from all acid-generating material (Waste Rock and pit wall rock composed of Category 2/3 and Category 4 material) would be captured and treated prior to discharge. The permanent surficial waste facilities (Category 1 stockpile and tailings basin) would contain material that is not expected to would never produce acidic leachate. The non-acid generating waste was identified using multi-year kinetic tests (humidity cells) on NorthMet rock samples, in which alkalinity released (by dissolution of the silicate minerals) exceeded acidity production (by sulfide-mineral oxidation) in all rock and tailings that contained less than 0.12 percent sulfide S. This less than 0.12 waste rock with 0.12 percent sulfide S or less is the threshold for selecting non-acid generation mine waste is further supported by long-term humidity cell tests on NorthMet waste (i.e., 42 samples of Category 1 waste rock, with tests now run for over 450 weeks; and 33 humidity cell tests run between 84 and 304 weeks [Waste Characterization Data Package v12 (PolyMet 2015q, as cited in the FEIS), Section 4.3 and Attachment E, respectively]). These tests

demonstrate that tailings and Category 1 waste rock materials do not generate acidic leachate, and acid generation rates decreases over time as sulfide S minerals are depleted. The NorthMet Project design thus prevents the introduction of acidic leachate to surface water that could affect fisheries.

Theme WR 114

Theme Statement

The SDEIS does not adequately evaluate the loss of stream headwaters and its effect on fisheries and wildlife.

Thematic Response

The SDEIS and FEIS acknowledge a possibility that habitat could be affected from water chemistry changes resulting from the Land Exchange Proposed Action. Habitat loss from flow changes or riparian activities is not expected as a result of the NorthMet Project Proposed Action.

It is noted that under the Land Exchange Proposed Action, the federal estate would have a slight loss to first-order stream spawning habitat.

Theme WR 115

Theme Statement

The NorthMet Project Proposed Action would cause detrimental and irreversible effects on water resources at and near the Mine Site and Plant Site and in other non-designated areas. These effects include chemical effects, loss of water resources, loss of wild rice and loss of wetlands. The SDEIS does not provide assurance that chemical concentrations in groundwater and surface water would continue to meet water quality standards. The detrimental effects cause by the NorthMet Project Proposed Action would persist for hundreds of years and mining would last only 20 years.

Thematic Response

The FEIS acknowledges that the NorthMet Project Proposed Action would cause adverse effects. FEIS modeling indicates that water quality impacts would not be significant as measured against FEIS evaluation criteria. It is also acknowledged that water quality modeling performed in support indicates that water treatment systems in some form and at some scale would be needed indefinitely at the Mine Site and Plant Site. This long-term treatment is proposed as part of the NorthMet Project Proposed Action. As described in FEIS Section 3.2.2.4, *Minnesota Rules* 6132.1200, require that before a Permit to Mine can be issued, financial assurance instruments covering the estimated cost of reclamation must be submitted and approved by the MDNR. Irreversible effects are disclosed in FEIS Section 7.3.1.

Theme WR 116

Theme Statement

Assumed leakage from WWTF ponds is lower than values cited in literature.

Thematic Response

The WWTF equalization basins have a single geomembrane liner. During the summer months (April through September), when water is expected to be in the basins, the liner leakage rate is 5 gallons/acre/day as determined in the Mine Site Water Modeling Data Package (PolyMet 2015m, as cited in the FEIS). The USEPA HELP model was used to estimate this value. This is a reasonable value for ponds installed with good site preparation and installation practices. It is unclear in the comments which literature values are being cited.

Theme WR 117

Theme Statement

The FEIS should acknowledge that current mitigation at the south end of the Tailings Basin does not capture all seepage, and that some of the tailings water is being released to Second Creek. A topographic map figure should be included in the FEIS to demonstrate this finding. This discharge would continue with the NorthMet Project Proposed Action. Additional details on the location of the cut-off berm and trench, groundwater contours, and water quality should be disclosed.

Thematic Response

It is acknowledged that there is currently incomplete capture of impacted water at SD026. Cliffs Erie is currently addressing this issue by upgrading the performance of the existing capture system and, if necessary, constructing new systems to enhance capture. If 100 percent capture is not attained by the Cliffs Erie upgrades, the Proposer has committed, under the NorthMet Project Proposed Action, to installing additional systems in Second Creek to achieve this level of performance regardless of the types of measures required. A summary of the southern seepage collection system is provided in FEIS Section 3.2.2.3.10; details are available in the Plant Site Water Management Plan (PolyMet 2015i, as cited in the FEIS).

Theme WR 118

Theme Statement

The FEIS should describe how the south Tailings Basin capture system would be modified to achieve acceptable capture efficiency. Designs should aim for 100 percent capture.

Thematic Response

The Project Proposer has committed to collecting all of the south seepage from the Tailings Basin that makes its way to Second Creek by implementing additional improvements to the existing seepage management system, if necessary. Potential measures that could bring the capture efficiency of the system to 100 percent include improvements to the existing dam such as

lining the upstream dam face with bentonite and injecting grout into the dam. If seepage were observed to bypass the existing dam, a second dam could be constructed approximately 500 feet downstream of the existing system, in an area where the Second Creek headwaters valley is more constricted and any remaining subsurface seepage would have come to the surface. This potential second dam could be constructed as an earthen dam with a clay or concrete cutoff wall (extending to bedrock if necessary) in order to achieve 100 percent capture of the surface seepage. See FEIS Section 5.2.2.3.2 for more information.

Theme WR 119

Theme Statement

The “analog method” used in the SDEIS is not acceptable for evaluating wetland effects associated with mine pit dewatering; this issue must be evaluated using a mathematical analysis that considers site-specific geology and hydrologic conditions. Alternatively, the analog method should be based not on the Canisteo Mine, but instead on the Soudan Mine in Soudan Underground Mine State Park, which is overlain by till similar in thickness and composition to that found at the NorthMet Mine Site, so the results would not be as overestimated.

Thematic Response

FEIS Section 5.2.2.3.2 summarizes the analog approach and its use in evaluating the extent of pit drawdown. The complex mix of bedrock, glacial till, and wetland soils at the Mine Site makes it difficult to accurately quantify drawdown at any specific location; thus, the use of the analog method was utilized in lieu of MODFLOW to estimate pit drawdown. Additionally, there is a general lack of connectivity between the shallow water table in the wetlands and the deeper bedrock aquifer.

The analog approach was developed using available well data from the Canisteo Mine Pit, which is the only mine pit within the Mesabi Iron Range that has an associated water balance study with well data that could be used to assess potential drawdown effects. Additionally, the Canisteo Mine Pit data are believed to provide a reasonably conservative estimate of the maximum extent of surficial groundwater drawdown that would result from the proposed PolyMet mine pits. Insufficient data exists for the Soudan Mine to be useful as an analog.

The Co-lead Agencies are not relying solely on the potential impact zones determined in the analog method for the FEIS, but would be monitoring wetlands for potential indirect effects as part of an adaptive management plan. Permit conditions would include a plan for additional compensatory mitigation if indirect wetland impacts were identified, and appropriate changes to the adaptive management plan would be made as required.

The Co-lead Agencies believe that the use of the analog approach and the use of 20 percent metric described in FEIS Section 5.2.3 as factors considered in identifying potential indirect effects to wetlands is a credible and reasonable approach consistent with the requirements of NEPA.

Theme WR 120

Theme Statement

The SDEIS assumption that wetlands have limited hydraulic connectivity to the underlying surficial aquifer is not supported by site information. There are no data to suggest that wetlands are perched or semi-perched waterbodies. The SDEIS does not indicate the closest locations where impacted surficial aquifer groundwater or impacted surface water could affect wetlands.

Thematic Response

The FEIS evaluates drawdown effects on wetlands and associated surface water features using observations made at other Iron Range mine sites with open pits and similar geology (i.e., analog method). See FEIS Sections 5.2.2.3.2 and 5.2.3 and responses to themes WR 119, WET 08, and WET 09 for additional information.

Theme WR 121

Theme Statement

Information from the Minnamax project was not used to evaluate wetland dewatering effects.

Thematic Response

FEIS Section 5.2.2.3.2 summarizes the analog approach used to evaluate dewatering effects. Available well data from the Canisteo Mine Pit near the Cities of Coleraine and Bovey, Minnesota -- which is the only mine pit within the Mesabi Iron Range that has an associated water balance study with well data -- was used to evaluate dewatering effects. Please refer to the responses to themes WET 08 and WET 09 and FEIS Section 5.2.3 for more information on the potential for wetland drawdown.

Theme WR 122

Theme Statement

Constructed wetlands for water treatment require substantial acreage and are not feasible if the wild rice standard is applied year-round (that is, not seasonally) due to cold weather.

Thematic Response

Non-mechanical treatment systems (e.g., constructed wetlands) are not part of the NorthMet Project Proposed Action, which relies solely on mechanical treatment. Non-mechanical treatment as an adaptive management measure may be considered during operations and closure if pilot studies demonstrate their utility and cost-effectiveness for water treatment and water disposal, and, if eventually proposed, would be addressed in future permitting.

Theme WR 123

Theme Statement

The FEIS should acknowledge that certain constituents in Colby Lake currently exceed water quality standards and arsenic concentrations are elevated and the NorthMet Project Proposed Action would increase these concentrations. A TMDL study on Colby Lake is needed.

Thematic Response

The water quality results of Colby Lake are reported in FEIS Section 5.2.2.3.2.

The Co-lead Agencies acknowledge that arsenic currently exceeds the water quality criterion of 2 µg/L in Colby Lake and is predicted to do so under the NorthMet Project Proposed Action. However, it is also predicted that Colby Lake arsenic would continue to exceed the criterion under the CEC scenario (i.e., without the NorthMet Project Proposed Action). As predicted by the water quality model, the NorthMet Project Proposed Action arsenic concentrations are virtually identical to the CEC concentrations up to mine year 52. After that time, the NorthMet Project Proposed Action concentrations are slightly higher than the CEC concentrations; however, the difference is not more than 0.05 µg/L. The Co-lead Agencies conclude that this small increase above CEC concentrations does not constitute an unacceptable impact associated with the NorthMet Project Proposed Action.

A TMDL study is not required to assess impacts in the FEIS.

Theme WR 124

Theme Statement

Colby Lake water used for augmentation is higher in sulfates than existing tributary stream water, and would result in damage to downstream wild rice beds. The use of Colby Lake water for augmentation would require reverse osmosis treatment prior to discharge to surface water. FEIS Table 6.2.2-6 (formerly Table 6.2-6 in the SDEIS) does not include NorthMet augmentation flow from Colby Lake to Embarrass River tributaries. This source has a higher sulfate concentration than the Waste WWTF effluent, and should be included in the Table.

Thematic Response

The NorthMet Project Proposed Action has been modified since the SDEIS to address this issue. The Project Description in the FEIS indicates that no Colby Lake water would be used for direct surface water augmentation. All water used for stream augmentation would be treated prior to being added to hydrologically affected waters. If and when non-mechanical water treatment is implemented at the Plant Site, Unnamed Creek, Trimble Creek and Mud Lake Creek stream augmentation would no longer be necessary.

Theme WR 125

Theme Statement

The FEIS should acknowledge that use of Colby Lake water for augmentation would increase mercury loading to the Embarrass River.

Thematic Response

The Project Description in the FEIS indicates that no Colby Lake water would be used for direct surface water augmentation. All water used for augmentation would be treated by the WWTP prior to discharge. See FEIS Section 5.2.2.3.2 for more information.

Theme WR 126

Theme Statement

Based on case history information, the SDEIS consistently underestimates liner leakage rates for waste rock stockpiles, WWTF equalization basin and the Hydrometallurgical Residue Facility. The FEIS should provide clear justification for assumptions and inputs used to estimate liner leakage. Liner leakage would pollute groundwater.

Thematic Response

The assumed liner leakage rates are based on a combination of literature values, experience at mine sites, experience at other types of industrial facilities, manufacturer documentation, and information provided in standard engineering guidance documents (Section 5.2.2.3 in the Mine Site Water Modeling Data Package [PolyMet 2015m, as cited in the FEIS]). Liner leakage rates were estimated using the USEPA-approved HELP model, where simulations combined NorthMet Project Proposed Action design values for slopes and subgrade design with the published values for average liner defects per acre.

It is acknowledged that there have been historical instances where poor-quality liner installations have failed or leaked at relatively high rates. However, for the high-quality liner installations to be used for the NorthMet Project Proposed Action, the assumed liner leakage rates are reasonable and consistent with industry standards. While solid waste landfills may typically be smaller than the project facilities, the liner leakage rates are expressed on a unit area basis, so the results can be scaled to larger facilities. Further, the waste rock stockpiles where liners would be used are only temporary and monitoring would provide early warning if they are not functioning properly.

Theme WR 127

Theme Statement

The assumed effectiveness of the Category 1 Stockpile cover is not supported and may be over-estimated. Cover effectiveness should be a probabilistic input. The FEIS should address deterioration in liner and cover performance and the need for periodic cover replacement. These assumptions should be reviewed to determine whether the FEIS should assume an increase in

liner leakage over time as the membranes deteriorate. The FEIS should describe the replacement schedule for the Category 1 Stockpile cover membrane, as well as contingencies if leakage below the Hydrometallurgical Residue Facility liner causes unacceptable effects on groundwater.

Thematic Response

Some water is predicted to leak through the liners as a result of tears or defects in the geomembrane liners and this potential effect is included in the GoldSim model. The quantity of water leaking through the liners is determined by the liner design and effectiveness.

The Hydrologic Evaluation of Landfill Performance model was used to estimate liner leakage, including the use of uncertainty analysis. Leakage rates are summarized in FEIS Table 5.2.2-27 and Section 5.2.2.5.4, and are included in the Mine Site and Plant Site Water Modeling Data Packages (PolyMet 2015m and 2015j, respectively, both as cited in the FEIS).

Water mitigation measures are summarized in Section 5.2.2.3.5.

It should be noted that the liners used for the Category 2/3 and 4 Stockpiles would be temporary and only be used for a maximum of 20 years. It is unlikely liner replacement would be required in this timeframe if the liner were installed properly.

For the Category 1 Stockpile geomembrane cover, which would be overlain by a vegetative soil cover, maintenance would be required to ensure its effectiveness. The Adaptive Water Management Plan (AWMP) (PolyMet 2015d, as cited in the FEIS) describes modification to the cover system in Section 3.4.3.2 that could also be made before and after installation. This is also summarized in FEIS Section 5.2.2.3.5. Despite maintenance and modifications, if deterioration of the liner were indicated, either visually or by systematic increases in flows to the containment system, then mitigative actions would be undertaken that may include liner repair/replacement and replacing soil that may have been eroded. If full depletion of constituents from the stockpile required more than 1,000 years, the geomembrane could need to be replaced.

The Hydrometallurgical Residue Facility would be double-lined at the bottom to facilitate collection of water that has contacted the hydrometallurgical residue. More specific, the double liner would consist of a composite liner system utilizing a geomembrane liner above a geosynthetic clay liner with a second liner placed above the first, separated by a leakage collection system, substantially removing all hydraulic head from the lower liner. This design would virtually eliminate leakage from the Hydrometallurgical Residue Facility to groundwater resources. The collection system capture rate was calculated and included in Section 5.2.2.5.4 of the document Plant Site Water Modeling Data Package (PolyMet 2015j, as cited in the FEIS). The Residue Management Plan (PolyMet 2014r, as cited in the FEIS) includes a description of the operating plans, monitoring procedures, and adaptive management approaches for the Hydrometallurgical Residue Facility. Information on the design of the Hydrometallurgical Residue Facility is in the FEIS in Section 3.2.2.3.7 and 3.2.2.3.10, and further detailed with respect to geotechnical stability in Section 5.2.14.2.3.

Theme WR 128

Theme Statement

The SDEIS places too much reliance on untested and unproven engineered mitigation measures and technologies, such as reverse osmosis, that must work flawlessly for very long periods of time to reduce pollutants from entering surface waterways and groundwater. There is no acknowledgement that many of these measures would degrade over time and require constant monitoring, periodic replacement, and financial assurance to pay for their upkeep. It is unclear what mitigation PolyMet has committed to, and who and by what means NorthMet Project Proposed Action performance would be enforced.

Thematic Response

It is the Co-lead Agencies' opinion that engineered systems can operate successfully over long periods of time if they are properly monitored and maintained. The FEIS provides a comprehensive description of proposed water treatment and seep collection systems including groundwater containment and synthetic liners/covers. This includes conceptual designs and discussions of the types of monitoring used to assess performance. Detailed designs are provided in supporting documents, which are fully referenced in the FEIS. The FEIS also discusses long-term operation, maintenance, and periodic replacement of engineered systems. It is acknowledged that certain components of the engineered systems would need to be replaced when monitoring indicated that performance is marginal and not readily compensated for by adaptive mitigation measures.

A detailed financial assurance analysis would be part of the permitting phase and is not a required component of the FEIS. The financial assurance process would fully consider long-term monitoring and periodic replacement of equipment including, but not limited to, water treatment hardware and synthetic liners/covers. The Financial Assurance package for the NorthMet Project Proposed Action would insure that future funding would be available if and when adaptive mitigation measures or component replacements are needed to achieve performance specifications.

Mitigation measures have been adopted into the NorthMet Project Proposed Action through engineering design and management. An overview of the evolution of the NorthMet Project Proposed Action with respect to alternatives analysis is provided in FEIS Section 3.2.3.3. PolyMet commits to monitoring and management through application of management plans that form the NorthMet Project Proposed Action; these plans are listed at the start of FEIS Section 3.2.2. Specific mitigation and monitoring measures relating to water are described in FEIS Sections 5.2.2.3.5 and 5.2.2.3.6.

Theme WR 129

Theme Statement

Over timeframes of hundreds of years, it is likely that some mitigation measures would fail and release contaminated water to the environment before corrective actions can be taken.

Thematic Response

Provided that financial assurance and long-term management is in place, engineering controls could be operated within performance specifications for as long as necessary to meet environmental objectives. Monitoring would allow potential failures to be recognized and corrected before there is a release of impacted water to the environment. With appropriate monitoring and pre-planned contingency actions, and adequate financial assurance, it is technically feasible to maintain the operation of engineered systems indefinitely into the future.

Theme WR 130

Theme Statement

The NorthMet Project Proposed Action does not incorporate adequate mitigation. The SDEIS does not adequately discuss the adaptive mitigation measures that would be used to control unexpected water releases that could impact water chemistry, hydrologic or thermal regimes from the NorthMet Project Proposed Action sites to waterbodies such as the St. Louis River and its tributaries. In many cases, the SDEIS states that mitigation measures would be implemented if needed, but does not describe what those measures would be. What has been committed to by PolyMet is unclear. Triggers for potential changes to designs to collect and manage polluted drainage should be outlined in the FEIS, including why or how underdrains would be added to certain stockpiles should be fully described.

Thematic Response

Mitigation measures have been adopted into the NorthMet Project Proposed Action through engineering design and management. An overview of the evolution of the NorthMet Project Proposed Action with respect to alternatives analysis is provided in Section 3.2.3.3. PolyMet commits to monitoring and management through application of management plans that form the NorthMet Project Proposed Action; these plans are listed at the start of FEIS Section 3.2.2.

FEIS Section 5.2.2.3.5 describes Mine Site and Plant Site adaptive water management measures and under what circumstances they would be triggered and implemented. These adaptive measures would be adjusted accordingly during the construction and operation of the NorthMet Project Proposed Action, based on monitoring results, performance modeling, and engineering assessments. Examples include improving WWTP performance and Tailings Basin pond cover performance.

With regards to the use of foundation underdrains in stockpiles, these would be used to provide gravity drainage should elevated groundwater be encountered, to prevent or minimize the potential for excess pore pressures adversely affecting the performance of the liner system as the stockpile is loaded. As stated in FEIS Section 5.2.2.3.2, all temporary stockpiles (Category 2/3,

Category 4, and Ore Surge Pile) would have an underdrain system of minimum grade of 0.5 percent.

Theme WR 131

Theme Statement

The SDEIS does not discuss monitoring or contingencies for failure of pumps, the Colby Lake pipeline, the tailings pipeline, or pipelines between the Plant Site to the Mine Site, despite the fact that these systems may need to run and be funded for centuries after the mine closes. What water is piped where and when is confusing.

Thematic Response

As discussed in the FEIS, financial assurance and long-term management would be in place to assure that engineering controls could be operated within performance specifications for as long as necessary to meet environmental objectives. The Permit to Mine, which would be required before the NorthMet Proposed Action Project could begin, would describe the monitoring required to comply with discharge requirements.

The monitoring would allow potential failures to be recognized and corrected before a release of impacted water to the environment. With appropriate monitoring and pre-planned contingency actions, it is technically feasible to maintain the operation of engineered systems indefinitely into the future. Financial assurance adequate to: 1) monitor/inspect the engineered systems, 2) repair or replace components as necessary, and 3) apply adaptive mitigation measures that are shown to be cost-effective would be required under the Permit to Mine. Financial assurance is described in FEIS Section 3.2.2.4.

FEIS Figures 3.2-5 through 3.2-8 show the proposed water management features, infrastructure, and flow at NorthMet Project area.

Theme WR 132

Theme Statement

The SDEIS provides no contingencies for tailings embankment failure.

Thematic Response

The Project Description in the FEIS indicates that the Tailings Basin design would meet appropriate Factors of Safety and that Tailings Basin embankments would be monitored and inspected on a routine basis and repaired or strengthened on an as-needed basis. Financial assurance would be in place to perform these activities indefinitely into the future.

Theme WR 133

Theme Statement

The SDEIS includes no discussion of the installation of the south Tailings Basin seepage capture system and the proposed seepage capture system has not been designed to collect any seepage from the east side of the Tailings Basin.

Thematic Response

The Project Proposer has committed to collecting all of the south seepage from the Tailings Basin that makes its way to Second Creek by implementing additional improvements to the existing seepage management system if necessary. Potential measures that could bring the capture efficiency of the system to 100 percent include improvements to the existing dam such as lining the upstream dam face with bentonite and injecting grout into the dam. If seepage is observed to bypass the existing dam, a second dam could be constructed approximately 500 feet downstream of the existing system. This is an area where the Second Creek headwaters valley is more constricted and any remaining subsurface seepage would have come to the surface. This potential second dam could be constructed as an earthen dam with a clay or concrete cutoff wall (extending to bedrock if necessary) in order to achieve 100 percent capture of the surface seepage.

The east side seepage containment system is designed in the same manner as the groundwater containment system on the northern and western sides of the Tailings Basin. The east side seepage containment system would be designed to efficiently collect the Tailings Basin seepage while minimizing the collection of unimpacted water that would continue to flow from east to west towards the Tailings Basin. The unimpacted water flowing towards the Tailings Basin would be directed to the swale that would be constructed north of the East Dam consistent with the NorthMet Project Proposed Action as described in the SDEIS and FEIS, while the seepage collection system on the interior of the groundwater containment system would be constructed at an elevation lower than the swale to maintain an inward gradient across the containment system.

Theme WR 134

Theme Statement

The SDEIS provides no technical justification for the finding that waste rock segregation would be effective. It is unclear why Category 1 Stockpile seepage capture and treatment is necessary given its percentage of sulfur and the predictions that it would not generate acidic leachate. Why doesn't PolyMet stockpile the higher sulfur rock from the Category 1 stockpile in the Category 2/3 stockpile? This would potentially lower post-closure costs if it would eliminate the need to treat water that comes in contact with the Category 1 stockpile.

Thematic Response

Rock segregation by chemical properties is the primary purpose of mining operations. The designation of rock as waste and ore is a universally applied method for directing material excavated from hard rock mines. There is a long history of rock segregation on the Iron Range and regulatory agencies annually review the placement of rock. Technology like GPS has improved segregation practices. Moreover, calculations show if all Category 2/3 Stockpile rock

were to be placed in the Category 1 Stockpile, the average rock sulfur concentration would be 0.10 weight-percent sulfide S. This is less than the 0.12 weight-percent sulfide cut-off that defines the rock at the Category 1 Stockpile. While acid generation is not expected, the proposed containment system that would be constructed around the Category 1 Stockpile to capture water coming from the stockpile would ensure that water is managed in the event of unexpected constituent-loading from the stockpile.

To support the environmental classification of waste rock, 89 rock samples were subjected to kinetic tests (synthetic weathering). The samples were pre-selected to be spatially dispersed across the deposit, included rock from each of the major lithologic units, and captured the range in metal and sulfide S concentrations (see Table 4-1 in SRK 2007b, as cited in the FEIS). Non-acid-generating material (Category 1 waste rock samples defined as having no more than 0.12 weight-percent sulfide S) was identified through the results of 13 long-term (greater-than 420 weeks) kinetic tests. These tests found that all Category 1 rock samples, "...yielded pH above 6 throughout the program, typically fluctuating between 6.5 and 7.5 after an initial decline" (Section 4.1.4 and Large Table 1 in PolyMet 2015q, as cited in the FEIS). Although leachate from the Category 1 Stockpile is not predicted to be acidic, water quality model predictions indicate the need for mitigation.

To support mine planning and waste-rock handling, PolyMet developed a geologic "block model," which is a three-dimensional grid that represents the deposit and that provides an estimate for ore grade and sulfide S concentration in each grid block. The estimates of sulfide S in all of NorthMet waste and ore are based on interpolation of sulfide S analyzed in recovered drill core (approximately 18,800 analyzed samples). To ensure that the estimates of sulfide S concentration in the waste rock are accurate, the Co-lead Agencies commissioned an independent review of the geostatistical analysis used to develop the sulfide S distribution in the block model. For this, the reviewer obtained the entire dataset of sulfide S analyses on core samples. This audit found that the number and spatial distribution of the sulfide analyzed supported the geologic block model, which was developed to describe the ore and waste rock distribution in the deposit (Optitech 2012).

Theme WR 135

Theme Statement

Groundwater mapping is incomplete. The FEIS should address the flow and seepage of groundwater and should include information related to the stability of aquifers.

Thematic Response

Groundwater mapping has been performed by a combination of water levels measured in monitoring wells and calibrated groundwater flow models that predict hydraulic head distributions between the measurement locations. The calibration procedure refines the estimated hydrologic properties (e.g., hydraulic conductivity) of hydrogeologic units. The hydraulic head maps and refined properties developed in this manner are considered sufficiently reliable and accurate for impacts analysis and design of mitigation measures.

Theme WR 136

Theme Statement

The SDEIS provides no technical justification for the assumed effectiveness of land application of impacted waters.

Thematic Response

The NorthMet Project Proposed Action would not rely upon land application of impacted waters as a means for treatment.

Theme WR 137

Theme Statement

The SDEIS provides no technical description of potential non-mechanical water treatment systems. The SDEIS provides no technical justification of its effectiveness, details on when it would be implemented, nor does it describe how the commitment to transition to non-mechanical treatment would be enforced.

Thematic Response

A specific design of non-mechanical treatment is not included in the Project Description and the NorthMet Project Proposed Action would rely on mechanical treatment for as long as necessary. During operations and closure, the use of non-mechanical treatment may be considered as an adaptive management measure if pilot and other feasibility studies indicate that this method has potential utility in accordance with permit conditions, and is cost-effective. In the FEIS, the possible future use of non-mechanical treatment is stated as a long-term goal, but the details of how such systems would operate would be determined once operations begin and site specific data could be used for pilot/feasibility studies, and if the systems are eventually proposed they would be addressed in future permitting. Obtaining water quality measurements is highly desirable when designing site-specific non-mechanical treatment systems because they provide better reference points than modeling for necessary system performance. Reference to a seasonal application of the wild rice standard has been removed from the description of these potential future non-mechanical treatment systems for the FEIS.

Theme WR 138

Theme Statement

The SDEIS does not describe the frequency of cover and liner replacement or acknowledge that leaks are most often due to accidental flaws in installation.

Thematic Response

Some water is predicted to leak through the Category 2/3 and 4 geomembrane liners as a result of tears or defects and this effect is included in the GoldSim model. The Hydrologic Evaluation of Landfill Performance model was used to estimate liner leakage, including the use of uncertainty analysis. Leakage rates are summarized in FEIS Table 5.2.2-27 and Section 5.2.2.3.2, and are included in the documents Mine Site and Plant Site Water Modeling Data Packages

(PolyMet 2015m and 2015j, respectively, both as cited in the FEIS). Mitigation measures are summarized in FEIS Section 5.2.2.3.5. It should be noted that the liners used for the Category 2/3 and 4 Stockpiles would be temporary and would only be used for a maximum of 20 years. It is unlikely liner replacement would be required in this timeframe if the liner is installed properly.

For the Category 1 Stockpile geomembrane cover, which would be overlain by a vegetative soil cover, maintenance would be required to ensure its effectiveness. The Adaptive Water Management Plan (AWMP) (PolyMet 2015d, as cited in the FEIS) describes modification to the cover system in FEIS Section 3.4.3.2 that could also be made before and after installation. This is also summarized in FEIS Section 5.2.2.3.5. Despite maintenance and modifications, if deterioration of the liner were indicated, either visually or by systematic increases in flows to the containment system, then mitigative actions would be undertaken that may include liner repair/replacement and replacing soil that may have been eroded. If full depletion of constituents from the stockpile required more than 1,000 years, the geomembrane could need to be replaced.

The Hydrometallurgical Residue Facility would be double-lined at the bottom to facilitate collection of water that contacted the hydrometallurgical residue. More specifically, the double liner would consist of a composite liner system utilizing a geomembrane liner above a geosynthetic clay liner with a second liner placed above the first, separated by a leakage collection system, substantially removing all hydraulic head from the lower liner. This design would virtually eliminate leakage from the Hydrometallurgical Residue Facility to groundwater resources. The collection system capture rate was calculated and included in Section 5.2.2.5.4 of PolyMet 2015j, as cited in the FEIS. The Hydrometallurgical Residue Management Plan includes a description of the operating plans, monitoring procedures, and adaptive management approaches for the Hydrometallurgical Residue Facility. Information on the design of the Hydrometallurgical Residue Facility is in FEIS Section 3.2.2.3.10.

Theme WR 139

Theme Statement

The FEIS should describe the groundwater and surface water monitoring plans and systems rather than stating that monitoring plans would be determined during the permitting phase. Furthermore, the FEIS should state who would be responsible for water monitoring. It seems inadvisable to depend on PolyMet to perform such a critical function, especially when it is potentially hurtful to their bottom line. Where monitoring shows effluent limit exceedances, enforcement and corrective actions needs to be taken. An understanding of baseline groundwater flow direction is necessary before implementing a monitoring system.

Thematic Response

FEIS Section 5.2.2.3.6 provides a description of the monitoring plans proposed by PolyMet. Monitoring would be used on a continual basis to document compliance with permit conditions, annually validate and update water models, and provide input to optimize operations of adaptive engineering controls. The FEIS provides information on objectives, monitoring summary, and general location for monitoring of process water streams, storm water, surface discharges, groundwater, wetlands, and surface water in the Partridge River and Embarrass River watersheds (as applicable). For groundwater monitoring, the general number of sampling locations and frequency are identified. For surface water, general sampling locations and timeline are

identified. As mentioned in the FEIS, the water monitoring plans would be finalized in detail (including specific locations, frequencies, and parameters) during the NPDES/SDS water permitting and water appropriations processes and updated as required during the life of the NorthMet Project Proposed Action.

PolyMet, as the assigned Permittee for the NorthMet Project Proposed Action, would be responsible of carrying out the proposed monitoring activities as described in the legally enforceable permits. The permits, supported by state and federal laws, include provisions that address failure to comply with the terms and conditions of the permit, including those related to conducting required monitoring.

Theme WR 140

Theme Statement

The FEIS should discuss contingencies in the event that Colby Lake and Whitewater Reservoir cannot be used for drinking water due to mine withdrawals and contributions of polluted water.

Thematic Response

Colby Lake is classified listed as a Class 1B waterbody (protected for domestic consumption) and is currently used as a potable water source for the City of Hoyt Lakes. As stated in FEIS Sections 4.2.2.2.2 and 5.2.2.3.2, recent monitoring data show elevated concentrations of aluminum, iron, mercury, and manganese, which at times exceed secondary drinking water standards. The City of Hoyt Lakes currently treats the water drawn from Colby Lake to remove these constituents prior to distribution. Additionally, Colby Lake is classified as “impaired waters” as it is on the Minnesota 303(d) TMDL List due to mercury concentrations in fish tissue.

With the proposed designs and engineering controls, the water quality model predicts that the NorthMet Project Proposed Action would not cause or increase the magnitude of a current exceedance of Colby Lake surface water evaluation criteria at the P90 level. Furthermore, the model predicts a slight decrease in P90 concentrations of aluminum, iron, and manganese over time.

Based on current conditions and uses and the predicted conditions, no issues with continued use Colby Lake as a potable water source have been identified.

Theme WR 141

Theme Statement

The FEIS should discuss the monitoring necessary to ensure wildlife protection, human health, and water quality related to open water in the East Pit wetland, West Pit Lake, and Tailings Basin pond.

Thematic Response

Based on the results of water quality modeling, the water quality of the West Pit Lake, East Pit wetland, and Tailings Basin pond is predicted to be at concentrations not injurious to wildlife or incidental human contact. On-site monitoring of waterbodies within facility boundaries would likely be a part of a monitoring program. Monitoring details would be finalized in the permitting

process. FEIS Section 5.2.5.2.3 discusses potential effects on wildlife from incidental contact with the Tailings Basin pond and pit lakes. FEIS Section 7.3.4 discusses potential human health impacts. FEIS Section 5.2.2.3.6 discusses on-site water monitoring.

Theme WR 142

Theme Statement

The FEIS should discuss monitoring and mitigation associated with potential effects on drinking water wells.

Thematic Response

With regard to water wells, the FEIS groundwater impacts analysis indicates that drinking water standard-based evaluation criteria would be met at the Mine Site and Plant Site property boundaries, which are upgradient of current and possibly future residential or domestic water wells. Evaluation criteria can be found in Section 5.2.2. If evaluation criteria are met at the properties boundaries, it is highly unlikely that the NorthMet Project Proposed Action could cause exceedances of groundwater standards outside the property boundary. Note that at the Plant Site, groundwater standards for some parameters may currently be exceeded beyond the property boundary as a result of legacy issues with the Tailings Basin; however, engineering controls included as part of the NorthMet Project Proposed Action are expected to address these exceedances over time.

Theme WR 143

Theme Statement

SDEIS does not adequately describe the dual proposed reverse osmosis systems including: the design, discharge locations, and timing of implementation; treatment processes; the results of pilot testing; reliability; cost, effectiveness; operations; and management, including that of potential overflows.

Thematic Response

The Project Description in the FEIS indicates that an RO system (or equivalent performing technology) would be constructed at the WWTP at the Plant Site at the beginning of the NorthMet Project Proposed Action and that an RO unit would be added to the WWTF at closure if water monitoring of sulfate concentrations during operations indicated the need to do so. Pilot-testing of an RO system was conducted by the Proponent and is reported in the document *Final Pilot Testing Report* (Barr 2013f, as cited in the FEIS). The final detailed design, treatment process, operation, and maintenance of the RO systems to be installed would be included as part of the permitting process.

Theme WR 144

Theme Statement

The SDEIS does not adequately describe measures that would be taken in the event of short-term or long-term reverse osmosis system failure.

Thematic Response

RO is a standard water treatment technology and industrial-scale systems have been operated around the world for decades. The FEIS describes the proposed RO system as being modular with redundant treatment streams. If one or more of the membranes were to fail, the flow could be quickly diverted to standby cells and no flow would pass through the RO system untreated. Further, membrane failure tends to be gradual and provide advanced warning so corrective actions could be taken before there was a loss of treatment. The system would be designed to have storage capacity for the incoming influent so the system could be shut down for brief periods for equipment repair/replacement, with the stored influent treated after the system were back online.

PolyMet would contract with specialty service companies providing self-contained truck-mounted RO systems that could transported to the site on short notice for temporary treatment while modifications were made to the resident RO system (if ever necessary).

Theme WR 145

Theme Statement

The FEIS should provide additional detail on the characterization, and the risks of temporary storage, transportation and disposal of treatment residuals (brines and solids), including uranium.

Thematic Response

Sludge produced by the chemical precipitation system would be managed at the Hydrometallurgical Residue Facility during operations or disposed off-site at an appropriately licensed solid waste disposal facility. During reclamation sludge would be hauled to an approved off-site landfill. During operations, the reject concentrate from the WWTP would be transported to the WWTF via railcar, fed to the precipitation system via a transfer pump, and directed to the applicable precipitation train. During closure and long-term maintenance, the WWTP residual solids generated from thermal treatment would be transported off site for disposal. The description of treatment residual disposal in the FEIS is at a sufficient level of detail for the FEIS to assess their potential for impact on the environment. There is no uranium risk or exposure associated with the NorthMet Project. FEIS Section 5.2.13 addresses risk and management of hazardous materials associated with the NorthMet Project Proposed Action.

Theme WR 146

Theme Statement

The SDEIS does not adequately describe the precipitation process to be used at the WWTF.

Thematic Response

FEIS Section 5.2.2.3.1 describes the chemical precipitation and membrane filtration treatment methodologies to be used at the WWTF based on the predicted water loads and constituents modeling.

Theme WR 147

Theme Statement

The FEIS should describe the influent and effluent assumptions and targets for the WWTF and WWTP. Influent concentrations for some parameters are underestimated or not considered which affects effluent concentrations.

Thematic Response

The influent concentrations of all chemical constituents to the WWTF and WWTP, based on information from GoldSim modeling, are presented in the Mine Site Data Package and Plant Site Data Package (PolyMet 2015m and PolyMet 2015j, respectively, both as cited in the FEIS).

Because the water treatment facilities would be designed systems, they could be engineered to achieve target effluent concentrations. The assumed effluent treatment concentrations in the FEIS are based on extensive laboratory-scale and pilot-scale testing conducted by PolyMet and on case histories of currently operating systems at mine sites.

Theme WR 148

Theme Statement

The FEIS should describe contingencies if water treatment flow rates are higher than expected.

Thematic Response

The WWTF to be used at the Mine Site for mine years zero to 40 would be designed to have a larger treatment capacity than expected. The excess treatment capacity would be sufficient to handle all reasonable flow rates that could occur during mine operations and reclamation. In the unlikely event that influent flow rates were greater than the WWTF capacity, the excess flow could be diverted to the Plant Site RO system, which would also be designed to have excess treatment capacity. The preliminary design of the WWTP would be based on estimates for the volumetric flow and chemical composition of Plant Site water from the seepage capture pond-level management systems, but the WWTP treatment system would be part of the adaptive management system, so that its capacity could be “adapted, as necessary, in response to the actual conditions encountered during the Project, the monitoring results, and the conditions estimated by continued model updating” (Section 4.2.4 of PolyMet 2015d, as cited in the FEIS).

RO systems (or equivalent performing technology) would be used at the Plant Site for the entire life cycle of the NorthMet Project Proposed Action and at the Mine Site during closure. These systems would be designed with excess flow capacity and redundant treatment streams. The modular design of the RO systems would allow the ability to add capacity in the unlikely event that influent flow rates exceeded both the primary and redundant design flow rates. PolyMet would contract with specialty service companies providing self-contained truck-mounted RO systems that could be transported to the site on short notice for temporary treatment while modifications were made to the resident RO system (if ever necessary).

Theme WR 149

Theme Statement

The SDEIS generally underestimates sulfate concentrations at points of compliance. There is insufficient information to determine whether this mine would contribute to significant degradation of the waters of the United States due to sulfate discharges. Permits must be denied on this basis.

Thematic Response

NorthMet Project Proposed Action-related sulfate concentrations at groundwater and surface water evaluation locations would mostly be dependent on chemical release rates from chemical source areas including mine pits, stockpiles, and the Tailings Basin. In addition, sulfate concentrations would be strongly influenced by the capture efficiency of containment systems along the outside perimeter of the Tailings Basin and surrounding the Category 1 Stockpile.

GoldSim inputs pertaining to chemical release rates were scrutinized by the Co-lead Agencies and extensively reviewed and modified through a cooperative process with the Project Proponent and Cooperating Agencies. These inputs are considered realistic median values based on NorthMet geochemical characterization and information obtained from similar mine sites. The capture efficiencies used for containment systems at the Mine Site and Plant Site are considered reasonable or conservatively low based on subsidiary MODFLOW modeling specifically meant to address this issue. The Co-lead Agencies believe that GoldSim inputs for these processes are reasonable and do not have any systematic tendencies leading to underestimates in sulfate concentrations at the evaluation locations.

The GoldSim modeling is probabilistic so that most chemical release inputs are put into the model as probability distributions (rather than single deterministic values). The mean (or central-tendency) values in these distributions are considered by the Co-lead Agencies to reasonably conform to median values based on geochemical characterization. In addition, the range of probable values above and below the mean do not bias the overall probability distributions to higher or lower release rates from what is indicated by the data. Note further that evaluation of NorthMet Project Proposed Action-related impacts is based on P90 sulfate concentrations, which are always higher than the P50 (median) concentrations.

Given the above discussion, the Co-lead Agencies believe that GoldSim-computed sulfate concentrations are not systematically underestimated at evaluation locations at the Plant Site and Mine Site.

The evaluation and decision of whether or not the NorthMet Project Proposed Action may or may not discharge into surface waters where water quality standards are exceeded is a permit decision.

Theme WR 150

Theme Statement

The SDEIS does not account for accumulation of sulfate in tailings or other waste.

Thematic Response

The GoldSim water- and solute-transport models track the mass of all sulfate released from the oxidation of sulfide minerals. If sulfate concentrations in pore water were below the concentration cap, all of the sulfate released in a time step could migrate out with the flowing water. But if enough sulfate were released over a time step that the sulfate concentrations in pore water exceeded the concentration cap, then the pore water would be set equal to the concentration cap, and the mass of excess sulfate would be stored in the model as a “labile” phases (i.e., a solid phases that remains in place, but is assumed to be able to dissolve in each new model time step). The result of this method is that when solute release produces sulfate concentrations above the concentration cap, the effluent remains at the concentration cap, and the eventual release of the stored “labile” sulfate causes the sulfate concentrations in effluent to remain at the cap for a longer duration. This method is applied to waste rock and tailings. Waste rock and wall rock contains “non-contacted” rock an additional reservoir for “labile” sulfate. This is the portion of the rock that is not flushed by percolating water, and sulfate is released from this zone when (and if) the rock is submerged in water. This same approach is applied to all solutes as part of the model design to preserve mass balance.

Theme WR 151

Theme Statement

The SDEIS does not adequately consider the amount or effects of dust and depositional impacts, and ore spillage from rail cars on groundwater, surface water, and wetlands.

Thematic Response

The Project Description in the FEIS includes routine inspections of the Transportation and Utility Corridor to identify accumulations of dust or ore spillage.

Regarding dust, given the majority of the dust that could leave the NorthMet Project area could be characterized as low sulfide/low metal, potential impacts would be controlled by: 1) the commitment to treat all runoff from disturbed areas as process wastewater, and 2) the facilities would be subject to an air quality Fugitive Emissions Plan. Significant impact on water resources or historic properties is not expected.

All active areas at the Mine Site and Plant Site would be subject to a Fugitive Dust Control Plan approved by the MPCA, which describes management of fugitive dust generated from unpaved roads across the NorthMet Project area, rock dumping and loading locations on the Mine Site,

and areas potentially subject to wind erosion on the Plant Site (see Section 4.1.6 and Section 4.3.9 in PolyMet 2015a, as cited in the FEIS).

Regarding potential spillage, any significant accumulations would be removed by a combination of machines and hand work. Ore transport would be by special railcars that minimize dust and spillage, where, since the SDEIS, the Proposer has committed to retrofit the railcars to better control spillage. It is unlikely that there would be sufficient spillage to affect the quality of surface water or groundwater, as discussed in FEIS Section 5.2.2.3.2. See FEIS Section 3.2.2.4 for more information on the railcars, and Sections 5.2.3 and 5.2.7 for impacts of railcar spillage and dust on wetlands and air quality, respectively. The effect of dust falling on the disturbed portions of the Mine Site would be controlled by the perimeter dike and ditch system, which would route runoff to the WWTF (see Section 4.1.5.3 and Large Figures 19 through 21 of PolyMet 2015a, as cited in the FEIS).

Theme WR 152

Theme Statement

The SDEIS does not adequately incorporate the findings of recent research on the influence of sulfates and sulfides on the growth of wild rice. Research into and evaluation of the Minnesota sulfate wild rice water standard are ongoing, and application of the standard (where it applies, what time of year, and what the numeric standard should be) may change. The FEIS should incorporate the most recent MPCA research and needs to consider the findings of “Effects of Sulfate on the Biomass and Seed Production of Wild Rice.” Given regulatory uncertainty and the lack of wild rice locational data, the FEIS should assume all waters surrounding the NorthMet Project Proposed Action site are wild rice waters.

Thematic Response

The FEIS recognizes the MPCA is overseeing a variety of studies on wild rice. At applicable surface water locations, the FEIS evaluated impacts using an evaluation criterion based on the current 10 mg/L standard for sulfate concentration in waters used for production of wild rice. This impact assessment metric is keyed to the current regulation.

It is recognized that the MPCA is currently evaluating the current wild rice sulfate water quality standard and, as part of that process, new information on potential contributing factors on the growth of wild rice has been generated. However, that information has not yet been holistically reviewed in the context of its possible influence on the wild rice standard. Future change to the wild rice sulfate standard, if any, is speculative and outside the scope; applying research findings outside the basis of the current rule is not appropriate.

The FEIS includes descriptions of the Plant Site WWTP and Mine Site WWTF, both of which would be capable of discharging treated wastewater at concentrations at or below 10 mg/L as demonstrated by pilot-testing already conducted. More detailed information on these treatment systems would be available as part of the permitting process. However, should a more stringent standard be developed in the future, operation of the RO treatment systems (or equivalent performing technology) could be adjusted to meet a more stringent effluent limit.

See FEIS Sections 5.2.2.1.2, 5.2.2.3.2, and 5.2.2.3.3 for more information.

Theme WR 153

Theme Statement

Seasonal application of the Minnesota sulfate standard is not technically justified; the standard needs to be applied year round. If seep collection and non-mechanical water treatment after closure do not work as planned, the seasonal discharge would have a greater effect than predicted in the SDEIS.

Thematic Response

Neither seasonal application of the wild rice standard nor non-mechanical treatment systems would be part of the NorthMet Project Proposed Action, which would rely solely on mechanical treatment and year-round application of the sulfate standard. Non-mechanical treatment may be considered during operations and closure if pilot studies demonstrated their utility and cost-effectiveness for water treatment and water disposal.

Theme WR 154

Theme Statement

Regulatory standards need to consider historical and current wild rice areas. Historical wild rice harvesting occurred upstream of MPCA-designated waters. The wild rice standard therefore needs to be applied to entire Embarrass River Watershed and additional portions of the Partridge River Watershed.

Thematic Response

For purposes of the EIS, the MPCA has previously provided draft staff recommendations as to what waters in the Embarrass River and Partridge River should be considered waters used for production of wild rice, to which the current 10 mg/L wild rice sulfate standard applies. The MPCA staff reviewed all available relevant information in making their recommendations.

Theme WR 155

Theme Statement

The Land Exchange Proposed Action would not compensate for current and future loss of wild rice areas. The SDEIS must be rejected until it contains an analysis of the effects of groundwater pollution on Land Exchange Alternative B.

Thematic Response

The Land Exchange Proposed Action would result in the public ownership of additional wild rice beds by the acquisition of Tract 1. Tract 1 contains Little Rice Lake, which supports a continuous population of wild rice. Wild rice also grows along the Pike River south of Little Rice Lake and in isolated populations on Hay Lake. FEIS Section 4.3.4.2.5 provides further discussion of wild rice on Tract 1. Wild rice does not currently grow within the proposed federal land boundaries. As a result, the public would have better opportunities for wild rice harvesting on Tract 1, where there is currently no opportunity to harvest wild rice directly on the federal lands (i.e., no known wild rice populations) despite the public water access onto the federal lands. A carry-down boat

launching access is located on Tract 1, which may provide private access for wild rice harvesting on the Tract 1 lands. Access to wild rice beds on the federal lands would not be lost as a result of the Land Exchange Proposed Action, but access to wild rice beds on Tract 1 would be gained.

The Land Exchange Proposed Action and Lane Exchange Alternative B would not directly result in groundwater pollution. Any impacts from the NorthMet Project Proposed Action on groundwater within the federal lands included under Land Exchange Alternative B are considered in FEIS Section 5.2.2.3.2.

Theme WR 156

Theme Statement

Sulfates and toxic metals from the NorthMet Project Proposed Action that are not captured for treatment would affect water quality and wild rice production. This would harm and could even prevent the traditional, treaty-protected harvesting of wild rice by the Bands. Water quality is a legal right for Native Americans.

Thematic Response

It is acknowledged that the NorthMet Project Proposed Action would increase concentrations of some metals at some evaluation locations. However, the NorthMet Project Proposed Action would not cause predicted concentrations to be above applicable water quality standard-based evaluation criteria. Evaluation criteria can be found in Section 5.2.2. Water quality and quantity modeling predictions for SW-005 and PM-13 indicate that the NorthMet Project Proposed Action would not result in adverse impacts on wild rice. These locations are the nearest downstream locations in the Partridge River and Embarrass River, respectively, and were previously recommended by the MPCA staff to be considered as waters used for production of wild rice. Impacts on wild rice further downstream in these waters, or on wild rice resources regionally throughout the treaty areas, would not be expected.

Theme WR 157

Theme Statement

The NorthMet Project Proposed Action may affect wild rice and other aquatic plants that are making a recovery in these waters. Effects on wild rice in the vicinity of the NorthMet Project Proposed Action must be more rigorously analyzed and reported, including the extent to which wild rice beds would decrease as a result of the NorthMet Project Proposed Action and how this could impact the quality and quantity of wild rice available for consumption by people or wildlife. The FEIS should assess the effects of winter water releases from the NorthMet Project Proposed Action on spring sulfite levels in the seedlings of downstream wild rice beds. The FEIS should also provide additional details about mitigation of wild rice effects.

Thematic Response

Water quality and quantity modeling predictions for SW-005 and PM-13 indicate that the NorthMet Project Proposed Action would not result in adverse impacts on wild rice. These locations are the nearest downstream locations in the Partridge River and Embarrass River, respectively, and were previously recommended by MPCA staff to be considered as waters used

for production of wild rice. Impacts on wild rice further downstream in these waters, or on wild rice resources regionally throughout the treaty areas, would not be expected.

Theme WR 158

Theme Statement

The NorthMet Project Proposed Action would increase mercury and sulfate pollution in the St. Louis River Watershed, including the Partridge River and Embarrass River, which is already impaired for these pollutants. This has serious implications for human health and wild rice. Iron mines have already created water quality problems like wild rice dead zones and concerning mercury levels.

Thematic Response

The FEIS indicates that the NorthMet Project Proposed Action would result in a reduction in sulfate-loading to the Embarrass River at the monitoring site (PM-13), and a small increase in sulfate-loading to the Partridge River resulting in an overall decrease in loading to the St. Louis River. The FEIS also indicates a net decrease of mercury-loadings of approximately 0.6 grams per year (i.e., a net decrease of 1.2 grams per year in the Partridge River and a net increase of 0.6 grams per year in the Embarrass River) and therefore would not contribute to cumulative effects on mercury-loading to the St. Louis River. Based on FEIS modeling predictions, the NorthMet Project Proposed Action is not anticipated to have adverse effects on downstream wild rice. Consequently, the NorthMet Project Proposed Action does not include, or need to include, mitigation for the cultivation of new wild rice beds in unaffected waters.

Theme WR 159

Theme Statement

The St. Louis River downstream from the PolyMet site is already heavily impacted by sulfate, and wild rice production in the watershed is a fraction of what it once was. The state should reduce or eliminate problem pollution sites before permitting. The FEIS should analyze cumulative effects of the NorthMet Project Proposed Action on sulfates and wild rice in the NorthMet Project area and the St. Louis River Watershed as a whole. Cumulative effects on wild rice in the 1854 Ceded Territory also need to be addressed.

Thematic Response

Sulfate loading is predicted to decrease overall as a result of the NorthMet Project Proposed Action. Although sulfate loadings are predicted to increase slightly in the Partridge River Watershed (0.1 percent) as a result of the NorthMet Project Proposed Action, this is offset by a large decrease in the Embarrass River Watershed (21 percent at PM-13), resulting in a significant net decrease in overall sulfate-loadings to the St. Louis River as a result of the NorthMet Project Proposed Action. The NorthMet Project Proposed Action is also predicted to have negligible impact on the hydrology of either the Partridge River or Embarrass River. Therefore, the NorthMet Project Proposed Action is not considered to have the potential to contribute to cumulative effects on hydrology and water quality in the St. Louis River. As a result, the CEEA

for surface water is defined by the Partridge River and Embarrass River watersheds as shown on Figure 6.2.2-1.

Theme WR 160

Theme Statement

Given the mounting evidence demonstrating negative effects on wild rice from relatively low levels of sulfides, the positive correlation between levels of sulfate in water column and sulfides in sediment combined with the remaining uncertainties about long-term effects and the relationship between sulfate and methyl mercury, add to the weight of evidence against weakening the 10 mg/L sulfate standard.

Thematic Response

The water quality evaluation criterion for sulfate for the SDEIS and the FEIS for waters previously recommended by MPCA staff to be waters used for production of wild rice (represented by evaluation locations SW-005 in the Partridge River and PM-13 in the Embarrass River) is the current Class 4A wild rice sulfate water quality standard of 10 mg/L.

Theme WR 161

Theme Statement

The NorthMet Project Proposed Action would meet the strict Minnesota standard for wild rice waters. The SDEIS makes it very clear that there would be a net decrease in both sulfate and mercury loadings as a result of this NorthMet Project Proposed Action. The NorthMet Project Proposed Action is not expected to damage downstream wild rice beds. Overall concerns about wild rice beds are unfounded, since wild rice beds are found in many nearby lakes that historically had no wild rice. Wild rice harmed by sulfides associated with the NorthMet Project Proposed Action could be mitigated through the cultivation of new wild rice beds in unaffected waters. The USFS and the State of Minnesota have planted wild rice in the area with very good success.

Thematic Response

The FEIS indicates that the NorthMet Project Proposed Action would result in a reduction in sulfate loading to the Embarrass River at the monitoring site (PM-13), and a small increase in sulfate-loading to the Partridge River resulting in an overall decrease in loading to the St. Louis River. The FEIS also indicates a net decrease of mercury-loadings of approximately 0.6 grams per year (i.e., a net decrease of 1.2 grams per year in the Partridge River and a net increase of 0.6 grams per year in the Embarrass River) and therefore would not contribute to cumulative effects on mercury-loading to the St. Louis River. Based on FEIS modeling predictions, the NorthMet Project Proposed Action is not anticipated to have adverse effects on downstream wild rice. Consequently, the NorthMet Project Proposed Action does not include, or need to include, mitigation for the cultivation of new wild rice beds in unaffected waters.

Theme WR 162

Theme Statement

Sulfate and wastewater from the NorthMet Project Proposed Action would exceed the state 10 mg/L standard for wild rice and would likely eliminate wild rice in the St. Louis River and its tributaries. Since sulfate levels in wild rice beds downstream of the Proposed Mine already exceed the standard, the FEIS should demonstrate that the NorthMet Project Proposed Action “would have an acceptably high probability of not increasing sulfate concentrations in these areas.” The SDEIS does not currently meet this test. The Partridge River would exceed the standard during low-flow conditions.

Thematic Response

The discharge from WWTFs using RO technology (or equivalent performing technology) is expected to meet the wild rice sulfate standard of 10mg/L during operations and closure. The FEIS closely evaluated the potential changes to sulfate concentrations as a result of the NorthMet Project Proposed Action in the Embarrass River and Partridge River at evaluation locations representing the location of wild rice production waters subject to the wild rice sulfate water quality standard of 10 mg/L. The analysis showed that the NorthMet Project Proposed Action would result in a reduction of sulfate loading to the Embarrass River and only a very slight potential increase in loading to the Partridge River. Consequently, the NorthMet Project Proposed Action is not anticipated to have adverse effects on downstream wild rice. As part of the permitting process, the MPCA would continue to evaluate the NorthMet Project Proposed Action’s potential sulfate contributions to the Embarrass River and Partridge River based upon all available relevant information to ensure compliance with applicable standards.

Theme WR 163

Theme Statement

Although the MPCA has specified that only certain wild rice producing waters are protected under the wild rice sulfate water quality standard, the rights of Ojibwe people to gather wild rice on off-reservation land was affirmed by the U.S. Supreme Court in 1999. Therefore, all wild rice beds in the Ceded Territory are protected under 1864 Treaty. The SDEIS fails to explain how the NorthMet Project Proposed Action would meet the statutory requirements regarding wild rice water quality standards and the Clean Water Act.

Thematic Response

Water quality and quantity modeling predictions for SW-005 and PM-13 indicate that the NorthMet Project Proposed Action would not result in adverse impacts on wild rice. These locations are the nearest downstream locations in the Partridge River and Embarrass River, respectively, and were previously recommended by MPCA staff to be considered as waters used for production of wild rice. Impacts on wild rice further downstream in these waters, or on wild rice resources regionally throughout the treaty areas, would not be expected.

Theme WR 164

Theme Statement

The MPCA has postponed their decision on sulfate levels in waters that support wild rice beds. When standards are still undecided, decisions pertaining to those standards ought not to be concluded. If the rule-making process is not complete, the FEIS should not rely on a preliminary draft recommendation from MPCA based on incomplete knowledge.

Thematic Response

The evaluation in the FEIS is based on the current Class 4A wild rice sulfate standard of 10 mg/L applicable to waters used for production of wild rice and previous draft MPCA staff recommendations identifying the location of waters used for production of wild rice. It is not appropriate for the EIS to speculate as to if or how the standard, or application of the standard, may evolve.

Theme WR 165

Theme Statement

Underestimated Partridge River baseflows in the Mine Site GoldSim model lead to underestimated recharge, incorrect surficial deposit hydraulic conductivities, and underestimated chemical loading to groundwater and the Partridge River in the Mine Site GoldSim model. As a result, the SDEIS version of the Mine Site GoldSim model is invalid, and the model should be revised to include inputs that are consistent with the correct baseflows.

Thematic Response

As discussed in the response to theme WR 003, Partridge River groundwater baseflows used in the SDEIS and transferred to the FEIS are reliable best estimates and are not erroneously low. This is because the SDEIS (and FEIS) groundwater baseflow values were based on winter 1986-77 and winter 1987-88 stream gaging in the Partridge River that occurred when there were no discharges from the Northshore Mine. When expressed as a groundwater baseflow yield per unit area, the similar results for both the Partridge and Embarrass River watersheds (approximately 0.05 cfs per square mile) lends credibility to the approach used.

As discussed in the response to theme WR 004, the low-flow measurements at gaging station SW-003 are not reliable indicators of groundwater baseflow due to the complicating effects of Northshore Mine pumped discharges to the Partridge River.

The Mine Site MODFLOW model was recalibrated based on new groundwater level data collected through the end of 2013; however, calibrations performed for the FEIS used the same Partridge River baseflows as were used in SDEIS. Revised hydraulic conductivities and recharge values that come from MODFLOW recalibration informed the FEIS Mine Site GoldSim model.

Groundwater baseflow discharge varies with time and is a reflection of longer-term weather and climatic conditions. The variability of groundwater baseflow discharge is demonstrated by the examination of estimated values for several years using different methods. Evaluation of these values affirms that groundwater baseflows used in the Mine Site GoldSim model are reliable and appropriate for FEIS impact evaluation.

Theme WR 166

Theme Statement

The Mine Site GoldSim model does not adequately consider hydraulic connectivity between wetlands and groundwater in the surficial deposits.

Thematic Response

Using an observational approach based on data from similar nearby mine sites (i.e., analog method), the Co-lead Agencies concluded that drawdowns in the surficial aquifer would not be expected to extend very far from the mine pits. This is explained by the following factors: 1) the surficial aquifer is thin and moderately permeable, 2) the surficial aquifer is subject to aerial recharge, and 3) the surficial aquifer is underlain by low-permeability bedrock that limits downward leakage from the surficial unit. These factors support the conclusion that wetland drawdown did not need to be included in the Mine Site GoldSim model. See FEIS Section 5.2.2.3.2 for more information on the analog method.

It is acknowledged that there is some degree of hydraulic interaction between wetlands and the surficial aquifer at the Mine Site. However, attempts to quantitatively model the effects of these interactions on drawdown and water quality would be highly uncertain and potentially misleading. The FEIS approach was to not model hydraulic connections between wetlands and the surficial aquifer in the Mine Site GoldSim model, but instead to rely on future monitoring and adaptive mitigation measures in the unlikely event that wetlands were affected by the NorthMet Project Proposed Action. See FEIS Sections 5.2.2.3.5 and 5.2.2.3.6 for more information on adaptive mitigation and monitoring at closure.

Theme WR 167

Theme Statement

There are numerous discrepancies and concerns regarding surficial groundwater flowpaths in the Mine Site GoldSim model. Three critical issues are that the model does not account for northward flowpaths (e.g., to Yelp Creek and One Hundred Mile Swamp), inappropriately assumes constant saturated thickness for the surficial flowpaths, and uses the wrong distance to the Partridge River for the East Pit—Category 2/3 flowpath. In addition, the hydraulic conductivity distributions for the surficial aquifer are not technically justified, are based on means rather than the full range of measured values, and do not consider the likely presence of higher permeability features such as buried stream channels. It is unclear if different hydraulic conductivity values are chosen for each flowpath during each simulation. The GoldSim flowpaths are not accurate, compared to flow trajectories in the Mine Site MODFLOW model. With regard to transport, the effective porosity value is not justified and sorption parameters are speculative and not sufficiently conservative and do not account for the saturation of adsorbed solutes within flowpaths. Pollutant travel times are underestimated. The model does not consider lateral dispersion in the surficial flowpaths or vertical dispersion of chemicals into bedrock. The SDEIS provides no rationale for the assumption that groundwater can migrate long distances without any discharge to wetlands and streams. The FEIS should disclose where the model predicts upwelling of groundwater into wetlands and other surface water features.

Thematic Response

FEIS Mine Site MODFLOW modeling and hydrogeologic relationships for operations and closure conditions indicate that northward flow from the mine pits and Category 1 Stockpile would be non-existent or minimal. Northward flows (if any) would not be sufficient to cause impacts to groundwater or surface water. As a consequence, there are no northward groundwater flowpaths in the FEIS Mine Site GoldSim model.

The groundwater flowpaths in the Mine Site GoldSim model are simple streamtubes with uniform linear groundwater flow. While the linear flowpath streamtubes do not exactly line up with flow trajectories predicted by the Mine Site MODFLOW Model, the streamtubes have hydraulic gradients, recharge, flow directions, and flowpath distances that are similar to those generated by the MODFLOW model. The difference between the GoldSim flowpaths and results of the MODFLOW model are of secondary importance and do not diminish the reliability of the GoldSim predictions of groundwater transport from mine facilities to the evaluation locations and the Partridge River.

The assumption of constant saturated thickness for the GoldSim groundwater surficial flowpaths is reasonable given site data and the purpose of the flowpath analyses in the GoldSim model (that is, average groundwater flow and chemical transport).

The distance from the East Pit to the Partridge River is based on the average distance to the river shown on FEIS Figure 5.2.2-7 (2,120 meters or 6,955 feet).

The surficial aquifer hydraulic conductivity distribution used in the FEIS Mine Site GoldSim model represents the probabilistic distribution of the mean hydraulic conductivity and should not represent the full range of measured values. The range of the probability distribution is expected to capture natural heterogeneity in the flowpaths including the effects of buried channels (if any).

In the Mine Site GoldSim model, a different hydraulic conductivity distribution is used for each groundwater flowpath. A new hydraulic conductivity value for each flowpath is statistically selected at the beginning of each realization of the Monte Carlo simulation.

The effective porosity of 30 percent is reasonable for an unconsolidated granular material.

Not considering lateral and vertical dispersion tends to overestimate chemical concentrations in the surficial flowpath, which is conservative for impacts analysis.

The sorption values used for selected constituents are based on USEPA guidance documents. Due to the low absolute concentrations of constituents modeled with adsorption, it was reasonable (and standard practice) to assume that adsorption sites would not become “saturated.” This was also a reasonable assumption for fractured bedrock, because diffusion can transport chemicals from fractures into the rock matrix, which greatly increases the available adsorption sites. For constituents not modeled with adsorption, the approach was conservative because the transport analysis would tend to overestimate groundwater concentrations and underestimate travel times.

It is acknowledged that there could be groundwater discharge to wetlands along a surficial groundwater flowpath and this process is not incorporated into the GoldSim model. This process was not modeled because it is considered speculative and quantitatively uncertain. The Co-lead Agencies’ approach is to monitor water levels and water quality in the wetlands during operations, reclamation, and closure to identify mining effects on wetlands (if any). If monitoring

were to identify the potential for violation of regulatory criteria, adaptive mitigation measures would be initiated to mitigate the impact. See FEIS Section 5.2.3.3 for more information on wetland monitoring and possible future mitigations.

Theme WR 168

Theme Statement

There are numerous discrepancies and concerns regarding bedrock flowpaths used in the Mine Site GoldSim model. One critical issue is that the bedrock hydraulic conductivity is far too low compared to field testing and information from other sites. In addition:

- The model does not consider the effects of fractures, and uses inputs that are intentionally chosen to eliminate significant bedrock flow and transport;
- The model is biased in that it uses the Duluth Complex as the basis for very low bedrock hydraulic conductivity;
- The model inappropriately treats bedrock as being hydraulically isolated from the overlying surficial deposits; and
- The effective porosity and sorption values used for bedrock are unrealistic.

The SDEIS needs to be reviewed to account for these discrepancies.

Thematic Response

In the FEIS Mine Site GoldSim model, bedrock flowpaths have been reconfigured with a bulk hydraulic conductivity that is approximately one order of magnitude higher than what was used in the SDEIS. In addition, the flowpaths are remodeled to be 15 meters thick, consistent with the concept of an upper more-permeable bedrock zone interpreted from RQD data (in the SDEIS model, the bedrock flowpath was 100 meters thick). Fracture flow in bedrock is considered by using an appropriate bulk hydraulic conductivity and low effective porosity (0.05) as a reasonable surrogate for fracture porosity and chemical diffusion into the matrix between fractures.

The bedrock flowpaths in the Mine Site GoldSim model are physically situated in Duluth Complex rocks, so it is appropriate to use the Duluth Complex as the basis for bedrock hydraulic conductivity.

In the FEIS Mine Site GoldSim model, the bulk hydraulic conductivity of the bedrock flowpaths is two to three orders of magnitude lower than the hydraulic conductivity of the surficial flowpaths, so it is reasonable to neglect flow between bedrock and surficial deposits.

The sorption values used in the model are based on USEPA guidance documents.

Theme WR 169

Theme Statement

The Mine Site GoldSim model does not consider the presence of higher permeability bedrock structures (faults and fracture zones), despite the fact that these types of features are known to exist in bedrock. The model incorrectly assumes that pit water would not enter the bedrock groundwater system.

Thematic Response

The FEIS indicates that structural faults may exist between mine facilities and perennial streams that receive groundwater discharge. Because the landscape is covered with surficial deposits and there are limited bedrock outcrops, the existence of faults is conjectural and locations, at best, can only be inferred. It is unknown if faults (if and where they exist) behave as conduits or barriers to groundwater flow. Given these uncertainties, it is unlikely that a new, practical field program, with a goal to identify faults, would provide data to reasonably inform the impact assessments. The management approach is to set up a robust monitoring program during operations and closure to provide direct or indirect evidence on the existence of hydrologically significant faults. If significant faults are identified (i.e., faults which could lead to violation of water quality standards), then adaptive measures would be employed to mitigate the fault-related effects. See FEIS Sections 5.2.2.3.5 and 5.2.2.3.6 for further information.

Theme WR 170

Theme Statement

The Mine Site GoldSim model does consider the fact that uppermost bedrock tends to have higher hydraulic conductivity than deeper bedrock. This characteristic has been documented in evaluations at other nearby mine sites and in studies conducted by the Minnesota Geological Survey.

Thematic Response

In the FEIS Mine Site GoldSim model, bedrock flowpaths have been reconfigured with a bulk hydraulic conductivity that is approximately one order of magnitude higher than what was used in the SDEIS. In addition, the flowpaths are remodeled to be 15 meters thick, consistent with the concept of an upper more-permeable bedrock zone interpreted from RQD data (in the SDEIS model, the bedrock flowpath was 100 meters thick). Fracture flow in bedrock is considered by using an appropriate bulk hydraulic conductivity and low effective porosity (0.05) as a reasonable surrogate for fracture porosity and chemical diffusion into the matrix between fractures.

Theme WR 171

Theme Statement

An independent flow/transport model of the Mine Site and Plant Site developed and reported by Myers differs substantially from the SDEIS models. In particular, compared to the SDEIS models, the Myers model predicts: higher groundwater flow rates, higher pit dewatering rates, greater effects on the Partridge River, higher flow rates to the WWTF, higher sulfate concentrations in groundwater, higher stockpile seepage rates and concentrations, higher areal recharge, higher hydraulic conductivity of surficial deposits, and higher bedrock hydraulic conductivities. In addition, the Myers model predicts that copper concentrations would exceed water quality standards at the Partridge River that pump-and-treat of East Pit backfill is not hydraulically feasible, and that extensive drawdown would occur between the dewatered pits and the Partridge River. Some commenters have noted that the Myers model computed negative concentrations near chemical sources/sinks, which is impossible, and that some chemical sources have concentrations that are orders-of-magnitude higher than reasonable maximum field values.

Thematic Response

The differences between the Myers model and the FEIS models can be described as follows:

- The Myers model considers higher groundwater baseflows in perennial streams and this leads to higher recharge and higher hydraulic conductivities for surficial deposits. Reliable gaging data for the Partridge and Embarrass rivers indicate lower baseflows and associated lower recharge and hydraulic conductivities used in the FEIS models.
- The Myers model generally assigns higher hydraulic conductivities to bedrock units. These values are higher than what can be justified by field-testing at the NorthMet Project area or indicated in Barr 2014b, as cited in the FEIS).
- The Myers model does not include all groundwater capture systems presented in the FEIS Project Description.
- The Myers model does not use concentration caps, so that computed chemical concentrations in some mine-related chemical sources are much higher than what is reasonable or observed at other similar mine sites.
- The Myers model uses lateral and vertical dispersion, while the FEIS models do not. These uncertain processes tend to reduce chemical concentrations in the surficial aquifer, which is the dominating hydrogeologic unit that transports chemicals from mine facilities to the perennial rivers. With regard to dispersion, the Myers model would tend to compute lower chemical concentrations in the surficial aquifer compared to the FEIS models. By not considering lateral and vertical dispersion, the FEIS models tend to be conservative (i.e., more likely to overestimate impacts) compared to the Myers model.

These issues are discussed in more detail in the memorandum titled: “Comparison of the Myers Groundwater Flow/Transport model with the FEIS Impacts Analysis Models” (ERM 2015). Given the above deficiencies of the Myers model, it is not considered a reliable basis for evaluating future impacts associated with the NorthMet Project Proposed Action.

Theme WR 172

Theme Statement

The Mine Site GoldSim model should be revised to show groundwater concentration distributions along flowpaths at different points in time, as well as concentration distributions 200 years after closure. The FEIS should justify the use of cobalt as an indicator of nonreactive transport. For constituents assumed to be nonsorbed, the FEIS should state that actual migration velocities would be less than or equal to modeled seepage velocity. The FEIS should also acknowledge that groundwater concentrations are generally underestimated by the GoldSim model.

Thematic Response

Potential groundwater impacts are assessed at specific evaluation locations for each flowpath. This methodology satisfies both federal and state environmental review requirements to inform regulators, the project proponent, and public of the type, extent, and reversibility of impacts. Monitoring would typically occur at the source origins to document whether flowpath water quality predictions are being satisfied. If not, then contingency and/or adaptive measures would be applied to address potential concerns. See FEIS Section 5.2.2.1.1 for information on evaluation locations.

Cobalt was used to illustrate groundwater transport at the Mine Site because it is released by oxidation of the major source materials (waste rock and pit walls), is assumed in the GoldSim model to migrate unattenuated (i.e., travels in groundwater at an average velocity equal to the rate at which groundwater travels), and enter the surficial flowpaths at concentrations higher than baseline groundwater. Groundwater cobalt concentrations thus illustrate the time required for solutes released from sulfide-bearing mine waste to reach their peak concentration at the evaluation locations, as illustrated in concentration-versus-time plots (see FEIS Figure 5.2.2-19) and described in FEIS Section 5.2.2.3.2.

The FEIS has been modified to indicate that, “Some the constituents modeled as unattenuated in the GoldSim model may in fact exhibit some attenuation due to adsorption onto surfaces in the surficial and bedrock aquifer. The peak concentrations of these solutes would arrive at the evaluation locations later than estimated in the GoldSim model, though the peak concentrations of such late-arriving solutes would be lower than the concentrations estimated under the assumption in the FEIS of unattenuated transport” (FEIS Section 5.2.2.2.3, subheading “Contaminant Transport in Groundwater from Waste Rock”).

The GoldSim modeling was designed to evenly bracket uncertainty in model parameters, though ranges for a few parameters were skewed so as to tend towards producing higher concentrations at model evaluation locations. Thus, model results are an attempt to accurately represent a balanced assessment of uncertainty.

Theme WR 173

Theme Statement

There are numerous issues associated with chemical sources used in the Mine Site GoldSim model. Critical issues are that the model:

- Does not consider internal storage with the Category 1 and other stockpiles;
- Consistently underestimates chemical loadings (flow and concentration);
- Incorrectly assumes that chemical loading from submerged backfill and pit walls is near zero; and
- Provides no technical justification that East Pit backfill can be maintained saturated during pump-and-treat.

The FEIS should show flows and concentrations of water leaving chemical sources over time, flows and concentrations of water transferred between the Mine Site and Plant Site, residual concentrations at chemical sources after closure, and P90 concentrations over time. The use of concentration caps is not adequately explained or justified. In addition, the model does not consider: chemical leaching from unsubmerged pit walls, pit lake stratification, leaching from submerged pit walls due to dissolved oxygen in pit water, seasonal flushing of waste rock and pit walls, and that Category 1 stockpile drainage (and chemical loading) may vary over time or occur as slugs. The probabilistic inputs associated with chemical sources do not capture the full range of possible chemical loadings. The FEIS should acknowledge that the East Pit rinsing plan is untested and may fail, and that the north pit wall of the East Pit would contribute a substantial load of sulfate and metals to pit water. No groundwater capture systems are proposed downgradient of the pits, seepage through the Category 1 Stockpile may be underestimated, and pits and stockpiles remaining after closure would leach contaminated water for hundreds of years. With regard to the West Pit, the FEIS should acknowledge that the pit would not be a hydraulic/chemical sink when full, and that the plan for accelerated refill would cause contaminants to reach the Partridge River sooner, and the FEIS does not provide contaminant levels from the West Pit flowpath at the Partridge River where groundwater discharges to surface water. For the East Pit and West Pit, the FEIS should show predicted outflows (and concentrations) into surficial deposits and bedrock over time after closure. The Reclamation Plan should ensure that specific goals for pit pools are established and achieved.

Thematic Response

The GoldSim Mine Site model assumes that the waste rock and ore stockpiles start with water at an approximate “field capacity” (i.e., no water drains from the facility unless water enters the top, but if water does enter the top of the facility in a time step, then same amount would flow out the bottom). Although excess water is not stored in the rock, GoldSim maintains a mass balanced on all chemical constituents, so any solutes released from the rock than can’t dissolve and leach out in a time step are stored and released in later time.

The specific ranges for GoldSim parameters were selected to bracket evenly the uncertainty in model parameters and avoid underestimating estimates of chemical loading (MDNR et. al. 2011, as cited in the FEIS). In a few instances, model parameters are selected to produce larger ranges than indicated by simple statistical application of test data (e.g., solute release rates from waste

rock are based on the range in individual humidity-cell tests, not the range in the average; see Section 8.1.2.1 of PolyMet 2015q, as cited in the FEIS). But the Co-lead Agencies do not believe that there is a systematic bias toward underestimating flow or chemical load.

The rate of oxidation and associated release of acidity and metals from waste rock and wall rock after it is submerged under water was considered directly as part of the Impact Assessment Planning process (MDNR et. al. 2011, as cited in the FEIS). Supporting analysis found that after the rock was submerged by a layer of oxygenated water, the rate of oxidation in the rock would decrease by at least a factor of approximately 800 relative to the oxidation rate when it was exposed directly to atmospheric oxygen (Day 2008). Based on this analysis, which is consistent with general results of studies on subaqueous disposal of sulfide-bearing mine waste, the GoldSim model assumed that oxidation in submerged wall rock and waste rock was negligible.

FEIS Section 5.2.2.3.1 accurately describes how East Pit backfill would be flooded as it is emplaced during operations to maintain water within 5ft of the backfill surface using effluent from the WWTF and storm water runoff. The Co-lead Agencies' review of the model found that the footprints and depths of East/Central Pit are correctly incorporated into the three-dimensional model mesh, and that appropriate boundary conditions are used to simulate pit inflows. During reclamation (year 21 – 40), “water from the East Pit would also be pumped to the WWTF and treated...”, after which treatment of water in the East Pit may continue into closure and long-term maintenance (Section 2.1.1 of PolyMet 2015d, as cited in the FEIS).

Estimates for mass loading and effluent concentrations from Mine Site facilities are presented in Attachment I and J of PolyMet 2015m, as cited in the FEIS; for Plant Site tailings facility, values for these model results are presented in Attachments D through I of PolyMet 2015j, as cited in the FEIS. Estimated flows between facilities vary in response to stochastic parameters such as monthly precipitation, but characteristics describing water flow into groundwater flowpaths and average flows to treatment facilities are in Attachment B of PolyMet 2015j, as cited in the FEIS, and Attachment B (Input Variables for the Mine Site Model) of PolyMet 2015m, as cited in the FEIS.

Concentration caps are, “empirical upper-concentration values...estimated in part using measured behavior of laboratory tests on waste rock from the NorthMet Deposit [and] measured in effluent from field-scale facilities of similar waste rock Section,” is accurate (FEIS Section 5.2.2.2.3). Concentration caps are illustrated in measured composition of effluent from the Amax Stockpiles, in this case showing their dependence on pH (Large Figure 23 through 27 in the Waste Characterization Data Package—PolyMet 2015q, as cited in the FEIS).

Regarding the release of chemical loads as “slugs” from pit wall or waste rock, this can occur in the GoldSim model if solutes that exceed concentration caps are stored as labile phases. These stored loads would be released as a “slug” over a single time step if higher precipitation increases. Submerging backfill and wall rock produce a second type of slug, as any solutes stored in “non-contacted” rock are assumed to be released immediately upon inundated by water.

The ranges for probabilistic solute-release parameters were developed during the Impact Assessment Planning effort (MDNR et. al. 2011, as cited in the FEIS), and are adequate for representing uncertainty in estimates of water quality for the FEIS.

Regarding the absence of groundwater capture systems down gradient from the East Pit and West Pit, the analysis of effects presented in the FEIS are based on a model that does not have pit capture systems in place, and no additional capture trenches are proposed.

Seepage through the Category 1 stockpile is based on liner leakage rates for the cover, which are derived from combination of literature values, experience at mine sites, experience at other types of industrial facilities, manufacturer documentation, and information provided in standard engineering guidance documents (Section 5.2.2.3 in PolyMet 2015m, as cited in the FEIS). Liner leakage rates were estimated using the HELP model, where simulations combined NorthMet Project design values for slopes and subgrade design with the published values for average liner defects per acre.

It is acknowledged that there have been historical instances where poor-quality liner installations have failed or leaked at relatively high rates. However, for the high-quality liner installations to be used for the Proposed Action, the assumed liner leakage rates are reasonable and consistent with industry standards. While solid waste landfills may typically be smaller than the NorthMet facilities, the liner leakage rates are expressed on a unit area basis, so the results can be scaled to larger facilities.

It is acknowledged that the NorthMet Project Mine Site pits and waste rock would be long-term loads of some solutes to groundwater relative to the continuation of existing conditions. Estimates for these loads are presented in Attachment I of PolyMet 2015m, as cited in the FEIS.

The FEIS does not assume that the West Pit would be a sink, but instead acknowledges that outflow to the surficial and bedrock aquifers would be related to lake level. Concentrations in the West Pit Lake surficial and bedrock flowpaths are presented in Attachment J (Concentration Statistics at the Groundwater Evaluation Locations) of PolyMet 2015m, as cited in the FEIS.

The FEIS recognizes that active site management would be tied to attaining specific water-quality goals: “The objective of closure is to provide mechanical or non-mechanical treatment for as long as necessary to meet regulatory standards at applicable groundwater and surface water compliance points” (FEIS Section 5.2.2).

Finally, State rules for mineland reclamation and water appropriations require impacted watershed to be returned as close as possible to pre-mining characteristics.

Subtheme WR 173-1

Theme Statement

Provide values for volumetric flow rates and solute concentration estimates for the water released from each source and in each waste water stream, with concentrations before and after application of concentration caps and adsorption and reported in units comparable to water quality standards. Include specific values for solute concentrations and routing of runoff from waste rock.

Thematic Response

Estimates for mass loading and concentrations from the Mine Site facilities, including effluent from waste rock and ore stockpiles, are presented in Attachment H of the Mine Site Water Modeling Data Package (PolyMet 2015m, as cited in the FEIS). The assessment of

environmental effects is not based on concentrations in specific mine features, so the source concentrations are not presented with regulatory criteria. Rather, groundwater evaluation criteria are provided in Large Table 1 Groundwater Quality Standards Applicable to the NorthMet Project Modeling in the Mine Site Water Modeling Data Package (PolyMet 2015m, as cited in the FEIS). They also can be found in Section 5.2.2 of the FEIS.

The NorthMet GoldSim water quality model has not been run without concentration caps in source materials or adsorption-related attenuation in groundwater because these are widely observed effects in mine environments. Thus, eliminating these effects from the GoldSim model would not be realistic, and such a model would not improve the assessment of environmental effects.

Adsorption is widely observed in studies of metal transport in groundwater, and is an important-enough effect that the USEPA provides guidance documents with screening level values for adsorption (as “Kd”) to support estimates of exposure to solutes migrating in groundwater (USEPA 2005, as cited in the FEIS). This literature review by the USEPA indicates that Kd for the four metals assumed to be affected by adsorption in the NorthMet surficial aquifer (arsenic, antimony, copper, and nickel) vary widely across different sites. In response, the GoldSim modeling at NorthMet selected values from the low end of this range (i.e., values that produce rapid transport in groundwater, and thus earlier arrival at groundwater evaluation locations [PolyMet 2015j, as cited in the FEIS]). But eliminating entirely the effect of adsorption from the GoldSim model would not improve the assessment of environmental effects. The Co-lead Agencies thus do not believe that the GoldSim water quality model needs to be run without adsorption-related attenuation in groundwater.

The effect of concentration caps can be seen in measured composition of effluent from the Amax Stockpiles, in this case showing their dependence on pH (Large Figures 23 through 27, PolyMet 2015q, as cited in the FEIS). The selection of specific values for concentration caps was considered by the Co-lead Agencies (see Table 1, MDNR et al. 2011, as cited in the FEIS), and specific ranges for concentration caps in waste rock are presented in Tables 1-30 through 1-33 in the NorthMet Mine Site Water Modeling Work Plan (Barr 2012c, as cited in the FEIS).

Subtheme WR 173-2

Theme Statement

Provide estimates for pH, sulfate, and alkalinity predicted in the PolyMet pit lakes and tailings effluent, and compare these to the values observed in natural and mine-produced lakes in the region.

Thematic Response

Estimates for the concentration of all modeled solutes in the West Pit Lake are presented in the Attachment H of the Mine Site Water Modeling Data Package (PolyMet 2015m, as cited in the FEIS). For the Tailings Basin effluent, estimated concentrations are presented in Attachment G of the Plant Site Water Modeling Data Package (PolyMet 2015j, as cited in the FEIS).

The pH of water is a dynamic parameter that reflects chemical equilibrium condition, and is not predicted explicitly by the GoldSim model for any of the NorthMet Project area waters, including the West Pit Lake. However, the West Pit Lake is a component of the active water

management and treatment system during and after the 20-year operating life of the mine, and its water quality would be monitored as part of the NorthMet Project Proposed Action (PolyMet 2015d, as cited in the FEIS; Large Figure 1, Water Treatment Overall Flow Sheet-Operations, and Large Figure 3, Water Treatment Overall Flow Sheet- Long-Term Closure.)

Water quality in the West Pit Lake would be controlled by pumping and, where necessary, treatment. Most of the effluent from the Tailings Basin would be captured and treated, and the GoldSim model results and associated effects presented in the FEIS account for some bypass of the capture system. Because the environmental effect of the West Pit Lake and Tailings Basin are not dependent on water quality of other lakes, the Co-lead Agencies do not plan to compare model results for the West Pit Lake to water quality in other lakes in the region.

Subtheme WR 173-3

Theme Statement

Provide estimates of water balance on the Mine Site to illustrate whether the West Pit will eventually overflow.

Thematic Response

Plans for managing water in the West Pit during operations and into closure include actively maintaining the West Pit Lake water level so that it remains below the spillway to the Partridge River until the lake meets discharge standards. Specifically: “No discharges are planned from the Mine Site during operations and reclamation. During long-term closure, West Pit water would be pumped to the Mine Site Waste Water Treatment Facility (WWTF) as needed to prevent the West Pit from overflowing. An NPDES/SDS permit would be required to discharge WWTF effluent to the Partridge River” (PolyMet 2015m, as cited in the FEIS). Maintaining the West Pit Lake level below the discharge point is incorporated in the GoldSim modeling.

The FEIS Section 5.2.2.3.2 indicates that West Pit Lake water would not be allowed to overflow direct to the Partridge River until it can meet effluent limits.

Subtheme WR 173-4

Theme Statement

PolyMet should “bolt, wire, and shotcrete” the pit walls to inhibit the migration of water and pollutants in and out of the pit (as done by Kennecott at its Flambeau Mine).

Thematic Response

The current Mine Site GoldSim water quality model of the proposed West, Central, and East pits does not include any plans to add bolts or surficial coatings to the pit wall rock. Instead, the assessment of effects in the FEIS considers oxidation reactions and the associated solute release assuming that the wall rock is exposed to the atmosphere, and that oxidation ceases only when the wall rock is covered by backfill (in the East and Central pits), submerged by the pit lake (in the West Pit), or the available sulfide minerals are fully oxidized. The parameters used to estimate oxidation rates in pit walls (thickness of reactive veneer, decay in reaction rate, oxidation after wall rock is submerged in the lake, metal releases for different wall rock types,

etc.) were considered in detail by the Co-lead Agencies, and are described in the Waste Characterization Data Package (PolyMet 2015q, as cited in the FEIS), Section 9 Geochemical Parameters – Pit Lake. The estimates for wall rock oxidation rates used in GoldSim were consistent with observed rates in field studies at other mines. The Co-lead Agencies thus believe that the current analysis of environmental effects is adequate, and that the NorthMet Project Proposed Action does not need to alter the pit wall surfaces with bolts, wire, shotcrete, or other surface treatments.

Subtheme WR 173-5

Theme Statement

Provide estimate for the effects of outflow from the West-Pit and backfilled East and Central Pits on the quality of receiving groundwater, including an analysis where the sulfate concentration is much higher than currently predicted.

Thematic Response

Estimates for mass loading from the Mine Site facilities are presented in Attachment H of the Mine Site Water Modeling Data Package (PolyMet 2015m, as cited in the FEIS). The effect of effluent from these Mine Site facilities on the quality of receiving groundwater is presented in Attachment J.

The specific ranges for GoldSim parameters were selected by the Co-lead Agencies to evenly bracket the uncertainty in model parameters and avoid underestimating estimates of chemical loading. Comparison tests of the GoldSim model found that the model may underestimate solute release in some cases (e.g., a comparison of GoldSim estimates to measured effluent from the existing Amax piles found that the model tended to overestimate sulfate concentrations [PolyMet 2015q, as cited in the FEIS, Section 8.2.7 Scale-Up Model Verification]). But the Co-lead Agencies do not believe that there is a systematic bias toward underestimating chemical loading or concentration of sulfate or other constituents.

Subtheme WR 173-6

Theme Statement

Demonstrate that the reactive backfilled East Pit would remain saturated during mining and perpetually beyond this in closure.

Thematic Response

Water quality in the backfilled East Pit would be managed by actions taken before, during, and after flooding of the pit. At the time of initial backfilling, the waste rock and overburden material that is backfilled into the East Pit would be treated with limestone to reduce acidity and maintain basic pH (PolyMet 2015q, as cited in the FEIS). During operations, the East Pit would be flooded as backfill is emplaced to maintain water within 5 ft of the backfill surface using effluent from the WWTF and storm water runoff, as described in Section 5.2.2.3.1 of the FEIS. The Co-lead Agencies' review of the GoldSim model found that the footprints and depths of the combined East/Central Pit are correctly incorporated into the three-dimensional model mesh, and that appropriate boundary conditions are used to simulate pit inflows. The plan for treating water

in the East Pit backfill is not contingent on rapid flushing, but instead allows pumping at a rate that would not dewater the backfill.

During reclamation (years 21 to 40), "...water from the East Pit would also be pumped to the WWTF and treated..." after which treatment of water in East Pit may continue into long-term closure (PolyMet 2015d, as cited in the FEIS). The Co-lead Agencies believe that the existing plans, as described in the FEIS, are sufficient to ensure that the East Pit backfill would remain saturated perpetually beyond closure.

Subtheme WR 173-7

Theme Statement

Provide an estimate for pH in the West Pit Lake, along flow paths, and in the Partridge River.

Thematic Response

Solution pH is a dynamic parameter that reflects chemical equilibrium condition, and is not predicted explicitly by the GoldSim model for any of the NorthMet Project area waters, including groundwater, the Partridge River, and the West Pit Lake. However, sulfide minerals oxidation in the NorthMet mine rock can cause pH to decrease, and where pH becomes acidic, this causes an increase in oxidation rates, modeled concentration caps, and associated solute concentrations in leachate. These effects from pH are incorporated explicitly into the GoldSim model in the calculations of solute loads from both the non-acid-generating and acid-generating wall rock in the West Pit (PolyMet 2015q, as cited in the FEIS).

The lake water quality would be affected by pH (e.g., if the lake water became acidic, then concentration caps would be higher, and the concentrations of some metals could be higher). However, the West Pit Lake is not a passive basin, but is instead a component of the NorthMet Project Proposed Action's active water management system, so that during and after the 20-year operating phase, its water quality would be monitored and treated as part of the NorthMet Project Proposed Action (Large Figure 1 and Large Figure 3 of PolyMet 2015d, as cited in the FEIS).

Regarding predicting water quality along flowpaths, please see the response to theme WR 177.

Subtheme WR 173-8

Theme Statement

Expand model analysis to determine whether a slug of water and solutes could be released periodically from Waste Rock stockpiles.

Thematic Response

The GoldSim model of waste rock stockpiles is configured so that it can release slugs of accumulated solutes under three conditions. As observed in weathering of waste rock under field conditions, solutes are released from waste rock in proportion to the time over which it is exposed to air. During a dry period, GoldSim stores constituents released by oxidation as a soluble but immobile phase. These stored constituents are then available to dissolve and flush out as a slug in the first occurrence of percolating water, as would occur in a rainy month following one or more dry months. A second type of concentration slug occurs at the onset of acidic

conditions, where the constituent-release rates and concentration caps applied in the GoldSim model both increase (PolyMet 2015q, as cited in the FEIS). Third, waste rock submerged under water (i.e., as occurs in the East Pit backfill) produces a slug release when the solutes stored in non-contacted portion during the air-oxidation period are allowed to dissolve (up to the concentration caps) when the rock is submerged. The Co-lead Agencies believe that the GoldSim model configuration described in the FEIS adequately addresses slug releases of constituents from waste rock.

Subtheme WR 173-9

Theme Statement

Expand model analysis to consider solute transport in groundwater with no retardation effect.

Thematic Response

Adsorption is widely observed in studies of metal transport in groundwater, and is an important enough effect that the USEPA provides guidance documents with screening level values for adsorption (as “Kd”) to support estimates of exposure to solutes migrating in groundwater (USEPA 2005, as cited in the FEIS). This literature review by the USEPA indicates that Kd for the four metals assumed to be affected by adsorption in the NorthMet surficial aquifer (arsenic, antimony, copper, and nickel) vary widely across different sites. Adsorption parameters were also used from laboratory studies for antimony. In response, the GoldSim modeling selected values from the low end of this range (i.e., values that produce rapid transport in groundwater, and thus earlier arrival at groundwater evaluation locations [PolyMet 2015m, as cited in the FEIS]).

But eliminating entirely the effect of adsorption from the GoldSim model would not improve the assessment of environmental effects. The Co-lead Agencies thus do not believe that the NorthMet GoldSim water quality model needs to be rerun without adsorption-related attenuation in groundwater.

Subtheme WR 173-10

Theme Statement

Modify the model of the West Pit Lake to include the effect of sulfide oxidation caused by air pulled into the pit walls to fill the voids that are desaturated by groundwater drawdown.

Thematic Response

PolyMet provided the Co-lead Agencies with calculations used to determine the mass of sulfate released by the additional oxidation in pit wall rock caused by air pulled in to replace the voids emptied as groundwater in bedrock drains into the pit (PolyMet 2014b). This approach assumes that the volume of water extracted from bedrock is replaced by an equal volume of air, and all of the oxygen in this entering air reacts with sulfide minerals in the wall rock.

The volume of water extracted from bedrock was estimated to be equal to the total inflow to the pits from bedrock in the time between the beginning of mining and the time when pit flooding begins (i.e., the point of maximum drawdown in the bedrock). At the concentration of oxygen in

air ($8.89 \text{ mole O}_2/\text{m}^3$), the reaction ratio for pyrrhotite oxidation ($0.44 \text{ mole SO}_4/\text{mole O}_2$), and the molecular weight of sulfate (96 g/mole), each cubic meter of air pulled into the bedrock wall rock would release 375 g SO_4 .

In the West Pit, the estimated volume of water extracted from bedrock is $2.79 \times 10^5 \text{ m}^3$, which when converted to airflow into pit wall rock, would release $1.13 \times 10^5 \text{ kg SO}_4$.

When this mass is mixed into the full West Pit ($1.05 \times 10^8 \text{ m}^3$), this would add 1.1 mg/L to the concentration of the West Pit, or approximately 1.5 percent increase relative to the P50 concentration of 77 mg/L SO_4 estimated by GoldSim without this air-advection effect, and also approximately 1 percent of the range in uncertainty in West Pit sulfate concentration at year 20 (i.e., P10 to P90 range is approximately 50 to 100 mg/L [PolyMet 2015m, as cited in the FEIS; Figure H-11-24.2 SO_4 in the West Pit]).

For the East Pit, the MODFLOW model result indicates that $2.55 \times 10^6 \text{ m}^3$ of bedrock groundwater would be removed, and the air to replace it would produce $9.7 \times 10^5 \text{ kg SO}_4$. At the full volume of the East Pit ($1.44 \times 10^7 \text{ m}^3$), this would add 67 mg/L to the sulfate concentration, or an increase of 2.6 percent relative to the GoldSim model P50 prediction of $2,578 \text{ mg/L}$ sulfate in the current model without the air-advection effect.

The effects of advection-induced air oxidation are small for the Mine Site pits in part because the bedrock porosity is small (0.05; Barr 2012c, as cited in the FEIS, Table 1-1), so that drawdown around the pits would produce a relatively small amount of water from bedrock.

The Co-lead Agencies believe that constituent release from this advective air flow into bedrock by dewatering is small enough relative to both absolute concentrations and current uncertainty in the GoldSim model that this effect can be ignored in the FEIS.

Theme WR 174

Theme Statement

The Mine Site GoldSim model underestimates chemical concentrations in non-contact runoff from the mine facilities (particularly sulfate).

Thematic Response

Non-contact runoff from the NorthMet Project Proposed Action-related mine facilities represents overland flow that would not contact ore, tailings, waste rock, or processing residues. This flow would generally contact natural ground, soil/vegetated covers, and synthetic plastic materials. This water would not be chemically impacted to any significant extent and its chemical concentrations would be similar to natural runoff. See the response to theme WR 151 for additional information.

Theme WR 175

Theme Statement

The FEIS should include a sensitivity analysis for numerous parameters used in the Mine Site GoldSim model, including Partridge River baseflow. In the model, evapotranspiration from stockpiles should use a sample standard deviation rather than population standard deviation. The

FEIS should indicate what all pumped flows are used for, and should acknowledge that accelerated refill of the West Pit would increase chemical loading to groundwater. The FEIS should also acknowledge that chemical loading from the Mine Site is very small compared to natural loading in the Partridge River, and that the One Hundred Mile Swamp flows into the BWCAW.

Thematic Response

To better understand the relationship of groundwater baseflow to the GoldSim model's water quality impact projections, a sensitivity analysis for the Mine Site was conducted to evaluate if predicted Project impacts are sensitive to groundwater baseflow values. The sensitivity analysis considered the relationship of various model inputs to groundwater baseflow including hydraulic conductivity, recharge, and surface runoff chemical concentrations. It also reflected consideration of the flow data collected at SW-003 in requiring groundwater baseflows at all locations on the Partridge River be increased by a factor of 4 (e.g., 0.5 to 2 cfs at SW-003). The results indicate that modeled groundwater and surface water concentrations are sensitive to changes in groundwater baseflow. However, the NorthMet Project Proposed Action's ability to meet groundwater quality and surface water quality evaluation criteria is not sensitive to changes in baseflow. Evaluation criteria can be found in Section 5.2.2.

The probabilistic inputs for evapotranspiration are based on an evaluation performed at the Amax test pile (Eger and Lapakko 1985). Measurements and back-calculations performed in that study were used to develop a best-estimate mean and standard deviation of the stockpile evapotranspiration.

The FEIS has revised text to indicate where pumped flows are transported at both the Mine Site and Plant Site and between the sites. It is acknowledged in the FEIS that accelerated refill of the West Pit would result in seepage of impacted pit water into the West Pit surficial flowpath sooner than if the pit were to refill naturally. The FEIS acknowledges that chemical loading from the Mine Site would be small compared to natural chemical loading in the Partridge River and that there are portions of the One Hundred Mile Swamp that contribute water to the BWCAW, however those portions would be unaffected by the NorthMet Project Proposed Action.

Theme WR 176

Theme Statement

With regard to water treatment and discharge, the Mine Site GoldSim model underestimates pit inflows and, therefore, underestimates water treatment flow rates. If treatment rates are higher, sludge production would be higher and costs would be higher. The FEIS should provide flow rates and influent concentrations over time, treated water discharge locations, flows, and timing, and contingencies to handle extreme weather events.

Thematic Response

Pit inflows predicted by the FEIS Mine Site MODFLOW model and used to inform the FEIS Mine Site GoldSim model are sensitive to the hydraulic conductivities of surficial deposits and bedrock units. The MODFLOW model's prediction of pit inflows is reasonable because the hydraulic conductivities used in the model are best estimates, based on site characterization.

The FEIS contains new text and tables indicating water treatment flow rates, influent concentrations, and effluent concentrations over time. The FEIS also indicates where treated water would be transported to at different stages of the NorthMet Project Proposed Action. Because the GoldSim model uses monthly time steps, the analysis does not explicitly consider extreme storm events. However, the design of engineered facilities would entail Factors of Safety that ensure the ability to handle a 100-year storm event.

Theme WR 177

Theme Statement

Evaluation locations in the Mine Site GoldSim model do not adequately assess effects on groundwater and Partridge River surface water, and specifically do not address effects on the Partridge River upstream of evaluation location SW-004, which would be affected by chemicals from the Category 2/3 Stockpile and East Pit. In general, evaluation locations need to consider the nearest locations where impacted groundwater could affect wetlands and other surface waterbodies. The Mine Site GoldSim model does not provide a quantitative analysis of wetland effects, and incorrectly assumes that groundwater does not upwell into wetlands or other surface waterbodies along the surficial flowpaths. The FEIS should disclose that the groundwater quality criteria for cobalt, aluminum, and possibly copper are exceeded in the Category 2/3-East Pit surficial flowpath. The FEIS should provide a more detailed discussion of sulfate in the Partridge River, and should acknowledge that the model likely underestimates sulfate concentration in the River. The FEIS should show the distribution of chemical concentrations in the groundwater flowpaths at 200 years after closure. The model does not simulate appropriate (seasonal) timing of natural processes such as recharge. The model should evaluate specific conductance, which is a regulated water quality criterion. The assessment of effects should be based on both Health Risk Limits and Clean Water Act compliance points. Implementation of the Land Exchange alternative would also require different evaluation locations (property boundaries).

Thematic Response

Potential groundwater impacts are assessed at specific evaluation locations defined for each flowpath. This methodology satisfies both federal and state environmental review requirements to inform regulators, the project proponent, and public of the type, extent, and reversibility of impacts. Monitoring would typically occur at the source origins to document whether flowpath water quality predictions were being satisfied. If not, then contingency and/or adaptive measures would be applied to address potential concerns. See FEIS Section 5.2.2.1.1 for information on evaluation locations.

Surface water monitoring station SW-004 is used to estimate the effects of Mine Site facilities on surface water because it has baseline values for water quality and flow (Mine Site Water Modeling Data Package, Large Table 10 Surface Water Data Summary Partridge River Watershed and Wyman Creek) and incorporates the cumulative effects of solutes released from the Category 2/3 Stockpile and East Pit, Ore Surge Pile, WWTF ponds, and Overburden Storage and Laydown Area (PolyMet 2015m, Large Figure 28 Mine Site Groundwater Flow Paths – Surficial Aquifer). Thus, if the NorthMet Project Proposed Action did not cause a water quality exceedance at SW-004, then it would not produce an exceedance farther upstream, where

cumulative mine site loads would be proportionately smaller than the lower flows that would be observed upstream.

Figures showing sulfate groundwater concentration distributions through time for the West Pit and the Category 2/3 flowpaths are in Section 6.3.2 of PolyMet 2015m, as cited in the FEIS.

It is acknowledged that there could be groundwater discharge to wetlands along a flowpath and the Mine Site GoldSim model does not explicitly incorporate wetlands or potential hydraulic connectivity between wetlands and the surficial aquifer. This process was not modeled because it is considered speculative and quantitatively uncertain. The Co-lead Agencies' approach is to monitor water levels and water quality in the wetlands during operations, reclamation, and closure to identify mining effects on wetlands (if any). If regulatory criteria were violated, adaptive water mitigation measures would be initiated to mediate the impact. The monitoring and mitigation for potential indirect effects would be determined during permitting. FEIS Section 5.2.3.3 has been revised to include more information on the monitoring and mitigation plan for the potential indirect wetland effects.

Regarding exceedances in groundwater quality evaluation criteria in the Category 2/3-East Pit Surficial flowpath, predicted concentrations were compared to applicable criteria (Large Table 1 in PolyMet 2015m, as cited in the FEIS). Aluminum is a secondary standard (range 50–200 µg/L), established by the USEPA to assist with managing drinking water for aesthetic considerations; it is not based on risk to human health. Aluminum concentrations were estimated by GoldSim (Figure J-01-02.2 of PolyMet 2015m, as cited in the FEIS), but because local groundwater already exceeds the aluminum sMCL, estimated concentrations above the sMCLs are not be considered exceedances of the groundwater evaluation criteria (Section 2.1 of PolyMet 2015m, as cited in the FEIS). Cobalt is reported in the Category 2/3-East Pit Surficial flowpath (Figure J-01-02.2 of PolyMet 2015m, as cited in the FEIS), but cobalt does not have a groundwater quality criterion. The maximum copper concentration at the property boundary in this flowpath is far lower than 1,000 µg/L, the groundwater standard for copper of (Figure J-01-13.2 and Large Table 1, respectively, in PolyMet 2015m, as cited in the FEIS).

The GoldSim modeling was designed so as to bracket evenly the uncertainty in model parameters. The Co-lead Agencies do not believe that the Mine Site GoldSim model produces a systematic underestimate of sulfate concentrations in the Partridge River.

Recharge is simulated as a fraction of precipitation, and precipitation varies monthly (Attachment, B Input Variables for the Mine Site Model, Table 1-11 Seasonal Distribution of Annual Open Water Evaporation and Annual Precipitation, in PolyMet 2015m, as cited in the FEIS).

Electrical conductance provides an estimate for TDS. There are TDS standards for surface water (700 mg/L) and groundwater (500 mg/L), and, at the request of the MPCA, GoldSim results include estimates for TDS at each time step, calculated by summing major solutes (Section 6.2.6.2 of PolyMet 2015m, as cited in the FEIS).

The FEIS and associated estimates of solute concentrations in groundwater are for the evaluation locations as identified under the Land Exchange Proposed Action. There is no change in applicable evaluation locations across the land exchange alternatives.

The surface water quality standards used in the FEIS are from *Minnesota Rules* 7050, which derive from the Clean Water Act; where Lake Superior Basin rules apply (Chapter 7052, which

do consider human health), they are used as evaluation criteria (Section 2.2 of PolyMet 2015m, as cited in the FEIS). The groundwater evaluation criteria are generally federal or state drinking water standards, which are mostly health-based. Evaluation criteria can be found in Section 5.2.2.

Theme WR 178

Theme Statement

The Mine Site GoldSim model should be rerun. It does not incorporate known hydrology and geochemistry, and is not sufficiently accurate for effects evaluation. The Myers model produces results that are different from the SDEIS modeled effects.

Thematic Response

The Mine Site GoldSim model has been modified and rerun for the FEIS based on new monitoring data, recalibrations, and issues raised in comments to the SDEIS. The FEIS model is considered to be sufficiently accurate for impacts analysis.

The Co-lead Agencies have reviewed the Myers model (ERM 2015), but given the reliability issues discussed in WR 171, the Co-lead Agencies do not believe the results are valid for assessing NorthMet Project Proposed Action-related impacts in the FEIS.

Theme WR 179

Theme Statement

Due to the low bedrock hydraulic conductivities assumed at the Mine Site, the pit inflow rates used on the Mine Site GoldSim model are underestimated. The Myers model predicts pit inflow rates approximately two times higher than the rates used in the GoldSim model and also predicts extensive drawdown between the pits and the Partridge River. The GoldSim model should consider ranges of pit inflow rates, and should treat these as probability inputs in the model. West Pit inflows are also underestimated because Partridge River water would enter bedrock fractures and flow to the pit.

The GoldSim model does not evaluate the effects of large-scale drawdown associated with pit dewatering. The SDEIS should provide both the modeled drawdown at SW-003 and an explanation of the area used for groundwater inputs to the Partridge River and how those inputs correlate with the groundwater elevation contour map.

Thematic Response

Pit inflows predicted by the FEIS Mine Site MODFLOW model and used to inform the FEIS Mine Site GoldSim model are sensitive to the hydraulic conductivities of surficial deposits and bedrock units. These hydraulic conductivities are reasonable best-estimates, so the inflow predictions are reasonable best-estimates, as well. The Co-lead Agencies do not agree that the predicted pit inflows are underestimated.

The Co-lead Agencies have reviewed and acknowledge the existence of the Myers model, but given the reliability issues discussed in WR062 and WR171, the Co-lead Agencies do not

believe the results are valid for assessing NorthMet Project Proposed Action impacts in the FEIS. These issues are discussed in more detail in ERM 2015.

Best estimate pit inflows over time are determined from the calibrated FEIS Mine Site MODFLOW model and these results are used to inform the FEIS Mine Site GoldSim model. The uncertainty in the groundwater inflow rate is represented with a probability distribution that scales the model-estimated inflow values. This log-normal distribution is defined such that the mean is the MODFLOW-estimated value (scaling factor of 1.0) and the 95 percent confidence interval extends from approximately 0.75 to 2.0.

There is no evidence of pervasive fractures or faults that behave as groundwater conduits connecting the Partridge River mine pits. Pit inflows are related to the bulk hydraulic conductivity of bedrock units, which are inputs to the FEIS Mine Site MODFLOW model. Best-estimate pit inflows predicted by the MODFLOW model are used to inform the FEIS Mine Site GoldSim model.

Large-scale drawdown affects in bedrock associated with pit dewatering is assessed in the FEIS Mine Site MODFLOW model, not the Mine Site GoldSim model. See the Water Model Data Package for more information (PolyMet 2015m, as cited in the FEIS).

In the Mine Site MODFLOW model, the Partridge River is modeled with river cells having high conductance values. As a consequence, there is no appreciable groundwater drawdown at the River, including the SW-003 location. The model predicts that the Partridge River at SW-003 is a gaining stream for both the NorthMet Project Proposed Action and for Continuation of Existing Conditions. The areas used to compute river cell conductance values are explained in PolyMet 2015m, as cited in the FEIS. Conductance values were calibrated so that hydraulic heads in the vicinity of the river cells were similar to estimated groundwater levels in the surficial aquifer adjacent to the Partridge River.

Theme WR 180

Theme Statement

The SDEIS does not adequately consider future climate change impacts, including its effects on: weather patterns, rainfall, storm events, droughts, sea level rise, vegetation types, vegetation distributions or mitigation.

Thematic Response

Estimates of monthly and annual rainfall amounts were based on best available data obtained from weather stations near the Proposed Action site. In the GoldSim models, these parameters were treated as uncertain inputs and assigned probability distributions to capture the range of possible future conditions. While climate change may occur in the future, it cannot be stated at this time if in the long-term there would be more or less rainfall. Thus, the probabilistic approach to rainfall used in GoldSim represents a technically defensible method for dealing with this issue.

Individual storm events and frequency are not incorporated into the GoldSim models. Rainfall inputs are monthly and annual. The effects of individual storms are considered by designing facilities to handle a 100 year - 24 hour storm event based on current data. If over time, climate change causes a gradual increase in annual rainfall, the 100 year storm event would be redefined to a larger value and mine facilities would be upgraded to handle a larger design storm.

Theme WR 181

Theme Statement

The FEIS should describe the water balance and mechanisms of consumptive use at the Mine Site, including diversion of Colby Lake water for mine process, reduction of flows in the Partridge River, evaporation from ponds and pit lakes, increased evapotranspiration from wetlands, and evaporation and disposal of reverse osmosis reject water. The use of Colby Lake water for augmentation or consumptive use should be discouraged since it is a small lake and fresh water is scarce and valuable. Appropriating water from Colby Lake would lower its water quality. Regional impacts from water use should be considered.

Thematic Response

In the FEIS Project Description, there is no direct diversion of Colby Lake water to the Mine Site.

During operations, some of the mine pit inflow water would be sent to the Tailings Basin pond and used for process makeup water. This represents a water diversion from the Partridge River watershed to the Embarrass River watershed. Some of this water would percolate into the tailings, be collected at the tailings toes, treated, and discharged to Embarrass River tributaries for augmentation. The consumptive use this component of Colby Lake water would be evaporation from the Tailings Basin pond, water loss during ore processing, and disposal/evaporation of RO reject water when this water is eventually treated at the WWTP.

There is no expectation of increasing the overall area of wetlands at the Mine Site, so evapotranspiration from wetlands would not increase under the NorthMet Project Proposed Action compared to current (natural) conditions.

The Mine Site GoldSim model tracks all water diversions and the main consumptive uses at the Mine Site including evaporation from ponds, evaporation from pit lakes, and disposal/evaporation of RO reject water. Most other water flows are returned to the natural system with or without treatment.

The annual average water withdrawal rate from Colby Lake (sent to Plant Site) would be 1.68 cfs during operations. The annual maximum withdrawal rate during operations would be 3.89 cfs. During reclamation and closure and long-term maintenance, water would not be withdrawn from Colby Lake. There are no plans to use Colby Lake water to directly augment flows in perennial streams at the Plant Site.

During operations (mine years 0 to 20), water would be pumped from Colby Lake to the Plant Site and used for makeup water at the processing plant and the Hydrometallurgical Residue Facility. GoldSim tracks these flows and computes the water balance for Colby Lake on a time-step by time-step basis. The average Colby Lake drawdown was modeled at 0.3 feet, with an average annual water level fluctuation of about 3.6 feet, compared to 3.9 feet for zero withdrawal. During operations, the average inflow reduction to Colby Lake is estimated to be 0.6 cfs and the maximum inflow reduction (year 12) is estimated to be about 1 cfs. During closure and long-term maintenance, inflow to Colby Lake would be increased by an annual average of about 0.6 cfs. In the FEIS, the GoldSim model has been modified to provide more accurate estimates of the Lake water quality. While there are some project-related effects on the lake water chemistry, the Co-lead Agencies have concluded that the effects do not constitute an

unacceptable impact to Colby Lake. Because flow and water quality impacts to Colby Lake are minimal, it is further concluded that impacts downstream of Colby Lake would also be minimal and not constitute an unacceptable NorthMet Project Proposed Action-related impact.

Theme WR 182

Theme Statement

The FEIS should describe the water balance and mechanisms of consumptive use at the Plant Site, including reduction of flows in the Embarrass River, evaporation from the Tailings Basin pond, water use in ore processing, transfer of water to the Mine Site, and evaporation and disposal of reverse osmosis reject water. Dewatering water should be reused on site if possible. The FEIS should also describe the volume of water required, the water's origin, and the timeframes for use at the Tailings Basin.

Thematic Response

See the response to theme WR 181 for information on water diversions from Colby Lake, and between the Partridge River Watershed and the Embarrass River Watershed.

The Plant Site GoldSim model tracks all water diversions and the main consumptive uses at the Plant Site including evaporation from the Tailings Basin pond, water loss to ore processing, and disposal/evaporation of RO reject water. Most other water flows are returned to the natural system with or without treatment. The FEIS has a new table summarizing the quantities of consumptive water use at the Mine Site and Plant Site, including but not limited to items listed in the theme. See Mine Site Data Package and Plant Site Data Packages (PolyMet 2015m and PolyMet 2015j, respectively, both as cited in the FEIS) for a summary of NorthMet Project Proposed Action-related consumptive uses.

The GoldSim models track water balances for the Mine and Plant Site facilities, and many of these flows are reported in the FEIS. More comprehensive reporting of water balances is provided in the NorthMet Project Water Modeling Data Package Volume 1 - Mine Site" and "NorthMet Project Water Modeling Data Package Volume 2 - Plant Site" (PolyMet 2015m and 2015l, respectively, both as cited in the FEIS).

Theme WR 183

Theme Statement

The SDEIS does not demonstrate that mine water use and augmentation would maintain wetlands, headwater streams, and the St. Louis River Watershed hydrology.

Thematic Response

FEIS Section 5.2.2.3.2 summarizes that the NorthMet Project Proposed Action would not affect groundwater levels along the Transportation and Utility Corridor (other than as a result of the West Pit dewatering, which is discussed as part of the Mine Site) or at the former LTVSMC processing plant. The NorthMet Project Proposed Action would affect groundwater levels at the Mine Site during operations by dewatering the active mine pits and pumping water to the Plant Site (years 0 to 11) or to the East Pit and Tailings Basin (years 11 to 20). During years 20 to 40,

water from the Plant Site would be pumped to the West Pit to accelerate flooding and help return groundwater levels to near pre-mining conditions. However, potential impacts on wetland or stream hydrology are not expected beyond areas immediately adjacent to the West Pit (as estimated from the analog method of estimating indirect wetland impacts from mine pit dewatering). The monitoring and mitigation for potential indirect effects would be determined during permitting. FEIS Section 5.2.3.3 has been revised to include more information on the monitoring and mitigation plan for the potential indirect wetland effects.

The cumulative effects analysis in FEIS Section 6.2.3.3.1 of the SDEIS concludes that the NorthMet Project Proposed Action would not have a significant effect on the St. Louis River hydrology.

Theme WR 184

Theme Statement

Use of Colby Lake water (which has mercury concentrations of approximately 5 ng/L) to augment upstream flow would violate Great Lakes mercury standard of 1.3 ng/L.

Thematic Response

The NorthMet Project Proposed Action described in the FEIS would include treatment of all water that would be discharged at the Plant Site, including water used for flow augmentation. The amount of water from Colby Lake used for flow augmentation would be low; however, any water used for augmentation would be treated prior to discharge. PolyMet proposes that tributaries be monitored that extend from the Tailings Basin. Additional information has been included in FEIS Section 5.2.2.3.6.

Theme WR 185

Theme Statement

The SDEIS does not provide a technical justification for the requirement to augment flows to within 20 percent of current conditions, nor does it address minerals and nutrients to maintain aquatic ecology, wetland ecology, or the need of riverine systems to be flushed to maintain ecosystem health.

Thematic Response

The NorthMet Project Proposed Action described in the FEIS includes treatment of all water that would be discharged at the Plant Site including water used for flow augmentation. The amount of water from Colby Lake used for flow augmentation would be low; however, any water used for augmentation would be treated prior to discharge. PolyMet proposes that tributaries that extend from the Tailings Basin be monitored. Additional information has been included in FEIS Section 5.2.2.3.6. Potential impacts on aquatic species are addressed in FEIS Section 5.2.6.

Theme WR 186

Theme Statement

The FEIS discussion of stream augmentation needs to consider flows in Yelp Creek and other tributaries of the Partridge River and Embarrass River.

Thematic Response

The FEIS evaluated the need for stream augmentation as a result of the NorthMet Project Proposed Action. The flow of Yelp Creek would not change. Flow to the tributaries of the Embarrass River and Second Creek would be augmented under the NorthMet Project Proposed Action. Partridge River flows would not require augmentation. The FEIS recommends surface water flow monitoring in creeks and rivers surrounding the NorthMet Project area. If data were to indicate that the NorthMet Project Proposed Action had resulted in unacceptable flow reductions, augmentation would be considered.

Theme WR 187

Theme Statement

The FEIS discussion of stream augmentation needs to consider flows in the Partridge River at SW-004a, SW-004, SW-003 and SW-002.

Thematic Response

Partridge River flows would not require augmentation because the MDNR does not require augmentation unless the median annual flow changes by more than 20 percent. This threshold is not predicted to be exceeded at SW-004, which is an appropriate location to assess potential drawdown. The FEIS recommends surface water flow monitoring in creeks and rivers surrounding the NorthMet Project area. If data were to indicate that the NorthMet Project Proposed Action had resulted in unacceptable flow reductions, augmentation would be considered.

Theme WR 188

Theme Statement

The FEIS discussion of consumptive use and augmentation must consider the effects of prolonged droughts.

Thematic Response

This issue would be relevant to the NorthMet Project Proposed Action if augmentation water were not available to maintain surface water flows to within 20 percent of what they would be under drought conditions without the NorthMet Project Proposed Action. Typically the two go hand-in-hand. During a drought, there could be less water available for augmentation, but the amount of augmentation water needed to maintain lower surface water flows under drought conditions would also be less. The sources of augmentation water for the NorthMet Project Proposed Action (mainly water treatment effluents) are expected to be sufficient to handle

normal and drought conditions. The Co-lead Agencies' approach is to monitor the amount of augmentation water required and available for years with variable rainfall and evaluate if a shortfall could occur during a prolonged drought. If it were apparent that a shortfall could occur, adaptive measures would be proposed to ensure that the 20 percent requirement could be met during a prolonged drought.

Theme WR 189

Theme Statement

There are numerous general concerns with and deficiencies in the GoldSim model used for the SDEIS. These concerns relate to model assumptions, inputs, and methodology, as well as inadequate QA/QC and the appropriateness of using GoldSim for a mining project. In addition, the model should include a scenario with probable maximum precipitation. Modeling is not reliable out hundreds of years. The water models should be re-run.

In addition, the SDEIS itself has numerous general deficiencies. The FEIS should have a better discussion and explanation of GoldSim setup, inputs, accuracy, and assumptions, which inputs are treated as probabilistic, and should acknowledge that GoldSim has not been widely used for NEPA effects analysis. The FEIS should better explain the reasons for using 200- and 500-year simulations. In addition, the FEIS should report flows and concentrations at all facilities and discharge locations; should acknowledge that chemically impacted mine water would enter groundwater and surface water outside the property boundary; and should acknowledge that under closure, streamflows would not return to pre-mining conditions. Presentation of exceedances is inconsistent between supporting documentation and the SDEIS.

Thematic Response

The GoldSim model was selected because it includes the computational tools required to conduct probabilistic simulation of the NorthMet Project Proposed Action water balance, solute release, and solute transport. Specific QA/QC procedures that were applied to the data collection and modeling are in Section 4.3.4.3 and Attachment L of PolyMet 2015m, as cited in the FEIS, and Section 4.3.4.3 and Attachment N of PolyMet 2015j, as cited in the FEIS. The level of QA/QC conducted for the FEIS is adequate, and the GoldSim Model is an appropriate tool for simulating water balance and water quality.

The FEIS provides adequate detail on the GoldSim model's setup. FEIS Section 5.2.2.2.3 (Water Quality Modeling [GoldSim]) describes GoldSim as a computer platform designed to conduct dynamic simulations and that includes the ability to conduct probabilistic analysis. Subsections of FEIS Section 5.2.2.2.3 provide details on the assumptions used to estimate water flow and the release and transport of solutes at both the Mine Site (Partridge River Watershed) and Tailings Basin (Embarrass River Watershed). In particular, details of the GoldSim model design and its simulation of proposed features are presented in FEIS Figures 5.2.2-7 and 5.2.2-10.

It is acknowledged that the NorthMet Project Proposed Action would release solutes and cause an increase in loading of some solutes to surface water and groundwater relative to the continuation of existing conditions. Estimates for mass-loading from Mine Site facilities are presented in Attachment I of the Mine Site Water Modeling Data Package. Estimates for mass-loading from the Plant Site Tailings Basin are presented in Attachment G of PolyMet 20105j (as cited in the FEIS).

It is also acknowledged that the NorthMet Project Proposed Action would alter stream flows relative to existing conditions. However, the flows would be similar to existing conditions. Where and when necessary, surface streams would receive treated augmentation water to maintain stream flow to within plus or minus 20 percent of existing natural flows. The augmentation water would generally consist of water obtained from the capture systems or mine pits, and treated at the WWTF or WWTP prior to discharge.

The Co-lead Agencies have made an attempt to communicate modeling results clearly in the FEIS. Deviations from the presentations in technical documents were at times necessary. Mine Site GoldSim inputs—be they deterministic or uncertain—are contained in Attachment C of PolyMet 2015m, as cited in the FEIS, and Attachment B of PolyMet 2015j, as cited in the FEIS. It is acknowledged that modeling results for hundreds of years in the future should be viewed with appropriate caution.

An Environmental Impact Statement need not evaluate worst-case scenarios associated with extreme flooding or drought or identify mitigation or management activities around those scenarios. The FEIS and its supporting documentation do disclose a range of potential environmental effects that can be anticipated and identifies mitigation for those effects as appropriate.

Theme WR 190

Theme Statement

The NorthMet Project Proposed Action minimizes water resource impacts. Similar mines have experienced success. Water model runs sufficiently disclose impacts by presenting results out to 200 or 500 years to address slow moving water. Effects on water resources in the NorthMet Project area and in the Lake Superior Basin have been thoroughly addressed in the SDEIS and reviewed by Co-lead agencies and deemed satisfactory. Water treatment and capture systems designs, engineering controls, and monitoring and mitigation measures would protect water resources. The water model demonstrates that the NorthMet Project Proposed Action would meet the standards set in Minnesota state law and federal initiatives. Acid rock drainage would not be created.

Thematic Response

These comments generally supported the findings in the SDEIS that the NorthMet Project Proposed Action would minimize impacts to water quality. Because no specific information was provided, no changes were made to the EIS.

Theme WR 191

Theme Statement

The FEIS should address the quantities or volumes of sediment from erosion that could contaminate surface water.

Thematic Response

PolyMet proposes to collect non-contact storm water runoff from undisturbed and reclaimed vegetated areas within the Mine Site and route it to the Partridge River via existing drainage patterns to the extent possible. There would be the potential for increased suspended solids. PolyMet would provide sedimentation ponds at the outlet locations to manage suspended solids prior to discharge to surface waterbodies (see Figures 3.2-5, 3.2-6, 3.2-7, and 3.2-8). These sedimentation ponds should be adequate to manage suspended solids, but monitoring of the discharge is recommended as part of any water quality permit. Due to the containment systems at the Plant Site, no erosion is expected to impact surface waters downgradient from the tailings basin.

Theme WR 192

Theme Statement

The P90 impact threshold can be interpreted differently. One in ten projects might result in unacceptable contamination. Ten percent of the time concentrations of solutes would be higher. Descriptions of how P90 values are determined from GoldSim runs (described in the SDEIS page 5-77) appears incorrect. P90 level presents the worst-case analysis of water quality (SDEIS page 5-77) are simply untrue as the P90 level presents a worst-case scenario only if everything goes exactly as intended: if no mistakes were made in designs, calculations, or modeling inputs, if no mistakes are made in operations, if no larger-than-expected storms occur, etc.

Thematic Response

The GoldSim model was developed primarily to estimate the effects on surface and groundwater quality from the NorthMet Project Proposed Action. NEPA does not require probabilistic analysis for disclosing effects, but a probabilistic model yields a more realistic estimate for predictions by addressing the uncertainty of some input parameters than simpler modeling methods. A second benefit of using a probabilistic model is the ability to accommodate divergent opinions. In this case, competing perspectives among technical experts could often be addressed by widening the range of values for specific model parameters.

A disadvantage of using a probabilistic model is that it increases the burden on the EIS preparer by producing results that are more complicated to interpret and explain. For the NorthMet Mining Project and Land Exchange FEIS, the major simplification is to use the P90 model results when comparing simulation results to water quality evaluation criteria. If the P90 concentration of a solute equals the evaluation criteria, then there is a 10 percent probability that the actual concentration would exceed the criteria. The P90 concentration is not a “worst-case” value, but rather a model threshold selected so that plans are based on solute concentrations than are probably higher than would actually occur. In the NorthMet GoldSim results, nearly all of the

P90 solute concentrations were below the evaluation criteria at evaluation locations, so the chance that any of these would exceed the criteria is less than 10 percent. Further, when comparing model results to evaluation criteria, the comparison used the maximum P90 model value obtained from over the entire simulation period (200 or 500 years for Mine Site and Plant Site, respectively). In these cases, if the P90 equaled the evaluation criterion, it would mean that there is a 10 percent chance that the concentration of the solute would ever exceed the criteria, and that over most of the simulation period, the chance of exceedance would be less than 10 percent. Importantly, the water quality model is designed to provide a reasonable estimate for water-quality effects and to help plan for water treatment, but it is not a guarantee of outcomes. Actual protection of quality in receiving waters would rely on the monitoring and contingency plans put in place during the permitting and financial assurance process.

The discussion in the FEIS under the “Application of Evaluation Criteria to Probabilistic Modeling Results” heading in Section 5.2.2.2.3 has been revised to more clearly describe the interpretation of probabilistic water quality model results.

Theme WR 193

Theme Statement

The XP -SWMM and GoldSim models are not accurate predictors of potential pollutant inputs into these riverine systems. The potential for overflow during large storm events were not part of these model calculations. The Co-lead Agencies did not require PolyMet to consider the stochastic modeling capabilities of MODFLOW and MT3DMS (the transport module available for use with MODFLOW). Nor does PolyMet provide any support for its statement that GoldSim is “widely used in the industry.” The Co-lead Agencies have not demonstrated why a publicly available model, such as MODFLOW, which was used in the initial DEIS in 2009, is not adequate and more accepted to characterize the water quality and quantity at the PolyMet site. Use of a publicly available model, such as MODFLOW, rather than a proprietary one, would have made review and analysis of the PolyMet model far easier for the public.

Thematic Response

The NorthMet Project Proposed Action facilities would be designed with excess storage to handle large storm events by routing water to mine pits or the Tailings Basin pond instead of discharging untreated contact water. In the event of an extreme event (e.g., 100-year storm), excess water would remain in the mine pits, which would essentially have unlimited storage capacity with mine operations in the pits temporarily shut down. Even during an extreme event, no untreated water would be discharged to a natural waterbody. More information on storm water would be acquired during permitting.

Regarding use of a publicly available model, selecting GoldSim was in part a response to public comments on the DEIS to improve the transparency and comprehensibility of the modeling, as well as disclose probabilities of outcomes to help the public and Co-lead Agencies assess environmental risks. See FEIS Section 5.2.2 and FEIS definitions for more information.

By downloading the free GoldSim Player, one can view, navigate, and run GoldSim models. This allows a modeler to distribute a model to others without requiring them to license GoldSim. Manuals are also available free for download.

Theme WR 194

Theme Statement

The use of the Duluth Complex as a hydrogeologic analogue is difficult to support. The Giants Range Batholith is Archean in age, more than 1.5 billion years older than the Duluth Complex, and therefore the assumption that the two units have similar stress, weathering, and erosional histories is deficient when applied to numerical modelling of smaller-scale sites, especially for predicting solute transport. Instead, the development of conceptual models that employ techniques whereby discrete fractures or fracture zones are more fully considered, results in improved prediction of solute transport, including better estimates of travel times, and recognition of variation in flow directions and discrete pathways in three dimensions.

Thematic Response

It is presumed that this comment refers to using the Duluth Complex as a hydrologic analog for the Giants Range Granite at the Plant Site. In fact, the only conceptual connection made between the Duluth Complex and Giants Range Granite is the idea of the upper 10 to 15 meters of bedrock being more fractured and more permeable than deeper bedrock. Due to the large number of exploration coreholes at the Mine Site, there are abundant RQD data to support this concept. The limited RQD data at the Plant Site do not conflict with this concept, but do not provide sufficient independent data for a firm interpretation. There are studies conducted at other sites to indicate that an upper more-permeable zone in bedrock is typical of the Iron Range, regardless of the bedrock rock type. So the RQD observations in Duluth Complex rocks at the Mine Site are taken as credible evidence that upper Giants Ridge Granite at the Plant Site also has an upper zone 10 to 15 meters thick with increased fracturing and hydraulic conductivity compared to deeper bedrock. Note that the hydraulic conductivity of the upper zone of Giants Range Granite is determined from 2014 packer tests conducted in five boreholes along the perimeter of Tailings Basin that were advanced 4.0 to 6.2 meters below the top of rock (not Duluth Complex testing conducted at the Mine Site).

Methods have been developed evaluating chemical transport through discrete fracture systems in hard rock. However, it is acknowledged within the industry that these theoretically based methods are simply not practical and reliable for large field sites. Discrete fracture transport models require intensive characterization of fracture apertures, orientations, and pervasiveness that can never be accomplished for a large field area. These models have only been applied successfully to small rock masses at pilot test sites, but never to a large-scale field problem. For field-scale evaluations, the standard of the industry is to treat fractured rock as an equivalent porous medium and use surrogate parameters (e.g., low effective porosity) to model chemical transport within the large rock mass. This is the approach taken in the FEIS and it is the only practical method that can be employed for impact evaluation.

Theme WR 195

Theme Statement

The NorthMet Project Proposed Action is a source of great concern and should not proceed due to potential impacts to water resources or the duration of water treatment necessary. There is a lack of experiential and other evidence to support the claim that sulfide, open pit copper nickel, or copper cobalt mining can be done without causing watershed pollution; it cannot be demonstrated that contaminated groundwater or surface water won't leave the site; it is contrary to MDNR's mission, the NorthMet Project Proposed Action would violate water quality standards for generations to come; the costs would not be worth the benefits, water is a natural resource with inherent economic value, it is more valuable than ore, it is essential to Minnesotans' quality of life and water quality in lakes and rivers should be protected.

Thematic Response

The hydrologic and water quality modeling indicate that impacted groundwater would leave the NorthMet Project. At the Mine Site, this would include seepage of West Pit and East Pit water into groundwater during closure that would slowly migrate south to the Partridge River. If flow to the north via bedrock is predicted, mitigation will be implemented to prevent it. At the Plant Site, surficial groundwater would bypass the capture system and allow subsurface tailings water to continue a slow migration towards the Embarrass River. A key feature of the NorthMet Project Proposed Action is to evoke management strategies and engineered facilities that would minimize the flow of impacted water leaving the NorthMet Project area to a rate that is small compared to diluting recharge and diluting flows in the rivers (hundreds to thousands of gpm). The GoldSim water quality models acknowledge and quantify the flow rates and chemical concentrations of these excursions from the Mine Site and Plant Site, but show that the associated chemical-loading would be sufficiently small that groundwater quality evaluation criteria would not be exceeded at the evaluation locations. Further, the modeling shows that water quality evaluation criteria either would not be exceeded in surface water or would not increase the frequency of exceedances that would occur under non-NorthMet Project Proposed Action conditions.

It is acknowledged that operation, maintenance, and periodic replacement of environmental controls would be required during closure. Regardless of the precise duration of effects or water treatment at either the Mine Site or Plant Site, there would be measures available to address impacts to natural resources. *Minnesota Rules* 6132.3200 specifies that it is a goal for a mining area to be maintenance-free. Passive water treatment is described as a long-term goal if future pilot studies were to demonstrate that it could be successful. The decision to go to passive treatment at some time in the future would be based on monitoring of actual NorthMet Project area conditions and pilot-testing, rather than predictive modeling and would be subject to applicable permitting requirements at that time. Regardless of treatment mechanism, financial assurance would be required under *Minnesota Rules* 6132.1100 before the State of Minnesota's Permit to Mine can be issued. Permit conditions and financial assurance would be required to perform reclamation and closure activities for as long as these activities are needed. FEIS Section 3.2.2.4 describes financial assurance process and requirements.

Theme WR 196

Theme Statement

The effects to water resources cannot be modeled satisfactorily due to climate change and the uncertainty about future hydrology, which prevents a comprehensive analysis of water flow. Climate change is progressing so rapidly that it is not possible to predict with accuracy the extent of pollutant migration into the hydrological system. Mitigation must be planned from the basis that passive water treatment is not applicable due to the inability to accurately project rainfall and to accurately project future rainfall and climate change.

Thematic Response

Passive water treatment is not part of the Project Description and is only described as a long-term goal if future pilot studies were to demonstrate that it could be successful. The decision to go to passive treatment at some time in the future would be based on monitoring of actual NorthMet Project area conditions and pilot-testing, rather than predictive modeling and would be subject to applicable permitting requirements at that time.

Climate change is a legitimate concern, but its effects are not rapid as indicated by climate modeling done by research institutions and government agencies. It is the Co-lead position that long-term monitoring of climate and NorthMet Project area conditions would provide adequate advanced warning that climate change issues needed to be addressed and adequate time to implement adaptive mitigation measures if they are needed.

Theme WR 197

Theme Statement

The FEIS should address potential environmental impacts to water resources from the NorthMet Project Proposed Action, not only state if the water quality standards would be met. Potential environmental analyses or discussions that should be added to the FEIS include: how water quality is determined; if the environmental impacts are greater as water is being released into two watersheds; how evaporation in backwaters, marshes and ephemeral flooded ponds affects constituent loading; if filling of wetlands would increase flooding; whether or not there is any point along the Embarrass, Partridge, or St. Louis Rivers where sulfate or metals would tend to precipitate (due to local chemistry) and accumulate mass of additional sulfate and other metals build up in Colby Lake (Partridge River) or Sabine or Wynne Lakes (Embarrass River); whether or not the mass of sulfate would lead to an increase in the methyl mercury concentrations in Colby, Sabine, or Wynne Lakes; and whether the high volume carries those pollutants down to Lake Superior and the St. Louis River delta.

Thematic Response

Water resources are considered not to be significantly impacted if water quality evaluation criteria are met at evaluation locations and there are no substantial changes to surface water flows. If water quality evaluation criteria are not met under the Continuation of Existing Conditions modeling scenario, the FEIS evaluates whether the NorthMet Project Proposed Action causes or increases concentrations to an unacceptable degree. Using these definitions,

GoldSim water quality modeling predicts that the NorthMet Project Proposed Action would not lead to impacts to groundwater and surface water.

The modeling indicates no significant impacts at downstream station SW-005 on the Partridge River and PM-13 on the Embarrass River. Although modeling was generally not performed downstream of these surface water locations (except Colby Lake), it is concluded that there would be no impacts downstream of the locations since natural processes tend to not increase surface water concentrations.

Surface water features mentioned in the theme text are generally not on flowpaths with water potentially affected by the NorthMet Project Proposed Action.

Predicted chemical concentrations in off-site, potentially NorthMet Project Proposed Action-affected waters are not high enough to cause precipitation or solids accumulation in surface waterbodies.

Theme WR 198

Theme Statement

The Mine Site and Plant Site are in a water rich part of the country that is subjected to freeze and thaw conditions. This would cause extreme challenges to pollution prevention.

Thematic Response

Given the mitigation proposed for the NorthMet Project Proposed Action and the experience of the mining industry in cold climates, freeze and thaw are not expected to compromise PolyMet's ability to operate in accordance with regulatory requirements.

Theme WR 199

Theme Statement

Studies should be done of the water quality in areas proposed to substitute for the exchanged lands in the Partridge River watershed.

Thematic Response

FEIS Sections 4.3.2, 5.3.2, and 6.3.2 discuss water resources in area of the Land Exchange Proposed Action.

Theme WR 200

Theme Statement

Mining does not appear in the list of six water allocation priorities allocation determined by the commissioner (SDEIS page 4-23), and would appear to be a low priority for allocation of water. It is not explained who the commissioner is or what organization the commissioner is with.

Thematic Response

The MDNR Commissioner (currently Commissioner Landwehr) has responsibility for adopting rules allocating waters for consumptive use based upon priorities contained in Minnesota Statute 103G.261.

Theme WR 201

Theme Statement

Much of the information in Chapter 5 of the SDEIS depends upon the use of water models with which a layperson has no familiarity. Chapter 5 also uses technical terms and technical documents which are difficult to understand. Supporting information for technical documents sometimes cannot be found. Therefore, the ability to judge whether the models being used for decision making are competent has to fall to the experts; however, there is no discussion of the water models by experts in the SDEIS. Despite the use of many water models, a lot of this work appears to be “educated guesswork” that would have to be field monitored and checked for accuracy at the time the mine is operating and that is pretty late to make changes.

Thematic Response

The Co-lead Agencies have attempted to clarify and simplify FEIS text. Summaries are provided in the Executive Summary, and in the first part of each section within FEIS Chapter 5, including Section 5.2.2 for water impacts from the NorthMet Project Proposed Action. FEIS supporting information can be acquired by contacting the MDNR Environmental Review Unit. The text in the FEIS reflects the opinions of water resources experts from the Co-lead Agencies and that of other experts who have provided input to the FEIS through comments or direct dialogue with the Co-lead Agencies. It is acknowledge that monitoring of the NorthMet Project Proposed Action is a critical element to understanding and controlling environmental impacts and enforcing regulatory requirements.

Theme WR 202

Theme Statement

The SDEIS does not describe water resources impacts from probable or worst-case NorthMet Project Proposed Action failure scenarios or weather events.

Thematic Response

Neither NEPA nor MEPA implemented through Environmental Quality Board Rules requires the evaluation of worst-case or failure event scenarios. By not explicitly considering these scenarios, the Co-lead Agencies are adhering to these regulations.

Theme WR 203

Theme Statement

Mineral exploration leads to environmental harm. This impacts baseline conditions and was not considered. How can the USFS ignore the lack of funding to monitor the extent of exploratory drilling and the necessary future monitoring of the sites for acid mine drainage?

Thematic Response

Natural background (unimpacted) conditions have been disclosed in the FEIS informing the baseline for the evaluation of environmental effects.

Theme WR 204

Theme Statement

The discussion of beryllium, thallium and manganese groundwater concentrations at the NorthMet Project Proposed Action site is misleading. Water samples have been impacted by mining. Concentrations of manganese in surface waters at the former LTVSMC tailing basin already exceed Minnesota's Health Risk Limit.

Thematic Response

Natural background concentrations were used to establish groundwater evaluation criteria for impact evaluation in FEIS Section 5.2.2.1. The same dataset that was used to define natural background water quality for use in the water quality impact modeling was used to develop site-specific evaluation criteria for the FEIS. At the Plant Site, 49 background thallium samples were collected from the bedrock and 50 background manganese groundwater samples were collected from the surficial aquifer. At the Mine Site, 320 background beryllium groundwater samples were collected from the surficial aquifer and 49 samples were collected from the bedrock. Three hundred and eleven background manganese groundwater samples were collected from the surficial aquifer and 49 background manganese samples were collected from the bedrock. Forty-nine background thallium samples were collected from the bedrock. For information on how evaluation criteria were determined, see Section 4.3.4.2 of PolyMet 2015j, as cited in the FEIS, and Section 4.3.4.2 of PolyMet 2015m, as cited in the FEIS.

A.6 RESPONSES TO EDITORIAL COMMENTS

Table A-4 lists each editorial comment, the name of the sender, and the corresponding response.

Table A-4 *Editorial Comments and Responses*

Sender	Comment	Response
1854 Treaty Authority	This section also contains language about “1854 Treaty Authority-regulated species”. We suggest removing or altering this language. The Fond du Lac Band also exercises treaty rights in the 1854 Ceded Territory, and has their own regulations. Further, the 1854 Treaty Authority maintains seasons and limits on some species, but these are not the only species of importance.	Text has been added to clarify the definition of “1854 Treaty Authority-regulated species” in Section 5.2.9.2.2. As discussed in this section, Fond du Lac has its own regulations applicable to the 1854 Ceded Territory. The discussion of “1854 Treaty Authority-regulated” species or resources is not inclusive of all species important to the Bands. Instead, the lists serve as the most updated and best available data for the most common game species or tribally harvested resources on the 1854 Ceded Territory.
Becky Milanese	GLOSSARY Page lx- geosynthetic membrane cover- what is this made of and would we expect decomposition over time from natural forces or the sulphuric wastes?	Chapter 3 includes information on the proposed geomembrane covers.
Becky Milanese	IMPLAN- How accurate is this model? Who or which agency uses this modeling?	IMPLAN is described in Section 5.2.10.
Becky Milanese	MODFLOW- How accurate is this and who uses it?	MODFLOW is a water model used for impact analysis as described in FEIS Section 5.2.2.
Becky Milanese	National Pollutant Discharge Elimination System (NPDES) Permits- No agency is listed as responsible for issuance of these permits and setting their limits and requirements.	FEIS Section 2.6 discusses permits and describes that the MPCA would be responsible for NPDES permits
Becky Milanese	Page lx-GoldSim- what is a engineered systems model? Which analysis gets used in which place and who uses these models?	GoldSim is a water model used for impact analysis as described in FEIS Section 5.2.2.
Becky Milanese	Page lxi- Humidity cell- Who or which agency uses this test? Hydrometallurgical residue- what is an amorphous form?	Humidity cell tests are described in FEIS Section 5.2.2.2.3. The term “amorphous form” has been removed from the glossary.
Becky Milanese	Page lxiii- Monte Carlo Simulation- Who or what agency uses this simulation and determines its use and outcome?	Monte Carlo is defined in the glossary as, “A computerized mathematical technique that allows people to account for risk in quantitative analysis and decision-making. The simulation furnishes the decision-maker with a range of possible outcomes and the probabilities they will occur for any choice of action.” It generates model permutations for probabilistic results and ranges as described FEIS in Section 5.2.2.2.3.
Becky	Page lxiv- Paste or thickened tailings- what is a homogeneous nonsegregated	Homogeneous nonsegregated mass is material that is uniformly mixed so there are not defined layers of different

Sender	Comment	Response
Milanese	mass?	materials.
Becky Milanese	Page lxix- Wastewater treatment facility (WWTF) & Wastewater Treatment Plant (WWTP) - What is the difference between these two and who permits and oversees their discharges?	The WWTP (Plant Site) and WWTF (Mine Site) are described in FEIS Sections 3.2.2.3.10 and 3.2.2.1.8, respectively, and discharges would be managed under the permits described in Section 2.6.
Becky Milanese	Page lxxv- Permeable reactive barrier- Huh? Who installs and maintains this barrier? Is it a separate facility?	A permeable reactive barrier is an option for non-mechanical water treatment and is discussed in FEIS Chapter 3 and Section 5.2.2.
Becky Milanese	Page lxxvi- Reject concentrate- What happens to this water or brine?	Reject concentrate from the WWTP would be treated at the WWTF, and the reject concentrate from the WWTF RO would be evaporated and the residual solids disposed of off-site.
Becky Milanese	Page lxxvi-lxxvii- Spill Prevention Control and Countermeasure (SPCC) Plan- Who produces, writes, revises and oversees this plan.	The project proponent would be responsible for the SPCC plan and would be overseen by regulators under permit.
Becky Milanese	Pumping Test- Who uses these tests and determines the results and effects that need to be considered?	Pumping tests are used and interpreted by the project proponent and their consultants. Results are analyzed in the FEIS to characterize groundwater flow and contaminant transport.
Becky Milanese	Reclamation- Who oversees this and decides that it is done in a proper manner?	Reclamation would be undertaken by the project proponent and overseen by the MDNR under the Permit to Mine per FEIS Section 3.1.1.6.
Becky Milanese	XP-SWMM- Which agency uses this modeling software and what is it used to determine.	XP-SWMM is a surface water model used for impact analysis as described in FEIS Section 5.2.2.
Bert Hyde	Pg 4-45 and 46, 47 – The content of these pages is so well hidden that I could not understand what the author was trying to communicate.	The FEIS has been revised to improve writing clarity.
Bert Hyde	Pg 3-114, 3.2.2.3.7. High purity gypsum is a useful product – it should not be managed as waste – waste is ultimately very expensive.	No change made.
Bob Tammen	It has been my experience in the industry that acid draining from a mine is referred to as Acid Mine Drainage. Industry efforts to euphemize the term to Acid Rock Drainage is sadly unprofessional and should be corrected in the glossary and in the SDEIS. 4-165 “The Plant Site is located north of the Laurention Divide...Misprint? The plant is South of the divide. See map. 4-376 Last paragraph. Heal should be heel. 5-5 “located in...Mesabi Iron Range” The mine is located in the Duluth Complex in the Superior National	Regarding the use of the term, “Acid Mine Drainage” or “Acid Rock Drainage,” no change has been made. Regarding the location of the Plant Site in relation to the Laurentian Divide, change has been made as requested. Regarding the use of “heal” or “heel,” change has been made as requested.

Final Environmental Impact Statement (FEIS)
NorthMet Mining Project and Land Exchange

Sender	Comment	Response
	<p>Forest.</p> <p>Once again, the SDEIS deserves an EU-3.</p> <p>6-9 6.2.2.1.6 Essar...begin operation in 2014. Essar will not begin operation in 2014. Update SDEIS.</p> <p>6-7 Table 6.2-1 Mesaba Energy Project. The IRRRB has granted Mesaba Energy an option to purchase land near Hibbing for a gas power plant. Update table.</p> <p>6-1 reasonably foreseeable. The impacts of developing a 10 billion ton ore body as described by geologists in Minnesota should be evaluated as reasonably foreseeable.</p>	
Bob Wagner	II. Contradicting statements on stream flow, Executive Summary p. 39, table 51 and (appendix C sub sec 1) “reduce water flows to range of annual natural variability	The text of the Executive Summary has been updated to improve clarity.
Center for Biological Diversity	the discussion of mine pit inflow does not provide a citation at all, see SDEIS 5-90.	Change has been made, as requested.
Grand Portage Band	The SDEIS also speculates that the tribes will benefit economically from the Project through additional visitation to Band-operated Casinos, but provides no data to back up the statement: “Increased employment and income associated with the NorthMet Project Proposed Action could increase visitation and revenues at [area tribal gaming] facilities.” This statement is entirely unsupported by any market analysis and must be deleted from the socioeconomic assessment of the Project.	No change made.
Joel Roberts	There are discrepancies among the various descriptions of this construction in the SDEIS and the relevant references. These should have been resolved before the SDEIS was released.	No change made.
klhanson@fro ntiernet.net	[Text from SDEIS] “Based on the results...would not exceed applicable environmental evaluation criteria except for two water constituents as a side effect of the project.” - [should read] Would exceed applicable environmental evaluation criteria for two water constituents.	FEIS text has been revised to read, “Based on the results....would exceed applicable environmental evaluation criteria for two water constituents as a side effects of the project.”
Michele Ross	In most cases, either the federal MCL or the Minnesota Health Risk Limit (HRL) is selected, but higher SDEIS evaluation criteria were chosen for beryllium, manganese and thallium “...based on background water quality”. Although manganese exceeded the federal MCL of 50 µg/L in most samples, Table 4.2.2-6 in the SDEIS indicates most of the groundwater samples collected near the proposed Mine Site were near or below the state Risk	There are no drinking water wells at the Mine Site. The FEIS bases water quality evaluation criteria off of regulatory requirements. Using regulatory requirements to assess risk best informs the permitting process--a major objective of EISs. RAA guidance is not likely to be promulgated, either because of a high level of uncertainty

Sender	Comment	Response
	Assessment Advice (RAA) levels of 100 µg/L for infants and 300 µg/L for children and adults. MDH recommends the RAA values be used as the groundwater evaluation criterion for manganese... Use 100 µg/L for infants and 300 µg/L for children and adults as the groundwater evaluation criterion for manganese.	about the numeric guidance, because the methods used to develop the guidance are different than the methods in rule, or because the resulting guidance is qualitative rather than a water value. The RAA values were added as a footnote to FEIS Table 5.2.2-1.
Michele Ross	[T]he detections of beryllium near the proposed Mine Site indicate background concentrations in the aquifers are generally below the federal MCL of 0.4 µg/L and only slightly above the MDH HRL of 0.08 µg/L. MDH recommends the HRL be used as the groundwater evaluation criterion, as beryllium concentrations in the Plant Site flow paths are also predicted to exceed the HRL in areas where domestic wells are present... Use 0.08 µg/L as the groundwater evaluation criterion for beryllium.	Groundwater standards include primary and secondary drinking water standards and the HRL. <i>Minnesota Rules</i> 7060.0600, subpart 8, states that “where the background level of natural origin is reasonably definable and is higher than the accepted standard for potable water and the hydrology and extent of the aquifer are known, the natural level may be used as the standard.” The groundwater evaluation criterion for beryllium at the Mine Site is 0.39 µg/L. At the Plant Site, it is 0.54 µg/L. The basis for the evaluation criteria is Minnesota Rules. The MDH HRL of 0.08 µg/L is disclosed in FEIS Table 5.2.2-1.
Northeastern Minnesotans for Wilderness	[The SDEIS] states that the proposition that “taconite tailings appear to be a sink for mercury in full-scale actual tailings basins in northern Minnesota, at least similar to other media like soils . . . is supported by surface and groundwater monitoring around the existing LTVSMC Tailings Basin, which found mercury concentrations consistent with baseline levels (see Table 4.1-31), generally averaging less than 2.0 ng/L.” SDEIS 5-202. This statement in regards to groundwater appears to be blatantly false. And an attempt to learn more from Table 4.1-31 was thwarted by the fact that there is no Table 4.1-31.	Change has been made, as requested. The reference to Table 4.1-31 has been removed from the text, and replaced with an appropriate table reference.
Northeastern Minnesotans for Wilderness	Regarding scenic integrity objectives (SIOs), the SDEIS states that it used SIO definitions in the Forest Plan for evaluating the Federal lands but used a 1995 Forest Service publication to evaluate the non-Federal lands. SDEIS 4-349. The discrepancy is not explained. The SDEIS needs to provide sufficient information to determine whether this difference could lead to inaccurate comparisons.	No change made.
Patty Lange	It has been brought to my attention that the maps outlining the drainage area around the proposed mine in the environmental study for the Polymet mine are incorrect.	The referenced figures have been revised for the FEIS, and now include additional features that add clarity to the hydrology.
Patty Lange	The fact that the incorrect maps outline the swamp with a dashed teal line on satellite maps with green backgrounds makes it extremely difficult to see. This discrepancy between the environmental impact statement maps and US	The outline of the One Hundred Mile Swamp on figures has been revised to make it more visible. No other changes made.

Sender	Comment	Response
	government maps makes this environmental impact study inadequate.	
Paul Stolen	Sulfate loadings, reference to MPCA {2006}, p. 5-208. This MPCA document is quoted in Reference #42 in Appendix A of these comments. This MPCA document refers primarily to sulfate permitting issues rather than impact assessment, and is also outdated in enough respects to question its utility for this EIS.	Citation has been revised to “MPCA 2006a,” to refer to the MPCA Strategy to Address Indirect Effects of Elevated Sulfate on Methylmercury Production and Phosphorus Availability, published by the MPCA in October 2006, which is the approach source in this context.
Phil Larson	<p>Glossary</p> <p>The glossary contains a number terms whose definition is inconsistent with standard usage. These include:</p> <p>Drift: Material such as sand, clay, gravel, and rocks transported and deposited by a glacier or glacial process.</p> <p>Glacial deposit: A collection of various-sized rocks and debris that is deposited by a glacier as it advances or recedes across a landscape. There are many types of deposits, including till, drift, erratics, and moraines. (Note: sediment deposits of glacial origin are termed ‘drift’, less commonly ‘glacial drift’. Erratics refers to individual clasts, while ‘moraines’ refer to a landform, not a sediment type.)</p> <p>Glacial till: Direct glacial deposits of rocks, gravel, or boulders that are unsorted and unstratified. (Note: all till is by definition glacial in origin; there is no need to include the modifier ‘glacial’.)</p> <p>Surficial glacial deposit: A collection of various sized rocks and debris deposited by glacial activity that is left on the earth’s surface after the glacier recedes. (Note: ‘surficial glacial deposit’ is not used in the text of the SDEIS.)</p> <p>Till: see Glacial till</p> <p>These definitions should be revised to conform to accepted usage. The following definitions are taken from the Glossary of Geology (5th Edition) :</p> <p>Drift A general term applied to all rock material (clay, silt, sand, gravel, boulders) transported by a glacier and deposited directly by or from the ice, or by running water emanating from a glacier. Drift includes unstratified material (till) that forms moraines, and stratified deposits that form outwash plains, eskers, kames, varves, fluvioglacial sediments, etc.</p> <p>Outwash Stratified detritus (chiefly sand and gravel) removed or “washed out” from a glacier by meltwater streams and deposited in front of or beyond the end moraine or the margin of an active glacier. The coarser material usually is deposited nearer to the ice.</p> <p>Till Dominantly unsorted and unstratified drift, generally unconsolidated,</p>	The glossary is deemed adequate for the FEIS.

Sender	Comment	Response
	<p>deposited directly by and underneath a glacier without subsequent reworking by meltwater, and consisting of a heterogeneous mixture of clay, silt, sand, gravel, and boulders ranging widely in size and shape.</p> <p>In addition to adapting these definitions, I recommend that the definition of ‘surficial aquifer’ be modified to indicate that the aquifer is hosted by unconsolidated sediment, including drift.</p>	
Phil Larson	<p>Notes on Nomenclature</p> <p>The text of the SDEIS contains a number of inconsistent usages of terminology:</p> <ul style="list-style-type: none"> • The text mentions ‘glacial till’ 33 times, and ‘till’ alone 29 times. ‘Till’ should be used in all cases. • The text mentions ‘glacial drift’ 6 times, and ‘drift’ alone 7 times. ‘Drift’ should be used in all these cases. • The glossary does not define ‘outwash’. The text mentions ‘glacial outwash’ 5 times, and ‘outwash alone 3 times. ‘Outwash’ should be used in all these cases. • The text uses the term ‘surficial deposits’ 25 times, although the term is not defined in the glossary. The usage suggests that this refers to all unconsolidated sediments lying above bedrock, including drift (till and outwash), peat, and other sediment. • In a number of cases, usage of the term ‘till’ is confused or inconsistent: • Page 4-95 – “several soil borings into the surficial till identified the composition as layers of clay and sand, plus cobbles and boulders”. In this case ‘till’ is the sediment type, and by definition contains particle sizes ranging from clay to boulders. • Page 4-151 – “The depth of soil and till overlying the bedrock”. • Page 4-367 – “areas of glacial till (typically silty sand)”. Either the sediment is till, or silty sand. By definition it cannot be both. • Page 4-376 - “native till material that ranges from clay to gravel”. In this case ‘till’ is the sediment type and by definition contains particle sizes ranging from clay to gravel. <p>In several instances, the term ‘till soil’ is used. Till is a sediment type. A soil may develop at the surface of a till deposit, however the entire thickness of the till is not soil. ‘Till’ alone suffices in these instances.</p> <p>In a number of other cases, convoluted sediment descriptions are given, when</p>	<p>Text within the FEIS has been updated since the SDEIS - not all suggested edits have been applied.</p>

Sender	Comment	Response
	<p>it is likely the sediment is simply till. In these cases, the non-specific and complex description gives the impression of extreme heterogeneity in sediment deposits, rather than a relatively homogeneous till deposit. For example:</p> <ul style="list-style-type: none"> • Page 4-45 – “The overlying surficial sediments at the Mine Site are poorly sorted and range from very dense clay to well-sorted sand with boulders and cobbles”. This sediment is highly likely to be simply till. • The term ‘overburden’ as defined in the glossary appears to be inconsistently applied. Although it is defined as all unconsolidated sediment and waste rock overlying the mineral deposit, in most places it appears to refer to only the unconsolidated material overlying bedrock. For example: <ul style="list-style-type: none"> • Page 3-15 – “overburden and waste rock” • Page 3-17 – “overburden and waste rock” • Page 3-37 – “use of waste rock, overburden, and peat” • In other cases, ‘overburden’ clearly refers to only the unconsolidated sediment overlying bedrock. For example: <ul style="list-style-type: none"> • Page 3-44 – “Three types of overburden are present at the site: unsaturated overburden, saturated overburden, and peat.” <p>The term ‘soil’ is not defined in the glossary. In most cases, the term is used in a manner referring to unconsolidated materials at the surface, containing organic matter, and capable of supporting life. In other cases, it appears to be used in a geotechnical sense, referring to unconsolidated sediment overlying bedrock, equivalent to usage of the term ‘overburden’. In these cases, the term appears to be applied to the entire thickness of drift or till overlying bedrock, similar to usage of ‘surficial deposits’ noted above. For example,</p> <ul style="list-style-type: none"> • Page 4-149 – “lateral flow that is either on the surface or within the subsurface soil.” Soil used in this sense refers to either drift or the surficial aquifer. • Page 5-201 – “mercury stored in rock, soil, peat, and vegetation.” Soil used in this sense refers to drift. • Page 5-227 – “The Mine Site contains localized heterogeneous vertical and horizontal hydraulic conductivities within each soil unit.” Soil used in this sense refers to drift. <p>A clear distinction need to be made between soil referring to the shallow</p>	

Sender	Comment	Response
	surface layer containing or	
Phil Larson	Note on usage of Unified Soils Classification System (ASTM D 2487-83) The USCS was used to describe unconsolidated sediments recovered from boreholes drilled in support of the NorthMet Project. It is important to note that this system is designed to best describe and name relatively well-sorted unconsolidated sediments with a unimodal particle size distribution. As such, poorly sorted sediments with potentially multimodal particle size distributions (e.g. till) are not well-described using this classification. Relatively minor changes in the relative proportions of clay-silt-sand-pebble-boulder may lead to application of multiple group symbols and the perception of significant heterogeneity within what is in actuality a relatively homogeneous till sequence. In cases where USGS group symbols and nomenclature are utilized in the SDEIS and supporting documents, it is advisable that sediment identified as till be explicitly name as such, e.g. GC (till).	Not all instances changed. The FEIS is for public use - technical description can be found in the reference materials.
Phil Larson	Geology of the Mine Site: The observation is made that “the surficial till is a heterogeneous and laterally discontinuous zone with a composition ranging from very dense clay to well-sorted sand.” This statement seems to use the term ‘heterogeneous’ to refer to the poor sorting and wide particle size range of what is likely a relatively homogeneous till. The lateral discontinuity in the till referred to in this case is likely its thickness, not its sedimentological heterogeneity. Here, and elsewhere in the document, well-defined, consistent, and judicious application of the terms ‘heterogeneous’ and ‘homogeneous’ when describing tills is advised.	No change made.
Robert Tammen	Several documents refer to PolyMet and Poly Met (Two words). There must be a reason for having two different legal entities. The SDEIS should explain the difference and perhaps declare which will get dividends and which will have environmental clean up liability.	FEIS text has been revised to ensure consistent use of “PolyMet.”
Robert Tammen	4-165 “The Plant Site is located north of the Laurentian Divide...Misprint? The plant is South of the divide. See map.	Text has been revised to indicate the Plant Site is south of the Laurentian Divide.
Robert Tammen	4-376 Last paragraph. Heal should be heel.	FEIS text has been revised to refer to the “base of the dam.”
Robert Tammen	5-5 “located in...Mesabi Iron Range” The mine is located in the Duluth Complex in the Superior National Forest. Once again, the SDEIS deserves an EU-3.	Text has been revised to state, “The NorthMet Project Proposed Action would be located near an historic mining area, known as the Mesabi Iron Range ...”
Robert Tammen	Table 6.2-1 Mesaba Energy Project. The IRRRB has granted Mesaba Energy an option to purchase land near Hibbing for a gas power plant. Update table.	The list of Projects has been updated.

Sender	Comment	Response
	At the same meeting the IRRRB granted the City of Hibbing an option to purchase land for a possible Racino. This was probably an effort to pressure tribal interests by threatening to compete with Fortune Bay and Black Bear casinos. The actions were connected and should be analyzed.	
Robert Tammen	6-9 6.2.2.1.6 Essar...begin operation in 2014. Essar will not begin operation in 2014. Update SDEIS.	The FEIS has been revised to address this comment.
Robert Tammen	A-5 Thematic Response. AQ-1. Oar should be ore.	Change has been made, as requested.
Roger A Powell	Figure 6.2.3-1 does not show the corridor that the text on page 5-374 states that it shows. The figure must be revised to show the corridor.	The SDEIS cited an incorrect figure number. The FEIS has updated the figure number to be 6.2.5-1.
Roger A Powell	Figures 5.2.2-18, 19 and 41a of the SDEIS show PSO, contradicting the text.	No change has been made to FEIS Figures 5.2.2-18 and 5.2.2-19. The text associated with FEIS Figure 5.2.2-44 has been changed, as requested.
PolyMet	PolyMet suggests revising the first sentence in the second full paragraph on page 5-6 to read: "...PolyMet proposes a containment system that would capture about 99 percent of seepage from the Tailings Basin..."	No change made.
PolyMet	The first sentence on page 5-54 states that for Category 1 rock, "...instead of using lab tests, the rate of oxidation and constituent release was estimated from studies of seepage release measured in Dunka Mine rock....". PolyMet suggests revising the first sentence to read "... instead of using lab tests, the rate of oxidation and constituent release in the field was estimated from lab release rates that were scaled using the results of studies of seepage release measured in Dunka Mine rock..."	Change has been made, as requested.
PolyMet	It is important to note that the Central Pit will not exist until after the Category 4 Stockpile has been decommissioned and the Category 4 waste rock has been relocated to the East Pit for subaqueous disposal. The most apparent benefit of relocating the Category 4 Stockpile as part of the Proposed Action Design Changes is that by locating the stockpile over an area that will be subsequently engulfed by the Central Pit, the overall area of surface disturbance (including vegetation, wetlands, etc.) of the NorthMet project will be reduced.	No change made.
PolyMet	The second to last sentence should read: "Compensation proposed at the Aitkin Site would be expected to meet in-kind compensation, resulting in a compensation ratio for effects to wetlands with rare or exceptional functions or difficult-to-replace bogs of 1.75:1, and if in advance, the ratio would be reduced to 1.5:1."	No change made.

Sender	Comment	Response
PolyMet	The second to last sentence in the second paragraph should read: “Compensation proposed at the Hinckley Site would be expected to meet the in-kind incentive, resulting in a compensation ratio for effects to wetlands with rare or exceptional functions or difficult-to-replace bogs of 1.75:1, and if in-advance, the ratio would be reduced to 1.5:1.”	No change made.
PolyMet	The last full sentence on the page should read: “Compensation proposed for the Zim Site would be expected to meet both in-kind and in-place incentives, thereby reducing the compensation ratio for effects on wetlands with rare or exceptional functions or difficult-to-replace bogs from 2:1 to 1.5:1.”	No change made.
PolyMet	The third paragraph states that the United States Army Corps of Engineers (“USACE”) and the Minnesota Department of Natural Resources (“MDNR”) studied “the original NorthMet Project Proposed Action” between 2005 and 2009. Use of the defined term “NorthMet Project Proposed Action” in this context is confusing because the proposed action studied in the Draft EIS was substantially different than the proposed action being studied in the SDEIS. To avoid confusion over the nature of the alternatives studied in the two documents, PolyMet recommends changing the language to state that “Between 2005 and 2009, the USACE and MDNR evaluated PolyMet’s original mining proposal.”	Change has been made, as requested.
PolyMet	The terms “NorthMet Mining Project” and “Land Exchange,” rather than the defined terms “NorthMet Project Proposed Action” and “Land Exchange Proposed Action,” are used on these pages. To avoid confusion, PolyMet recommends consistent use of the defined terms.	FEIS text has been reviewed to ensure consistent use of these terms.
PolyMet	Under the heading “Cooperating Agencies,” the SDEIS describes USEPA’s responsibilities to review and comment on an EIS under Section 309 of the Clean Air Act. USEPA does this for all Environmental Impact Statements, even when it is not acting as a cooperating agency. USEPA has formally participated in the preparation of the current SDEIS as a cooperating agency, which is not the same thing as fulfilling its responsibilities under CAA Section 309. PolyMet recommends clarifying this point by adding a sentence to this paragraph that explicitly notes EPA’s status as a cooperating agency.	Section 1.2.1 has been revised to provide improved clarity on the USEPA’s role.
PolyMet	PolyMet recommends explicitly referencing and incorporating into the SDEIS those portions of the FSDD and the 2009 DEIS that address alternatives. This should increase understanding of the iterative process of alternatives review that the SDEIS already references in several places... these changes should also be reflected in the Executive Summary, which tends to focus on the SDEIS alternatives review process, without fully acknowledging the role	FEIS Section 3.2.3 has been revised to address this comment.

Sender	Comment	Response
	played by alternatives review in the FSDD and the 2009 DEIS.	
PolyMet	PolyMet recommends including an updated version of Table 3.2-4 from the 2009 DEIS somewhere in the Final EIS, either directly in the discussion of alternatives or as an appendix. This would provide context for the discussion of alternatives review and the elimination of alternatives that are not discussed as part of the SDEIS process... [these changes should also be reflected in the Executive Summary, which tends to focus on the SDEIS alternatives review process, without fully acknowledging the role played by alternatives review in the FSDD and the 2009 DEIS.]	No change made.
PolyMet	The Final EIS accordingly should clarify that the alternative of proceeding with the Land Exchange Proposed Action in the absence of the NorthMet Project Proposed Action was considered but eliminated from detailed analysis in the SDEIS because it is represented by the combination of “no action” on the NorthMet Project Proposed Action and Land Exchange Proposed Action Alternative A. This could be accomplished by adding a brief description of the Land Exchange Proposed Action as a “stand alone” action in Section 3.3.3.3. The alternative would not be eliminated as unreasonable, but rather it would not require further analysis because its impacts were already revealed and evaluated in the SDEIS detailed evaluation of other alternatives.	The FEIS presented the range of alternatives that were developed for the Land Exchange Proposed Action as well as those that were considered but eliminated from detailed analysis. The Land Exchange Proposed Action would not have been entertained if not for the NorthMet Project Proposed Action. While benefits of the Land Exchange Proposed Action could accrue without associated mining, this could be true for lands throughout the Superior National Forest. The catalyst for the Land Exchange Proposed Action is the proposed mining activities, current permit applications, and the need to address the conflict associated with split ownership of mineral and surface rights.
PolyMet	PolyMet recommends that the USFS ensure that the Executive Summary is updated to conform to any changes made in the Final EIS. The independent grounds for undertaking the Land Exchange Proposed Action should be particularly clear in the revised Executive Summary, because many readers likely will rely on the Executive Summary to understand the contents of the EIS.	The Executive Summary has been revised to reflect updated information since publication of the SDEIS.
PolyMet	the SDEIS concludes that there will be no cumulative impact on recreational and visual resources. It bases this conclusion on the fact that there are no significant cumulative impacts on individual specific resources that factor in to the assessment of recreational and visual resources (such as air quality, wetlands, etc.). The phrasing used implies that the co-leads have analyzed the effects on recreational and visual resources from impacts to these specific resources individually, rather than collectively. PolyMet suggests clarifying that the agencies have analyzed whether the impacts on these resources, although insignificant when considered individually, would have any impact on recreational and visual resources when combined and has concluded that	No change made.

Sender	Comment	Response
	there would be no significant impact.	
PolyMet	The SDEIS should also use consistent language regarding the scope of the cumulative effects assessment areas throughout Chapter 6. On page 6-2, the SDEIS states: “For all resources, future temporal boundaries are the expected service life of the mining activities, including closure (years 20 to 40) and post-closure restoration (year 40 and beyond).” PolyMet recommends removing this sentence, which is not an accurate description of the temporal boundaries for all resources. Indeed, the very next sentence on page 6-2 rightly states that “temporal boundaries for each resource are defined within the respective resources’ sections of this analysis.” That sentence should remain as the sole, accurate explanation of temporal boundaries.	FEIS language will be updated as appropriately
PolyMet	The first sentence on this page indicates that completion of mining in the East Pit will occur in “approximately year 11” after the start of mining. By contrast, the first sentence in the paragraph following the three bullet points states that mining in the East Pit will end “by year 11” after the start of mining. The second statement is inaccurate. Mining in the East Pit will end approximately 11 years after mining, but not necessarily by year 11.	No change made. The SDEIS stated that “after year 11,” mining would be completed in the East Pit.
PolyMet	In the last paragraph of the Mining Operations Section on page ES-23, the SDEIS defines “process water” in connection with the Mine Site. On page ES-24, the SDEIS refers to “Plant Site process water.” To clarify and define terms, page ES-23 should be changed to refer to “Mine Site process water,” and “Plant Site process water” should be defined by adding a sentence (see bold text below) to the last paragraph of the Processing Operations Section on page ES-23: “Water seepage from the Tailings Basin would be collected by the groundwater containment system and sent to either the Tailings Basin pond or the Plant Site WWTP. All other water that is collected at the Plant Site, such as water used during processing, and water that contacts the plant site facilities (collectively referred to as Plant Site process water) will also be treated at the Plant Site WWTP. Treated water would be used to augment flows in the streams that would otherwise receive reduced flows because of the Tailings Basin groundwater containment system.”	Terminology has been revised for clarity.
PolyMet	PolyMet recommends that the Executive Summary explicitly state that aluminum concentrations in the water, or the lowering of the hardness caused by storm water, represent natural or background concentrations and/or are the result of natural processes, not process water from the NorthMet Project.	The Executive Summary text has been updated to improve clarity.
PolyMet	The SDEIS indicates that the NorthMet Project could potentially “affect	The Executive Summary text has been updated to improve

Sender	Comment	Response
	<p>water quality by increasing solute concentrations above Class 2B (aquatic life) standards.” This appears to refer to the aluminum and lead exceedances discussed earlier in the Executive Summary. As explained in Comment 6 above, PolyMet recommends that the Executive Summary explicitly state that any such exceedances would be the result of background and/or naturally occurring concentrations or processes, not process water from the NorthMet project.</p>	<p>clarity.</p>
<p>PolyMet</p>	<p>The second full paragraph beginning with the phrase “natural resources” does not accurately summarize the discussion of cultural resources in the SDEIS. PolyMet recommends that the paragraph be replaced with the following: “Cultural resources under NEPA can also include natural resources of cultural importance to the Bands. The Co-lead agencies have considered the effects of the Proposed Action on such resources, including 1854 Treaty resources, under NEPA. The Co-lead agencies have concluded that, while the Proposed Action has the potential to have effects on 1854 Treaty resources, construction and operation of the Proposed Action is not likely to significantly reduce overall availability of 1854 Treaty resources that are typically part of subsistence activities in the 1854 Ceded Territory.”</p>	<p>No change made.</p>
<p>PolyMet</p>	<p>In Table 1, the Land Use effects of the Proposed Connected Actions are described in the first bullet point as “[n]o effects on land use that would require changes in ordinances or comprehensive forest plans.” This language is confusing, given that the NorthMet Project Proposed Action would involve the construction of an open pit mine. PolyMet proposes changing this language to say: “Changes in land use would occur after the Land Exchange Proposed Action and would not require changes in ordinances or comprehensive forest plans.”</p>	<p>No change made.</p>
<p>PolyMet</p>	<p>Although the co-lead agencies have concluded that a segment of the Beaver Bay to Lake Vermilion Trail is an eligible historic property, the SDEIS alternates between referring to the “BBLV Trail” and the “BBLV Trail Segment.” To ensure consistency with the co-leads’ eligibility determination, PolyMet recommends that the agencies consistently refer to the property as the “BBLV Trail Segment.”</p> <p>This comment applies throughout all Cultural Resources sections in the SDEIS.</p>	<p>FEIS text has been revised to ensure consistent use of “BBLV Trail Segment.”</p>
<p>PolyMet</p>	<p>PolyMet recommends that the section of the chart dealing with “Cultural Resources & Historic Properties” be referred to simply as “Cultural Resources” since that term is inclusive of historic properties.</p>	<p>Change has been made, as requested.</p>

Sender	Comment	Response
PolyMet	The first sentence in Section 2.3.2.2, “Revised Proposed Action and Alternatives,” states that the NorthMet Project Proposed Action has “changed greatly since the release of the DEIS.” The use of the phrase “changed greatly” is ambiguous. The modifications to the proposal studied in the DEIS are described in detail elsewhere in the SDEIS. PolyMet accordingly recommends revising the first sentence in Section 2.3.2.2 to read: “As a result of input from the public, Cooperating Agencies, and the Co-lead Agencies via the workgroups, and additional modeling and impact analyses, PolyMet’s mining proposal has been modified since the release of the DEIS.”	Section 2.3.2.2 has been revised based on this comment and other project modifications since publication of the SDEIS.
PolyMet	The second bullet point in Section 2.4.2, “Adequacy Determination/Records of Decision,” states that the USACE will issue a ROD “[f]ollowing a 30-day comment period.” Under NEPA, the 30-day period following issuance of a Final EIS is not a “comment period.” Rather, under 40 C.F.R. § 1506.10(b), agencies are simply prohibited from making a decision on the proposed action until 90 days after publication of a notice of availability for a draft EIS, or 30 days after publication of a notice of availability for a final EIS. The Council on Environmental Quality regulations do not require agencies to solicit comments on the FEIS during this 30-day waiting period.	Section 2.4.2 of the FEIS, which addresses the Adequacy Determination and Record of Decision process, has been revised since the SDEIS.
PolyMet	The first bullet on this page does not specify which permits would be transferred to PolyMet. The Minnesota Pollution Control Agency has stated that the NPDES permit for the Tailings Basin would not be transferred. Instead, a new permit would be issued.	Section 2.6 of the FEIS, which identifies the key permits that would be required for the NorthMet Mining Project and any further changes would be beyond the scope of this EIS.
PolyMet	The fourth bullet on this page refers to a “bentonite layer on top of the Tailings Basin to restrict oxygen and water infiltration with pond.” PolyMet recommends clarifying that there is a bentonite layer on the outer dam slopes during construction and that, during closure, a bentonite layer will be added to the top of the Tailings Basin. As currently written, the reader may incorrectly assume that a bentonite layer will be added at construction, below the new tailings.	Change has been made, as requested.
PolyMet	Reclamation of the Category 1 Stockpile is scheduled to begin in Year 14. As currently written, reclamation of the Category 1 Stockpile is included only in Years 16-20. It should also be included in Years 11-16.	Change has been made, as requested.
PolyMet	The movement of waste rock from the Category 2/3 stockpile to the pit will be completed by the end of operations (Year 20). As currently written, the SDEIS incorrectly indicates that this activity will occur after year 20.	Change has been made, as requested.
PolyMet	The transmission lines are not shown correctly on these figures [Figures 3.2-5 through 3.2-9]. The figures should show a connection between the	Change has been made, as requested, based on updated GIS mapping provided by PolyMet.

Sender	Comment	Response
	transmission line south of the Central Pit and the line south of the Category 1 stockpile.	
PolyMet	The second paragraph on this page states that unsaturated overburden use would require MDNR approval. This is not accurate. Unsaturated overburden should not require approval from the MDNR.	Change has been made, as requested.
PolyMet	The fourth sentence of the third paragraph on this page should state: "Applications for saturated overburden would include those where water contacting the construction material would be collected or drained to the mine pits, where it would be placed back below the water table or above a membrane liner system." There should be an 'or' in this sentence.	Change has been made, as requested.
PolyMet	For clarity, PolyMet suggests editing the second paragraph and the beginning of the third paragraph in this section as follows: "Figure 3.2-11 shows the containment system that would consist of a cutoff wall (a low permeability hydraulic barrier extending down to bedrock) combined with a drainage collection system surrounding the perimeter of the stockpile near its toe. The cutoff wall would have a hydraulic conductivity specification of no more than 1×10^{-5} centimeters per second (cm/sec)."	Change has been made, as requested.
PolyMet	The last sentence in the paragraph under the heading "Reclamation Planning" correctly states that PolyMet will submit an annual Contingency Reclamation Plan pursuant to <i>Minnesota Rules</i> 6132.1300. In the interest of completeness, the paragraph should also note that the rules require PolyMet to provide financial assurance sufficient to carry out that reclamation plan.	Change has been made, as requested.
PolyMet	The second paragraph inaccurately refers to disposal of material (remaining ore and sediment from ditches and process water ponds) in the West Pit. This material would be disposed in the East Pit, as described in Section 2.1.2 of the Reclamation Plan (v3) (Rail Transfer Hopper).	Change has been made, as requested.
PolyMet	The fifth sentence of the second paragraph on this page refers to the overburden sloping as "height-to-vertical ratio of 2.5:1." Height and vertical mean the same thing (i.e., both refer to the vertical plane). PolyMet suggests changing this to read either "horizontal-to-vertical" or "length-to-height".	FEIS text has been revised to "horizontal-to-vertical ratio of 2.5:1".
PolyMet	On page 3-64, the SDEIS states: "The WWTF would be upgraded to include RO treatment to achieve an effluent with a sulfate concentration of less than 10 mg/L." Similarly, the SDEIS states on page 3-123: "The WWTP would be constructed south of the Tailings Basin near the coarse-crusher and would	No change made.

Sender	Comment	Response
	<p>include a RO unit designed to achieve a sulfate concentration of 10 mg/L in effluent. The design of the WWTP could be adjusted to accommodate varying influent streams and discharge requirements.”</p> <p>It is not clear when reading the two statements copied above that the water treatment goal for the effluent sulfate concentration of 10 mg/L is based on meeting the current 10 mg/L sulfate standard for waters used for the production of wild rice (Minnesota Rule 7050.0224, Class 4A water quality standard). To clarify, and because that standard is subject to adjustment, the statement “to achieve an effluent sulfate concentration that meets the sulfate standard for waters used for the production of wild rice” should be used instead of “to achieve an effluent with a sulfate concentration of less than 10 mg/L.”</p>	
PolyMet	<p>The last sentence inaccurately states state the Category 4 Stockpile would be completely removed by year 12 to allow mining in the Central Pit. The Central Pit mining begins in Year 11, as stated earlier in the SDEIS (such as Table 3.2-4). Therefore, the Category 4 Stockpile would be completely removed by year 11.</p>	Change has been made, as requested.
PolyMet	<p>The second paragraph describes reclamation of the Ore Surge Pile as “...any remaining material would be relocated to the West Pit after operations cease.” However, no material will be disposed of in the West Pit. As described in Section 7.2.2 of the Rock and Overburden Management Plan (v5), any material remaining in the Ore Surge Pile at the end of operations will be transported to the Process Plant for processing or disposed of in the East Pit.</p>	Change has been made, as requested.
PolyMet	<p>The fifth paragraph on this page, which lists all ponds that would be either filled or converted to wetlands, should include the Rail Transfer Hopper Pond.</p>	Change has been made, as requested.
PolyMet	<p>The fourth paragraph under the heading “Water Management” states that “[b]ased on the current GoldSim P90 model predictions, treatment activities could be required for a minimum of 200 years at the Mine Site” This statement is inaccurate and inconsistent with the discussion of the GoldSim water quality modeling elsewhere in the SDEIS.</p>	Change has been made, as requested.
PolyMet	<p>Section 1.3.2.2 should identify the fact that PolyMet does not agree with the USFS legal position. This could be done by cross-reference to the appropriate sections in the 2009 DEIS that discuss this issue in greater detail than the SDEIS. For example, a simple cross-cite to Section 1.3.2.2 of the 2009 DEIS would ensure that the reader is aware that additional information on this topic is contained in the 2009 DEIS. PolyMet notes that the SDEIS repeats the</p>	The FEIS has been revised to address this comment.

Sender	Comment	Response
	USFS position (i.e., that mining cannot occur within the Federal Lands) in many places; as a result, it would be appropriate to note that PolyMet does not agree in most of the places where this issue is described.	
PolyMet	The SDEIS states: “Throughout operations, the average annual makeup water drawn from Colby Lake would vary between 20 and 810 gallons per minute (gpm), with an average annual demand of 275 gpm.” These numbers are inaccurate. The sentence should be revised to show a variation between 120 and 860 gallons per minute (gpm), with an average annual demand of 320 gpm. This section should also acknowledge that additional Colby Lake water would be needed for stream augmentation.	Change has been made, as requested.
PolyMet	In the second full paragraph on this page, PolyMet recommends providing additional details on the probable maximum precipitation (PMP) to make it clear that the likelihood of the emergency overflow channel being used is extremely low. PolyMet suggests editing the text to read: “Pond elevation would be controlled by pumping any excess FTB pond water to the WWTP. An emergency overflow channel would be constructed as a backup means of controlling pond elevation, but discharge from the emergency overflow is not expected. The emergency overflow is provided for protection of the dams in the rare event that freeboard within the FTB is not sufficient to contain all stormwater. Such instances have the potential to occur in the event of a probable maximum precipitation (PMP) rainfall event or some fraction thereof. PMP rainfall events are rare and such an event has a low likelihood of being experienced during the life of the basin. The PMP does not have an assigned return period, but it is usually assumed by hydrologists to be on the order of 100 million to 10 billion years. Based on extrapolation of 72-hour rainfall depth data from US Weather Bureau-Office of Hydrology Technical Paper TP 49, and the assumed return period of the PMP of 100 million years, a 1/3 PMP event could occur roughly once in 1,000 years and a 2/3 PMP could occur once in 500,000 years. On this basis, even though there is a low likelihood of overflow, it is standard practice in dam design to accommodate even low probability overflows in a manner that protects the integrity of the dams. Given the low likelihood that there would ever be flow in the emergency overflow channel, it is not considered in the impact analysis.”	Change has been made, as requested.
PolyMet	The third paragraph in Section 3.2.2.3.12, “Reclamation and Long-term Closure Management,” contains a list of “reclamation objectives” and “post-reclamation activities.” These terms are not used consistently with the	Change has been made, as requested.

Sender	Comment	Response
	<p>applicable Minnesota Rules. Under the non-ferrous rules, there are two distinct periods during reclamation: closure and post-closure. "Closure" is a "process" that begins when mining ceases, and ends when the reclamation standards identified in the reclamation plan have been achieved. Thus, while it may be reasonable to describe "reclamation objectives" for the NorthMet Project Proposed Action, it would be more accurate to indicate that these objectives will be achieved during the closure process. "Post-closure maintenance" activities are defined in the applicable rules as activities necessary to "sustain reclamation." Postclosure maintenance activities begin when the closure process is complete, and end when active reclamation (e.g., water treatment plants) is no longer necessary to sustain reclamation standards. Thus, the activities described in this paragraph as "postreclamation" are more accurately described as "post-closure maintenance activities." The same comment applies to text on page 3-137.</p>	
PolyMet	<p>The first sentence of the third paragraph in Section 3.2.2.4, "Financial Assurance," states that the engineering design and planning needed to calculate financial assurance "is typically made available during the permitting process and was not available at the time that this SDEIS was prepared." While this statement is generally accurate, it leaves a misleading impression that something is missing from the SDEIS. The paragraph should specify that NEPA and MEPA regulations do not require a discussion of financial assurance, and that PolyMet has voluntarily provided as much information as possible at the present time.</p>	Section 3.2.2.4 has been revised to address this comment.
PolyMet	<p>The first sentence in the second full, non-bulleted paragraph on this page indicates that a final Reclamation Plan and Contingency Reclamation Cost Estimate will be based on studies "finalized through permitting (pursuant to the EIS process)." This reference to permitting pursuant to the EIS process is confusing and should be clarified. PolyMet is not certain what the SDEIS is trying to convey about the relationship between the permitting and EIS processes, but it should be noted that those are separate processes and that information gathered during the EIS process will be used when agencies make permitting decisions.</p>	Change has been made, as requested.
PolyMet	<p>Table 3.2-16 on page 3-147 provides a comparison of DEIS and SDEIS proposed actions. The table cell corresponding to the first row/first column of the table should state that "Category 1 and 2 waste rock would be stored in a permanent lined/ soil covered stockpile (Category 1/2 Stockpile) north of the</p>	Change has been made, as requested.

Sender	Comment	Response
	<p>west pit (years 1-11).” This edit makes clear that the SDEIS proposed action (described in the second column of the table as including “a geomembrane cover system”) will include a significantly improved cover system relative to the cover described in the DEIS.</p> <p>The third column of Table 3.2-16 should also acknowledge the other improved outcomes related to the addition of a geomembrane cover system to the Category 1 Stockpile. For example, the following additional bullet could be added to column three: “Substantial reduction of stockpile seepage volume that will need to be collected and treated at the WWTF and significant improvement in West Pit water quality in closure.”</p>	
PolyMet	<p>General comment on all Cultural Resources Sections in Chapters 4, 5 and 6: The SDEIS often references consultation with the Bands and SHPO, but fails to include PolyMet in these references. When discussing consultation under Section 106 of the NHPA, PolyMet, as the project proponent, should be identified as a consulting party and should be included in the explanation of the Section 106 process. Examples of where PolyMet should be noted/included as a consulting party include: the third to last sentence on page 4-259 (Section 4.2.8.3); the last full sentence on page 4-262 (Section 4.2.9.2.1); the second to last sentence in Section 4.2.9.2.2 on page 4-263; the second to last sentence in the second to last paragraph on page 4-264; the second to last paragraph on page 4-302; the last full paragraph on page 4-303; the third paragraph on page 4-555; the second and third paragraphs on page 5-479; the first full paragraph on page 5-482; the second to last full paragraph on page 5-483; the last paragraph on page 5-673; and the first paragraph on page 6-89.</p>	Change has been made, as requested.
PolyMet	<p>This table lists the mercury TMDL target date for Sabin Lake, Esquagama Lake, and Colby Lake as 2015. The target date for those water bodies is 2025. (source: MPCA 2013. Minnesota’s Final 2012 TMDL List (Section 303(d) Impaired Waters List. List approved by USEPA, July 25, 2013).</p>	Change has been made, as requested. Table 4.2.2-2 has been revised to include 2025 as the TMDL target date for Sabin Lake, Esquagama Lake, and Colby Lake.
PolyMet	<p>In the first sentence of the second paragraph, the order of Duluth Complex and Partridge River intrusion should be switched. The Partridge River intrusion is part of the Duluth Complex.</p>	Change has been made, as requested.
PolyMet	<p>In the second sentence of the second paragraph, the use of “Mesabi Iron Range” is misleading, as it could give the impression that the Duluth Complex is in direct contact with the Biwabik Iron Formation, which is not the case. PolyMet recommends listing a geologic unit (Virginia Formation)</p>	Change has been made, as requested.

Sender	Comment	Response
	here, rather than the more vague term “Mesabi Iron Range.” In addition to the cross-section shown on Figure 3.2-10, it would be helpful to include a plan view bedrock geology map to illustrate the geometric relationships between the various bedrock units.	
PolyMet	The second sentence of the second full paragraph states: “Based on limited MDNR well records within the NorthMet Project area, natural groundwater levels in the glacial till vary seasonally between 3 and 10 ft bgs.” This sentence incorrectly states that the data is limited. Site-specific data on seasonal water level fluctuations is found in the Water Modeling Data Package Volume 1 – Mine Site (referenced in the SDEIS as PolyMet 2013i). PolyMet 2013i provides information on water level fluctuations observed in 24 wells completed in the glacial till at the Mine Site, some with over nine years of water level measurements. Water level fluctuation varies between wells, but the overall range observed in a single well is typically less than 4 ft.	Change has been made, as requested.
PolyMet	The range of dates cited in the bullets listed under “Baseline Groundwater Quality” is inconsistent with the groundwater data used for water quality modeling. For example, 2012 data from MW-05-02, MW-05-08, and MW-05-09 were used for the modeling. PolyMet recommends removing the dates from these bullets or revising the list so that range of dates is consistent with data used to develop Table 4.2.2-6. The range of dates for groundwater data used for the water quality modeling is as follows: <ul style="list-style-type: none"> • Three older wells in the surficial aquifer, sampled from March 2005 through June 2012. • 21 newer wells in the surficial aquifer, installed in November 2011 – February 2012, sampled following installation through June 2012. • Five observation wells in the upper 100 ft of the bedrock, sampled from 2006 to 2010 (current SDEIS text is correct for this bullet). • Four large-diameter bedrock wells, sampled during aquifer testing in 2005 and 2006. 	Change has been made, as requested.
PolyMet	It is not clear how the baseline values that are shown in Table 4.2.2-6, and used for comparison with the site-specific data, were selected. The Northeast MN baseline data appear to be derived only from the “unconfined buried Quaternary aquifer” category. However, the MPCA study also includes data for “buried Quaternary artesian aquifers” and “Quaternary water table aquifers.” Either the range shown in Table 4.2.2-6 should reflect data from all	Values in FEIS Table 4.2.2-6 were taken only from one of the three tables provided in the 1999 MPCA study. For the FEIS, minimum and maximum data was extracted from all three tables and provided. Conclusions have not changed; however, the range of concentrations has increased.

Sender	Comment	Response
	Quaternary aquifers in the MPCA report or the Final EIS should provide an explanation as to why only a certain subset of data presented is provided.	
PolyMet	The first paragraph describes USGS gage 04015475 as the flow record most representative of the Project area. However, this section also should acknowledge the presence of the recently-installed (for Teck American) flow gage at the Dunka Road crossing near the southeast corner of the proposed Mine Site (monitoring location PM-3/SW003) and note that, while closer to the Mine Site, the short period of record is insufficient for use in the SDEIS. This gage also should be shown on Figure 4.2.2-1.	Change has been made, as requested.
PolyMet	In the first paragraph, the text describing existing upper Partridge River water quality should mention mercury and aluminum concentrations exceeding water quality standards. The text also describes dissolved oxygen at SW002 as the only consistent exceedances. PolyMet reads the term “consistent” as meaning that all samples at that location exceeded the standard, but that should be made more clear the text. The term “consistent exceedances” also appears in section 4.2.6.1.2 (page 4-220), and it should be used in the same way in that section.	No change made.
PolyMet	There are multiple inaccuracies in Table 4.2.2-14 that should be addressed: <ol style="list-style-type: none"> 1. The average concentrations presented in Table 2.2.2-14 should include 2012 data. The 2012 data is included in Large Table 10 of the Water Modeling Data Package, Volume 1 – Mine Site v12. 2. The number of samples at SW004a and SW004b in footnote 5 is incorrect and should also include 2012 samples. The 2012 data omitted from the number of samples is included in Large Table 10 of the Water Modeling Data Package, Volume 1 – Mine Site v12. The number of samples at SW004a and SW004b should be 12 samples for each location. 3. The ranges of concentrations presented in Table 4.2.2-14 do not include the 2012 data and, therefore, may be inaccurate if maxima or minima occurred in 2012. 4. The range provided for mercury concentrations (<0.0025 ng/L to 0 ng/L) is not accurate; mercury concentrations provided in the Water Modeling Data Package – Volume 1 Mine Site v10 range from <0.5 ng/L to 18.5 ng/L. 	Change has been made, as requested.
PolyMet	Section 4.2.2.2.2, p. 4-77, Table 4.2.2-14, Section 4.2.2.2.2, p. 4-80, Table 4.2.2-15, Section 4.2.2.2.2, p. 4-87, Table 4.2.2-18, Section 4.2.2.3.2, p. 4-123, Table 4.2.2-29, Section 4.2.2.3.2, p. 4-132, Table 4.2.2-35:	The referenced tables have been revised to address this comment.

Sender	Comment	Response
	The minimum values in constituent concentration ranges shown in these tables are presented as less than half the minimum detection limit. Minimum concentrations (when not detected) should be presented consistently as either less than the minimum detection limit (e.g., “ < 10 mg/L”) or as a numeric value equal to half the minimum detection limit without a less than symbol (e.g., “ 5 mg/L”). If the latter approach is used, the footnotes should note that minimum values represent one half the detection limits.	
PolyMet	The third sentence of the fourth paragraph presents a recharge rate of 0.3 in/yr, which is inconsistent with the mean value of 0.61 in/yr used in the GoldSim model. As discussed in Sections 5.2.1.3.1 and 5.2.1.3.2 of this document, average net recharge in the Embarrass River watershed is estimated at 0.61 inches per year. A recharge rate of 0.3 in/yr represents the minimum value used in the GoldSim recharge distribution (PolyMet, 2013j; Section 5.2.1.3.2); however, it would be more appropriate to use the average value, rather than the minimum value, for the groundwater flow discussion in the SDEIS.	FEIS Table 5.2.2-11 reports the GoldSim P50 (median) aquifer recharge flux input of 0.76 in/yr for all Tailings Basin flowpaths.
PolyMet	Data for the Cell 1E pond should be included in this table. Cell 1E pond data are shown in Large Table 7 of the NorthMet Project Water Modeling Data Package, Volume 2 - Plant Site, Version 9, March 1, 2013.	No change made.
PolyMet	Regarding the first sentence, PM-13 is not “just downstream of the Heikkila Lake tributary.” It is more accurate to say PM-13 is downstream of the Unnamed Creek tributary.	The FEIS has been revised to address this comment.
PolyMet	In the second sentence, it is unclear what “low flows” refers to. Based on the low flows presented in Table 4.2.2-27, PolyMet assumes the co-leads are referring to “baseflow.” This should be clarified.	Change has been made, as requested.
PolyMet	In the third paragraph, the text describing the number of samples collected at PM-12.2, PM-12.3, and PM-12.4 should include data from 2012 (2012 data appears to be included in subsequent Table 4.2.2-29). The 2012 data is included in Large Table 4 of the Water Modeling Data Package, Volume 2 – Plant Site v9.	The FEIS has been revised to address this comment.
PolyMet	The row for PM-12 should reflect that data was collected in 2012 at this location.	Change has been made, as requested.
PolyMet	Data for PM-11 should not be presented in Table 4.2.2-34, which is titled “Summary of Surface Water Quality Monitoring Data for the Tailings Basin Surface Seeps.” Monitoring location PM-11 is located downstream of the Tailings Basin on Unnamed Creek and is not representative of a seep. Data for PM-11 should be included in Table 4.2.2-35 (which includes tributary	Change has been made, as requested.

Sender	Comment	Response
	streams) instead.	
PolyMet	In the second to last sentence of the first full paragraph, it should be clarified that seepage and dead spruce trees are not a cause-and-effect relationship. There are many beaver dams in the area that likely play a role in the presence of dead spruce trees.	The FEIS has been updated to address this comment.
PolyMet	The last sentence under “National Hierarchical Framework of Ecological Units” reads: “Inclusion of the One Hundred Mile Swamp would likely complete representation of prominent ELTs in LTA 212Le11.” Polymet suggests clarifying by revising this sentence is to say: “The One Hundred Mile Swamp and the two other sites surveyed provide a complete representation of the prominent ELTs present within LTA 212Le11.”	Change has been made, as requested.
PolyMet	The third sentence of the third paragraph suggests that PolyMet will submit a revised wetland permit application. In fact, PolyMet has already submitted a revised wetland permit application, which appears as “PolyMet 2013q. NorthMet Project Revised Wetland Permit Application, Version 1. Issued August 19, 2013” in the references.	The FEIS has been updated to address this comment.
PolyMet	The first sentence of this section references three figures for the location of the Mine Site, in relation to Iron Lake and the Laurentian Divide. However, none of the figures show Iron Lake or the Laurentian Divide. The text should be revised to account for this or the figures should be edited to include Iron Lake. This issue occurs in other sections as well, such as the first sentence of Section 4.3.3.1.	The FEIS text has been edited. The Laurentian Divide boundary was added to FEIS Figure 4.2.2-1, and FEIS Section 4.2.3 refers to this figure. The reference to Iron Lake was removed.
PolyMet	The third sentence of the first paragraph should cite the USACE memo (USACE, May 2013) in addition to the baseline wetland type evaluation.	No change to EIS; USACE memo does not cite this information.
PolyMet	The first sentence of the third paragraph reads as though vegetation types are indicative of pre-settlement conditions. However, this is misleading, as there has been a significant amount of logging disturbance throughout the mine site.	The FEIS has been updated to address this comment.
PolyMet	General comment in Sections 4.2.4, 4.3.4, 5.2.4 and 5.3.4 Scientific and common names are used inconsistently throughout these sections. PolyMet recommends using consistent terms throughout the document for clarity.	Change has been made, as requested.
PolyMet	The text on page 4-192 names three ETSC species in Transportation and Utility Corridor, but Table 4.2.4-7 only lists one of these species. This inconsistency should be resolved.	No changes made. The text preceding this Table 4.2.4-7 explains that the other species overlap the Mine Site, and thus are not double-counted in the Transportation and Utility Corridor.

Sender	Comment	Response
PolyMet	General Comment to Sections 4.2.5, 4.3.5, 5.2.5, 5.3.5[:] PolyMet recommends either substituting the word “bat” for the term “Myotis” or adding “(bat)” after “Myotis.”	Change has been made, as requested.
PolyMet	In the fifth paragraph, the statement that lynx critical habitat “includes most of northeastern Minnesota” is imprecise. PolyMet recommends adding the clarification that the USFWS designated critical habitat does not include most of the Iron Range.	No change made.
PolyMet	The last sentence of the third paragraph references “forest and brush habitats” but parenthetically cites MIHs 1 to 14. PolyMet believes the citation was intended to be MIHs 1 and 14.	No change made.
PolyMet	Regarding the last sentence of the third paragraph [(under Bald eagle heading)], there are no standing dead trees in the existing LTVSMC Tailings Basin.	Text has been clarified to state, “Eagles may use standing dead trees near the existing LTVSMC Tailings Basin for perching.”
PolyMet	The second paragraph should reference Moose zone 3, not Moose zone 30.	No change made. The moose zone is 30 according to MDNR information and maps.
PolyMet	The fourth sentence of the second paragraph incorrectly states that the Tailings Basin is “unlikely to be heavily used by wildlife.” The Tailings Basin is a local refuge for herds of deer, small mammals and wolves.	No change made.
PolyMet	The first sentence in the first paragraph references the Longnose, Wetlegs and Wyman creeks as surface water features in the Upper Partridge River Watershed. However, there is no discussion on these creeks or a reference to a previous discussion in the SDEIS. PolyMet recommends either providing a similar discussion of that provided for Mud Lake, Yelp Creek, and Second Creek on page 4-214 or explaining why such analysis is not provided.	Change has been made, as requested.
PolyMet	The second sentence uses the term “watershed” while the third sentence uses the term “larger watershed.” PolyMet suggests explaining the difference between a “watershed” and a “larger watershed.”	No change made.
PolyMet	The first sentence of the third paragraph should be revised to add Yelp Creek to the list of streams where “no fish or macroinvertebrate community or habitat characteristics could be documented”	No change made. Fish and macroinvertebrate sampling occurred at the confluence of Yelp and Partridge River.
PolyMet	The source of data for these stream surveys should be revised as “Source: Breneman 2005, Barr 2011b, and MPCA 2011c.” Barr 2011b is the source of the information for the PM sites.	Change has been made, as requested.
PolyMet	PolyMet recommends that the introductory paragraph state that the NHPA process is proceeding on a parallel path to the NEPA process, and that effects on cultural resources have also been considered and analyzed under NEPA.	No change made.

Sender	Comment	Response
PolyMet	The last sentence of the introductory paragraph states: "Cooperating agencies have not participated in production or endorsement of any components of the EIS or the NorthMet Project." This statement is not entirely accurate, since the tribes have participated in the production of components of the EIS relative to cultural resources as well as the Major Differences of Opinion. The EIS should describe the tribes' participation in the development of the EIS.	Change has been made, as requested.
PolyMet	The second-to-last paragraph is unclear, both with respect to whether it is discussing groundwater and/or surface water, and with respect to how that discussion fits into the APE analysis. Figure 4.2.9-5, which is not referenced in this paragraph, is a groundwater quality APE, but most of the paragraph discusses surface water quality. PolyMet recommends revising this paragraph to explain how groundwater and surface water affect the APE.	Change has been made, as requested.
PolyMet	The term "Sensitive Fines" is used on the Figure, yet neither Geotechnical Data Package, Vol. 1, Version 4, nor preceding versions use the name "Sensitive Fines." April 12, 2013 Geotechnical Data Package, Vol. 1, Version 4 uses the name "Fine Tailings/Slimes." This material type is missing from the Legend on the lower left corner of Figure 4.2.14-3.	Information in the figure was sourced from the Geotechnical Data Package Volume 1 (PolyMet 2014x, as cited in the FEIS). Sensitive fines have been removed from the FEIS figures.
PolyMet	Units and labels are missing from axes [of Figure 4.2.14-3] (e.g., elevation in feet amsl and distance in feet) and the dashed lines in the figures are not in the legend (layers of material).	Dashed lines removed, distance and elevation on axis.
PolyMet	In the first full sentence [of Section 4.3.3.1.1, p. 4-434], floodplains should be clearly defined, and PolyMet recommends including a figure showing mapped floodplains with wetlands.	A definition of floodplain is included in the FEIS and the floodplains are shown on Figures 4.3.3-2 and 4.3.3-5.
PolyMet	The table combines coniferous bogs and coniferous swamps. PolyMet recommends separating these two wetland types here, in the same way that they are separated for discussions of the federal lands. This is also an issue in Tables 4.3.3-6, 4.3.3-8, 4.3.3-10, 4.3.3-12.	Please refer to theme WET17 response.
PolyMet	The table contains inaccurate acreage for open bog and shallow marsh. Open bog should be 2.1 acres, and shallow marsh should be 84.1 acres. In addition, the third sentence under Table 4.3.3-6 should also be edited from: "Large bogs dominate much of the east-central portion of Tract 1" to the suggested "Shrub swamps dominate much of the east-central portion of Tract 1." The current sentence is inaccurate because there are only 2 small bogs (2.1 acres total) on the Hay Lake parcel.	Tables in the FEIS have been corrected. FEIS language was reviewed and no change to this sentence.
PolyMet	In footnote 2 [of Table 4.3.4-5], PolyMet suggests deleting the phrase "additional populations may be present in more marginal, secondary habitat that was not surveyed, or in wetter areas." There is no evidence (no survey) of	Change has been made, as requested.

Sender	Comment	Response
	additional populations in marginal, secondary habitat, and the SDEIS should make that clear.	
PolyMet	This section [(4.3.5.2.1)] discusses “species of tribal concern.” This is not a legal category. PolyMet recommends deleting this phrase.	No change made.
PolyMet	The first sentence in the second paragraph should be revised to read “Some of the non-federal lands... ” Not all of the non-federal lands have streams, creeks, rivers, or lakes on them.	Change has been made, as requested.
PolyMet	This paragraph incorrectly compares Coyote Creek with Stony River. These are not comparable systems. The Stony River is a higher order, more diverse aquatic system than the first order, headwaters Coyote Creek. It cannot be assumed that the conclusions drawn from the studies for Stony River are applicable to Coyote Creek.	No change made. The text is not comparing the two systems but only states that since high quality habitat is likely present in Coyote Creek some of the fish species present within the Stony River could be present in the headwater habitats of Coyote Creek.
PolyMet	The second paragraph is one sentence and cites “MIH 14.” PolyMet recommends that this paragraph first provide some description of the MIH 14 before making the statement it currently contains.	Change has been made, as requested.
PolyMet	The first sentence of the second full paragraph states that the “groundwater containment system would capture at least 90 percent of seepage from the Tailings Basin.” This is incorrect. The system will capture 100% of surface seepage and upwelled water, and at least 90% of seepage that remains as groundwater flow. Overall, 99% of seepage from both surface and groundwater will be captured. The sentence, as written, implies that the system will be less effective than it will be.	Change has been made, as requested.
PolyMet	<p>The 4th paragraph states: “With the proposed design modifications and engineering controls, the water quality model predicts that the NorthMet Project Proposed Action would not cause or increase the magnitude of an exceedance of the groundwater and surface water quality evaluation criteria at the P90 level for any of 28 solutes at 29 groundwater or surface water evaluation locations within the Partridge River and Embarrass River watersheds...”</p> <p>PolyMet proposes the following language: “With the proposed design modifications and engineering controls, the water quality model predicts that the NorthMet Project Proposed Action would not cause or increase the magnitude of an exceedance of the groundwater and surface water quality evaluation criteria at the P90 level for any of the 27 solutes and mercury (further addressed below) at 29 groundwater or surface water evaluation locations within the Partridge River and Embarrass River watersheds...”</p>	The FEIS has been revised to address this comment.

Sender	Comment	Response
PolyMet	<p>The 3rd paragraph states: “Within the water quality modeling, estimated concentrations for these six metals are compared to hardness-based standards at each model evaluation location and each model time step to determine compliance with the evaluation criteria.”</p> <p>PolyMet proposes the following language: “Within the water quality modeling, modeled concentrations for these six metals are compared to hardness-based standards at each model evaluation location and each model time step to determine compliance with the evaluation criteria.”</p>	Change has been made, as requested.
PolyMet	<p>The 4th paragraph states “Methylmercury is much more of a problem than inorganic mercury, in that it can accumulate to concentrations of concern in the aquatic food chain, it is more bioavailable than inorganic mercury, and it can bioaccumulate in fish, wildlife, and humans.” The term “problem” suggests a conclusion, when this sentence is actually describing concerns.</p> <p>PolyMet proposes the following language: “Methylmercury is more of a concern than inorganic mercury, in that it can accumulate to concentrations of concern in the aquatic food chain, it is more bioavailable than inorganic mercury, and it can bioaccumulate in fish, wildlife, and humans.”</p>	Change has been made, as requested. The word “problem” has been replaced with the word “concern”.
PolyMet	<p>The first sentence at the top of the page reads: “Research suggests that total mercury concentrations in streams and methylmercury content in fish are roughly proportional within individual watersheds (USGS 2010), such that, for example, a 5 percent increase in total mercury in water would be expected to result in about a 5 percent increase in mercury content in fish within that watershed.”</p> <p>This sentence should be changed to clearly state that the potential incremental change in fish mercury concentration is an evaluation criterion and that MPCA’s Mercury Risk Estimation Method (MMREM) was used to assess the potential changes in fish mercury concentrations in nearby lakes. The MMREM is a method that relies on empirical fish contamination data, combined with the principle of proportionality between mercury in fish and atmospheric deposition (MPCA 2006a, as cited in the FEIS, MMREM guidance document).</p>	Change has been made, as requested. Additional text has been included.
PolyMet	Modeling results for location UC-1 are not presented in the SDEIS. Therefore, this location should not be shown in Figure 5.2.2-6 as a model evaluation location.	Change has been made, as requested.
PolyMet	The 3rd and 4th sentences of the first paragraph should be clarified to reflect that the Plant Site MODFLOW model was not calibrated to baseflow in the Embarrass River, nor was the model used to estimate baseflow.	Change has been made, as requested.

Sender	Comment	Response
PolyMet	Regarding the last sentence on the page, the regional MODFLOW model calibration was not updated to the revised baseflow estimates from XP-SWMM. The Mine Site Water Modeling Data Package Attachment C provides: “The regional model calibration was not updated because the original calibration did not incorporate a baseflow estimate and previous sensitivity analysis indicated that the local-scale model results were not sensitive to the lateral boundary conditions that were defined by the regional model (Barr, 2007). Therefore, the perimeter boundary conditions for the local-scale model remained unchanged.”	Change has been made, as requested.
PolyMet	The footnote on the “Specific yield” column of the table [(5.2.2-9)] only applies to the surficial deposits, not the entire column in the data table.	Change has been made, as requested.
PolyMet	The 1st paragraph states: “GoldSim was programmed with a suite of complex algorithms to estimate the release of contaminants from mine facilities (i.e., “sources”) and their transport to groundwater and surface water evaluation locations.” PolyMet suggests the following language: “GoldSim was programmed with a suite of algorithms to estimate the release of contaminants from mine facilities (i.e., “sources”) and their transport to groundwater and surface water evaluation locations.”	Change has been made, as requested.
PolyMet	The 1st paragraph states: “The onset of acidic pore water is also problematic, as these conditions cause the rate of sulfide oxidation to increase and the concentration of metals to increase as precipitates dissolve.” PolyMet suggests the following revision: “The onset of acidic pore water is also of concern, as these conditions cause the rate of sulfide oxidation to increase and the concentration of metals to increase as precipitates dissolve.”	Change has been made, as requested.
PolyMet	<p>The bulleted list near the middle of the page provides slightly incorrect sulfide sulfur ranges for the waste rock classification criteria, as well as an incorrect reference for this information. The sulfide sulfur classification criteria for the categories of waste rock should be revised as follows:</p> <ul style="list-style-type: none"> • Category 1 – sulfur content less than or equal to 0.12%. • Category 2 – sulfur content greater than 0.12% and less than or equal to 0.31%. • Category 3 – sulfur content greater than 0.31% and less than or equal to 0.60%. • Category 4 – sulfur content greater than 0.60%. <p>Categories 2 and 3 are combined to produce Category 2/3 with sulfur content greater than 0.12% and less than or equal to 0.60%.</p>	Change has been made, as requested.

Sender	Comment	Response
	This information can be found in Section 4.4.1 of the Waste Characterization Data Package v10 (PolyMet 2013)	
PolyMet	The first sentence of the last paragraph on page 5-53 states that “the GoldSim model simulates constituent release from waste rock based on assumptions that either extrapolate from conditions observed under field-scale weathering of similar rock (Category 1 waste rock) or in laboratory tests (Category 2, 3, and 4 waste rock, and ore).” This should be revised to indicate that constituent release for all categories of rock is based on data from laboratory tests. Constituent release rates for all categories of rock are estimated by applying a scaling factor to lab rates to account for likely differences between field and lab conditions. The scaling approach differs between Category 1 and the other categories of rock, but release rates for all categories of rock are based on laboratory data.	Change has been made, as requested.
PolyMet	The second paragraph states: “The 80 percent rate is used because seepage from the south side of Tailings Basin is likely higher than the flow contribution to Second Creek that would occur from the Basin footprint for natural ground conditions (i.e., if the Tailings Basin were not present)”. This statement is not correct. The 80% is to limit the project impact on flow to +/- 20% of existing conditions, as is recommended by MDNR on Page 5-14.	Change has been made, as requested.
PolyMet	PolyMet suggests revising the third full paragraph as follows: “WWTP effluent that would be used remaining after flow augmentation to Second Creek would be discharged to the three Embarrass River tributaries (Unnamed, Trimble, and Mud Lake creeks), as partial or complete fulfillment of required augmentation to maintain downstream hydrology and wetland function in Second Creek and the three Embarrass River tributaries (Barr 2013a). Pumping from Colby Lake would be used to meet any remaining augmentation requirement.”	No change made.
PolyMet	The second paragraph states: “Tailings seepage bypassing the containment system (approximately 19.4 gpm) would continue...”. On page 5-8 (Section 5.2.2) and in Table 5.2.2-36, the flow bypassing the containment system is said to be “about 21 gpm.” PolyMet recommends revising for consistency.	Change has been made, as requested.
PolyMet	The active source period for the Category 4 Stockpile is incorrect. The stockpile will be removed during the development of the Central Pit and will be entirely removed by the end of Mine Year 11.	Change has been made, as requested.
PolyMet	The last full paragraph should acknowledge that the pH in the East Pit backfill will be monitored and adjusted by the addition of alkaline water from the WWTF as backfilling progresses in order to maintain circum-neutral	Change has been made, as requested.

Sender	Comment	Response
	conditions in the backfill pore water.	
PolyMet	The SDEIS states: “The quality of this aquifer inflow would reflect the quality of the pit lake water, which would gradually improve over time due to cycling through the WWTF.” However, the West Pit water will not be cycled through the WWTF during reclamation. PolyMet suggest revising the text to: “The quality of this aquifer inflow would reflect the quality of the pit lake water, which would gradually improve over time due to the effectiveness of the reclamation activities at the site.”	Change has been made, as requested.
PolyMet	The SDEIS states: “Cobalt was generally used to illustrate groundwater transport at the Mine Site because it is not attenuated and would enter the surficial flowpaths at concentrations higher than baseline groundwater.” This statement is misleading. PolyMet suggests rewording to the following: “Cobalt was generally used to illustrate groundwater transport at the Mine Site because the model did not account for attenuation, and would enter the surficial flowpaths at concentrations higher than baseline groundwater.”	Change has been made, as requested.
PolyMet	The first paragraph incorrectly states that flow augmentation must be at least 145 or 180 gpm, which is 80% of capture flow rate of the current south-side seepage. Table 5.2.2-40 shows 400 gpm, which is the correct rate for augmentation (see The Water Modeling Data Package – Volume 2 Plant Site v9). The same error is made in the last paragraph on Page 5-153 (Section 5.2.2.3.2).	No change made.
PolyMet	The first paragraph of this section only discusses quantities of seepage during closure and not operations. The paragraph below could be added to discuss these aspects during operation: “During operations, the Category 1 Stockpile would be uncovered. Infiltration would percolate to the bottom of the stockpile and be collected by the surrounding groundwater containment system. As the stockpile footprint is expanded, the total seepage during operations will increase up to a maximum annual flow of between 290 gpm and 440 gpm. Most of this seepage would be collected and sent to the WWTF for treatment; an estimated peak flow of 20 gpm to 30 gpm would pass below the containment system and be drawn by gravity into the dewatered West Pit.”	Change has been made, as requested.
PolyMet	This table [(5.2.2-28)] is consistent with what was provided in the AWMP, but the corresponding text on Page 5-125 leaves the inaccurate impression that the effluent targets were what was modeled as effluent concentrations. The text should be modified to match the table.	No change made.

Sender	Comment	Response
PolyMet	The use of the term “non-contact stormwater” in this table [(5.2.2-29)] and elsewhere in the text is somewhat confusing, as it seems to imply that this is water being managed by PolyMet. PolyMet recommends using the more appropriate term “unimpacted watershed runoff.”	No change made.
PolyMet	The first paragraph on this page should acknowledge that there is a low probability for exceedances caused by the project.	No change made.
PolyMet	Unnamed Creek should be included in the discharge locations for the WWTP effluent. SD006 is the location for Unnamed Creek, not Second Creek. The table organization contradicts language found in the last paragraph of page 5-177, which states “augmentation flow to Unnamed Creek would be via a single discharge near the current SD006 discharge.”	Change has been made, as requested.
PolyMet	The text states: “The rate at which contaminants would move through the groundwater would be the same as the groundwater seepage velocity downgradient of the containment system for all but four constituents (arsenic, antimony, copper, and nickel).” ..Because no attenuation values are used for the constituents – other than arsenic, antimony, copper, and nickel – the modeled rate of groundwater transport will be faster than the actual rate of transport in the ground. PolyMet recommends noting this fact in the text.	Change has been made, as requested.
PolyMet	The second to last paragraph states: “...the concentrations of these metals in the WWTP effluent would be significantly higher than the concentrations in the current Tailings Basin seepage...” This sentence should be revised to use the term “modeled concentrations...” The modeled effluent concentrations from the WWTP are higher than the values reported in pilot testing of the proposed treatment systems for the WWTP, but were selected to be near, and slightly below, the potential effluent limit for the modeled constituents to provide a conservative assessment of potential consequences related to downstream water quality. PolyMet also recommends making this adjustment in Table 5.2.2-47 on page 5-188.	Change has been made, as requested.
PolyMet	The second to last paragraph states: “...the average aluminum concentration in the WWTP influent and effluent would be about 10 mg/L...” This should be 10 µg/L.	Change has been made, as requested.
PolyMet	The first paragraph following the bulleted list states: “This dilution effect is demonstrated by the increase in measured aluminum concentrations from upstream tributary locations (UC-1, TC-1, and MLC-3) to downstream locations (PM-11, PM-19, and MLC-2), where upstream locations would average less than 100 µg/L compared to downstream locations averaging about 142 µg/L.” It is unclear whether this refers to observed or modeled	Change has been made, as requested.

Sender	Comment	Response
	conditions. The use of the term “measured” implies reference to actual, observed data, but stating that upstream locations “would average less than...” implies model results. It also is unclear whether the 100 µg/L and 142 µg/L figures are modeled or observed.	
PolyMet	There appears to be inconsistency in the chromium standard that is used in this chapter. The referenced pages state: “Among the six constituents with hardness-based evaluation criteria (cadmium, chromium (III), copper, lead, nickel, and zinc)...” and Table 5.2.2-4 lists chromium (III), as the evaluation criteria with a hardness based standard. However, later in the document, the standard for chromium (VI) is used in Tables 5.2.2-30 and 5.2.2-42 for example. Please clarify which standard was used for chromium, and why.	Change has been made, as requested.
PolyMet	The number of pit lakes should be 16, not 21 as reported in this table [(5.2.2-49)].	Change has been made, as requested.
PolyMet	The third paragraph states “...precipitation, which averages about 9.8 ng/L based on average volume-weighted mercury in precipitation as measured at the Marcell Experimental Forest deposition site in Itasca County (NADP 2013).” Barr’s analysis, consistent with the table on the next page, is based on 13 ng/L deposition based on the Fernberg Road site. PolyMet recommends citing the Fernberg Road concentration of 13.2 ng/L instead of the Marcell concentration of 9.8 ng/L. This comment also applies to the SDEIS’s cumulative impact discussion in the first paragraph of p. 6-31 and second paragraph of p. 6-33 (Section 6.2.3.3.4).	Change has been made, as requested.
PolyMet	The second bullet, when explaining the predicted increase in mercury loading to the Embarrass River, states: “Tailings Basin containment system, which would collect seepage from the Tailings Basin, with an estimated mercury concentration of 1.1 ng/L, and route it to the WWTP, which would discharge with an assumed mercury concentration of 1.3 ng/L, for a net increase of 0.2 ng/L of mercury as a result of wastewater treatment, which is a conservative assumption.” PolyMet suggests explaining that the reason this is conservative is because the WWTP would reduce mercury concentrations, and any additional mercury removal from installing a greensand filter, are not accounted for.	Change has been made, as requested.
PolyMet	The second bullet under NorthMet Project Proposed Action Design Changes states: “The location of the Category 4 Stockpile was shifted such that seepage would be captured in the Central Pit and East Pit and would minimize effects on surficial groundwater.” The terminology and locations used here are confusing. PolyMet suggests the following instead: “The	Change has been made, as requested.

Sender	Comment	Response
	location of the Category 4 Stockpile was shifted such that water contacting the stockpile would be captured in the East Pit and would minimize effects on surficial groundwater.”	
PolyMet	The sixth bullet states: “Refined Hydrometallurgical Flowsheet – A single (rather two) autoclave would be fed with nickel concentrate and produce copper concentrate produced with beneficiation refinements. The production of hydrometallurgical residue would be cut approximately in half with this design change. Residual copper would be recovered by cementation (contacting the leach solution with copper concentrate) to further upgrade the copper concentrate and to further reduce the production of hydrometallurgical residue.” To be more precise, the last phrase should be changed to: “. . . , and to potentially further reduce the production of hydrometallurgical residue.”	Change has been made, as requested.
PolyMet	The first bullet discusses subaqueous disposal of reactive waste rock, but it does not mention subaqueous disposal of some of the Category 1 waste rock. Although Category 1 waste rock is considered the least reactive waste rock, it should still be mentioned here.	Change has been made, as requested.
PolyMet	The fourth bullet discusses the use of side dump cars to haul ore and states: “Ore Transport – PolyMet proposes to use side-dump rail ore cars that would minimize ore spillage (PolyMet 2013c).” Side dump rail cars were proposed as part of the DEIS, as documented in DEIS Section 3.1.3; therefore, this is not a design change and should not be included in this section.	Change has been made, as requested.
PolyMet	The seventh bullet discusses the tailings basin containment system and refers to it as being “on the western, northern, and northeastern sides of the existing LTVSMC Tailings Basin.” The containment system is not located along the northeastern side of the tailings basin; it is located on the western and northern sides of the tailings basin, as described appropriately on SDEIS Page 3-116 (under Engineering Water Controls).	Change has been made, as requested.
PolyMet	The first bullet, as part of a tabulation of fixed engineering controls, states: “Process water management, including pipes, pumps, and process water ponds that would be used to separate and control stormwater and process waters.” This statement does not account for the fact that the process water ponds are lined. Accordingly, PolyMet recommends inserting “lined” before “process water ponds.”	Change has been made, as requested.
PolyMet	The flow monitoring for stormwater has footnotes stating that flows would be monitored continuously. There are no pumps associated with this infrastructure, so continuous flow monitoring is not proposed for stormwater flows. Flows are proposed to be monitored on a monthly basis as specified in	Change has been made, as requested.

Sender	Comment	Response
	the Water Management Plan – Mine (v2) Section 5.2.	
PolyMet	table [5.2.2-53] includes water level monitoring for Whitewater Reservoir. This was not included in the Water Management Plan – Mine and has never been discussed with the agencies.	The FEIS has been revised to reflect most recent documentation.
PolyMet	The fourth bulleted item is misleading and should be clarified by changing the text in parentheses to say “within Area 1.”	The FEIS has been revised to address this comment.
PolyMet	The first paragraph states “The analog approach was based on similar mine settings (e.g., within the glacial till region).” PolyMet proposes the following revision: “The analog approach used observations of groundwater response adjacent to iron range mines characterized by moderate to high hydraulic conductivity glacial and fluvial deposits overlying lower hydraulic conductivity bedrock.”	The FEIS has been revised to address this comment.
PolyMet	The third sentence of the first full paragraph should be clarified by identifying the source and rationale behind using 675 square meters of watershed area per meter of track in the contributing watershed as the method for identifying potentially impacted wetlands.	The FEIS has been revised to address this comment.
PolyMet	In the second sentence of the third paragraph, it is an overstatement to suggest that wetlands represent pre-European settlement conditions, as the area was likely logged several times since settlement.	The FEIS has been revised to address this comment.
PolyMet	The second bullet should read: “In-kind mitigation means the replacement of the impacted aquatic site with the same wetland plant community type.” See USACE, 2009, II.D.3.	The FEIS has been revised to address this comment.
PolyMet	The third bullet should read: “Out-of-kind mitigation means the replacement of an impacted aquatic site with a different wetland plant community type.” See USACE, 2009, II.D.3.	The FEIS has been revised to address this comment.
PolyMet	In the second paragraph, the rule citation is incorrect as is the interpretation of the rule. The second paragraph should read: “The Federal Mitigation Rule also states that “difficult-to-replace” aquatic resources include bogs (33 CFR 332.3(e)(3) and Preamble, page 19633). The majority of the wetlands that would be affected by the NorthMet Project Proposed Action would be “difficult-to-replace” (coniferous bog and open bog) (USACE 2013, as cited in the FEIS). The Federal Mitigation Rule includes a provision for a case-by-case determination of mitigation ratios higher than the minimum 1:1 where necessary to account for the difficulty of restoring or establishing the desired aquatic resource type and functions.”	The FEIS has been revised to address this comment.
PolyMet	The third sentence of the third paragraph is not supported by the data	The FEIS has been revised to address this comment.

Sender	Comment	Response
	collected for the project. None of the wetlands proposed to be affected by the project were rated as having exceptional vegetative diversity/integrity ratings.	
PolyMet	The second to last sentence in the fourth paragraph should read: "For effects on wetlands with rare or exceptional functions or difficult-to-replace bogs, the USACE may require additional compensation in accordance with District Policy and the Federal Mitigation Rule."	The FEIS has been revised to address this comment.
PolyMet	The first sentence of the second to last paragraph should read: "If none of these incentives are met, the minimum mitigation ratio required is 1.5:1."	The FEIS has been revised to address this comment.
PolyMet	The third paragraph states that base compensation ratios could be increased to 2:1. There is not rationale or reference provided for this statement, which is not specifically stated in the District Policy or Federal Mitigation Rule. The same comment applies to page 5-316 and page 5-321.	The FEIS has been revised to address this comment.
PolyMet	The 6 rows [in Table 5.2.3-17] beginning with "<50%..." and "<80%..." are not relevant to the PolyMet project and could be removed in order to maintain clarity.	The FEIS has been revised to address this comment.
PolyMet	The first paragraph after the list should read: "The financial assurance requirements would be part of the WCA permitting process for the NorthMet Project Proposed Action. Wetland replacement for the NorthMet Project Proposed Action is expected to be approved and constructed in advance of any authorized wetland effects (under the WCA approval) and, therefore, would not require financial assurance."	The FEIS has been revised to address this comment.
PolyMet	No reference is provided for the statements made in the fourth paragraph. Justification for why the wetland mitigation opportunities discussed in this paragraph were determined to not be practicable was provided in "Wetlands Mitigation Plan Supplement – Wetland Mitigation Planning and Siting Documentation," RS20T Draft-04, PolyMet, June 1, 2008. One additional difficulty with such wetland mitigation opportunities that was not discussed in the reference provided is the presence of severed mineral rights on many of those lands. In order to place restrictions on the land, as required for wetland mitigation, those mineral rights would need to be controlled.	The FEIS has been revised to address this comment.
PolyMet	In the last paragraph, the third sentence should read: "The mitigation would be considered in advance if the initial phases of restoration on all of the proposed off-site wetland mitigation sites would be completed at least one full growing season in advance of the authorized wetland effects provided initial performance standards are met for which the mitigation would compensate." Also, in the last paragraph, 939.4 acres is stated with no	The FEIS has been revised to address this comment.

Sender	Comment	Response
	reference. That number should be referenced to Tables 5.2.3-19 and 5.2.3-20 of the 404 permit application.	
PolyMet	In the fifth paragraph, the first sentence should read: “The minimum replacement ratio that would be allowed by the USACE is 1:1 (USACE, 2009) for those wetlands that would be replaced with the same wetland type, and at least one full growing season in advance of the authorized wetland effects provided initial performance standards are met; however, base compensation ratios could be increased to 2:1 (add reference) for effects on wetlands with rare or exceptional functions or difficult-to-replace bog wetlands.”	The FEIS has been revised to address this comment.
PolyMet	The first sentence in the last paragraph (before the bullet), should read: “Under the Minnesota WCA, the replacement ratio that would likely be allowed is 1.5:1, because the Aitkin Site wetlands are out of the NorthMet Project area watershed (see Tables 5.2.3-18 and 5.2.3-20).”	The FEIS has been revised to address this comment.
PolyMet	The first sentence in the second paragraph should read: “The minimum replacement ratio that would be allowed by the USACE is 1:1 (USACE, 2009) for those wetlands that would be replaced with the same wetland type, and at least one full growing season in advance of the authorized wetland effects provided initial performance standards are met; however, base compensation ratios could be increased to 2:1 (add reference) for effects on wetlands with rare or exceptional functions or difficult-to-replace bog wetlands.”	The FEIS has been revised to address this comment.
PolyMet	The first sentence in the third paragraph should read: “Under the Minnesota WCA, the replacement ratio that would likely be allowed is 1.5:1, because the Hinckley Site wetlands are out of the NorthMet Project area watershed (see Tables 5.2.3-18 and 5.2.3-20).”	The FEIS has been revised to address this comment.
PolyMet	The first sentence in the last paragraph should read: “The minimum replacement ratio that would be allowed by the USACE is 1:1 for those wetlands that are replaced with either the same wetland type, or at least one full growing season in advance of the authorized wetland effects provided initial performance standards are met; however base compensation ratios could be increased to 2:1 for effects on wetlands with rare or exceptional functions or difficult-to-replace bog wetlands.”	The FEIS has been revised to address this comment.
PolyMet	The first sentence on the page (continuing from the previous page) should read: “For low- to moderate-quality wetlands, the recommended base ratio of 1.5:1 would be reduced to 1.25:1 for in place and could be reduced to 1:1 if also either in-advance or in-kind.”	The FEIS has been revised to address this comment.

Sender	Comment	Response
PolyMet	The section on the Zim Site does not include any description of restoration methods and sequencing, which is included in the descriptions for the Aitkin and Hinckley sites. See “Zim Sod Wetland Mitigation Site Wetland Mitigation Plan” (PolyMet, November 2011) for an appropriate description.	The FEIS has been revised to address this comment.
PolyMet	A footnote should be added to the table [5.2.3-18] describing why there is 101.8 acres of on-site wetland mitigation shown in the second to last column but no associated wetland credits in the last column. Similarly, the same acreage is shown in the “On-Site (acres)” column, but no associated credits are shown in the “Total Credits” column.	The FEIS has been revised to address this comment.
PolyMet	The last paragraph states, “Approximately 72 percent of credits proposed would be located outside of the watershed.” This statement is misleading because all of the proposed credits are above the minimum 1:1 replacement ratio. In fact, 48 percent of the proposed impacts are proposed to be replaced in-kind, in-place, and ahead of time. If the on-site wetland mitigation were factored in, approximately 56 percent of the wetland impacts would be replaced within the watershed.	The FEIS has been revised to address this comment.
PolyMet	The numbers in the second sentence of the second paragraph are inaccurate. In this sentence, 7,350.7 acres should be 1,771.5 acres (based on Table 5.2.3-3; excluding the “no effect” acres) and 6,498.1 acres should be 587.1 acres (based on Table 5.2.3-4; excluding the “no effect” acres).	No change was made.
PolyMet	In the third paragraph, the third sentence should read: “At The Mine Site, an additional 16 monitoring locations are proposed and are planned within all wetlands that have received effect factor ratings of 3, 4, or 5 near the North Met Project area features and in several wetland with effect factor ratings of 1 or 2 located throughout the areas of potential indirect wetland impacts.” This is consistent with the information provided on page 5-336, second paragraph of the SDEIS.	The FEIS has been revised to address this comment.
PolyMet	The last sentence of the first full paragraph states: “Indirect effects were estimated by comparing the proximity of the NorthMet Project area infrastructure footprints to existing natural features.” Polymet suggests revising the text to read: “Vegetation communities can be affected by more than one of these types of indirect effects. For this reason, indirect effects on vegetation cannot be precisely quantified, as this would result in double-counting of vegetation community acreage where multiple indirect effects are manifested. The relative magnitude of indirect effects on vegetation communities can, however, be estimated. Typically, indirect effects are more likely to occur	The FEIS addresses this comment by adding the following text: “Typically, indirect effects are more likely to occur and/or are more likely to be evident in vegetation communities that are closer to Project components and other infrastructure (e.g., roads). Indirect effects tend to diminish with increasing distance from Project components and other infrastructure.”

Sender	Comment	Response
	and/or are more likely to be evident in vegetation communities that are closer to Project components and other infrastructure (e.g., roads). Indirect effects tend to diminish with increasing distance from Project components and other infrastructure.”	
PolyMet	In the discussion of the NorthMet Project’s effects on culturally important plants, the SDEIS discusses wild rice but notes that that “a distinct list of plant species important to the Bands is not available.” The Bands were cooperating agencies in preparation of the SDEIS, and accordingly had every opportunity to provide a distinct plant species list. If such a list is not available, PolyMet recommends stating that the Bands have not identified culturally important plants not already identified and discussed in the SDEIS.	No change made.
PolyMet	The text describes indirect effects as a certainty, when there is no basis for determining the likelihood and/or magnitude of indirect effects. Where the text makes statements such as “[Species name] may be indirectly affected by changes in hydrology”, the word “potentially” should be inserted (“may potentially be indirectly affected”) to more accurately reflect the uncertainty over the likelihood and/or magnitude of indirect effects.	Change has been made, as requested.
PolyMet	The eighth sentence of the second paragraph states: “Disturbance-tolerant species may, in some cases, actually be disturbance-dependent.” PolyMet recommends providing a citation for this claim or removing the sentence.	Change has been made, as requested. Sentence has been deleted.
PolyMet	In the second sentence of the eighth paragraph, it is misleading to state that “an average of 2,066 miles per day of vehicular traffic” would contribute to potential lynx impacts. The majority of those miles would be traveled within the pit/mine site and not along outside roads where lynx encounters would be far more likely.	No change made. The FEIS states that this traffic would primarily be from hauling ore within the Mine Site to rail siding and waste rock to the stockpiles. Further, the FEIS states that haul traffic would likely have little direct effect on lynx.
PolyMet	Second paragraph: The Transportation and Utility Corridor runs both parallel and perpendicular to the identified wildlife travel corridors.	Change has been made, as requested.
PolyMet	The last paragraph states: “Effects on aquatic biota from the lead exceedance due to changes in hardness are not well understood, but would likely increase the potential to adversely affect aquatic life.” This statement does not acknowledge that the modeling results predict increased potential for a lead exceedance (due to the use of a probabilistic model); rather, the statement incorrectly implies that there will inevitably be a lead exceedance.	Sentence was removed when updating section with v6 modeling results.
PolyMet	In the second paragraph, it should be noted that most of the floodplain on the federal land is outside of the Project Area.	No change made.
PolyMet	The right-most table column heading should be renamed “Non-FEMA	FEIS language has been revised to refer to mapped and

Sender	Comment	Response
	regulated floodplains.” A column should be added for “FEMA-regulated floodplains.” This comment also pertains to Table 5.3.3-7.	unmapped floodplains.
PolyMet	Table 5.3.3-5[:] The subtotal for open bog on non-federal lands is not accurate. The number should be 7.1 acres.	The FEIS has been revised to address this comment.
PolyMet	[In] Table 5.2.7-22... “Inhalation only acute” and “chronic non-cancer HI” should be displayed with 1 significant figure – i.e. 1 not 1.0.	The FEIS has been updated to address this comment.
PolyMet	In the last paragraph, the incremental risk at Wynne Lake for a recreational fisher should be as 0.07 in Plant Site AERA report, not 0.08.	No change made.
PolyMet	The third sentence of the first paragraph inaccurately states that H2SO4 was “screened out.” The estimated risk was added to the other chemicals evaluated to obtain the total.	No change made.
PolyMet	The sixth sentence of the first paragraph inaccurately states that H2SO4 was “screened out.” The estimated risk was added to the other chemicals evaluated to obtain the total.	No change made.
PolyMet	The third paragraph states: “Conceptual designs of the waste rock stockpiles, Tailings Basin, and Hydrometallurgical Residue Facility have been developed and shown by PolyMet, through an iterative design and model process, to meet the minimum safety factors and water quality criteria (see Section 5.2.2) acceptable to the Co-lead Agencies. PolyMet suggests changing the word ‘conceptual’ to ‘preliminary’.	Change has been made, as requested.
PolyMet	The second bullet under Design Criteria states: “Factor of safety greater than or equal to 1.3 for short-term, undrained strength conditions for soils that are not prone to static liquefaction using undrained strength conditions.” This sentence should be revised to indicate that this analysis does not include static liquefaction. Liquefaction is addressed subsequently.	No change made. The cited text is from the work-plan document.
PolyMet	The second paragraph uses the phrase “bulk tailings.” PolyMet recommends defining “bulk tailings” to limit potential confusion. LTVSMC Coarse Tailings are proposed for use in dam construction but since the Coarse Tailings may have occasional inclusions of fine tailings and slimes, the term “Bulk Tailings” has been used by PolyMet to describe the planned tailings borrow. The same comment applies to page 5-562, which states: “The proposed dams would be constructed from mechanically placed and compacted bulk tailings taken from the existing LTVSMC Tailings Basin as needed to produce the desired dam lift height and geometry. LTVSMC bulk tailings are currently defined as a mixture of tailings from the existing LTVSMC Tailings Basin.”	The use of bulk tailings is used respectively in context of NorthMet or LTVSMC.

Sender	Comment	Response
PolyMet	The eighth paragraph states: “As dams are constructed, exterior slopes would be covered with bentonite and vegetated. Upon reaching...” This statement is not completely accurate. On the exterior face of new dams, bentonite will be integrated into the near-surface layer of tailings. The dams will not be “covered with bentonite.”	No change made.
PolyMet	The second sentence states: “The predicted Factor of Safety values for Cross Section F at various stages of development of the Tailings Basin are summarized in Table 5.2.14-1. All slope stability factors are designed to meet the factors of safety required by the NorthMet Geotechnical Modeling Work Plan (PolyMet 2013n, Attachment A).” It is more appropriate to say that the slope stability factors are designed to meet the “applicable requirements of <i>Minnesota Rules</i> 6115.0300 through 6115.0520 and the factors of safety required by the Co-Lead agencies in the NorthMet Geotechnical Modeling Work Plan (PolyMet 2013n, Attachment A).” The first paragraph under Design Criteria on p. 5-556 contains similar language.	No change made.
PolyMet	The third paragraph states: “Modeling was undertaken to predict the long-term stability of the Tailings Basin. As shown in Table 5.2.14-1 and Table 5.2.14-4, the long-term closure slope stability Factors of Safety are above the minimum value required under the Work Plan.” It is more appropriate to say that the slope stability Factors of Safety “are above the minimum value deemed acceptable to the Co-lead Agencies and required under the Work Plan.” There is similar language in the last paragraph on p. 5-566.	No change made.
PolyMet	The second paragraph states: “Where monitoring or model updates indicate that the Factor of Safety for the Tailings Basin no longer meets design criteria, appropriate modifications to the Tailings Basin would be considered, modeled, and, if necessary, undertaken.” This sentence leaves doubt that prompt action will be taken if Factor of Safety values fall below design requirements. PolyMet recommends clarifying that mitigating measures will be explored and implemented as needed if at any time it is determined that Factor of Safety values have fallen below design requirements.	Change has been made, as requested.
PolyMet	The first paragraph states: “PolyMet took the steps listed below in order to demonstrate that the design of the Hydrometallurgical Residue Facility would meet the respective geotechnical requirements and would be in accordance with the NorthMet Geotechnical Modeling Work Plan (PolyMet 2013n, Attachment A).” PolyMet recommends revising the sentence to read: “PolyMet took the steps listed below in order to demonstrate that the design of the Hydrometallurgical Residue Facility would meet the Co-Lead Agencies respective geotechnical requirements and would be in accordance with the	The section describing the Hydrometallurgical Residue Facility has been updated for the FEIS.

Sender	Comment	Response
	NorthMet Geotechnical Modeling Work Plan (PolyMet 2013n, Attachment A) which was reviewed by the Co-Lead Agencies.”	
PolyMet	The third item under the first paragraph states: “Developed seepage and stability models using Geo-Slope International, Inc. modeling software (i.e., SLOPE/W, SEEP/W and SIGMA/W as necessary) for maximum facility dam height with minimum and maximum pond elevation, and post-closure – cover effective with minimum pond elevation the maximum.” The last phrase is poorly written and confusing. PolyMet suggests using the following revised text: “Developed seepage and global stability models using Geo-Slope International, Inc. modeling software (i.e., SLOPE/W, SEEP/W and SIGMA/W as necessary) for hydrometallurgical residue facility dam lifts 1, 2 and 3; each with maximum pond elevation, and an infinite stability model to analyze facility liner stability.”	Change has been made, as requested.
PolyMet	The text describing the figure [5.2.14-6] (see paragraph under “Identification of Design Cross Section” on p. 5-571) makes reference to Node A. Yet, Node A is not shown in the figure. There also is a blue dashed line (presumably denoting the phreatic surface in surrounding materials) that is not defined in the figure legend nor is the dashed line labeled in the figure.	Change has been made, as requested.
PolyMet	This Section [(5.2.14.2.3)] does not clearly distinguish between (1) the settlement of the Hydrometallurgical Residue Facility (HRF) foundation materials and resulting movement of the HRF liner system and (2) future consolidation of the residue deposited within the HRF and resulting movement of the residue surface. PolyMet recommends more detail to provide clarification.	The section describing the Hydrometallurgical Residue Facility has been updated for the FEIS.
PolyMet	The first paragraph states: “The results reported in Geotechnical Data Package Volume 2 Version 3 indicate that the proposed design of the Hydrometallurgical Residue Facility would meet all respective factors of safety as required (PolyMet 2012a). The modeling undertaken and results are summarized below.” PolyMet suggests revising the statement to say that the design “would meet all of the Co-Lead agencies’ respective factors of safety as required (PolyMet 2012a).”	No change made.
PolyMet	The first paragraph states: “Analysis of the new dams (i.e., those not supported by the existing LTVSMC Tailings Basin or natural topography) at their greatest height (at year 20) resulted in a computed Factor of Safety for the ESSA of 2.32, which is greater than the required minimum of 1.5.” The sentence should be revised to state that the resulting Factor of Safety is “greater than the Co-Lead Agencies’ required minimum of 1.5.”	No change made.

Sender	Comment	Response
PolyMet	The fourth sentence of the first paragraph states: “The minimum infinite slope stability safety factor for all Hydrometallurgical Residue Facility liner system components is 1.5.” It would be more appropriate if the sentence was revised to read: “The Co-Lead Agencies’ required minimum infinite slope stability safety factor for all. . . .”	No change made.
PolyMet	The last sentence in this paragraph is inaccurate because Coyote Creek and Stony River on Tract 3-Wolf Lands are not comparable systems. The Stony River is a higher order, more diverse aquatic system than the first order, headwaters Coyote Creek. It cannot be assumed that the conclusions drawn from the studies for Stony River are applicable to Coyote Creek.	Minor edits to Section 5.3.6.2.4 were made to further indicate that the sites chosen to represent Tract 3 were only assessed qualitatively.
PolyMet	The fifth paragraph states: “The only two reasonably foreseeable actions with the potential to significantly affect flow within the Partridge River and Embarrass River are the Mesaba Energy Project East Range Alternative Site and the Mesabi Mining Project, which would result in a net increase in Lower Partridge River flow as a result of pit dewatering for the foreseeable future.” This statement seems to ignore the eventual closure of the Northshore Peter Mitchell Pit (which is recognized elsewhere in the SDEIS). When that pit begins filling, Northshore will stop dewatering discharge to the Upper Partridge River. This would be a net decrease in flow relative to existing and modeled conditions. This action is anticipated within the modeling period but is not incorporated into the GoldSim model because the actual date of when this change would be made is not known. However, the potential for no discharge from Northshore to the Partridge River was considered in the sensitivity analysis conducted for the Project.	
PolyMet	The introduction to Section 6.2.3.4, “Wetlands,” on page 6-34 states that the cumulative effects analysis “focuses on direct effects” on wetlands. Page 6-43 indicates that there will not be indirect cumulative effects on wetlands because water flows will not be changed. This discussion is in some tension with the effects analysis in Chapter 5, which anticipates the potential for some indirect effects on wetlands. PolyMet recommends referencing the discussion in Chapter 5 as part of the cumulative effects discussion.	The FEIS has been revised to address this comment.
PolyMet	Regarding the third sentence of the third paragraph, no federally-listed plant species would be affected by the project because there are no federally-listed plant species in all of St. Louis or Lake Counties. PolyMet recommends re-phrasing the sentence to read, “No federally-listed plant species are known to occur on the NorthMet Project site.”	No change made.
PolyMet	In the final paragraph below Table 6.2-13, the qualifying statement regarding	No change made. This statement applies mostly to the

Sender	Comment	Response
	the lack of precision and the degree of uncertainty inherent in the evaluation methodology should be stated up front in Sections 4.2.4, 5.2.4 and 6.2.4.	cumulative analysis, as large habitat types are used in lieu of the NHIS database due to lack of data with reasonably foreseeable actions. This approach uses a best estimate based on available data.
PolyMet	The last paragraph states that “forestry management offers a greater range of options for ETSC plants to co-exist with the practice, as it can mimic natural disturbances.” This statement seems to be based on the previous statement in Section 5.2.4.2.1, p. 5-348, that “Disturbance-tolerant species may, in some cases, actually be disturbance dependent.” As stated in a prior comment, PolyMet believes this statement is misleading and that it is inaccurate to suggest that ETSC plants favor and/or are increased by disturbance regimes.	No change made. The statement regarding forestry management is accurate in that these practices can mimic windthrow or fire disturbances, which many native species are adapted to. Whereas many of the reasonably foreseeable projects would represent a complete land conversion. The statement in Section 5.2.4 was removed.
PolyMet	In the last sentence of the last paragraph, the increased percentage from the NorthMet Project Proposed Action alone should be 0.2 to 1.6 percent, not 0.2 to 1.8.	Change has been made, as requested.
PolyMet	PolyMet also recommends adding the following additional sentence at end of the paragraph at the top of the page: “This potential change is not likely statistically measureable and does not have any effect on the background fish Hg concentrations nor the current fish consumption advisories for the respective lakes.”	The following text has been added at the end of the paragraph: “This potential increase is not expected to have an appreciable effect on fish tissue mercury concentrations in the Embarrass River or Partridge River and does not have any effect on the background fish mercury concentrations nor the current fish consumption advisories for the respective lakes.”
PolyMet	<p>In the first complete paragraph, the description of how the HQ is calculated does not reflect the calculations in the MMREM spreadsheet. To estimate the potential incremental HQ, the incremental methylmercury exposure in mg/kg body weight per day and the reference dose are accounted for in the calculation. The derivation of the incremental HQ can be described as noted below:</p> <p>The incremental HQ calculation in the MMREM Spreadsheet uses the following methodology:</p> <ul style="list-style-type: none"> • Incremental daily mercury consumed (mg) = estimated incremental increase in fish mercury due to the Project (mg/kg) x the amount of fish consumed (e.g. 0.142 kg for a subsistence fisher) • Incremental methylmercury exposure (mg/kg BW – day) = Incremental daily mercury consumed x 1.07945 / adult body weight (70 kg) • Incremental HQ = Incremental methylmercury exposure (mg/kg BW – day) / Reference Dose of 1.00E-04 mg HgCH3/kg bw-day (i.e., the ratio 	Change has been made, as requested.

Sender	Comment	Response
	of the incremental methylmercury exposure divided by the reference dose in the same units).	
PolyMet	[In] Table 6.2-22... The incremental result for Mesabi Nugget noncancer acute should be 0.03. The percentages at the bottom should be 9% for Cancer and 7% for Noncancer Chronic.	Changes made
PolyMet	The third paragraph under the heading “1854 Treaty Resources” states that the NorthMet Project Proposed Action could affect treaty resources through the bioaccumulation of mercury in fish tissue. This statement is inconsistent with the SDEIS’s evaluation of cumulative effects on aquatic resources, which states that there will not be a significant increase of mercury in fish tissue. Because the subjective belief that such an effect may occur does not qualify as an effect under NEPA, the statement on page 6-95 should be removed from the SDEIS.	Increases of mercury in waterbodies from the NorthMet Project Proposed Action are discussed in FEIS Section 5.2.2, and cumulative increases are discussed in Section 6.2.3. Effects on the environment, including those from increased mercury, are all expected to meet the standards and regulations set forth by the appropriate state or federal agency or program. These laws are intended to protect important natural and cultural resources, and include but are not limited to the ESA, the CWA, and the CAA. Relative to 1854 Treaty resources and mercury, FEIS Section 6.2.3.10 is focused on the potential cultural cumulative effects on 1854 Treaty resources. Subsistence fishing and consumption is a common activity for the Bands in the 1854 Ceded Territory. Members of the Grand Portage and Fond du Lac bands are known to consume substantially more fish than the assumed statewide average. As such, increased cumulative mercury concentrations, and associated cumulative increases in mercury bioaccumulation in fish tissue, could therefore constitute an impact for Band members and other subsistence consumers of fish.
PolyMet	The final sentence in Section 7.3.1 indicates that the federal lands contain certain natural resources that are “culturally important” to the Bands. While it is accurate that these resources would be lost if the NorthMet Project Proposed Action moves forward, it is also true, and should be noted, that there is no evidence of the Bands accessing any resources at the Mine Site.	No change made.
PolyMet	The third sentence in the third paragraph of Section 7.3.1, “Irreversible or Irrecoverable Commitment of Resources,” states that while cultural resources may be adversely affected, those effects would be “minimized through avoidance.” Under Section 106 of the National Historic Preservation Act, avoidance is not the only means of addressing adverse effects on historic properties, including the cultural resources identified in the SDEIS. Agencies may also choose to adopt minimization or mitigation measures. Those options	No change made.

Final Environmental Impact Statement (FEIS)
NorthMet Mining Project and Land Exchange

Sender	Comment	Response
	should also be recognized in this paragraph.	
PolyMet	The final sentence in the first paragraph of Section 7.3.3, “Unavoidable Adverse Effects,” states that effects on water quality would remain after the implementation of mitigation measures. The paragraph should note that these effects would be minor, and not qualify as significant environmental effects.	No change made.
PolyMet	The first paragraph of Section 7.4, “PREFERRED ALTERNATIVE,” states that CEQ regulations do not require agencies to select a preferred alternative in a Draft EIS like the SDEIS. The same paragraph states that the USACE’s NEPA regulations (Appendix B of 33 C.F.R. Part 325) supersede the CEQ regulations’ “requirement to identify an agency-preferred alternative.” This description of these requirements is confusing. Neither the CEQ regulations nor the USACE regulations require the selection of a preferred alternative in the SDEIS.	The FEIS has been updated to address this comment.
PolyMet	Appendix B, p. 1, 1.2 Assessment of Material[:]. In the first sentence, “semi-qualitative” should be changed to “semi-quantitative.”	The Underground Mining Alternative Position Paper has not been updated since the SDEIS.
PolyMet	Appendix B, p. 4, 2.2 Availability[:]. The last sentence of this section should be changed to: “Notwithstanding economic considerations the underground mining alternative is available at the NorthMet Deposit.”	The Underground Mining Alternative Position Paper has not been updated since the SDEIS.
PolyMet	Appendix B, p. 5, 2.4.1 Mineralization at the NorthMet Deposit[:]. With respect to the bullet list of metal prices after the first paragraph, the referenced price for cobalt should be \$17.69 per pound.	The Underground Mining Alternative Position Paper has not been updated since the SDEIS.
PolyMet	Appendix B, p. 7, 2.4.2 Underground Mining Costs[:]. In Table 2, the Pre-production Capital Costs (\$ million) of 300 should be changed to 250. The Profit: Metal Value – Costs (\$ million) of -\$193 should be changed to -\$192 and -\$364 should be changed to -\$314.	The Underground Mining Alternative Position Paper has not been updated since the SDEIS.
USEPA	Comment# 23. Page 6-36, Table 6.2-8 and Pages 6-40 to 6-42, Table 6.2-11: There appear to be some inconsistencies between Table 6.2-8 and Table 6.2-11 with respect to reported future wetland and water resource numbers, including the bullet summaries for the Partridge River (Page 6-40) and Embarrass River (Page 6-42). For the Partridge River, Table 6.2-11 and bullet summary text note future condition with 3,516 acres of deepwater resources, while Table 6.2-8 indicates 1,922 acres. Recommendation: The FEIS should resolve or explain these inconsistencies.	The FEIS has been revised as requested.
USEPA	Comment# 24. Page 6-21, Section 6.2.3.3.2: the “Contributing Past, Present, and Reasonably Foreseeable Actions” section, lists twelve foreseeable future actions with potential cumulative effects on surface water hydrology and	The FEIS has been revised to ensure consistency with project names.

Sender	Comment	Response
	<p>quality in the Partridge River and Embarrass River watersheds. There is some inconsistency between this list and Table 6.2-1 (Page 6-7). “Cliffs Erie, LLC- Hoyt Lakes Area (former LTVSMC),” and “Cliffs Erie, LLC- Area 5 NW Pit” are not included in the table, at least not by these names.</p> <p>Recommendation: The FEIS should resolve or explain these inconsistencies, and use consistent names for foreseeable future actions to simplify cross-referencing by the reader.</p>	
USEPA	<p>Comment # 26. Pages 6-22 to 6-25 and 6-27 to 6-28, Section 6.2.3.3.3: This text does not reference sources of hydrological effects data for each action.</p> <p>Recommendation: The FEIS should reference sources of hydrological effects data for each action.</p>	Change has been made, as requested.
USEPA	<p>Comment # 33. Pages 4-261 through 4-264 refer to cultural resources/Section 106 resources solely as historic properties. Recommendation: The FEIS should make it clear that cultural resources include archaeological resources.</p>	Change has been made, as requested.
USFWS	<p>The temporary nature of the projected 500 direct jobs created during construction and additional 631 “operations-phase” jobs may result in a substantial need for temporary lodging that could impact to Voyageurs-area visitors in the form of hotel or motel room shortages.</p>	No change made.
USFWS	<p>Finally, the major differences of opinion between the lead agencies and the Bands, the Great Lakes Indian Fish and Wildlife Commission (GLIFWC), and 1854 Treaty Authority regarding the effects of the proposed actions should be resolved before any permits are issued.</p>	MDOs will be addressed during the appropriate permitting processes.
USFWS	<p>This section needs maps to illustrate the location and extent of Minnesota Biological Survey (MBS) Sites of High Biodiversity Significance in order to support the claim that the number of sites within the project area is small, and to show how much of the 100 Mile Swamp and Upper Partridge River Sites will be impacted.</p>	Change has been made, as requested.
USFWS	<p>Stating that less than 1 percent of the state’s Sites of High Biodiversity Significance would be affected is misleading because not all of these sites are of the same type.</p>	No change made.
USFWS	<p>When referring to Canada lynx (<i>Lynx canadensis</i>), page 5-365 the SDEIS states that, “Although the NorthMet Project Proposed Action would result in a reduction and fragmentation of lynx habitat at the Mine Site, little to no effect on statewide lynx populations would occur as it is unlikely that an individual lynx or pair of lynx would be affected by the habitat decrease.” This is unclear and misleading. Our suggested rewording of this is, “Although</p>	No change made.

Sender	Comment	Response
	the NorthMet Project Proposed Action would result in a reduction and fragmentation of lynx habitat at the Mine Site, little to no effect on statewide lynx populations would occur even if individual lynx are affected by the habitat decrease.”	
Water Legacy	[SDEIS, p. 4-45] there are no Foose and Cooper references listed in the SDEIS from either 1979 or 1980, so it is assumed the references and conclusions in this paragraph are from Foose and Cooper 1978 and 1981 which are cited in the list of references.	References to Foose and Cooper have been updated as requested.
Water Legacy	these statements [on pg 4-45] made relating to bedrock fractures are not supported by the references cited in the SDEIS. Neither of the two Foose and Cooper papers report that “the most extensive faults are largely filled with gouge.” Their only mention of fault gouge in these two papers is that they used its presence to trace fault zones in the field. Neither paper discusses distance groundwater may flow through faults and fractures in the Duluth Complex - in fact neither mention groundwater flow at all.	The FEIS now states that extensive bedrock fault zones may or may not be filled with gouge (references) and the effect of gouge on groundwater flow is uncertain.
Water Legacy	The SDEIS presents a discussion of lineaments lower on page 4-45 that, contrary to current geologic literature, downplays the relationship of lineaments to bedrock fractures and therefore their significance to the hydrogeology of the NorthMet Site. “Numerous lineaments have been mapped over northeastern Minnesota, but these have been associated with glacial deposition and not fracturing in the underlying bedrock (Morey 1981; Heutmaker and Morey 1982).” (SDEIS, p. 4-45) The cited literature refers to glacial “processes,” not glacial “deposition” (Morey, 1981; Heutmaker and Morey, 1982). These terms do not have the same meaning.	The FEIS now states the following: “Numerous lineaments have been mapped over northeastern Minnesota. An individual lineament may be related to glacial deposition/erosion (Morey 1981, as cited in the FEIS; Heutmaker and Morey 1982, as cited in the FEIS), a geologic contact between different bedrock types, and/or bedrock structures such as fault and fracture zones.”
Water Legacy	The quote... [(starting with “One exploration” ending with “world”)] from page 4-45 of the SDEIS stating that the upper fractured zone of bedrock has been removed by glacial scouring should be properly referenced or otherwise supported by data to be taken seriously. This statement is not supported by any of the cited references and is contrary to common knowledge that fractured bedrock is present at NorthMet. Drilling logs included in the SDEIS’ supplementary materials (PolyMet, 2013i; RS-35, RS-42 and RS-46) show intervals of weathered bedrock at multiple locations thereby reducing the credibility of this statement.	The FEIS now states that the top of bedrock has been scoured by glacial processes, but upper bedrock has not been necessarily removed.
Water Legacy	A few pages above, the term “fill” was used as a general term, now in this paragraph [on page 4-46] the term “alluvium” seems to be used as a replacement term for all surficial sediments. On page 4-149 the entire package of surficial sediments is referred to as “soil”. This is more than	Change has been made, as requested.

Sender	Comment	Response
	semantics; it leads to confusion as to exactly which surficial sediments are being referenced: the entire surficial sediment section or only till units or only alluvium units or only the post-glacial soil that exists at the land surface? This usage promotes a simplistic understanding of surficial geology, which in turn is converted into overly simple and inaccurate inputs to predictive models.	
Water Legacy	A figure showing this isopach map [referred to on page 4-45] inserted at this point in the SDEIS would be very helpful in envisioning how the surficial sediment type and thickness varies across the Mine Site. But this map neither appears in the SDEIS or among cited reference documents. The Table of Contents for Golder Associates (2007) lists the isopach map, but the file does not appear in the MDNR DVD set and was not available for review.	No change made.
Water Legacy	A detailed bedrock topography map would also be useful at several places in the SDEIS to illustrate where features such as troughs and bedrock valleys are located on the bedrock surface and to assess pathways that may transmit contaminated groundwater at the interface of the overburden and bedrock.	A figure has been added to the FEIS to address this comment.
Water Legacy	in Table 4.2.2-5... laboratory-derived hydraulic conductivity values for reported "silty sand" are shown as ranging from 0.00043 ft/day to 0.0081 ft/day. The difference between laboratory-derived hydraulic conductivity values of up to 167 ft/day reported in PolyMet, 2013 or even higher in Stark (1977) should be reconciled with the results from a silty sand presented in Table 4.2.2-5 in the SDEIS.	Laboratory permeameter tests nearly always underestimate the in situ hydraulic conductivity of natural materials. While the laboratory test results are reported, they were not used in estimating the hydraulic conductivity of surficial deposits. The estimated hydraulic conductivities of surficial deposits were based on a combination of borehole tests, model calibrations, and generic information.
Water Legacy	The SDEIS' claim [on page 4-43] of hydrologic separation from the Biwabik Iron Formation aquifer should be supported by a more robust reference than personal communication from one of PolyMet's consultants. The SDEIS should include an accurate geologic cross-section based on actual drilling information, showing the locations of faults and fractures, not a schematic or overly generalized cross-section where subsurface conditions can be so easily misrepresented.	Change has been made, as requested.
Water Legacy	The examples of incorrect usage of geologic terminology in the SDEIS below suggest the sections on geology were not given the level of editorial review appropriate for a scientific publication. "The NorthMet Deposit itself is below the surficial till in the layered mafic intrusive rocks of the Duluth Complex, which are part of the Partridge River intrusion." (SDEIS, p. 4-43) Actually the Duluth Complex is not part of the Partridge River intrusion. The Partridge River intrusion is part of the Duluth Complex.	Change has been made, as requested.
Water Legacy	[The examples of incorrect usage of geologic terminology in the SDEIS	Change has been made, as requested.

Sender	Comment	Response
	<p>below suggest the sections on geology were not given the level of editorial review appropriate for a scientific publication.] “The oldest of the sedimentary rocks is the Pokegama Quartzite. These sedimentary rocks are underlain by Archean granite of the Giants Ridge batholith.” (SDEIS, p 4-43) The correct terminology is Giants Range batholith, not Giants Ridge batholith. This same incorrect usage is repeated in several additional places on pages 4-94 to 4-95.</p>	
Water Legacy	<p>On page ES--- 42, the claim is made that alternatives were identified and screened in accordance with the requirements of 40 CFR 1505.1(e). This is an erroneous citation. The reference to 40 CFR 1505.1(e) refers to NEPA and agency decision-making procedures, not the preparation of an EIS. The correct citation is 40 CFR 1502.14, which states, “Alternatives including the proposed action. This section is the heart of the environmental impact statement. Based in the information and analysis presented in the sections on the Affected Environment (1502.15) and Environmental Consequences (1502.16), it should present the environmental impacts of the proposed action and the alternatives in comparison form, thus sharply defining the issues and providing a clear basis for choice among options by the decision maker and the public.”</p>	Change has been made, as requested.
Water Legacy	<p>The PolyMet SDEIS misrepresents and overlooks available information regarding tailings site geology. The SDEIS states, “Jennings and Reynolds (2005) mapped the surficial deposits around and beneath the Tailings Basin as Rainy Lobe Till, which functions as the surficial aquifer and is generally a boulder-rich till with high clay content” (SDEIS p. 4-95). However, the cited reference reports the surficial Rainy lobe till mapped in the vicinity of the proposed NorthMet project as “clay-poor.” Till matrix textures are reported to range from 48 to 87% sand, 9 to 40% silt and 0 to 13% clay, but “generally much less than 10% clay.” (Jennings and Reynolds, 2005). This is a sandy till, not a till with high clay content.</p>	Change has been made, as requested.

Final Environmental Impact Statement (FEIS)
 NorthMet Mining Project and Land Exchange

Sender	Comment	Response
Water Legacy	Statements in the SDEIS regarding groundwater seepage on the south side of the tailings site appear to be inconsistent. In one section, the SDEIS states, "Groundwater currently seeps from the existing LTVSMC Tailings Basin to the headwaters of Second Creek." (SDEIS, p. 5-153) In another narrative, the SDEIS claims that there would be no impacts on wetlands resulting from changes in groundwater flow since, "All of the seepage from the south side of the Plant Site is surface water." (SDEIS, p. 5-297).	Change has been made, as requested.
William K. Dustin	p.5-152 The evaluation criteria are not shown on the graph.	Change has been made, as requested.

A.7 INDIVIDUAL COMMENTS AND THEME ASSIGNMENTS

Each of the 16,469 unique, substantive comments identified within the submissions provided for the SDEIS is provided in Attachment 1 of Appendix A. The list is alphabetized by the sender's name, and also includes the theme(s) to which each comment was assigned.

A.8 DEIS COMMENT THEMES AND RESPONSES

The DEIS was made available to the public in the November 2009, with a 90-day comment period that ended on February 3, 2010. Following the release of the DEIS, public meetings were held in Aurora, Minnesota, on December 9, 2009 and Blaine, Minnesota, on December 10, 2009, to gather public comments on the DEIS.

The Co-lead Agencies received approximately 3,800 DEIS submissions from government agencies (federal, state, and local), tribal entities, local businesses, NGOs, private individuals, and PolyMet. These submissions generated approximately 5,900 distinct substantive comments. The comments were analyzed using a thematic approach, similar to the methodology described in Section A.2 of this appendix. Key issue areas identified by DEIS comments included cultural resources, air quality, wetlands, geotechnical stability, socioeconomics, and water resources.

Individual DEIS submissions, comments and theme assignments are included in Attachment 1 of this appendix.

SDEIS Appendix A listed the thematic statements and responses for public comment received on the 2009 DEIS. Table A-5 repeats these DEIS themes and responses, and also indicates which SDEIS theme(s) best respond to each DEIS theme. This listing does not necessarily include *all* applicable SDEIS themes. The relevant sections of the FEIS should be consulted for more detailed information.

Table A-5 DEIS Comment Themes and Relationship to SDEIS Themes

DEIS Theme Code	DEIS Theme Statement	DEIS Thematic Response	Corresponding FEIS Theme(s)
Section: Comparison of Alternatives (ALT)			
ALT1	The DEIS does not adequately define or study the No-Action Alternative.	The No Action Alternatives for the NorthMet Project Proposed Action and the Land Exchange Proposed Action are defined in Sections 3.2.3 and 3.3.3 of the SDEIS, respectively. The environmental consequences of the NorthMet Project No Action Alternative are addressed in the respective sections of Chapter 5. Comparisons of the NorthMet Project Proposed Action and the alternatives, including the No Action Alternative, are shown in Chapter 7.	ALT 14
ALT2	The DEIS does not adequately evaluate the Mine Site alternative and it fails to look beyond the proposed Mine Site.	The NorthMet Project Proposed Action and the alternatives have changed substantially since preparation of the 2009 DEIS (MDNR and USACE 2009, as cited in the FEIS). The “Mine Site Alternative” was incorporated into the Proposed Action and is no longer applicable as an alternative (refer to Section 3.2.3 of the SDEIS for more information). The Mine Site location depends on the presence of the viable NorthMet Deposit. The location of the Mine Site and alternatives are discussed in Section 3.2.3 of the SDEIS.	ALT 06, ALT 07, ALT 16
ALT3	The DEIS does not adequately evaluate the underground mining alternative. This alternative should not be eliminated from consideration on the basis of costs.	The underground mining alternative was revisited and determined not to be a viable alternative; therefore, it remains eliminated from further evaluation. The Co-lead Agencies prepared a position paper on the underground mining alternative; this document is attached as an appendix to the SDEIS. Alternatives considered for the NorthMet Project Proposed Action in the SDEIS are described in Section 3.2.3.	ALT 01, ALT 02
ALT4	The DEIS does not adequately evaluate the tailings basin alternative and fails to consider the reactions between seepage and the existing tailings.	The SDEIS NorthMet Project Proposed Action (including tailings management) and the alternatives have changed substantially since preparation of the 2009 DEIS (MDNR and USACE 2009, as cited in the FEIS). There is no longer a tailings basin alternative. Management of tailings as part of the NorthMet Project Proposed Action is addressed in Section 3.2.2 of the SDEIS. Environmental consequences are addressed in Section 5.2.	ALT 10, ALT 11
ALT5	The DEIS should provide additional details regarding mitigation and long-term management of the site, particularly related to water treatment.	The NorthMet Project Proposed Action has changed substantially since preparation of the 2009 DEIS (MDNR and USACE 2009, as cited in the FEIS). Mine Site and Plant Site water management are addressed in Section 3.2.2 of the SDEIS. Environmental consequences on water resources are	ALT 04, ALT 13, PD 01

DEIS Theme Code	DEIS Theme Statement	DEIS Thematic Response	Corresponding FEIS Theme(s)
		discussed in Section 5.2.2.	
ALT6	The DEIS fails to include quantitative information, such as numbers from key indicators for each resource, in the comparison of alternatives table.	The NorthMet Project Proposed Action and the alternatives have changed substantially since preparation of the 2009 DEIS (MDNR and USACE 2009, as cited in the FEIS). The NorthMet Project Proposed Action and alternatives are described in Chapter 3 of the SDEIS; Chapter 7 of the SDEIS provides a comparison of alternatives.	ALT 22
ALT7	The DEIS fails to adequately identify a preferred alternative.	Chapter 7 of the SDEIS provides a comparison of alternatives and discusses the agency position on offering a preferred alternative. Consistent with the CEQ regulations, the federal Co-lead Agencies are required to identify an agency-preferred alternative in a DEIS, if one exists, and in the FEIS unless another law prohibits the expression of such a preference. At this time, the Co-lead agencies have not identified a preferred alternative, and for the USACE, 33 CFR Part 325, Appendix B, supersedes identification of an agency-preferred alternative. No similar requirement to identify a preferred alternative exists for the MDNR under state law.	ALT 20
ALT8	The DEIS fails to consider a full range of alternatives to meet the intent of NEPA.	CEQ (1997, as cited in the FEIS) requires that a “reasonable range of alternatives” be analyzed. These may include those not carried forward for detailed analysis. The NorthMet Project Proposed Action in the SDEIS represents a project that has incorporated a number of previous alternatives and mitigation measures considered as alternatives at earlier stages of the EIS process. Many other alternatives have been identified but eliminated from detailed analysis because they didn’t offer potentially significant environmental benefits, did not meet the project’s purpose and need, or were not otherwise reasonable (technically or financially viable) in accordance with CEQ guidance. The NorthMet Project Proposed Action and alternatives are described in Chapter 3 of the SDEIS. Various other alternatives identified but eliminated in the DEIS are discussed in Section 3.2.3.	ALT 21, ALT 23
ALT9	The DEIS must address modifications and mitigation methods with less uncertainty.	The NorthMet Project Proposed Action, alternatives, and mitigation measures have changed substantially since preparation of the 2009 DEIS (MDNR and USACE 2009, as cited in the FEIS). Proposed mitigation measures are discussed in the respective parts of Section 5.2 and summarized in Chapter 7 of the SDEIS.	PD 01

DEIS Theme Code	DEIS Theme Statement	DEIS Thematic Response	Corresponding FEIS Theme(s)
Section: Air Quality (AQ) [Please note that “AQ” in the SDEIS applies to Aquatic Species]			
AQ1	The DEIS did not adequately address the potential for fugitive emissions from reactive waste rock, rail cars, tailings basin, or road travel. Further data is needed to evaluate the issue.	Based upon the comments provided on the DEIS, the analyses in Section 5.2.7 of the SDEIS were developed in the Co-lead Air IAP Workgroup. These include revised air emissions protocols for Class I, Class II, mercury deposition, AERA, and GHG assessments. Waste rock acidification was previously addressed and was updated as part of the SDEIS refinements. Based upon the Co-lead Air IAP workgroup, it was determined that any effects on air quality from fugitive dust from rail transport would be minimal due to the coarse nature of the ore. The potential for acidification effects associated with deposition of fugitive dust from rail car hauling was addressed under Water Resources. Surface Water IAP workgroup evaluated this issue and recommended that surface water quality data be collected to address this issue. Emissions from other fugitive emissions including mobile sources are also evaluated.	AIR 04
AQ2	The evaluation that the NorthMet Project Proposed Action would be a “new” rather than an “existing” source of air emissions was made incorrectly or needs further analysis.	Due to the 9-year inactivity of taconite-processing equipment currently owned by Cliffs Erie, LLC and backed by USEPA’s well-established reactivation policy, the MPCA has made a preliminary determination that those units would need to go through PSD applicability and new permitting if they were to be restarted by PolyMet.	SDEIS comments did not raise this topic.
AQ3	The potential for GHG emissions that contribute to climate change was not thoroughly analyzed in the DEIS, including the effects on carbon sequestration resulting from the disturbance of peat and the resulting impact on wildlife.	To address these comments, GHG issues have been assessed in a manner consistent with USEPA and MPCA guidance, and the CEQ’s Draft NEPA Guidance on Climate Change and Greenhouse Gas Emissions (February 18, 2010). This assessment is addressed in Section 5.2.7 and 5.3.7 of the SDEIS.	AIR 01
AQ4	Air quality modeling and analysis was not complete, lacks accurate data, did not consider all comments, or needs further explanation.	The procedures for inclusion of sources were described in the DEIS. Sources have been evaluated for inclusion based upon their potential to contribute to a significant effect. The proposed facility has not been determined to be a major source under the CAA for any of the criteria pollutants. Therefore, the analysis is consistent with MPCA requirements for permitting. Since the DEIS, the USEPA and federal courts have recently modified major source determination to include GHG emissions. The SDEIS reevaluated the major source status for the NorthMet Project Proposed Action and has shown that the proposed facility would not be determined a major source for GHG, or any other regulated pollutant, and thus, no formal major NSR is required, including federal-mandated modeling and BACT requirements. This assessment is addressed in Section	AIR 09

DEIS Theme Code	DEIS Theme Statement	DEIS Thematic Response	Corresponding FEIS Theme(s)
		5.2.7 of the SDEIS. The Class I, Class II, AERA, mercury deposition, and cumulative modeling analyses protocols for the SDEIS were updated to include the latest air quality regulations, including 1-hour NO ₂ and SO ₂ analyses, PM _{2.5} requirements, and GHG evaluations. The modeling protocols were revised in collaboration with the Co-lead Air IAP Workgroup and are incorporated as part of the SDEIS.	
AQ4A	Further modeling or studies, including a BACT analysis, should be completed.	There are no current requirements for federal BACT analysis for minor sources (see Theme AQ4). However, PolyMet conducted the equivalent of a major source BACT evaluations for PM _{2.5} (a minor source) and mercury. These evaluations contributed to the SDEIS analysis of the AERA, mercury bioaccumulation, PM _{2.5} , and asbestos-like fibers. The analyses are summarized in Section 5.2.7 of the SDEIS.	AIR 09
AQ4B	The cumulative impacts analysis for air quality lacked complete analysis. Specific contributing projects should be included.	The procedures for inclusion of sources were described in the DEIS. Sources are evaluated for inclusion based upon their potential to contribute to a significant effect. Specific contributing projects are identified in Chapter 6 of the SDEIS.	CU 02
AQ4C	Evaluation of the potential for asbestiform fibers and mineral fibers must be completed for the assessment of impacts to be considered complete.	Based upon the revised project, a qualitative evaluation of the effects from asbestiform fibers is included in Section 5.2.7 of the SDEIS.	AIR 03
AQ4D	The potential for acid rain and the resulting impacts should be addressed and analyzed.	The potential for acid rain is evaluated in the Class I regions nearby the NorthMet Project area. Effects of acidification were addressed in the DEIS. An expanded discussion of these effects, including additional lake communities, is included in Section 5.2.7 of the SDEIS.	SDEIS comments did not raise this topic.
AQ4E	The geographical scope of the DEIS is not sufficient to capture potential impacts.	Air quality effects are addressed based upon statewide established criteria for significant effects. Additional analyses were conducted for all representative Class I regions, including visibility and mercury deposition. Expanded acidification assessment for additional lake communities surrounding the NorthMet Project area is assessed in Section 5.2.7 of the SDEIS.	AIR 06, AIR 08, AIR 09
AQ5	Air quality monitoring plans and mitigation measures are insufficient or should be more thoroughly explained in the EIS document. Further mitigation measures should be pursued.	As discussed in the SDEIS, air emissions from the NorthMet Project Proposed Action would be less than PSD major source thresholds for all criteria pollutants. The MPCA is responsible for ensuring that the NorthMet Project Proposed Action would not exceed applicable standards during the permitting process. Permit requirements needed to ensure compliance with	PD 01

DEIS Theme Code	DEIS Theme Statement	DEIS Thematic Response	Corresponding FEIS Theme(s)
		standards will be included in any future permits. There will be an opportunity for public participation in the permitting process, as well.	
AQ6	The NorthMet Project Proposed Action's potential to exceed standards for air quality or endanger the health of humans and wildlife should be more thoroughly addressed. More risk assessment for human health impacts should be completed.	Air quality impact analyses in the DEIS follow State of Minnesota and federal guidelines, and effects were addressed in the DEIS. Based upon comments received on the DEIS and the availability of more recent information, additional analyses were conducted for the Class I, Class II, MAAQS, and NAAQS. In addition, updated AERA and mercury assessments were conducted to address risk assessment of human health effects. The updated analyses are addressed in Section 5.2.7 of the SDEIS.	HU 03, WI 03
AQ6A	The potential for mercury emissions to exceed standards or endanger the health of humans and wildlife was not adequately addressed.	PolyMet has revised the Mercury Deposition Analysis in collaboration with the Co-lead Air IAP Workgroup to include an expanded area up to 10 km from the facility, and includes potential sources up to 25 km from the facility. This expanded analysis incorporates several new lake regions, including Sabin Lake, Wynne Lake, Heikkila Lake, Colby Lake, and Whitewater Lake. Results of this analysis are discussed in Section 5.2.7 of the SDEIS.	AIR 05, AIR 06
AQ7	Permitting questions regarding emission thresholds and permitting criteria should be addressed.	As discussed in the SDEIS, air emissions from the NorthMet Project Proposed Action would be less than PSD major source thresholds for all criteria pollutants. The MPCA is responsible for ensuring that the NorthMet Project Proposed Action would not exceed applicable standards during the permitting process. Permit requirements needed to ensure compliance with standards will be included in any future permits. There will be an opportunity for public participation in the permitting process, as well.	AIR 13
AQ8	Issues regarding Class II classifications were inadequately addressed.	The analysis in the DEIS was based upon the most current available data and guidance. The SDEIS updates the existing analysis with the most current information and reflects the most recent review of potential mitigation measures (See Theme AQ4).	AIR 09
AQ9	Issues regarding Class I classifications were inadequately addressed.	Please see response to Theme AQ8.	AIR 08

DEIS Theme Code	DEIS Theme Statement	DEIS Thematic Response	Corresponding FEIS Theme(s)
Section: Compatibility with Plans and Land Use (CPLU)			
CPLU1	The NorthMet Project Proposed Action is inconsistent with biodiversity and habitat policies, such as those in the MFRC Landscape Plan.	Although an informative plan, per NEPA, the MFRC Landscape Plan is not part of the legal framework to which the SDEIS must conform. The Land Use Sections of SDEIS Chapters 4, 5, and 6 address the NorthMet Project Proposed Action's performance with respect to the land use aspects of the legal framework.	PER 35
CPLU2	The NorthMet Project Proposed Action is inconsistent with water quality, recreation, and cultural resources policies, such as those in the St. Louis River Management Plan.	Conformance with water quality, recreation, and cultural resources policies is addressed in the Water Resources, Socioeconomics, Land Use, Recreation/Visual, and Cultural Resources sections of SDEIS Chapters 5 and 6.	SDEIS comments did not raise this topic.
CPLU3	The NorthMet Project's compatibility with the Superior National Forest's Forest Plan should be specifically considered.	The Land Use sections of SDEIS Chapters 4, 5, and 6 evaluate compatibility with the Superior National Forest Plan.	LU 05
CPLU4	The Land Exchange Proposed Action with USFS should be concluded and evaluated before the EIS is completed.	The Land Exchange Proposed Action is fully evaluated as part of the SDEIS. See Chapter 5.3 of the SDEIS.	NEPA 13
Section: Cultural Resources (CR)			
CR1	The DEIS does not adequately address impacts to and mitigation measures for cultural resources, including those that relate to 1854 Treaty rights and tribal resource gathering.	The federal Co-lead Agencies are actively consulting with the federally recognized bands that have expressed an interest in consulting for the NorthMet Project Proposed Action to identify and address these and other related concerns. Consideration of effects on cultural resources or culturally significant natural resource that do not qualify for the NHPA addressed in SDEIS Chapters 4, 5, and 6.	CR 01
CR2	Section 106 consultation is needed prior to the completion of the EIS to address the presence of cultural sites and use of resources by tribal members.	The federal Co-lead Agencies have actively consulted with the three federally recognized Bands that have expressed an interest in consulting for the NorthMet Project Proposed Action, including interviews with Band members. Effects to cultural resources and culturally significant natural resources are addressed in the Cultural Resources section of SDEIS Chapters 4, 5, and 6.	CR 06
CR3	The 1854 Treaty Ceded Territory should be considered a traditional cultural property and the NorthMet Project Proposed Action's area of potential effect should be expanded to include 1854 Treaty Ceded Territory.	At the time the 2009 DEIS (MDNR and USACE 2009, as cited in the FEIS) was prepared, the Co-lead Agencies had not yet formally determined the area of potential effect determination. The Cultural Resources section of SDEIS Chapters 4 and 5 address the Co-lead Agencies' determination of the NorthMet Project Proposed Action's area of potential effect, as well as the	CR 04

DEIS Theme Code	DEIS Theme Statement	DEIS Thematic Response	Corresponding FEIS Theme(s)
		Co-lead Agencies' consideration of the 1854 Ceded Territory as a traditional cultural property.	
CR4	The EIS should discuss the federal government's trust responsibility as part of the 1854 Treaty and address potential impacts and proposed mitigation/compensation for loss of access to resources.	The Cultural Resources section of SDEIS Chapters 4 and 5 addresses the federal Co-lead Agencies' federal tribal trust responsibilities as part of the 1854 Treaty. These sections, along with relevant sections of Chapter 6, also address effects on, and any proposed mitigation for effects on cultural resources and culturally significant natural resources that do not qualify for listing on the NRHP.	CR 01
CR5	The EIS should further evaluate and /or remove reference and use of the draft work known as, "The Protocol to Assess Expanded Cumulative Impacts to Native Americans."	This document has been reviewed and protocol discussed. The SDEIS complies with CEQ guidance for the cumulative effects analysis.	CR 08
Section: Fish and Macroinvertebrates (FM) [FEIS Section Now Titled "Aquatic Species"]			
FM1	The DEIS does not adequately analyze the impacts from the Mine Site operation on fish and macroinvertebrate species. Particular concerns include seepage of mercury and other constituents, alteration of flow conditions, water quality exceedances, and bioaccumulation.	Effects on aquatic resources, such as fish and macroinvertebrate species, as a result of mercury seepage and potentially harmful constituents, alteration of flow, and bioaccumulation are discussed in detail in Sections 5.2.6 and 5.3.6 of the SDEIS.	AQ 05, AQ 06, AQ 07, AQ 11, AQ, 12, AQ 13, AQ 14, AQ 18, AQ 23, AQ 24, AQ 25, AQ 28
FM2	The DEIS does not provide sufficient baseline characterizations, including sampling and modeling, to effectively describe populations and potential effects on fish and macroinvertebrates.	Existing conditions, including baseline characterizations and any additional threatened or endangered species listed after the DEIS was released, are discussed in detail in Sections 4.2.6 and 4.3.6 of the SDEIS. Potential effects on these species are detailed in Sections 5.2.6 and 5.3.6 of the SDEIS.	AQ 01
FM3	The cumulative effects analysis needs to be expanded to include the effects of sulfate and mercury, bioaccumulation, climate change, and habitat degradation on the fisheries and macroinvertebrates of the region.	Cumulative effects on aquatic species and the metrics used for analysis of potential effects are included in Chapter 6 of the SDEIS.	AQ27
FM4	The DEIS lacks sufficient monitoring, adaptive management, and mitigation measures for aquatic species.	Monitoring plans and potential mitigation measures for the NorthMet Project Proposed Action are discussed in Sections 5.2.6 and 5.3.6, and Chapter 7 of the SDEIS.	AQ 30
FM5	The DEIS does not provide sufficient information to demonstrate compliance with	Existing aquatic habitat and species are described in Section 4.2.6 and 4.3.6 of the SDEIS. Effects to aquatic resources as a result of the NorthMet	PER 26

DEIS Theme Code	DEIS Theme Statement	DEIS Thematic Response	Corresponding FEIS Theme(s)
	federal and state permitting and guidance requirements including the CWA, state water quality standards, TMDL levels, and fish consumption advisories.	Project Proposed Action are described in Sections 5.2.6 and 5.3.6. The evaluation of the NorthMet Project Proposed Action’s potential environmental effects against EIS evaluation criteria is included in Sections 5.2.2, 5.2.6, 5.3.3, and 5.3.6 of the SDEIS. The Adaptive Water Management Plan (PolyMet 2015d, as cited in the FEIS) addresses the wastewater treatment systems that would be used to manage water (see Section 3.2.2 of the SDEIS).	
Section: Geotechnical Stability (GT)			
GT1	Detailed mitigation, alternatives, stability analysis, and contingency plan information must be included in the EIS, not deferred to permitting.	The NorthMet Project Proposed Action has changed substantially since preparation of the 2009 DEIS (MDNR and USACE 2009, as cited in the FEIS) and design and stability of the geotechnical features are further analyzed and addressed in Sections 3.2.2 and 5.2.14 of the SDEIS.	GT 07
GT2	Environmental consequences of dam failures must be disclosed in the EIS.	The NorthMet Project Proposed Action, including the design and geotechnical stability of the Tailings Basin and Hydrometallurgical Residue Facility, has changed substantially since preparation of the 2009 DEIS (MDNR and USACE 2009, as cited in the FEIS). The design of the Tailings Basin and Hydrometallurgical Residue Facility is discussed in Section 3.2.2 of the SDEIS. The structural integrity of the Tailings Basin and Hydrometallurgical Residue Facility and the proposed maintenance and adaptive management measures of these facilities to maintain that integrity is discussed in Section 5.2.14 and Chapter 7 of the SDEIS. Because the proposed design would meet the minimum factor of safety requirements, the potential for failure of the dams is considered low. Discussion of effects associated with such failure would be speculative and thus outside the scope of the SDEIS.	GT 15
GT3	The EIS must address disposal of coal ash and other non-taconite tailings materials in the existing LTVSMC Tailings Basin and any implications to Tailings Basin stability.	The NorthMet Project Proposed Action, including the design and geotechnical stability of the Tailings Basin and Hydrometallurgical Residue Facility, has changed substantially since preparation of the 2009 DEIS (MDNR and USACE 2009, as cited in the FEIS). The existing conditions at the existing LTVSMC Tailings Basin, and the structural integrity of the proposed Tailings Basin and Hydrometallurgical Residue Facility, are discussed in section 4.2.14 and 5.2.14 of the SDEIS.	HAZ 02

DEIS Theme Code	DEIS Theme Statement	DEIS Thematic Response	Corresponding FEIS Theme(s)
Section: Hazardous Materials (HM)			
HM1	The DEIS does not adequately address the assessment of operational type chemical waste for recycling.	Section 5.2.13 of the SDEIS addresses the preparation of a Hazardous Materials Management Plan. The Hazardous Materials Management Plan will describe the methods for handling, storage, and disposal. This may also include recycling of materials used or generated during the operations.	ALT 09, HAZ 02
HM2	The DEIS does not properly characterize ore and waste rock piles from the mining process as hazardous materials and hazardous waste in accordance with Minnesota Rules, nor does it adequately discuss the cumulative effects of these materials as “hazardous materials”.	Based on the <i>Minnesota Rules</i> , Chapter 7045.0120, Identification and Listing of Hazardous Waste-Exemptions and Special Requirements, this waste is exempted. Also see Chapter 7045.0214: Evaluation of Wastes, Subpart 1, “Any waste evaluated and exempted under part 7045.0075 or 7045.0120 does not need to be re-evaluated under this part.” Other waste in question will be properly evaluated and managed per the Hazardous Materials Management Plan for the facility. These issues are described in Section 5.2.13 of the SDEIS.	HAZ 02
HM3	The DEIS does not adequately analyze and address the risk associated with the transportation of materials of a hazardous nature.	Transportation of materials of a hazardous nature will be addressed in more detail in the NorthMet Project Proposed Action plan and the Hazardous Materials Management Plan (when developed), and is discussed in Section 5.3.13 the SDEIS.	HAZ 06
HM4	The chemical composition, toxicity, use, impact, and mitigation of chemical products discharged in wastewater and in the hydrometallurgical residue must be further addressed in accordance with federal and Minnesota hazardous waste regulations.	As described in Section 5.2.13 of the SDEIS, hazardous materials and potentially hazardous wastes will be characterized, managed, and disposed of or recycled per the Hazardous Materials Management Plan (to be completed), which will follow requirements of Minnesota Rules, Chapter 7045: Hazardous Waste.	HAZ 03
HM5	The DEIS does not adequately assess the nature and characteristics, including radioactivity, of cobalt.	Hazardous materials are addressed in Section 5.2.13 of the SDEIS. If present, cobalt-60 and other hazardous or potentially hazardous materials or wastes will be characterized and managed per the Hazardous Materials Management Plan (to be completed), which will follow requirements of Minnesota Rules, Chapter 7045: Hazardous Waste.	HAZ 03
HM6	The DEIS does not adequately consider the cumulative impacts of hazardous materials from other projects, including hazardous materials already in the watershed.	Evaluation of cumulative effects of hazardous materials on the watershed, as well as those from other projects, are addressed in further detail as appropriate in Chapter 6 of the SDEIS.	CU 15

DEIS Theme Code	DEIS Theme Statement	DEIS Thematic Response	Corresponding FEIS Theme(s)
Section: Irreversible and Irretrievable Commitment of Resources (IRR)			
IRR1	The DEIS does not adequately characterize the fossil fuels consumed during mine development, operation, and closure.	Irreversible and irretrievable commitments of these resources are discussed in Chapter 7 of the SDEIS.	AIR 02
IRR2	The DEIS does not adequately characterize the loss of natural and cultural resources, such as high-quality forests, wetlands, and traditional cultural activities.	Effects on cultural resources and the relationship between natural resources and cultural resources are discussed in Section 5.2.9 and 5.3.9 of the SDEIS. Irreversible and irretrievable commitments of these resources are discussed in Chapter 7 of the SDEIS.	NEPA 14
Section: Noise (N)			
N1	Noise impacts from operation of the NorthMet Project Proposed Action on the surrounding region are not properly modeled or explained in the DEIS.	To address this issue, Section 5.2.8 of the SDEIS includes a visual representation of noise contours to show the extent of noise effects on sensitive receptors within the surrounding region.	N 06
N2	The DEIS does not adequately address noise mitigation.	Noise mitigation measures and monitoring plans are addressed in Section 5.2.8 and Chapter 7 of the SDEIS.	PD 01
N3	The DEIS does not adequately characterize the cumulative effects of noise, including vibration, from the NorthMet Project Proposed Action and other activities.	Further modeling of the potential cumulative noise and vibration effects on the surrounding environment has been conducted since the preparation of the 2009 DEIS (MDNR and USACE 2009, as cited in the FEIS). Cumulative noise and vibration effects, and the metrics used for analysis of potential effects, are discussed in Chapter 6 of the SDEIS.	N 03
N4	The DEIS does not adequately characterize the effects of NorthMet Project Proposed Action-related noise, including blasting, on wildlife.	NorthMet Project Proposed Action--related noise effects on wildlife, including blasting, are discussed in detail in the Section 5.2.5 of the SDEIS.	N 04, N 05
N5	The DEIS does not adequately characterize the effects of project-related noise, including blasting, on human health.	NorthMet Project Proposed Action-related noise effects on human health, including blasting, are discussed in detail in the Section 5.2.7 of the SDEIS.	N 01
N6	The DEIS does not adequately characterize the impacts of discontinuous noise, such as blasting, on people who use the NorthMet Project area for recreation, fishing, and hunting.	The effects of discontinuous noise, such as blasting, on people who use the NorthMet Project area for recreation, fishing, and hunting are discussed in detail in Section 5.2.8 of the SDEIS.	N 02

DEIS Theme Code	DEIS Theme Statement	DEIS Thematic Response	Corresponding FEIS Theme(s)
Section: Project Description (PD)			
PD1	The DEIS does not adequately explain the Land Exchange Proposed Action, which is a connected action.	The Land Exchange Proposed Action is addressed as part of the NorthMet Project Proposed Action and alternatives throughout the SDEIS.	LAN 01
PD2	The DEIS NorthMet Project Description does not adequately describe the potential for release of contaminants, hazardous wastes, or acid rock drainage from waste rock, the Tailings Basin, or failure of liner systems on surface and groundwater quality standards.	The NorthMet Project Proposed Action, including management of waste rock and tailings, has changed substantially since preparation of the 2009 DEIS (MDNR and USACE 2009, as cited in the FEIS). Management of waste rock and tailings is addressed in Section 3.2.2 of the SDEIS. The potential effect of waste rock and tailings on surface and groundwater quality is addressed in Section 5.2.2 of the SDEIS.	GT 15
PD3	The DEIS does not adequately analyze the scope or effectiveness of closure and reclamation plans.	The NorthMet Project Proposed Action has changed substantially since preparation of the 2009 DEIS (MDNR and USACE 2009, as cited in the FEIS). Closure and reclamation of the NorthMet Project area is described in Section 3.2.2 and long term environmental consequences are described in Section 5.2 of the SDEIS.	PD 02, PD 06, PD 20
PD4	The DEIS does not adequately describe financial assurance.	Financial assurance for closure and remediation of the NorthMet Project area is addressed in Section 3.2.2.4 of the SDEIS.	FIN 01
PD5	The DEIS does not adequately describe the WWTF, including the seepage/discharge collection from the Tailings Basin or Hydrometallurgical Residue Facility.	The NorthMet Project Proposed Action, including details of water management at the Tailings Basin has changed substantially since preparation of the 2009 DEIS (MDNR and USACE 2009, as cited in the FEIS), and is further addressed in Section 3.2.2 of the SDEIS.	PD 03, PD 07, PD 11, PD 12, PD 13, PD 18
PD6	The DEIS does not fully evaluate geotechnical stability, including a stockpile stability analysis.	The NorthMet Project Proposed Action has changed substantially since preparation of the 2009 DEIS (MDNR and USACE 2009, as cited in the FEIS). The existing geotechnical conditions at the NorthMet Project area are discussed in Section 4.2.14. The design and structural integrity of the proposed geotechnical features is addressed in Sections 3.2.2 and 5.2.14 of the SDEIS.	All GT themes
PD7	The DEIS does not adequately describe the transportation of ore between the Mine Site and Plant Site or the necessary transportation infrastructure.	The transportation of ore between the Mine Site and Plant Site is discussed in Section 3.2.2 of the SDEIS.	PD 36
PD8	The DEIS contains insufficient baseline data, monitoring measures, mitigation methods, and modeling, and does not include newly identified	Existing environmental conditions including results of baseline modeling are discussed in Chapter 4 of the SDEIS. Management and mitigation measures of the NorthMet Project Proposed Action and alternatives are	Addressed throughout the FEIS.

DEIS Theme Code	DEIS Theme Statement	DEIS Thematic Response	Corresponding FEIS Theme(s)
	issues.	described in Chapter 3. Environmental consequences are addressed in Chapter 5. A summary and comparison of the mitigation and management measures for the NorthMet Project Proposed Action and alternatives and the environmental consequences is provided in Chapter 7 of the SDEIS.	
PD9	The DEIS NorthMet Project Description is not complete, and/or is not consistent with the PDEIS.	The NorthMet Project Proposed Action has changed substantially since preparation of the 2009 DEIS (MDNR and USACE 2009, as cited in the FEIS), and the description of the NorthMet Project Proposed Action and alternatives has been updated in the SDEIS.	All PD themes
PD10	The DEIS does not adequately describe the NorthMet Project Proposed Action's relationship to plant and wildlife species, habitat, and high quality forests and wetlands.	The existing environmental conditions and the potential environmental consequences relating to the NorthMet Project Proposed Action are addressed in Chapters 4 and 5 of the SDEIS, respectively.	All WI, VEG, and WET themes
PD11	The DEIS does not adequately describe the placement of waste rock piles and stockpiles of overburden.	The NorthMet Project Proposed Action, including management of waste rock and overburden, has changed substantially since preparation of the 2009 DEIS (MDNR and USACE 2009, as cited in the FEIS). Management of waste rock and overburden is addressed in Section 3.2.2 of the SDEIS.	PD 15
PD12	The DEIS does not adequately describe Superior National Forest plans and regulations or whether they will be adhered to.	The Land Exchange Proposed Action is described in Section 3.3. The potential effect of the proposed change in land use at the NorthMet Project area and the considerations for existing and surrounding land management are addressed in Sections 5.2.1 and 5.3.1 of the SDEIS.	PER 35
PD13	The DEIS does not adequately address due diligence on the NorthMet Project Proposed Action.	Due diligence for the NorthMet Project Proposed Action is addressed in Chapter 3 of the SDEIS.	All PD themes
PD14	The DEIS does not adequately describe the moratorium on sulfide mining in Wisconsin.	The moratorium in Wisconsin is outside the scope of the NorthMet Project Proposed Action, and is therefore not discussed in the SDEIS.	SDEIS comments did not raise this topic.
Section: Process (PRO)			
PRO1	The DEIS does not adequately adhere to the EIS/NEPA process or involve appropriate agencies.	Chapter 1 of the SDEIS provides information about the Cooperating Agencies that were included during the scoping period for the DEIS, as well as other agencies involved in development of the SDEIS. The three Co-lead Agencies (MDNR, USACE, and USFS) each ensured that federal and state environmental impact processes were followed, and that the process adhered to each agency's internal requirements.	NEPA 08
PRO2	The DEIS does not adequately analyze project	The NorthMet Project Proposed Action and the alternatives have changed	ALT 16, ALT 21

DEIS Theme Code	DEIS Theme Statement	DEIS Thematic Response	Corresponding FEIS Theme(s)
	alternatives, as there is too much uncertainty.	substantially since preparation of the 2009 DEIS (MDNR and USACE 2009, as cited in the FEIS). Alternatives (including the NorthMet Project No Action Alternative) are described in Chapter 3 of the SDEIS; a comparison of alternatives is provided in Chapter 7.	
PRO3	The DEIS contains insufficient data/studies, explanations of methodologies, and proposed mitigation measures.	New data and studies, methodologies, and mitigation measures are discussed in detail in the SDEIS. Individual resource-specific sections incorporate new data or studies and explanations of methodologies in Chapter 4, while mitigation measures are discussed in resource-specific sections of Chapter 5 of the SDEIS.	NEPA 08
PRO4	The DEIS does not adequately incorporate all connected actions and other actions into the cumulative effects analysis.	All connected actions, including the Land Exchange Proposed Action, are included in the cumulative effects analysis in Chapter 6 of the SDEIS. Resource-specific effects of the Land Exchange Proposed Action are included in Chapter 6 of the SDEIS.	CU 02, CU 08, CU 09, CU 13
PRO5	Analysis regarding the Cultural Resources section was not appropriately completed, as Section 106 consultation was incomplete.	The federal Co-lead Agencies are actively consulting with federally recognized Bands that have expressed an interest in consulting for the NorthMet Project Proposed Action. Consultation includes interviews with tribal members. Effects on cultural resources are addressed in the Section 5.2.9 of the SDEIS. The Section 106 evaluation must be complete before the federal agencies can complete their respective RODs.	CR 06
PRO6	The DEIS process did not allow adequate public participation, and specifically lacked adequate public comment periods or meetings. All issues of public opposition should be addressed.	The NEPA public participation process for the DEIS is discussed in detail in Section 2.2 of the SDEIS. Two meetings and a 90-day comment period were provided for the DEIS. A separate scoping period for the Land Exchange Proposed Action occurred in the fall of 2010. For the SDEIS, the number of public meetings and length of the comment period will be determined by the Co-lead Agencies. Public comments and positions voiced in the record at both public meetings and through written comments have been considered in the development of the SDEIS.	NEPA 11
PRO7	The DEIS does not adequately evaluate potential violations of laws or standards, such as the CAA, CWA, etc.	As described in Section 1.4 of the SDEIS, the NorthMet Project Proposed Action must comply with all applicable laws and standards. Resource-specific laws and regulations are discussed in the corresponding resource sections.	PER 26
PRO8	The DEIS does not adequately incorporate the Feasibility Study for the Land Exchange Proposed Action.	The Land Exchange Proposed Action is discussed in detail throughout the SDEIS. Individual chapters incorporate information from the USFS Land Exchange Feasibility Study, as well as other sources.	LAN 06

DEIS Theme Code	DEIS Theme Statement	DEIS Thematic Response	Corresponding FEIS Theme(s)
PRO9	The DEIS does not fully include tribal Cooperating Agency comments.	The federal Co-lead Agencies are actively consulting with the three federally recognized bands that have expressed an interest in consulting for the NorthMet Project Proposed Action. Discussion of tribal comments and concerns are a part of this consultation. These comments are addressed in the SDEIS and through ongoing consultation.	CR 06
PRO10	The DEIS does not adequately describe any financial assurance for the project or implications of an environmental disaster.	Financial assurance for closure and remediation of the NorthMet Project area is addressed in Chapter 3 of the SDEIS. A Co-lead Agency document dated August 23, 2011, describes the mechanism for addressing financial assurance in the SDEIS (Co-lead Agencies 2011).	FIN 05
Section: Socioeconomics (SE)			
SE1	The DEIS incorrectly implies that there are no economic benefits from the NorthMet Project No Action Alternative.	The SDEIS more clearly states that there would be no additional economic benefits from mining activity in the NorthMet Project No Action Alternative, but that other economic activity in the region would remain unaffected. Existing non-mining economic activity is described in greater detail in Section 4.2.10 the SDEIS.	SDEIS comments did not raise this topic.
SE2	The EIS should include a full EJ evaluation, focused specifically on impacts to local tribes.	The EJ analysis has been expanded, and is presented in Section 5.2.10.2.6 of the SDEIS, based on input from the Socioeconomic IAP Workgroup.	SO 09
SE3	The DEIS overestimates the NorthMet Project Proposed Action's relatively short-term employment benefits, and does not adequately address long-term, post-closure costs, or the "boom and bust" cycle associated with extractive industries.	These issues are addressed in Section 5.2.10 of the SDEIS, based on input from the Socioeconomic IAP Workgroup.	SO 04
SE4	The DEIS does not adequately account for the NorthMet Project Proposed Action's adverse long-term impact on the region's tourism and real estate economies, which are based on high environmental quality (actual and perceived).	Please see response to Theme SE3.	SO 02, SO 03
SE5	The EIS should evaluate the long-term community health impacts associated with pollution from the NorthMet Project Proposed Action.	Effects on human health are primarily addressed in Section 5.2.7 and 5.3.7 of the SDEIS. These include health effects from airborne, water-borne, and other sources related to the NorthMet Project Proposed Action.	HU 01
SE6	The low-grade character of the ore body is not adequately addressed.	Calculations in the DEIS Socioeconomics Section already take the quality of the ore into account. These inputs are more clearly stated in Section	SDEIS comments did not raise this

DEIS Theme Code	DEIS Theme Statement	DEIS Thematic Response	Corresponding FEIS Theme(s)
		5.2.10 of the SDEIS.	topic.
SE7	The EIS should address whether the NorthMet Project Proposed Action will emphasize hiring of local workers, therefore ensuring economic benefits to local communities.	Please see response to Theme SE3	SO 04
SE8	The DEIS did not discuss the specifics regarding inputs of the IMPLAN model and other economic data.	The inputs and methodology of the IMPLAN model are described in Section 5.2.10 of the SDEIS.	SO 08
SE9	The DEIS does not adequately evaluate socioeconomic impacts.	Potential socioeconomic effects on population, housing, employment, transportation, etc., are addressed in Sections 5.2.10 and 5.3.10 of the SDEIS. A Multi-agency (Co-lead and cooperating agencies) Workgroup met during 2011 to help define the scope of the socioeconomics analysis.	SO 04, SO 06
SE10	The DEIS does not adequately evaluate mineral rights.	Mineral rights for the NorthMet Project Proposed Action are discussed in Section 3.2.2 of the SDEIS.	LAN 04
Section: Vegetation (VE)			
VE1	The DEIS does not provide sufficient baseline characterizations of vegetation and other factors related to vegetation, such as groundwater modeling.	Existing conditions, including baseline characterizations and any additional threatened or endangered species listed after the DEIS was released, are discussed in detail in Sections 4.2.4 and 4.3.4 of the SDEIS. Details regarding inputs to modeling are included in resource-specific Sections of SDEIS Chapter 5.	VEG 09
VE2	The DEIS does not adequately address impacts to wild rice, aquatic vegetation, and farming from sulfates, sulfides, mercury methylation, and other constituents.	Effects resulting from vegetation exposure to potentially harmful constituents are discussed in detail in relevant Sections of SDEIS Chapter 5, such as water resources.	VEG 04, VEG 07
VE3	The DEIS reclamation plans are not sufficiently detailed. They do not adequately consider impacts from non-native and invasive species and should instead include native species.	Issues such as the spread of non-native and invasive species and potential effects on vegetation resources are addressed in Section 5.2.4 of the SDEIS. Reclamation plans, revegetation plans (including plant species proposed to be used during closure and reclamation activities), monitoring plans, and potential mitigation measures for the NorthMet Project Proposed Action are discussed in SDEIS Chapter 3.	VEG 05
VE4	The DEIS does not adequately consider the cumulative effect on non-listed flora populations, in addition to threatened and endangered species, in northeast Minnesota from	Cumulative effects on vegetative species, and the metrics used for analysis of potential effects, are discussed in Chapter 6 of the SDEIS.	VEG 08

DEIS Theme Code	DEIS Theme Statement	DEIS Thematic Response	Corresponding FEIS Theme(s)
	other similar projects, and does not discuss the extent and prevalence of these species in the region.		
VE5	The DEIS contains insufficient information to support its discussion of effects to threatened and endangered plant species, nor does it describe a plan to maintain these populations.	Potential effects on state-listed and RFSS plant species are discussed in Sections 5.2.4 and 5.3.4 of the SDEIS. A Biological Evaluation will be developed to address RFSS. There are no federally listed plant species in the NorthMet Project Area.	VEG 01
VE6	The DEIS does not adequately evaluate tribal utilization of important plant resources (wild rice, cedar, sage, etc.) at the Mine Site and Plant Site, since the Section 106 NHPA consultation was not finished at time of publication and documentation of these uses is often not available or recorded.	Section 106 consultation is ongoing. Potential effects on vegetation and plant species are discussed in Sections 5.2.4 and 5.3.4 of the SDEIS. Tribal utilization of plant species is discussed in the Cultural Resources sections of SDEIS Chapters 4 and 5.	CR 05, CR 06
VE7	The DEIS does not adequately identify the proposed organic nutrient amendments to the Tailings Basin and how these would promote the development of shoreline and near-shore aquatic vegetation.	Potential mitigation methods regarding vegetation are addressed in Section 5.2.4 of the SDEIS. This includes revegetation of the Tailings Basin and development of aquatic vegetation. Reclamation plans, revegetation plans, monitoring plans, and potential mitigation measures for the NorthMet Project Proposed Action are discussed in Chapter 3 of the SDEIS.	VEG 05
VE8	The DEIS does not adequately characterize impacts from sulfuric acid formation on vegetation, during transportation of the rock from the Mine Site to the Plant.	Spillage from rail cars is expected to be minimized through the use of mitigation methods such as seals on rail car doors and a different design than previous operations. Effects on vegetation resulting from rail car spillage are discussed in Section 5.2.4 of the SDEIS.	VEG 04, VEG 06
Section: Visual Resources (VI)			
VI1	The DEIS visual impact assessment does not provide sufficient characterizations of baseline conditions or impacts. A visual impact assessment that is comparable to past USACE practices should be provided.	Section 4.2.11 of the SDEIS includes an expanded discussion of baseline visual conditions.	SDEIS comments did not raise this topic.
VI2	The DEIS should include a discussion on the potential adverse visual impacts from the introduction of non-native species as a revegetation measure.	This topic is discussed in Sections 5.2.11 and 5.3.11 of the SDEIS.	SDEIS comments did not raise this topic.
VI3	The DEIS' conclusions regarding the extent and	This topic is discussed in Sections 5.2.11 and 5.3.11 of the SDEIS.	SDEIS comments

DEIS Theme Code	DEIS Theme Statement	DEIS Thematic Response	Corresponding FEIS Theme(s)
	impacts of light pollution are inadequate.		did not raise this topic.
VI4	The DEIS should evaluate the potential for haze and haze-related impacts on the BWCAW as a result of the NorthMet Project Proposed Action.	Haze and related effects are discussed in Section 5.2.7 and 5.2.11.	AIR 08
Section: Wetlands (WE)			
WE1	The DEIS does not adequately characterize the wetland baseline information; the wetland delineation and characterization of wetland areas /species should be reevaluated.	Characterization of wetland resources at the Mine Site has been reevaluated since the DEIS. Existing conditions, including baseline characterizations of wetland resources, are discussed in detail in Section 4.2.3 of the SDEIS. Further details regarding inputs to modeling are discussed in Section 5.2.3 of the SDEIS.	WET 07, WET 21
WE2	The DEIS does not adequately characterize the direct and indirect impacts to wetland resources from the NorthMet Project Proposed Action.	Direct and indirect effects on wetland resources from the NorthMet Project Proposed Action are discussed in detail in Section 5.2.3 of the SDEIS. Further analysis of the potential direct, indirect, and cumulative effects on wetland resources has occurred since the development of the DEIS and a Wetlands IAP Workgroup was formed to address the concerns raised on the DEIS. Related discussions are included in other Sections of SDEIS Chapter 5 (such as water resources).	WET 07, WET 08, WET 10, WET 11
WE3	The DEIS does not adequately address wetland mitigation for the NorthMet Project Proposed Action.	Wetland monitoring plans are discussed in Section 5.2.3 of the SDEIS. Wetland mitigation methods, including wetland ratios and justification for mitigation site locations, are also addressed in Section 5.2.3. PolyMet has now proposed a compensatory wetland mitigation site in the St. Louis River Watershed and one in an adjacent watershed, in addition to the two other sites identified in the DEIS.	WET 01, WET 03, WET 04, WET 05
WE4	The DEIS provides insufficient information to demonstrate compliance with federal and state wetland permitting requirements.	Existing wetland habitat, including wetland/habitat quality, is described in Sections 4.2.3 and 4.3.3 of the SDEIS. Effects on wetland resources at the Mine Site and Plant Site are included in Section 5.2.3 of the SDEIS. This discussion includes (where applicable) information to show how the effects of the NorthMet Project Proposed Action compare with federal and state wetland permitting requirements, which includes justification for mitigation site locations.	COE 02, COE 04
WE5	The DEIS does not adequately address the cumulative effects for wetland resources and the analysis should be redone.	Further analysis of the potential cumulative effects on wetland resources has occurred since the development of the DEIS and a Wetlands IAP Workgroup was formed to address the concerns raised in the DEIS. Cumulative effects on wetland resources, and the metrics used for analysis	WET 18

DEIS Theme Code	DEIS Theme Statement	DEIS Thematic Response	Corresponding FEIS Theme(s)
		of potential effects, are included in Chapter 6 of the SDEIS.	
WE6	The DEIS does not adequately analyze the effectiveness of the wetland treatment system (i.e., WWTF and passive wetland treatment system) and the potential for a longer duration. The SDEIS needs to further analyze the effectiveness and possibility for a longer duration.	Further analysis of the potential effects on wetland resources has occurred since the development of the DEIS, including formation of a Wetlands IAP Workgroup to address the concerns raised in the DEIS. The NorthMet Project Proposed Action no longer includes a wetland treatment system. See Chapter 3 for a description of the mechanical wastewater treatment systems planned for the Plant Site and Mine Site, as well as other wetland monitoring plans. Wetland monitoring plans and other wetlands effects are discussed in Section 5.2.3 of the SDEIS.	SDEIS comments did not raise this topic.
WE7	The DEIS does not adequately address the value of wetlands since the Land Exchange Proposed Action was not included in DEIS and the covenants on the Mine Site (Weeks Act) are being ignored.	Information on the Land Exchange Proposed Action, including conformance to the Weeks Act, Federal Land Policy and Management Act, the Forest Plan, and EOs 11990 (USEPA 1977) and 11988 (USFS 2004d, as cited in the FEIS) are included in Chapter 1 and Section 5.3.3 of the SDEIS.	WET 14, WET 17
WE8	The DEIS is inadequate in demonstrating how the water quality and release of mercury would impact wetlands.	Since publication of the DEIS, additional analysis of indirect wetland effects has been conducted, including effects on wetland water quality. A Wetlands IAP Workgroup was formed to address concerns raised in the DEIS. Potential wetland effects associated with degraded water quality and mercury release from the NorthMet Project Proposed Action have been further evaluated, and further analysis of potential effects on wetland resources has been conducted since the development of the DEIS. These effects are discussed in detail in Sections 5.2.3 and 5.3.3 of the SDEIS, and in related Sections of SDEIS Chapters 4 and 5 (such as water resources).	WET 11
Section: Wildlife (WI)			
WI1	The DEIS does not adequately incorporate the findings of biological assessments or comments prepared by other agencies (USACE, USFWS, USFS) related to impacts on threatened and endangered species or RFSS.	A BA and Biological Evaluation will be developed to address federally listed and RFSS, respectively. Discussions of potential effects on federally listed, state-listed, and Regional Forester Sensitive Species (wildlife) are included in the Vegetation and Wildlife Sections of SDEIS Chapter 5.	WI 11
WI2	The DEIS does not adequately analyze the direct and indirect effects (including habitat loss) on wildlife species including special-status species (e.g., endangered species). More surveys need to be completed for these species, and more emphasis should be placed on the effect on	Please see response to Theme WI1. Updated special-status species lists are included in Sections 4.2.5 and 5.2.5 of the SDEIS. Additional wildlife surveys were completed for the non-federal land exchange parcels and are discussed in Sections 4.3.5 and 5.3.5 of the SDEIS.	WI 01, WI 03

DEIS Theme Code	DEIS Theme Statement	DEIS Thematic Response	Corresponding FEIS Theme(s)
	specific areas such as the Once Hundred Mile Swamp and Mud Lake/Yelp Lake.		
WI3	The DEIS does not adequately evaluate tribal utilization of important and treaty-protected wildlife species (moose, furbearer species, etc.), because the Section 106 NHPA consultation was not finished at time of publication and documentation of these uses is often not available or recorded.	Section 106 consultation is ongoing. Discussion of potential effects on wildlife species is included in Sections 5.2.5 and 5.3.5 of the SDEIS. In addition, potential effects on 1854 Treaty resources have been addressed in Sections 4.2.9 and 5.2.9.	WI 09
WI4	The DEIS does not adequately consider the cumulative effect on non-listed wildlife populations (in addition to threatened and endangered species) in northeast Minnesota from other similar projects, including synergistic impacts of bioaccumulation of contaminants.	Cumulative effects on wildlife species, including RFSS and SGCN, are discussed in Chapter 6 of the SDEIS. Further discussion of reclamation and post-closure activities are discussed in Chapter 3 of the SDEIS. Non-federal lands to become federal/public are addressed in topic-specific discussions in Section 5.3 and Chapter 6 of the SDEIS. Mitigation for and restoration of wildlife corridors is discussed in Chapter 6 of the SDEIS.	WI 08
WI5	The DEIS does not adequately address the habitat value of quality for restored wetlands, particularly the Hinckley and Aitkin sites. These would not offer the same habitat for northern wildlife species since they are located so far south.	Existing wetland habitat, including wetland/habitat quality, is described in Sections 4.2.3 and 4.3.3 of the SDEIS. Wetland mitigation methods, including justification for mitigation site locations, are addressed in Sections 5.2.3, 5.3.3, and Chapter 7 of the SDEIS.	SDEIS comments did not raise this topic.
Section: Water Resources (WR)			
WR1A	The plan for post closure management to prevent pollution of groundwater or surface water is inadequate or unclear and given the inherent uncertainty in hydrology and geochemistry, and the Mine's long term potential to degrade water quality. The post-closure plan should include contingencies, mitigation strategies, and a detailed reclamation plan and financial assurances.	The Proposed Action has changed substantially since preparation of the 2009 DEIS (MDNR and USACE 2009, as cited in the FEIS) and water quality modeling has been revised accordingly. PolyMet has developed Adaptive Water Management Plans [PolyMet 2015d, as cited in the FEIS) that include contingencies and mitigation strategies if actual water effects turn out to be greater than modeled. Post-closure management is addressed in Section 3.2.2 and Chapter 7 of the SDEIS. During plant closure activities, demolition and reclamation of Plant Site infrastructure would be completed according to federal, state, and local agency permits and regulations. Financial assurance for closure and remediation of the NorthMet Project Proposed Action is addressed in Chapter 3 of the SDEIS. A Co-lead agency document dated August 23, 2011, describes the mechanism for addressing financial assurance in the SDEIS (Co-lead Agencies 2011).	WR 21, WR 35, WR131, WR 132

DEIS Theme Code	DEIS Theme Statement	DEIS Thematic Response	Corresponding FEIS Theme(s)
WR1B	The overall NorthMet Project Proposed Action monitoring plan for water quality is not adequate or described in sufficient detail.	Monitoring is addressed in detail in Section 5.2.2.3.6 of the SDEIS. Groundwater specific monitoring points will be located to evaluate the accuracy of predicted water quality effect. These prediction points were selected based on groundwater flow paths between Mine Site facilities (e.g., waste rock, tailings, pits, etc.) and the nearest surface waters (i.e., the Partridge River and Embarrass River). Surface water quality must be monitored and water quality standards met in all Embarrass River and Partridge River tributaries and main branches of these rivers, as determined by the MPCA.	WR 21
WR1C	Leaching of contaminants from waste rock stockpiles is problematic.	The NorthMet Project Proposed Action has changed substantially since preparation of the 2009 DEIS (MDNR and USACE 2009, as cited in the FEIS). The most reactive waste rock will be temporarily stored on liners, then placed in the East Pit and flooded with water before closure. Discussions of water resources effects (Section 5.2.2 of the SDEIS) account for temporary pollutant release by leakage through these liners. The less-reactive Category 1 waste rock pile that remains permanently on the surface will be surrounded with a water containment trench to capture seepage during and after mining. Water captured in the trench would be treated. A proposed geosynthetic cover would decrease water infiltration. The issue is addressed in Sections 3.2.2 and 5.2.2 of the SDEIS.	WR 01, WR 17
WR1D	The potential for pollution from railroad car ore spillage needs analysis.	The estimate of water quality effects in the SDEIS includes the release and transport of pollutants from ore spilled from rail cars. A monitoring plan for characterization of background water quality and evaluation of effects during operations has been developed. Mitigation strategies are part of the monitoring plan. Sections 4.2.2 and 5.2.2 of the SDEIS address this issue.	WR 151
WR1E	Studies and sampling were inadequate to assess and characterize baseline conditions of acid mine drainage, pollution (including sulfates, mercury, and methylmercury), groundwater (including flows), surface water, wetlands, wild rice, wildlife, and financial risks. As a result, the impact analysis of the NorthMet Project Proposed Action is inadequate.	Environmental sampling and analysis has continued into 2012, expanding the set of baseline environmental data since the 2009 DEIS (MDNR and USACE 2009, as cited in the FEIS). Updated baseline environmental conditions are presented in Section 4.2.2 (water quality, wild rice, and mercury), and Section 4.2.3 (Wetlands). The water quality model used to estimate effects of the project has been calibrated to these current conditions, and the deviation between the calibrated models and observed conditions are considered as one measure of prediction uncertainty (Section 5.2.3).	WR 03, WR 05, WR 08, WR 14, WR 25
WR1F	The proprietary models of pollutant production	The proprietary models used in the DEIS to estimate the release and transport of pollutants under NorthMet Project Proposed Action have been	WR 60, WR 61,

DEIS Theme Code	DEIS Theme Statement	DEIS Thematic Response	Corresponding FEIS Theme(s)
	and transport cannot be independently evaluated.	replaced in the SDEIS with a model that, though still proprietary, is essentially transparent and can be viewed and executed independently. The technical review included independent assessment to confirm that the model used the parameter values agreed upon by the Co-lead Agencies, and that the major model results could be reproduced using independent calculations. See Section 5.2.2 of the SDEIS.	WR 106
WR2A	The hydrogeology of the NorthMet Project site is not well understood. Therefore, the DEIS cannot reliably determine reliably aquifer drawdown from dewatering or whether pollutants from the Mine could travel in groundwater and degrade water in wells, lakes or rivers.	The NorthMet Project Proposed Action has changed substantially since preparation of the 2009 DEIS (MDNR and USACE 2009, as cited in the FEIS) and water balance studies. In particular, the number of wells used to characterize the Mine Site alluvium (the main area affected by dewatering) has been increased (Section 4.2.2), and the new information on water levels and water quality gained from these data have been used in the calibration of the updated water quality model (Section 5.2.2).	WR 07, WR 08, WR 10
WR2B	Climate change could increase (beyond assumptions in the DEIS) the volume of water flowing through the Mine causing increased transportation of pollutants in surface and groundwater.	This issue is addressed in Sections 5.2.2 and 5.3.2 of the SDEIS. Estimates of pollutant transport from the NorthMet Project Proposed Action use results of “down-scale” climate models (i.e., nested models that refine the estimated effect of climate change on local water balance using larger-scale model results) to estimate the range in pollutant migration from mine waste. The effects of extremely wet periods are included in the modeling.	WR 77, WR 180, WR 188, WR 196
WR2C	Pollutants released by the NorthMet Project Proposed Action could contaminate groundwater. These effects need to be estimated.	The NorthMet Project Proposed Action has changed substantially since preparation of the 2009 DEIS (MDNR and USACE 2009, as cited in the FEIS) and water quality modeling has been revised accordingly. Estimating the rate at which pollutants from mine waste could leach into groundwater is given high priority in the SDEIS modeling and is specifically discussed in Section 5.2.2 of the SDEIS. Pollutant concentrations in groundwater were estimated using probabilistic models; descriptions of predicted effects on groundwater and surface water quality are presented along with a discussion of uncertainty in model parameters.	WR 10, WR 12
WR2D	The liners under waste rock and waste facilities and /or hydrometallurgical waste cells may fail over time and may need to be replaced.	The NorthMet Project Proposed Action has changed substantially since preparation of the 2009 DEIS (MDNR and USACE 2009, as cited in the FEIS) and the SDEIS has changed accordingly. In particular, the lowest-sulfide (Category 1) waste rock that will be permanently stored in unlined facilities will be surrounded completely by a groundwater containment system that will capture seepage during and after mining to prevent discharge before it has been treated to meet discharge standards. After	WR 67, WR 126, WR 138

DEIS Theme Code	DEIS Theme Statement	DEIS Thematic Response	Corresponding FEIS Theme(s)
		closure, the Category 1 waste rock will be covered with a geomembrane to reduce water percolation and pollutant transport. The more reactive (Category 2, 3, and 4) rock will be stored temporarily in lined facilities, before being placed in the East Pit for permanent stabilization under the water table. Hydrometallurgical waste will be blended with lime to reduce metal solubility prior to disposal, and this material will be placed in double-lined facilities, which have been shown to have negligible leakage.	
WR2E	The model of pollutant transport from Mine Site facilities to groundwater and surface water does not adequately represent the NorthMet Project Proposed Action. The model does not adequately consider water flow through the Mine Site, all of the chemical constituents that may be leached from mine waste, or the known mechanisms of pollutant release and transport at hard rock sulfide mines.	The NorthMet Project Proposed Action has changed substantially since preparation of the 2009 DEIS (MDNR and USACE 2009, as cited in the FEIS) and water quality modeling has been revised accordingly. Estimating the rate at which pollutants from mine waste could leach into groundwater is given high priority in the SDEIS modeling and is specifically discussed in Section 5.2.2 of the SDEIS. The SDEIS expands the number of constituents included in the modeling from eight in the DEIS to 20 to include all inorganic constituents with drinking water standards. Pollutant concentrations in groundwater were estimated using probabilistic models. Descriptions of predicted effects on groundwater and surface water quality are presented along with a discussion of uncertainty in model parameters.	WR 49, WR 61
WR2F	The WWTF may not be able to adequately treat Mine Site water to meet discharge standards and there is no contingency for this. It is also unclear whether the WWTF would treat nitrates.	The state has reviewed the WWTF effluent water quality targets provided by PolyMet and, based upon currently available data, including RO pilot results, believes these targets could be met. Nitrates would be treated if they are included in the discharge permit. The WWTF will also be of modular construction, such that additional modules can be added for increased capacity if necessary.	WR 32
WR2G	The water quality models for the NorthMet Project Proposed Action produced recharge rates through the glacial till that seem implausible, based on USGS data. This should be reconciled by measuring recharge from water table wells and including recharge from all pathways, including meteoric water.	The NorthMet Project Proposed Action has changed substantially since preparation of the 2009 DEIS (MDNR and USACE 2009, as cited in the FEIS) and water quality modeling has been revised accordingly. Water quality modeling is specifically addressed in Section 5.2.2 of the SDEIS. Hydraulic characteristics of the glacial till, including hydraulic conductivity and recharge, were refined by reviewing data (including specific measurements of recharge through surficial till) from two nearby mines with similar hydraulic and geologic settings.	SDEIS comments did not raise this topic.
WR2H	Many of the wetlands in the NorthMet Project area may be hydraulically connected to groundwater, contrary to the assumption in the DEIS. Air photo interpretation is inadequate to	The potential for indirect wetland effects at the Mine Site is discussed in Section 5.2.2 of the SDEIS. This discussion is refined and expanded, compared to the 2009 DEIS (MDNR and USACE 2009, as cited in the FEIS), in particular by evaluating the effects of dewatering at two nearby	WR 53

DEIS Theme Code	DEIS Theme Statement	DEIS Thematic Response	Corresponding FEIS Theme(s)
	assess impacts on wetlands and Mud Lake. Empirical data used to address indirect wetland impacts needs better disclosure in the EIS.	mines with similar bedrock and surficial geologic conditions.	
WR2I	The point selected to evaluate impacts to surface or groundwater is inappropriate.	The NorthMet Project Proposed Action has changed substantially since preparation of the 2009 DEIS (MDNR and USACE 2009, as cited in the FEIS) and water quality modeling, proposed monitoring points, and proposed model evaluation locations have been revised accordingly. Water quality monitoring is specifically addressed in detail in Section 5.2.2.3.6 of the SDEIS. For groundwater, specific monitoring points will be located to evaluate the accuracy of predicted water quality effect. These prediction points were selected based on groundwater flow paths between Mine Site facilities (e.g., waste rock, tailings, pits, etc.) and the nearest surface waters (i.e., the Partridge River and Embarrass River). The surface water quality modeling includes 18 evaluation locations along the main branch of the Embarrass River, its tributary streams, and the main branch of the Partridge River, plus one evaluation point in Colby Lake.	WR 64, WR 109
WR2J	The evapotranspiration capability of the vegetated soil layer on the stockpiles has not been demonstrated.	The NorthMet Project Proposed Action has changed substantially since preparation of the 2009 DEIS (MDNR and USACE 2009, as cited in the FEIS) and no longer includes permanent stockpiles of Category 2, 3, or 4 waste rock where minimizing infiltration is important. The Category 1 Stockpile would be covered by a geomembrane liner, thereby dramatically reducing infiltration and the need to accurately model evapotranspiration. Section 5.2.2 of the SDEIS addresses this issue.	SDEIS comments did not raise this topic.
WR3A	The evaluation of tailings discharges is inadequate as there is a significant potential for oxidation from the tailings slurry discharge beach and the tailings pond, winter effects on tailings oxidation need better definition, and water quality and quantity leaving the tailings basin may be problematic, especially in the case of flooding.	The NorthMet Project Proposed Action has changed substantially since preparation of the 2009 DEIS (MDNR and USACE 2009, as cited in the FEIS) and water quality modeling has been revised accordingly. Water quality modeling is specifically addressed in Section 5.2.2 of the SDEIS. In addition, the SDEIS now uses a more robust probabilistic modeling approach that incorporates current data and information to present sufficient additional analysis. Finally, the flotation tailings will now be surrounded with a water containment system to capture seepage for storage and eventual treatment prior to discharge. Sections 3.2.2 and 5.2.2 of the SDEIS address this issue.	WR 45, WE 50
WR3B	There are concerns about water quality effects beyond the immediate NorthMet Project area, including BWCAW, the overall St. Louis River	There is no groundwater seepage or surface water drainage from the NorthMet Project area to the BWCAW or its waters. Surficial groundwater seepage and surface runoff from the NorthMet Project area drains to either	WR 38, WR 42, WR 80

DEIS Theme Code	DEIS Theme Statement	DEIS Thematic Response	Corresponding FEIS Theme(s)
	Watershed, and Lake Superior.	the Partridge River or the Embarrass River, both of which are tributaries of the St. Louis River and Lake Superior. All seepage and surface water runoff must meet applicable water quality standards at or before the property boundary. Section 5.2.2 of the SDEIS addresses this issue.	
WR3C	The DEIS' finding that there will be no surface water discharge is incorrect. The final EIS should acknowledge the application of NPDES permits to a variety of pathways for surface water discharge and to assess the potential for each, including the West Pit outflow.	The NorthMet Project Proposed Action has changed substantially since preparation of the 2009 DEIS (MDNR and USACE 2009, as cited in the FEIS) and the SDEIS has changed accordingly. There will be groundwater seepage from the Tailings Basin and the East Pit after it fills with water. These seepages (which are quantified in Section 5.2.2 of the SDEIS) will eventually become surface water draining to tributaries of the Embarrass River and Partridge River. All applicable groundwater and surface water standards must be met. There may also be direct discharge from the WWTF, which would require a NPDES permit, if there is excess water after make-up water needs are met. Beginning in approximately year 40, there could also be direct discharges from the West Pit Overflow; this discharged water would be treated at the WWTF prior to diversion into the West Pit.	SDEIS comments did not raise this topic.
WR3D	The NorthMet Project Proposed Action could result in AMD and the potential for additive toxicity to Lake Superior.	The NorthMet Project Proposed Action has changed substantially since preparation of the 2009 DEIS (MDNR and USACE 2009, as cited in the FEIS). There is a discussion on the potential for effects as it pertains to the impaired status of the St. Louis River (which flows into Lake Superior) and/or the TMDL process in Section 5.2.2 and Chapter 6 of the SDEIS. See also response to theme WR3C.	WR 01, WR 08, WR 10, WR 19, WR 25
WR3E	Water level changes in the Partridge River and Embarrass River and wetlands downstream of the tailing basin needs quantifying.	Changes in streamflow to the Partridge River and Embarrass River were modeled for the 2009 DEIS (MDNR and USACE 2009, as cited in the FEIS), and that modeling was revised for the SDEIS to reflect substantial changes in the NorthMet Project Proposed Action. These changes are addressed in Section 5.2.2 of the SDEIS. The small reduction in streamflow due to the NorthMet Project Proposed Action will result in an imperceptible change in river water level.	WR 45, WR 46, WR 47, WR 48
WR3F	Water quality and quantity impacts to Colby Lake and Hoyt Lakes' municipal water supply need better analysis. The DEIS should have discussed the following related issues: development of a TMDL or Manganese criterion for Colby Lake; effects on Colby Lake's water levels; quantity of water pumped to the WWTP;	These issues are addressed in Section 5.2.2 of the SDEIS. Colby Lake is one of the water quality modeling evaluation locations downstream of the Mine Site. Effects on Colby Lake are discussed in Section 5.2.2.3.2.	WR 43, WR 123, WR 140

DEIS Theme Code	DEIS Theme Statement	DEIS Thematic Response	Corresponding FEIS Theme(s)
	and levels of metals removal, including iron reduction, achieved by the Hoyt Lakes treatment plant.		
WR3G	In reference to lining the exposed Virginia Formation along the East Pit's north wall, literature citation notes that lime increases pH which, in turn, increases release of arsenic. The relationship between arsenic solubility and liming should be addressed.	The NorthMet Project Proposed Action has changed substantially since preparation of the 2009 DEIS (MDNR and USACE 2009, as cited in the FEIS). As described in Chapter 3 and Section 5.2.2 of the SDEIS, the more reactive waste rock and overburden would be backfilled to the East Pit, covering the Virginia formation, and would be permanently stored subaqueously, minimizing oxidation and the subsequent release of contaminants. Lime could be added to the East Pit during backfilling, as needed, in order to maintain circumneutral pH in the pit pore water, which would be pumped to the WWTF and returned to the East Pit as required to manage potential pollutant load. The volume of lime required would be determined through monitoring.	WR 27
WR3H	The DEIS needs to model for dissolved aluminum, not total, since dissolved is the standard.	Minnesota Rules 7050.0222 Subpart 1.B states that in the absence of a listed conversion factor for a particular metal to convert total to dissolved, the applicable conversion factor is one. Aluminum is not listed in Subpart 9; therefore, its conversion factor is one. That means, practically speaking, that total equals dissolved; therefore, modeling total aluminum is acceptable. Since the dissolved form of a metal, by definition, cannot be greater than the total metal, using total aluminum in the modeling can be considered conservative. Modeling criteria for aluminum and other constituents are discussed in Section 5.2.2.1.2, while future concentrations of aluminum are discussed in Section 5.2.2.3.2 (Partridge River) and Section 5.2.2.3.3 (Embarrass River).	WR 82
WR3I	There are potential exceedances of water quality standards due to the NorthMet Project Proposed Action, even after WWTF treatment. To demonstrate compliance with all applicable standards and regulations, the EIS should present additional analysis, suggest alternative designs and methods to prevent contamination that exceeds water quality standards, and should use more rigorous Impact Criteria imposed by downstream impaired waters (including TMDL and nondegradation criteria) for all chemicals on	The NorthMet Project Proposed Action has changed substantially since preparation of the 2009 DEIS (MDNR and USACE 2009, as cited in the FEIS) and water quality modeling has been revised accordingly. Water quality modeling is specifically addressed in Section 5.2.2 of the SDEIS. In addition, the SDEIS now uses a more robust probabilistic modeling approach that incorporates current data and information to present sufficient additional analysis to compare predicted effects against applicable standards and regulations. Specific (i.e., numeric) evaluation criteria related to sulfate and methylmercury for the impaired portion of the St. Louis River do not exist. Section 5.2.2 of the SDEIS therefore discusses potential methylmercury-related effects in downstream impaired waters qualitatively.	WR 52, WWR 54, WR 60, WR 64, WR 70, WR 82, WR 83

DEIS Theme Code	DEIS Theme Statement	DEIS Thematic Response	Corresponding FEIS Theme(s)
	the GLI list.		
WR3J	Lack of on or near-site streamflow data makes the DEIS' impact assessment questionable.	The Co-lead Agencies are comfortable with the modeling approach used for hydrologic impact assessment, especially since data collected during recent winters confirms that the model's baseflow estimates are conservatively low. It is also important to note that the total watershed area consumed within the NorthMet Project area is less than 7 percent at any location along the Partridge River, meaning that actual changes in streamflow will be very small. One or more permanent gauging stations along the Partridge River will be required during operations to aide in the determination of compliance with water quality standards.	WR 03, WR 04, WR 05, WR 06, WR 81, WR 91, WR 101, WR 105
WR3K	Ditches and dikes are not 100 percent effective. The materials used in ditch and storm water leachate collection systems must preclude seepage and be resistant to freeze/thaw cycles.	It is understood that the ditches and dikes that are part of the Category 1 Stockpile seepage collection system are not 100 percent effective. However, they will be engineered to an acceptable level of efficiency considering the low reactive potential of the Category 1 waste rock, and the modeling used to estimate project effects on water quality have assumed leakage rates observed in similar systems. This issue is addressed in Sections 3.2.2 and 5.2.2 of the SDEIS.	WR 17, WR 127
WR3L	Wetland treatment in the East Pit is inadequate for water treatment.	The NorthMet Project Proposed Action has changed substantially since preparation of the 2009 DEIS (MDNR and USACE 2009, as cited in the FEIS) and water quality modeling has been revised accordingly. Water quality modeling is specifically addressed in Section 5.2.2 of the SDEIS.	SDEIS comments did not raise this topic.
WR3M	The DEIS fails to analyze the impacts to water quality from the local deposition and run-off of metal emissions.	The NorthMet Project Proposed Action has changed substantially since preparation of the 2009 DEIS (MDNR and USACE 2009, as cited in the FEIS) and water quality modeling has been revised accordingly. Water quality modeling is specifically addressed in Section 5.2.2 of the SDEIS. In addition, the SDEIS now uses a more robust probabilistic modeling approach that incorporates current data and information to present sufficient additional analysis. Projected mercury emissions from the Plant Site have been subjected to an AERA, where potential mercury-related risks were assessed for fishing and subsistence users, where chronic risks are based on fish consumption. The findings of the agency-approved AERA are presented in the SDEIS.	SDEIS comments did not raise this topic.
WR3N	The potential effects of the NorthMet Project Proposed Action on wetlands, bogs, and peatlands were not adequately evaluated in the	Please see response to Theme WR3M.	WR 53, WR 64, WR 105, WR 112, WR 119

DEIS Theme Code	DEIS Theme Statement	DEIS Thematic Response	Corresponding FEIS Theme(s)
	DEIS.		
WR4A	<p>The modeling used for the DEIS must consider mercury methylation and provide a quantitative analysis of the discharge of mercury from all pathways during and after mining based on realistic data. Modeling should also consider estimates of expected variation in measures under varied conditions (e.g., fluctuating water levels in reservoirs and flood plains).</p>	<p>The NorthMet Project Proposed Action has changed substantially since preparation of the 2009 DEIS (MDNR and USACE 2009, as cited in the FEIS) and water quality modeling has been revised accordingly. Water modeling is specifically discussed in Section 5.2.2 of the SDEIS. The SDEIS gives high priority to estimating the rate at which pollutants from mining waste (e.g., tailings, waste rock, stockpiled ore, pit-wall rock, and hydrometallurgical process residue) could leach into groundwater. To ensure that the analysis for the SDEIS identified a realistic range for possible effects on water quality, the Water Resources IAP Workgroup identified ranges for values of most parameters used to estimate pollutant migration. The model of pollutant dissolution and migration considers water percolation rates through mine waste, leakage rates through lined facilities, and uses empirical tests on project materials to estimate dissolution rates for sulfide minerals and chemical attenuation by adsorption and precipitation (see Section 5.2.2.2.3). Quantitative modeling of methylmercury is beyond the scope of the SDEIS, due to the inherent complexity of the fate and transport of methylmercury in the environment. However, the potential for enhanced methylation of mercury and uptake in fish as a result of project discharges is qualitatively addressed in the SDEIS.</p>	<p>WR 158, MERC 02, MERC 08, MERC 23</p>
WR4B	<p>The DEIS fails to adequately address impacts of mercury and methylmercury, particularly on fish and humans. The DEIS should include an analysis of the impacts of methylmercury on fish communities, as well as on people and wildlife that consume the fish, social and economic impacts to fisheries, groundwater, surface water, wetlands, and sensitive areas and waterbodies with existing mercury impairments. The EIS should also explain why the addition of sulfates from the NorthMet Project Proposed Action will not result in additional mercury pollution, how the St. Louis River Watershed will be able to attain TMDL standards, and the potential for mercury demethylation and/or methylation in flooded mine pits.</p>	<p>The NorthMet Project Proposed Action has changed substantially since preparation of the 2009 DEIS (MDNR and USACE 2009, as cited in the FEIS) and water quality modeling has been revised accordingly. Estimating the rate at which pollutants from mining waste could leach into groundwater is given high priority in the SDEIS modeling and is specifically discussed in Section 5.2.2. Pollutant concentrations in groundwater were estimated using probabilistic models. Descriptions of predicted effects on groundwater and surface water quality are presented along with a discussion of uncertainty in model parameters. The SDEIS specifically addresses possible effects on people, fisheries, and wildlife based on the estimates of pollutant concentrations from the models. Quantitative modeling of methylmercury is beyond the scope of the SDEIS, due to the inherent complexity of the fate and transport of methylmercury in the environment. However, the potential for enhanced methylation of mercury and uptake in fish as a result of NorthMet Project Proposed Action discharges are qualitatively addressed in the SDEIS.</p>	<p>MERC 02, MERC 03, MERC 24</p>

DEIS Theme Code	DEIS Theme Statement	DEIS Thematic Response	Corresponding FEIS Theme(s)
WR4C	Monitoring, mitigation measures, and contingency responses for pollutant releases (especially sulfate and mercury) are inadequately described in the DEIS. The DEIS should explain how exceedances of these materials are to be regulated, define the goal of maintenance-free closure, and any financial safeguards that are in place to address future problems to water and soil as a consequence of industrial action.	These issues are addressed in Chapters 3 and 7 of the SDEIS. Under the SDEIS, the Category 1 waste rock facility and the Tailings Basin will be surrounded by containment systems to capture and treat seepage to reduce the pollutant load to groundwater. Groundwater monitoring points will be located to evaluate the accuracy of predicted water quality effect. During mine closure, the East Pit would be reclaimed as a wetland and the West Pit would flood with water to become a pit lake. Water from the West Pit will be treated as necessary at the WWTF and returned to the West Pit, or discharged to the Partridge River at concentrations that meet pollutant concentration thresholds. During post-closure, the WWTF will be used, as necessary, to treat effluent from the West Pit Lake, the Category 1 waste rock and the Tailings Basin to meet surface water quality standards before it is discharged. The WWTF will be run as long as necessary during operations and closure, until passive treatments are adequately demonstrated to meet water quality standards. During plant closure activities, demolition and reclamation of Plant Site infrastructure would be completed according to federal, state, and local agency permits and regulations.	WR 21, MERC 08, MERC 17
WR4D	The permitting of the NorthMet Project Proposed Action would violate the Great Lakes Compact of zero discharge of mercury to the basin and federal or state regulations that prohibit mixing zones (40 C.F.R. § 132, Appendix F, Procedure 3; Minn. R. 7052.0210, Subpart 3). The more rigorous Impact Criteria imposed by the downstream impaired waters and TMDL status and nondegradation under Minnesota Rules 7050 and 7052 should be used instead of the Great Lakes Initiative.	This issue is addressed in Chapter 1 of the SDEIS. Applicability of the Great Lakes Initiative is also discussed in Sections 5.2.2.1.2 (Evaluation Criteria), and Sections 5.2.2.3.4 (Mercury). The NorthMet Project Proposed Action has changed substantially since preparation of the 2009 DEIS (MDNR and USACE 2009, as cited in the FEIS), and water quality modeling has been revised accordingly. The SDEIS will use a more robust probabilistic modeling approach that incorporates current data and information to present sufficient additional analysis to compare predicted effects against applicable standards and regulations. Specific (i.e., numeric) evaluation criteria related to sulfate and methylmercury for the impaired portion of the St. Louis River does not exist. The SDEIS discusses potential methylmercury-related effects in downstream 'impaired' waters qualitatively in the Chapter 5 of the SDEIS. The water quality evaluation criteria in the SDEIS include the Lake Superior mercury standard.	WR 38, WR 125, WR 158, MERC 01
WR4E	Sequestration of mercury by soil, peatlands, and/or minerals is not adequately discussed in the DEIS. The EIS should include quantitative information on mercury sequestration from the MDNR study.	This issue was addressed in the DEIS. The NorthMet Project Proposed Action has changed substantially since preparation of the 2009 DEIS (MDNR and USACE 2009, as cited in the FEIS). The SDEIS uses a more robust probabilistic modeling approach that incorporates current data and information to present sufficient additional analysis. Quantitative modeling	SDEIS comments did not raise this topic.

DEIS Theme Code	DEIS Theme Statement	DEIS Thematic Response	Corresponding FEIS Theme(s)
		of mercury transport is beyond the scope of the SDEIS, due to the inherent complexity of the fate and transport of methylmercury in the environment. However, the potential for enhanced methylation of mercury are addressed in the SDEIS.	
WR4F	The NorthMet Project Proposed Action could potentially elevate sulfate concentrations above the 10 mg/L wild rice standard and could promote AMD with potential impacts on the health of aquatic vegetation, especially wild rice beds, which have significant cultural and ecological value. The EIS should thoroughly evaluate impacts on wild rice standards.	The NorthMet Project Proposed Action has changed substantially since preparation of the 2009 DEIS (MDNR and USACE 2009, as cited in the FEIS). The MPCA staff have made a draft recommendation that portions of the Partridge River downstream of the Mine Site be treated as waters used for the production of wild rice, meaning that the 10 mg/L sulfate evaluation criterion would apply to these reaches from April 1 to August 31. The NorthMet Project Proposed Action includes controlled outflow from the West Pit to comply with this standard. Modeling of the NorthMet Project Proposed Action indicates that sulfate concentrations in tributaries north of the basin and at PM-13 would decrease in comparison to the Continuation of Existing Conditions modeling scenario. These aspects of the NorthMet Project Proposed Action are described in Chapter 3, Chapter 7, and Section 5.2.2 of the SDEIS.	WR 149, WR 152, WR 156
WR5A	Inadequate consideration has been given to the long-term impact of mercury and sulfate emissions from the NorthMet Project Proposed Action, in combination with other cumulative impacts, on water resources (including groundwater, water supplies, exceedances of water quality standards, metal leaching, flow fluctuations, and hardness), wetlands, wild rice beds, changes in cover, and hydrology.	This issue is addressed Chapter 7 of the SDEIS. The estimates of effects from the NorthMet Project Proposed Action include release of sulfate and mercury from mine waste to groundwater and surface water. Additional mitigation described in the SDEIS includes groundwater containment systems around the Category 1 waste rock and Tailings Basin. Also, Category 1 waste rock will be covered with a geosynthetic layer to reduce infiltration, and the Tailings Basin surface and slopes would be amended with bentonite to reduce oxygen and water flow and thus reduce pollutant releases. The tailings system is designed with a goal of eventual discontinuation of groundwater seepage collection.	WR24, WR 159
WR5B	The cumulative impacts of the NorthMet Project Proposed Action with other mining projects must be addressed, especially the capacity of the rivers to assimilate wastewater effluent.	This issue is addressed Chapter 6 of the SDEIS.	WR 24, WR 159
WR5C	The applicant's assessment of uniquely affected communities is incorrect and cumulative effects of the NorthMet Project Proposed Action on health and biological resources, including wild rice, and wildlife populations (e.g., fish, moose),	These concerns are addressed in the topic-specific portions of Chapter 6 of the SDEIS, including Water Resources, Wildlife, Fish and Macroinvertebrates, and Socioeconomics.	WR 156, WR 159

DEIS Theme Code	DEIS Theme Statement	DEIS Thematic Response	Corresponding FEIS Theme(s)
	must be considered. These impacts could disproportionately affect minority communities, low income persons, and Indian tribal members, whose diets rely on fish to a greater extent than their non-Indian neighbors.		

A.9 ATTACHMENTS

Attachments to Appendix A, which are available separately from the FEIS, include the following:

- A PDF file containing the full text of all public comments on the SDEIS and corresponding theme assignments (NMetFEIS_AppendixA_All_SDEIS_Comment_Themes.pdf);
- A PDF file containing the full text of all SDEIS submissions received in electronic formats such as email, as exported from the Microsoft Access database used to organize submissions (NMetFEIS_AppendixA_All_SDEIS_Submissions.pdf);
- A PDF file containing one full text copy of each form letter submitted during the public comment period for the SDEIS, as well as a list of all individuals who submitted a copy of that form letter (NMetFEIS_AppendixA_SDEIS_Form_Letter_List.pdf);
- A PDF file containing the full text of all public comments on the DEIS and corresponding theme assignments (NMetFEIS_AppendixA_All_DEIS_Comment_Themes.pdf);
- An electronic folder containing a mix of electronic files comprising all attachments to public submissions on the SDEIS, as well as the full text of submissions not otherwise captured in the abovementioned Microsoft Access database (SDEIS_Submissions); and
- A folder containing PDFs of all public submissions on the DEIS (DEIS_Submissions).

1.0 INTRODUCTION

Section 1502.14 of the National Environmental Policy Act requires that Environmental Impact Statements (EISs) examine all reasonable alternatives to the proposed project. The Council on Environmental Quality defines reasonable alternatives as those that are practical or feasible from technical and economic standpoints and use common sense (Council on Environmental Quality 1981).

Under the Minnesota Environmental Protection Act, an EIS shall compare the potentially significant impacts of the proposed action with other reasonable alternatives to the project. However, *Minnesota Rule* 4410.2300 states that an alternative may be excluded from analysis in the EIS if it would not meet the underlying need or purpose of the project (State of Minnesota 2009).

In the Draft Environmental Impact Statement (DEIS) for the NorthMet Project, the Minnesota Department of Natural Resources (MDNR) and United States Army Corps of Engineers considered underground mining as an alternative to the proposed open pit(s) (MDNR and United States Army Corps of Engineers 2009). This alternative was eliminated because an underground mine would have a significantly reduced rate of operation that would not be considered economically feasible, and, therefore, would not meet the Purpose and Need of the NorthMet Project.

Following tribal and public comment on the DEIS, the Co-lead Agencies, who now include the United States Forest Service, reconsidered underground mining as an alternative to the NorthMet Project in preparation of a Supplemental Draft Environmental Impact Statement (SDEIS). This position paper provides an overview of the alternative screening process undertaken and the decision on whether to undertake a full evaluation of underground mining as an alternative in the SDEIS.

1.1 PURPOSE OF ASSESSMENT

Following its elimination from further consideration in the DEIS, tribal and public comments on the DEIS, as well as discussions during scoping of the Land Exchange, suggested the Co-lead Agencies reconsider underground mining as an alternative in the SDEIS.

The main reasons for reconsideration provided by the public and Bands were:

- the environmental benefits of underground mining compared to open pit mining, and
- that underground mining could be undertaken without the need for a Land Exchange.

1.2 ASSESSMENT MATERIAL

The information in the following subsections was used to inform a semi-qualitative screening analysis of the alternative. A detailed underground mine plan was not developed because PolyMet Mining Corporation (PolyMet) made the business decision to eliminate underground mining as a possible mining method at the NorthMet Deposit based on information that indicated it would not be economically feasible. Therefore, it was not possible to undertake a quantitative, side-by-side assessment of the underground mining alternative.

1.2.1 United States Steel

In the 1970s, the NorthMet Deposit was investigated by United States Steel (U.S. Steel) to evaluate the potential to mine the deposit using underground methods. The MDNR reviewed documentation relating to the U.S. Steel investigation (Patelke and Severson 2005; PolyMet 2007) and found the following was concluded by U.S. Steel:

- mineralization at the NorthMet Deposit was below the expected grades, and
- metallurgical technology available at that time was not sufficient to produce separate, distinct nickel and copper concentrates.

Consequently, the U.S. Steel information alone was not indicative of the potential economic viability of underground mining for the NorthMet Project.

1.2.2 PolyMet

PolyMet, through its consultant (Foth Infrastructure & Environment, LLC), assessed the economic feasibility of underground mining at the NorthMet Deposit based on the proposed open pit deposit (Foth 2012). The findings of this assessment are included in the *Economic Assessment of Conceptual Underground Mining Option for the NorthMet Project*, included with this paper as Attachment 1. A supplemental memorandum was also prepared by Foth to provide further information on the boundaries and model used in the analysis (Foth 2013). This memorandum, *Response to USEPA Questions Regarding: Economic Assessment of Underground Mining Report Dated October 2012*, is provided with this paper as Attachment 2. The information provided by PolyMet was reviewed by technical staff at the MDNR and was determined to be sufficient for a screening-level review of the feasibility of underground mining at the NorthMet Deposit.

2.0 SCREENING OF THE UNDERGROUND MINING ALTERNATIVE

The underground mining alternative for the NorthMet Project was reconsidered for the SDEIS using the same screening criteria as in the DEIS. The screening criteria were used to determine if the alternative would:

- offer significant environmental and/or socioeconomic benefits (over the Proposed Action or other alternatives),
- be available (legally, through surface access and mineral rights),
- be technically feasible (physically possible to construct and underground mine),
- be economically feasible (provide sufficient income to cover: operating, capital, and other costs with an adequate return to investors), and
- meet the Purpose and Need for the project.

The alternative would need to meet all of these criteria to merit further evaluation in the SDEIS. Evaluations of the underground mining alternative against each of the screening criteria are presented in the following subsections.

2.1 SIGNIFICANT ENVIRONMENTAL AND/OR SOCIOECONOMIC BENEFITS

Compared to the proposed open pit mine, the underground mining alternative would offer some significant environmental benefits, including:

- fewer direct effects on surface resources, including wetlands;
- less mine dewatering and, therefore, less water to be managed;
- less waste rock, which would result in:
 - a smaller surface footprint; and
 - reduced effects on surface water and groundwater.
- less ore mined at a slower rate, which would result in:
 - less tailings and hydrometallurgical residue to be managed;
 - fewer effects on surface water and groundwater; and
 - reduced air emissions from mining, transporting, and processing the ore, and constructing the Tailings Basin and Hydrometallurgical Residue Facility.

However, compared to the proposed open pit, an underground mining alternative for the NorthMet Deposit would have a reduced mining rate and life of mine. Consequently, a smaller mining operation would employ fewer workers for a shorter period of time, and would also reduce tax revenues to the state and localities (refer to Section 2.4, Economic Feasibility). Thus, the underground mining alternative would reduce the socioeconomic benefits, as compared to the proposed open pit.

Although the underground mining alternative would offer environmental benefits, it would result in reduced socioeconomic benefits. Additionally, because an underground mine at the NorthMet Deposit would not be profitable (refer to 2.4 Economic Feasibility), a for-profit company like PolyMet would not move forward with the project, thus any potential environmental or socioeconomic benefits associated with this alternative are moot.

2.2 AVAILABILITY

Minerals are available for PolyMet to mine at the NorthMet Deposit through private mineral lease agreements. Surface use could be available through the Land Exchange or other United States Forest Service approvals if an underground mining alternative were deemed viable and adopted by PolyMet.

The underground mining alternative is available at the NorthMet Deposit.

2.3 TECHNICAL FEASIBILITY

Technical feasibility considers whether or not it would be physically possible to create an underground mine at the NorthMet Deposit, disregarding economic feasibility and other considerations.

The NorthMet Deposit is a shallow, large-tonnage, low- to medium-grade mineral resource. Such deposits typically require backfilling, if mined using underground methods, to prevent caving. PolyMet considers that the following methods of underground mining could be technically possible at the NorthMet Deposit:

- Long-hole open stoping (backfilled). This involves the development of large stopes or caved rooms within a steeply dipping orebody. Caving is accomplished by long drill holes and blasting to collection shoots below.
- Short-back open stoping (backfilled). This is similar to long-hole open stoping, but smaller-caved stopes are created within a moderately dipping ore deposit.
- Room and pillar (backfilled). This involves mining the ore deposit (steep or shallow dipping) in tabular layers, with pillars of ore left in place to support the roof (hang wall). Rooms are created by drilling horizontally, blasting, and rubber tired hauling away.
- Mechanized cut and fill (backfilled). This is similar to room and pillar, except that no pillars are left behind. Instead, backfill sand or rock is placed during mining to support the roof.

The underground mining alternative is technically feasible for the NorthMet Deposit.

2.4 ECONOMIC FEASIBILITY

Economic feasibility is based on the balance of costs and profit margins against the value of the mineable material. Since PolyMet is a private sector and for-profit company, the value of the saleable material would need to provide sufficient income to cover operating cost (which includes, but is not limited to, the cost of mining, processing, transportation, and waste management), capital cost (to build and sustain facilities), an adequate return to investors, reclamation, and closure costs and taxes.

While low-confidence mineralization is known to extend along the strike beyond the proposed open pit outline, this material has not been evaluated in detail, there is no mine plan for it, and it is not included as part of the proposed NorthMet Project. A mine plan has only been developed for the proposed open pit. The following discussion is based on qualitative information and the experience of PolyMet and its consultants.

2.4.1 Mineralization at the NorthMet Deposit

The NorthMet Deposit is considered to be a near-surface, bulk, low-grade mineralization of copper, nickel, cobalt, platinum, palladium, and gold. The contained metal value of mineralization at the NorthMet Deposit has been modeled with a high level of confidence in the area proposed to be mined as part of the NorthMet Project (20 year open pit), and with lower confidence beyond the proposed open pit outline. The metal prices used in calculating the contained metal values (dollars per ton) at the NorthMet Deposit for this assessment are listed below:

- Copper = \$3.56 per pound,
- Nickel = \$9.47 per pound,
- Cobalt = \$11.69 per pound,
- Platinum = \$1,689 per troy ounce,
- Palladium = \$684 per troy ounce, and
- Gold = \$1,485 per troy ounce.

These metal prices were calculated on June 30, 2012, and are consistent with the National Instrument 43-101 reporting standard that is used for public disclosure of information relating to mineral properties on bourses supervised by the Canadian Securities Administrators.

For each specific pre-extraction tonnage, an *in situ* average net metal value per ton was calculated based on the grade of ore and accounting for reasonable dilution and extraction losses (refer to Section 2.3, Technical Feasibility). Results showed that there is a generally linear relationship between the total cumulative tonnage of material and its average net metal value (Figure 1)—i.e., there is progressively less material available at higher net metal values. There are 85,614 short tons (cumulative) that have an average net metal value of \$96.77 per short ton, and 227,017,162 short tons (cumulative) that have an average net metal value of \$33.18 per short ton.

Figure 1 *Tonnage vs. Average Net Metal Value*

Using underground mining would result in most of the NorthMet Deposit left unmined because of its low metal value (i.e., less value than the cost of mining and mineral processing). Other material would have to be left in place for safety reasons, to prevent collapse. The underground rate of extraction for mining with backfilling is typically between 90 and 99 percent. PolyMet assumed a 95 percent rate of extraction for its economic assessment of the underground mining alternative. Mined ore could also be diluted between 5 and 30 percent by waste rock, as a result of overblasting and blending at ore-to-waste boundary lines. A dilution of 5 percent was used by PolyMet for the economic assessment of underground mining.

2.4.2 *Underground Mining Costs*

The estimated operating and capital costs vary depending on the rate and method of mining and processing. For the purpose of the economic assessment, PolyMet estimated operating costs and pre-production capital costs for underground mining and mineral processing at the NorthMet Deposit based on published cost models that were validated by comparable projects and mines (Table 1).

Table 1 *Estimated Costs for an Underground Mine at the NorthMet Deposit*

Tons per Day	Operating Mining and Mineral Processing Cost per Ton (\$)	Pre-production Capital Costs (\$ million)
2,000	74	125
5,000	56.5	200
7,500	49	250
10,000	48.5	300
15,000	47	400

2.4.3 *Economic Feasibility*

Based on an optimal formula, the productive life of an underground mine was determined for increments of tonnages, from fewer than 4 million to 100 million tons. From these numbers, the daily rate of production was calculated. The net metal value of that extracted material was calculated based on the average metal value for that tonnage minus 5 percent royalty costs that would apply at the NorthMet Deposit. To estimate the total operating cost, the extracted tonnage was multiplied by the total operating cost per ton. To calculate the life-of-mine profit balance, the total costs were subtracted from the net value of the mined material (Table 2).

Table 2 *Economic Assessment of a Sample of Underground Mining Scenarios Considered*

Extracted Tonnage (million short tons)	Net extracted net metal value (\$ million)	Tons per Day	Productive Life of Mine (years)	Total Operating Cost (\$ million)	Pre-production Capital Costs (\$ million)	Profit: Metal Value – Costs (\$ million)
5	302	2,000	7	370	125	-\$193
20	1,077	5,000	11	1,130	200	-\$253
30	1,552	7,500	11	1,470	250	-\$168
50	2,386	10,000	14	2,450	300	-\$364
100	4,143	15,000	18	4,700	400	-\$957

Results show that for all tonnages the net profit is negative—i.e., underground mining is not economically feasible for the NorthMet Deposit.

2.5 *PURPOSE AND NEED*

The Purpose and Need of the NorthMet Project (Attachment 3) includes the ability to extract and process metals in a technically and economically feasible manner that generates sufficient income to cover: operating costs, capital costs, an adequate return to investors, reclamation, and closure costs and taxes.

Preliminary economic screening undertaken by PolyMet determined that the sale of metal precipitates and concentrates produced from an underground mining alternative would not be economically feasible to meet the requirements of the Purpose and Need. Because of this, the alternative was eliminated from further evaluation and a site-specific engineered underground mine plan was not developed.

The underground mining alternative does not meet the Purpose and Need for the project.

3.0 CONCLUSION

Alternatives need to meet all of the screening criteria to merit further evaluation. The summary of the screening results for the underground mining alternative are shown in Table 3.

The Co-lead Agencies found that while underground mining is technically feasible, available, and would offer significant environmental benefits over the proposed NorthMet Project, it would not be economically feasible and would not meet the Purpose and Need.

Since the underground mining alternative would not meet all of the screening criteria, it is not considered to be a reasonable alternative. Therefore, the underground mining alternative was eliminated from further evaluation in the SDEIS.

Table 3 *Underground Mining Alternative Screening Table*

Potentially Offer Significant Environmental or Socioeconomic Benefits?	Available?	Technically Feasible?	Economically Feasible?	Meets the Purpose and Need?
Yes*	Yes	Yes	No	No

*The underground mining alternative would offer significant environmental benefits, but would offer reduced socioeconomic benefits.

Economic Assessment of Conceptual Underground Mining Option for the NorthMet Project

Executive Summary

This report assesses the prospects of the economic viability of extracting any portion of the NorthMet deposit by underground mining. While a Canadian National Instrument 43-101 (NI 43-101) compliant mineral resource has been published for NorthMet on the basis of open-pit mining, no mineral resource has been defined for NorthMet on the basis of underground mining. This report has been prepared to provide information to agencies preparing the Environmental Impact Statement (EIS) for the NorthMet Project, in order to help them comply with National Environmental Policy Act (NEPA) and Minnesota Environmental Policy Act (MEPA) by adequately considering alternative mine development methods, such as underground mining.

There is no prospect of economically viable extraction of a portion of the shallow large tonnage low-to-medium grade NorthMet deposit by underground mining based on the analysis in this report. The tonnage/volume and grade (amount of metals) of rock within the NorthMet deposit does not generate enough revenue to pay for all costs associated with underground mining. The analysis of economic viability demonstrates that the value of metals per ton of rock, using metal prices defined in 2012, is too low to cover reasonable total operating costs and total pre-production capital costs, defined by cost models, resulting in a negative operating profit (operating loss) or a negative project profit (capital loss). Underground mining is not economically viable for the NorthMet project which is consistent with early studies at NorthMet, general rules for assessment of economic viability and similar mining operations elsewhere.

1 Introduction

NorthMet is a large tonnage and low-to-medium grade polymetallic copper-nickel-cobalt-palladium-platinum-gold deposit hosted by thick intrusive rocks located in St. Louis County in northeastern Minnesota (Poly Met, 2007). The concentration of metals occurs in four broadly defined horizons dipping between 15o to 25o to the southeast as determined by data from drill holes. Figure 1 shows the location of the deposit within the open-pit projected upwards to the surface. NorthMet was discovered in 1969 and early studies concluded that the tonnages and grades were not high enough to support underground mining. Subsequent work by Poly Met Mining, Inc. (Poly Met) has led to a delineated polymetallic mineral resource capable of being extracted by open-pit mining. The purpose of this report is to answer the question: Is there a prospect of economically viable extraction of a portion of the NorthMet deposit by underground mining?

1.1 Definition of a Mineral Resource

Poly Met's parent company, PolyMet Mining Corp., is a Canadian company and, therefore, reports under Canadian securities guidelines. Regulations and guidelines associated with National Instrument (NI) 43-101 establish the reporting standards of a mineral resource by a public Canadian company to the Canadian Securities Administrators.

While there are similarities between Canadian and U.S. reporting, there is an important distinction between the two standards for reporting resources and reserves. Poly Met's filings in the U.S. include the following cautionary note: the terms "measured and indicated mineral resource", "mineral resource", and "inferred mineral resource" used in this Management Discussion and Analysis are Canadian geological and mining terms as defined in accordance with NI 43-101, Standards of Disclosure for Mineral Projects (NI 43-101) under the guidelines set out in the Canadian Institute of Mining, Metallurgy and Petroleum (CIM) Standards on Mineral Resources and Mineral Reserves. U.S. investors are advised that while such terms are recognized and required under Canadian regulations, the Securities and Exchange Commission (SEC) does not recognize these terms. Mineral resources do not have demonstrated economic viability. It cannot be assumed that all or any part of a mineral resource will be upgraded to mineral reserves. Under Canadian rules, estimates of inferred mineral resources may not form the basis of or be included in feasibility or other studies. U.S. investors are cautioned not to assume that any part of an inferred mineral resource exists, or is economically or legally mineable. The terms mineral resources and reserves as used in this report conform to the definitions contained in NI 43-101. Mineral resources are not reserves and do not have demonstrated economic viability. Reserves are contained within the envelope of "measured" and "indicated" mineral resources. All economic calculations are done in U.S. Dollars.

NI 43-101 regulations and associated guidelines define a mineral resource as a concentration or occurrence of metals "in such form and quantity and of such a grade that it has reasonable prospects for economic extraction" (CIM, 2010). The reasonable

prospect of economically viable extraction is determined by the total cost of extraction as compared to the total extractable value of the ore. The cost of extraction depends on, among other costs, the cost of mining and mineral processing. Since the cost of open-pit mining is considerably lower than the cost of underground mining, it is common that an economically viable open-pit mineral resource cannot be viably extracted by underground mining due to the higher cost of underground mining. Thus, a concentration of metals classified as a mineral resource under NI 43-101 by open-pit mining is not a mineral resource by underground mining unless proven to have a reasonable prospect of economically viable extraction by that mining method.

Those concentrations with a prospect for economically viable extraction are subdivided into three classifications on the basis of geological confidence. A “measured” mineral resource is “so well established that they can be estimated with confidence sufficient to allow the appropriate application of technical and economic parameters, to support production planning and evaluation of the economic viability of the deposit” (CIM, 2010). An “indicated” mineral resource is less well characterized but, is sufficiently characterized to support evaluation of economic viability. An “inferred” mineral resource is only reasonably assumed to exist and since it is not sufficiently characterized it “must be excluded from estimates forming the basis of feasibility or other economic studies” (CIM, 2010).

The amount of geological data, the geological and grade continuity, and the mining method are factors (and others) in classifying a mineral resource as “measured”, “indicated”, or “inferred”. An open-pit mineral resource classified as “measured” or “indicated” or “inferred” may be classified differently on the basis of underground mining. Since generally more data are needed to characterize an underground mineral resource, the degree of confidence is more likely to be lower on the basis of underground mining.

Poly Met has defined an open-pit mineral resource at NorthMet and has subdivided this open-pit resource into “measured”, “indicated”, and “inferred” categories (Poly Met, 2007). Since the cost of open-pit mining is considerably lower than the cost of underground mining, there is no reason to assume that any of this open-pit mineral resource has a reasonable prospect of economically viable extraction by underground mining. No underground mineral resource has been defined at NorthMet.

Although the NorthMet open-pit mineral resource includes “measured”, “indicated”, and “inferred” levels of geological confidence, one cannot assume that any of these resources would be classified at the same level with respect to underground mining. Using “measured” and “indicated” mineral resources classified on the basis of open-pit mining for economic assessment of underground mining will result in an optimistic economic assessment when underground mining criteria are applied.

1.2 Mining of Shallow Large Tonnage Low-to-Medium Grade Deposits

Shallow large tonnage low-to-medium grade deposits are typically mined by open-pit methods. Underground mining of low-to-medium grade materials may not be economically viable because of the much higher cost of extracting the rock by underground mining methods as compared to open-pit mining methods. Economic viability considerations would lead to only the higher grade sections of the open-pit resource being mined via underground mining methods leaving behind lower grade materials that could otherwise be utilized. From a socio-economic perspective, the value of the material left behind is lost. For comparison, Kevista Mine is a large tonnage and low-to-medium grade polymetallic copper-nickel-cobalt-palladium-platinum-gold deposit hosted by thick intrusive rocks in Finland and scheduled for production in 2012 (First Quantum, 2011). The tonnage and grades are similar to NorthMet and the Kevista mineral resource will be extracted using open-pit mining. While mineralized rock at Kevista extends below the open-pit, future extraction of it is speculative.

1.3 Disclaimer

This report relies upon information provided by Poly Met, AGP Mining Consultants (AGP), and publically available documents. The assessment of the prospects for economically viable extraction utilizes simplifications, generalizations, assumptions, and qualifications within the scope of the assignment and is believed to be substantially correct. While NI 43-101 reports are relied upon and referred to in this report; this independent report is not a NI 43-101 technical report.

2 Boundaries of the NorthMet Resources

The boundaries of the open-pit mineral resource as defined by NI 43-101 compliant technical report (Poly Met, 2007) are the same boundaries that will be used to assess the prospects of economic viability of extraction by underground mining (Figure 1). This underground evaluation will use “measured” and “indicated” open-pit mineral resources even though these may be an over statement of the sufficiently characterized volume/tonnage of mineralized rock with respect to underground mining or, in other words, using open-pit defined resource numbers may result in an overly optimistic economic assessment. “Inferred” open-pit mineral resources are excluded from this economic assessment. *The term NorthMet deposit used in this report will refer to NI43-101 compliant measured and indicated mineral resources within the open-pit.*

There is mineralized rock outside of the volume of rock contained within the proposed open-pit. This mineralized rock occurs below the open-pit. While this mineralized rock is excluded from this report, speculatively it may be possible for it to be economically viable to extract decades in the future. Only approximately 10% of the measured and indicated resource is below the open-pit (Poly Met, 2007). The majority of inferred resource defined by Poly Met (2007) is below the open-pit. There is a lack of geological data to characterize the deep mineralized rock that in turn results in a lack of geological

confidence leading to the inferred classification. Mineralized rock below the open-pit is, in general, too poorly characterized to justify inclusion in this economic assessment.

3 Approach to Analysis of Economic Viability

To assess the prospect for economically viable extraction by underground mining of the NorthMet deposit, the total cost of extraction of the metals must be compared to the total revenue from the metals that are extracted. For underground mining to have the potential to be economically viable, the extracted net metal value must be greater than the total operating cost by a sufficient margin to pay for capital costs, taxes, and provide a reasonable profit.

At the earliest stages of evaluating a mineral occurrence, costs are approximated by using cost models, such as from InfoMine. The cost predicted using cost models will be compared to and supplemented by data from selected existing and proposed mines. At the next stage in project evaluation, scoping or preliminary economic assessment, costs are refined, but complete site data can be lacking. Cost models are still used at this stage to estimate costs as well as to validate site specific cost estimates. The costs used in this report for the economic assessment are comparable to the earlier stages of evaluation. The revenue estimates in this report use metal prices applicable to later, feasibility, stage of evaluation, and are of lesser error than cost estimates. The grade and tonnage are maximum estimates as they are defined by open-pit rather than underground mining criteria.

Wellmer (Wellmer, 1998) describes several general approaches for evaluating the productive life of a mine. Generally, mining companies will use a minimum of 10 years to average out the risk of the variation of metal prices. The optimal productive life of a mine calculated by empirical formula yields values such as extracted tonnage of 5 to 25 million tons mined for 9.5 to 14 years at a rate of production of about 1,250 to 6,000 tons per day upwards to extracted tonnage of 100 million tons mined for 21 years at a rate of production of about 14,000 tons (Wellmer, 1998). To simplify the economic assessment in this report, increments of total and daily production are used which are roughly similar to those obtained from the empirical formula.

4 Mining Method

Poly Met has proposed to mine the NorthMet deposit using open-pit mining which will result in the maximum economically viable recovery of the metals. Using underground mining would result in a significant fraction of the NorthMet deposit being left unmined because the unmined rock is too low of value to be viably extracted by underground methods. Underground mining is being assessed as an alternative to open-pit mining to ensure that the Environmental Impact Statement (EIS) is in full compliance with National Environmental Policy Act (NEPA) and Minnesota Environmental Policy Act (MEPA) and that alternative mine development methods, such as underground mining, are considered.

Underground mining of large tonnages at shallow depths has the potential to lead to collapse of the mine openings unless they are backfilled. If mine openings are allowed to collapse, the collapse is likely to result in caving and fracturing of the overlying bedrock and could lead to land surface subsidence. This in turn disrupts ground water and surface water (Kendorski, 2006). The NorthMet deposit has a shallow dip of between 15° to 25° to the southeast, a strike length of about 2.5 miles, with probable thickness of mining of 45 to 100 feet when extractable tonnage is on the order of 10 million tons (AGP, 2011) (Figure 2; blocks in open pit resource greater than \$65 net metal value per ton represent approximately 8 million tons). To minimize environmental impact by underground mining, the chance of collapse of the overlying rock must be minimized. Thus, this report is based on the assumption that backfilling of the mine will be required to minimize the chance of collapse of the overlying rock.

AGP (AGP, 2011) has assessed the applicable mining methods and concluded that possible mining methods include long-hole open stoping (backfilled), room and pillar (no back fill), or short back open stoping (no back fill) for a mine on the order of 10 million extractable tons. The latter two are considered unacceptable in this report unless backfilled to minimize the chance of collapse; only methods including backfill will be considered in this report. Mechanized cut and fill (backfilled) is another possible mining method. The underground rate of extraction for mining with backfilling is typically between 90 and 99% removal of the resource. For this report, the rate of extraction is assumed to be 95% removal of the resource.

Several factors can result in dilution of the ore such as overbreaking of rock by drill and blasting during underground mining and poor estimation of the boundary between valuable rock to be mined and waste rock. Dilution results in more tons of material to process and lowering of the overall grade of the material to be processed. In general, dilution varies between 5 and 30% (Wellmer, 1998); a value of 5% will be used in this report. At NorthMet the impact of dilution is small as higher value rock is surrounded by successively lower value rock. The diluting rock is assumed to have a value equivalent to the rock adjacent to the extracted tonnage along the tonnage-value curve described in Section 7.

5 Metal Prices

Evaluation of a mining project at the earliest stages may use metal prices that are lower than at a later stage to compensate for unknown risks. At later stages of evaluation when the start-up of a mine is nearer, pre-feasibility or feasibility study, metal prices often closely reflect current market conditions. NI 43-101 compliant feasibility studies use the three-year average metal prices, but also often include forecasts of price and demand for the purpose of evaluating the validity of using such metal prices. For the purpose of this report, the only metal prices used will be the three-year average metal price to June 30, 2012 provided to Theodore J. Bornhorst, LLC by Poly Met (personal communication) (Table 1); these metal prices are consistent with prices currently used in NI 43-101 feasibility and pre-feasibility studies published on System for Electronic Document Analysis and Retrieval (SEDAR) operated by Canadian Securities

Administrators. These metal prices are consistent with or higher than long-term forecasts.

6 Rates of Metal Recovery

The valuable rock extracted by underground mining is crushed, ground to a fine grain size, and subjected to a sequence of mineral processing steps to concentrate the minerals containing the metals of value. Due to imperfect mineral processing, some minerals containing metals of value are lost to the waste tailings. Laboratory testing quantifies the rate of recovery during processing of the valuable rock (ore) to a mineral concentrate. The metals in the concentrate are recovered by further processing (smelting or hydrometallurgy and refining); these rates have been quantified. The rates of recovery from rock to concentrate and from concentrate to metal are those specific to NorthMet as given in Table 1.

7 Net Metal Value

Net metal value per ton of rock represents the value of metal recoverable and payable from the rock at the assumed metal prices model after accounting for the rates of recovery and deduction of refining costs (described in Poly Met, 2007).

The total cumulative tonnage with grades higher than a specific level can be quantified by rigorous study (described in Poly Met, 2007). Using the open-pit model described by Poly Met (2007), AGP (personal communication) provided Theodore J. Bornhorst, LLC with a series of cumulative tonnages and average grades for the NorthMet deposit. The average net metal value per ton was calculated for each of these average grades (Table 2). The log cumulative tonnage versus average net metal value per ton has a well-defined regular variation (Figure 3). This relationship is adequate for the prediction of cumulative tonnage and average net metal value per ton for an economic assessment of underground mining of the NorthMet deposit.

8 Operating Costs of Mining

For this economic assessment, operating costs are estimated from cost models, such as InfoMine USA, Inc. Selected operating and proposed mines are used to compare and supplement the operating costs assumed for this report. While adjustments are made to the comparables to account for obvious differences with a possible NorthMet setting, there is no assurance these adjustments are adequate.

Operating cost models are usually subdivided according to mining or processing method and daily rate of production. Operating costs are linearly related to daily rate of production for the range of 1,000 to 5,000-7,500 tons per day depending on mining method (InfoMine USA, 2009). Above 5,000-7,500 tons per day the rate of change in operating cost decreases as operating costs approach a 'minimum'. All costs are inflated to 2012 level based on the average rate of change in InfoMine cost models from 1998 to 2009. Increments of extractable tonnage and daily rate of production will be used in this study and for each increment a 2012 total operating cost will be assigned;

total operating cost is the sum of underground mining, mineral processing, and “general and contingency” costs (general is not central to production of saleable metal and contingency is added to cover uncertainties in cost estimates).

8.1 Discussion of Operating Costs at Rates of Production up to 5,000 Tons Per Day

The operating cost of room and pillar underground mining using shaft access without backfill from InfoMine cost model (InfoMine USA, 2009) is approximately \$40 and \$32 per ton for 2,000 and 5,000 tons per day production respectively without “general and contingency”. Cemented backfill typically represents roughly 20% of mining operating costs (Grice, 1998; Stebbins and Schumacher, 2001). The operating cost of room and pillar underground mining with backfill is projected to be about \$50 and \$40 per ton for 2,000 and 5,000 tons per day production without “general and contingency”. Long-hole open stoping with sand backfill and shaft access from InfoMine (InfoMine USA, 2009) is about \$32 and \$20 per ton for 2,000 and 5,000 tons per day production respectively without “general and contingency”, but at NorthMet cementing of backfill will likely be necessary which will increase the model cost. AGP (AGP, 2011) estimated that long-hole open stoping with backfill operating cost was in the range of \$44 to \$52 at 5,000 tons per day suggesting that the InfoMine estimates are too low. Mechanized cut and fill is about \$49 for 2,000 tons per day. The Podolsky Mine, Levack Mine, McCreedy West Mine in the Sudbury district utilize a combination of long-hole open stoping with cemented and uncemented backfill, cut and fill, and shrinkage mining methods with a range of mining operating costs of \$76 to \$38 for 1,250 and 2,250 tons per day without “general, administration and contingency” (FNX, 2009). *The estimated 2012 underground mining operating costs for this report are \$51 for 2,000 tons per day and \$40 for 5,000 tons per day without “general and contingency”.*

A three concentrate flotation mill cost model from InfoMine (InfoMine USA, 2009) is the closest approximation to mineral processing of a complex ore such as NorthMet with cost of about \$19.5 and \$13 per ton for 2,000 and 5,000 tons per day production respectively without “general and contingency”. For comparison, a one concentrate mineral processing InfoMine cost model at 5,000 tons per day is about \$12.5 per ton as compared to the one concentrate Copperwood, Michigan prefeasibility mill cost estimate of \$11.75 per ton at 5,000 tons per day without “general, administration, and contingency” (Orvana, 2011). A preliminary economic assessment for Lac des Iles in Thunder Bay, Ontario for complex ore with a similar suite of metals uses a mineral processing operating cost of \$14 per ton at about 6,000 tons per day production without “general, administration, and contingency” (North American Palladium, 2010). *The estimated 2012 mineral processing operating costs for this report are \$19.5 per ton for 2,000 tons per day and \$13 per ton for 5,000 tons per day without “general and contingency”.*

For copper and nickel Lac des Iles in Thunder Bay, Ontario (North American Palladium, 2010) the “general” and administration costs used in preliminary economic assessment were \$3.30 per ton and “contingency” was \$2.00 per ton (not inflated to 2012). For

Copperwood, Michigan the “general” and administration prefeasibility estimate was \$3.35 per ton (Orvana, 2011; not inflated to 2012). *The 2012 “general and contingency” for this report are \$3.50 per ton.*

8.2 Total Operating Costs at Rates of Production up to 5,000 Tons Per Day

This report will use 2012 total operating costs of \$74 per ton at 2,000 tons per day and \$56.5 at 5,000 tons per day with an assumed rate of extraction of 95% removal of the resource. These costs will be linearly extrapolated and applied to rates of production between 1,000 and 5,000 tons per day. Based on the optimal life of mine formula as described above, 5,000 tons per day operating cost will be applied to total extracted tonnage of up to 26 million tons (Table 3).

For comparison, total operating costs at copper – nickel-PGE Lac des Iles deposit are estimated at about \$56 per ton (scaled to include backfill) at about 6,000 tons per day (North American Palladium, 2010). The lead-zinc-silver-copper Pitarrilla property prefeasibility study reported total operating costs adjusted for shaft access and inflation of \$39.5 per ton for a combination of backfilled room and pillar and long-hole stoping mining at the rate of 4,000 tons per day (Silver Standard, 2009). The nickel-copper-PGE-gold Eagle’s Nest property has estimated total operating cost of \$79 per ton for bulk stoping with cemented backfill at 4,500 tons per day production (Noront Resources, 2011). AGP (AGP, 2011) long-hole open stoping mining costs when combined with mineral processing and “general and contingency” costs yield total operating costs of between about \$50 and \$59 at 5,000 tons per day of production. The copper-nickel-PGE Podolsky Mine, Levack Mine, McCreedy West Mine in the Sudbury district utilize a combination of long-hole open stoping with cemented and uncemented backfill, cut and fill, and shrinkage have an average total operating cost of \$88 per ton between 1,250 and 2,250 tons per day (FNX, 2009). The nickel-copper Lockerby Mine, in the Sudbury district, has estimated total operating costs of approximately \$160 per ton using sublevel long-hole stoping with cemented backfill at approximately 1,000 tons per day production (First Nickel, 2011) as contrasted with the nickel-copper-cobalt-PGE-gold Bucko Mine, Manitoba which has estimated total operating costs of approximately \$72 per ton using Long-hole stoping with cemented backfill at approximately 1,000 tons per day production (Crowflight Minerals Inc., 2009). In comparison, the linearly projected 1,000 ton per day total operating cost to be used in this report is approximately \$80. While these comparisons demonstrate the difficulty in assigning a total operating cost lacking site specific data, they nevertheless support that the 2012 total operating costs used in this report are reasonable and within the level of error usually assumed at this level of assessment.

8.3 Discussion of Operating Costs at Rates of Production Between 5,000 to 15,000 Tons Per Day

The technical feasibility of mining of more than 50 million tons by underground methods from the shallow open-pit (Figure 2) is speculative. AGP (AGP, 2011) describes

probable openings of 45 to 100 feet high for extracted tonnage on the order of 10 million tons. For larger amounts of extracted tonnage (> 26 million tons) larger cumulative openings will increase the difficulty of mining. In spite of this technical uncertainty, tonnages up to 100 million will be assessed with rates of extraction of up to 15,000 tons per day.

Above 5,000-7,500 tons per day the rate of change in operating costs decreases as operating costs approach a 'minimum.' Estimating the operating cost of underground mining large tonnages at such shallow depths while avoiding collapse is difficult. InfoMine cost models are for standard underground mining and thus, will provide a cost minimum that is likely to be too low as applied to mining large tonnages underground at NorthMet in the shallow confines of the open-pit. InfoMine cost models (InfoMine USA, 2009) demonstrate that operating cost for long-hole open stoping with sand backfill begins to approach a "minimum" cost at about 3,600 tons per day; the rate of change from 3,600 to 7,200 tons per day is less. The operating cost of room and pillar mining and other mining methods, including backfill, tend to approach a "minimum" cost between 4,000 to 10,000 tons per day production. Applying the rate of change associated with backfilled room and pillar mining to a \$40 per ton mining operating cost at 5,000 tons per day, yields an estimated underground mining operating cost of \$28 per ton at 7,500 tons per day. Applying the rate of change associated with long-hole open stoping with sand backfill, to a \$40 per ton mining operating cost at 5,000 tons per day, yields an estimated operating cost of \$39 per ton at 7,500 tons per day production. Since long-hole open stoping reaches a minimum operating cost near 5,000 tons per day the difference between the mining operating cost at 5,000 and 7,500 tons per day is small.

As daily production increases from 7,500 to 15,000 tons per day it is expected that operating costs may be lower due to increased efficiencies related to scale but equally likely it is expected that operating costs may be even higher than increased efficiencies due to complexities of removal of such a large thickness of rock at such shallow depths while avoiding collapse. *Hence, for this report the same underground mining operating cost estimate will be used for 7,500, 10,000 and 15,000 tons per day production; \$33 per ton 2012 underground mining operating cost without "general and contingency".*

Comparisons of mining costs from operating or proposed mines for high daily rates of underground production are more difficult to obtain and large daily rates of underground extraction with backfill are less common. In addition, differences with a possible NorthMet setting may render the comparison invalid. The Young-Davidson gold mine in Ontario utilizes a combination of sublevel caving, long-hole shrinkage, and longitudinal retreat with paste backfill and unconsolidated rock fill (www.auricogold.com). The underground mining operating cost is \$32 to \$34 per ton at 8,000 tons per day (www.auricogold.com). The Blue River tantalum-niobium mine, BC Canada, proposes using room and pillar mining with paste backfill to recover 70% of the orebody at a 2012 estimated mining cost of \$32 per ton at 7,500 tons per day (AMEC, 2012). A Press Release by Commerce Resources Corp. states that the \$32 per ton mining cost can be lowered to \$22 with the elimination of backfilling (www.commerceresources.com); the

latter \$22 is consistent with InfoMine (InfoMine USA, 2009) room and pillar mining with no backfill cost estimate of \$23. These comparisons demonstrate the 2012 underground mining operating costs used in this report are reasonable and within the level of error usually assumed at this level of assessment.

Cost models for mineral processing at all levels of daily production are applicable for this economic assessment. A three concentrate flotation mill cost model from InfoMine (InfoMine USA, 2009) is the closest approximation to mineral processing of a complex ore such as NorthMet with costs of about \$12.5, \$12, and \$10.5 per ton for 7,500, 10,000 and 15,000 tons per day production respectively without “general and contingency”. *The 2012 operating cost for mineral processing used in this report will be \$12.5, \$12, and \$10.5 per ton for 7,500, 10,000 and 15,000 tons per day production respectively without “general and contingency”.*

The same “general and contingency” used for 1,000 to 5,000 tons per day production will be used for higher levels of daily production.

8.4 Total Operating Costs at Rates of Production Between 5,000 to 15,000 Tons Per Day

Total 2012 operating costs in this report will be \$49, \$48.5, and \$47 per ton for 7,500, 10,000 and 15,000 tons per day production.

Comparisons of total operating costs from operating or proposed mines for high daily rates of underground production are more difficult to obtain. The Williams Mine, Marathon, Ontario uses long-hole stoping with paste backfill to underground mine and process simple gold ore with an average grade of about 2.35 g/ton gold at a daily rate of about 8,500 tons per day (www.barrick.com). The total cash operating cost (includes limited amount of lower cost open-pit mining) is about \$775 per oz. for 2011 and \$834 for the 1st quarter of 2012 (www.barrick.com). The estimated total operating cost is \$58.5 per ton for 2011 and \$63 per ton for the beginning of 2012. The Brunswick Mine, New Brunswick, Canada uses open stoping and end slicing with paste backfill to mine a zinc, lead, copper, and silver ore with about 8.3% zinc at the rate of about 10,000 tons per day (www.xstrata.com). Presentation materials by Xstrata shows that the Brunswick Mine has total cash operating costs higher than the other principal source of zinc for North America zinc operations and from a cash cost of \$0.32 to 0.40 per lb of zinc, an estimated total operating cost is \$53 to \$66 per ton, but this is an uncertain estimate. The Young-Davidson gold mine in Ontario utilizes a combination of sublevel caving, long-hole shrinkage, and longitudinal retreat with paste backfill and unconsolidated rock fill with estimated total operating cost of \$45 to 51 per ton 8,000 tons per day (www.auricogold.com). These comparisons demonstrate the 2012 total operating costs used in this report are reasonable and within the level of error usually assumed at this level of assessment.

9 Pre-Production Capital Costs

For this economic assessment, estimates of pre-production capital costs are made from cost models, such as InfoMine USA, Inc., and are compared to and supplemented by selected operating and proposed mines. All costs are inflated to 2012 level based on the average rate of change in InfoMine cost models from 1998 to 2009.

Capital cost models are usually subdivided according to mining or processing method and daily rate of production. Capital costs are linearly related to daily rate of production from about 1,000 to 7,500 tons per day depending on mining and processing method (InfoMine USA, 2009). Increments of extractable tonnage and daily rate of production will be used in this study and for each increment a single capital cost will be assigned.

The pre-production capital cost of room and pillar underground mining using shaft access without backfill from InfoMine (InfoMine USA, 2009) is about \$60 million, \$95 million, and \$125 million for 2,000 and 5,000, 7,500 tons per day production respectively without “contingency”, environment, closure, and reclamation. The capital cost for long-hole open stoping with sand backfill and shaft access from InfoMine (InfoMine USA, 2009) is about \$45 million, \$80 million, and \$115 million for 2,000 and 5,000, 7,500 tons per day production respectively without “contingency”, environment, closure, and reclamation. Capital cost for mechanized cut and fill is about \$60 million for 2,000 tons per day production without “contingency”, environment, closure, reclamation. A three concentrate flotation mill cost model from InfoMine (InfoMine USA, 2009) is the closest approximation to mineral processing of a complex ore such as NorthMet with a capital cost of about \$47 million, \$71 million, and \$98 million 2,000, 5,000, and 7,500 tons per day production respectively without “contingency”, environment, closure, reclamation. The InfoMine cost model estimates of total pre-production capital cost are about \$110 million, \$170 million, and \$225 million without “contingency”, environment, closure, reclamation. For comparison, room and pillar mining without backfill and a one concentrate mineral processing plant at Copperwood, Michigan has a prefeasibility estimated pre-production capital cost of approximately \$205 million at 7,500 tons per day without closure and sustaining capital (Orvana, 2011). A preliminary economic assessment for Lac des Iles in Thunder Bay, Ontario for complex ore with a similar suite of metals has an estimated pre-production capital cost of approximately \$220 million at about 6,000 tons per day including “contingency” capital but without development and sustaining capital (North American Palladium, 2010). AGP (AGP, 2011) estimated that long-hole open stoping with backfill capital cost is approximately \$190 million at 5,000 tons per day. The comparisons suggest that the pre-production capital cost InfoMine estimates are reasonable although more likely low because these estimates do not include “contingency” and pre-production expenditures especially exploration, permitting and environmental analysis. To develop underground mining at NorthMet a significant amount of additional exploration drilling is likely.

The 2012 pre-production capital costs with “contingency” for this report are estimated to be \$125 million, \$200 million, and \$250 million for 1-2,000, 5,000, and 7,500 tons per day production but without environment, closure and reclamation. Linear extrapolation

yields 2012 pre-production capital cost of about \$300 million and \$400 million for 10,000 and 15,000 tons per day production.

10 Other Considerations

Inflation during production is not considered in this report. Inflation of costs is assumed to be offset by increases in the metal prices. The estimated federal and state tax on operating profits after depreciation and depletion is a significant cost that will lower the internal rate of return in cases when operating profit exceeds pre-production capital costs. Pre-production capital costs are assumed to be equity financed and thereby eliminating the cost of debt. The royalty applicable to this report for NorthMet is 5%.

11 Analysis of Economic Viability

The economic assessment in this report for the NorthMet deposit uses tonnage and grades specific to NorthMet, rates of recovery and refining deductions specific to NorthMet, current metal prices consistent with NI 43-101 reporting standards, total operating costs and pre-production capital costs from published cost models that are validated by comparable projects and mines, and the actual royalty specific for NorthMet. Based on optimal formula, the productive life of an underground mine was determined for increments of tonnages from <4 to 100 million tons and from these numbers the daily rate of production was calculated (Table 3). For each increment the daily rate of production was fixed to simplify the analysis since total operating costs and total pre-production capital costs are closely related to the daily rate of production; for simple cash flow analysis the productive life of mine rounded to the nearest year based on the life of mine calculated from daily production and total tonnage. A total operating cost and total pre-production capital cost, as in Sections 8 and 9, was assigned to each increment based on daily rate of production (Table 3).

A spectrum of extracted tonnages was assessed (Table 4). For each specific pre-extraction tonnage, an *in situ* average net metal value per ton was calculated by log10 linear extrapolation between adjacent pairs on the tonnage-average net metal value per ton curve. A rate of extraction of 95% removal of the resource was used in determining the total extracted value without dilution. A 5% dilution was used with the diluting average net metal value per ton calculated by log 10 linear extrapolation assuming the diluting rock has a value in continuum with the pre-extraction tonnage. The total net metal value was calculated for the pre-extraction cumulative tonnage and dilution minus the yearly treatment charge (Table 4). The extracted tonnage was multiplied by the total operating cost per ton to estimate the total operating cost. Operating profit was calculated by subtracting total operating cost from total revenue minus royalty. Pre-tax operating profit minus pre-production capital costs is also calculated (Table 4).

The “rules-of-thumb” is that operating cost should be about ½ of the total net metal revenue after royalty and the remaining ½ is generally sufficient to cover taxes, capital costs, and profit (Wellmer, 1998). On this basis, underground mining is not likely to be economically viable at NorthMet.

For tonnages with a negative operating profit or a loss, underground mining is not economically viable. For all extracted tons, except 30 and 35 million, there is a predicted operating loss or underground mining at these tonnages is not economically viable. The total operating profit has to exceed the total pre-production capital cost else the mining project is not economically viable; the initial investment is not recovered. *At all tonnages the total operating profit minus the total pre-production capital cost is negative or in other words for all tonnages underground mining is not economically viable.*

12 Discussion and Conclusions

This report assesses the economic viability of extracting the NorthMet deposit by underground mining methods. Due to the higher cost of underground mining as compared to open-pit mining, if the NorthMet deposit was extracted by underground mining a significant amount of the lower grade materials would inevitably be left behind or lost from a socio-economic perspective. This economic assessment utilizes reasonable estimates of input variables to answer the question: Is there a prospect of economically viable extraction of a portion of the NorthMet deposit by underground mining?

The volume/tonnage and grade of mineralized rock are defined using open-pit defined resource numbers rather than potentially more restrictive underground mining criteria and may result in an overly optimistic economic assessment. The metal prices are defined using a three-year trailing average and do not account for the risk of lower prices with no change in costs. While the total operating costs are less precise, they are demonstrably within acceptable error for this level of economic assessment. The operating costs do not include operating capital expenditures. While the total pre-production capital costs are also less precise, they too are demonstrably within acceptable error for this level of economic assessment. These estimates are more likely to be too low than too high since they do not fully account for capital costs associated with the environment, closure and reclamation.

Early studies of the NorthMet deposit concluded that the tonnages and grades were not sufficient to support underground mining. *This economic assessment of conceptual underground mining of the NorthMet deposit demonstrates that underground mining methods are not economically viable. Based on this assessment, there is no prospect of economically viable extraction of a portion of the NorthMet deposit by underground mining.*

RE: Response to USEPA Questions Regarding: Economic Assessment of
Underground Mining Report Dated October 2012

The following document addresses the United States Environmental Protection Agency (EPA) comments and suggestions in their memo dated March 19, 2013 related to InfoMine, analog data, and inferred ore deposits.

InfoMine Parameters/Use of Analog Data

InfoMine cost data is a common source of information for mineral resource evaluation, but it has not been used exclusively to determine the economic viability of underground mining of the NorthMet Deposit. The October 2012 report also includes additional references to other mining project cost estimates to cross-validate the cost estimates used in the report.

The EPA response letter, dated March 19, 2013, requests additional documentation of the parameters and calculations with respect to the cost estimates. A list of costs used to arrive at the total cost is provided in the attached Table A. The mining, processing, and general and contingency costs are described in detail in the text of the report (Sections 8.1, 8.2, 8.3, and 8.4). The InfoMine cost models are given in increments of production rate. InfoMine model cost versus production rate graphs were used to estimate the cost at the production rate cited in the report. In some cases, the InfoMine cost estimates were adjusted to include cemented backfill as cited in the text. All InfoMine 2009 costs were inflated to 2012 levels based on the average rate of change in the InfoMine models from 1998 to 2009. The total operating costs given in Table 4 of the report are derived by multiplication of the extracted tonnage at 95% rate of

extraction and 5% dilution column times the total operating cost from Table 3 for the applicable daily rate of production.

Models at all levels include a degree of uncertainty. The report includes cross-validation of the cost estimates to decrease the degree of uncertainty even though an analysis of uncertainty of the cost estimates is not usually done at the stage of defining a mineral resource as described in the report. However, as suggested in the EPA response letter, dated March 19, 2013, the economic analysis was completed using 5% lower costs (best economic case) as given in the attached Table B. Table C, attached, provides an economic analysis using data from the original Tables 1 and 2 in the report, and Table B provided here, and further demonstrates underground mining is not economically viable.

Inferred Ore Deposits

Economic evaluation of mineral prospects follows a progressive path beginning with initial determination of a mineral resource, followed by a scoping study or preliminary economic assessment, and then pre-feasibility, and feasibility studies. A mine feasibility study is typically done when there has been sufficient drilling to define an ore body of sufficient size to be economically as well as technically viable. In most cases there is not a hard boundary to the mineralization. Therefore, exploration to define the initial ore body will generally identify mineralization beyond the actual ore body.

The NorthMet feasibility study and all of the analysis in the environmental review and proposed permit applications relate to the ore body. The company has not considered whether mineralization outside the defined pit envelope may be economically recoverable or by what means it could be economically recoverable, or what additional work would be needed to establish a data base of sufficient statistical quality to be able complete a feasibility study on such mineralization.

In the analysis of underground mining potential, we deliberately used very favorable scoping numbers in order to show potential underground mining economics in a positive light, yet the project still fails on the most fundamental economic grounds – revenues from the sale of product would not cover the cost of building and operating the project. AGP included mineralization that is outside the pit envelope even though there is insufficient information on this mineralization to be able to do more than a speculative, conjectural analysis. As discussed in the report, this mineralization does not meet Securities and Exchange Commission standards to be described as reserves under any mining method. Additionally, inferred mineral resources are speculative and are not allowed in economic assessment studies that conform with NI 43-101.

Attachment 3
NorthMet Project and Land Exchange
Purpose and Need Statement

NORTHMET MINING PROJECT AND LAND EXCHANGE SDEIS

PURPOSE AND NEED

Applicant's Purpose and Need Statement

The applicant's stated purpose of the NorthMet Project is to exercise PolyMet's mineral lease to continuously mine, via open pit methods, the known ore deposits (NorthMet Deposit) containing copper, nickel, cobalt, and platinum group elements to produce base and precious metal precipitates and flotation concentrates by uninterrupted utilization of the former LTV Steel Mining Company (LTVSMC) processing plant.

The purpose of the proposed Land Exchange is to consolidate the surface and mineral ownership of the lands involved at the Mine Site. PolyMet has a lease to mine the minerals on its NorthMet Deposit, which is surrounded by active and abandoned taconite mines in the mining district near Hoyt Lakes. The surface of these lands is owned by the United States.

The need for the NorthMet Project is driven by domestic and global demand of these products. Demand continues to rise for these metals due to the expansion of the green economy and rising demand from developing countries like India, China, and Brazil. Based on the closure of LTVSMC and other job losses in northeastern Minnesota, there is also a need for jobs and economic development in the area.

Co-lead Agencies' Purpose and Need Statements

NorthMet Project and Land Exchange Purpose and Need Statement

The Purpose and Need for the Combined Proposed Action is:

- For PolyMet to utilize its leased mineral rights and recover commercial quantities and quality of semi-refined metal concentrates, hydroxides, and precipitates from the NorthMet ore body in northern Minnesota, and to process the recovered ore by reutilizing the former LTVSMC processing plant.
- To extract metals in a safe, environmentally responsible, energy-efficient, and economically feasible manner subject to mitigation measures designed to avoid or minimize environmental effects to the extent practicable.
- To extract and process metals in a technically and economically feasible manner, such that there would be sufficient income to cover: operating cost (which includes but is not limited to the cost of mining, processing, transportation, and waste management), capital cost (needed to build and sustain facilities), an adequate return to investors, reclamation, and closure costs and taxes.
- To eliminate surface and mineral conflicts within the Superior National Forest by exchanging federal lands for non-federal lands that have equal or greater value.

NORTHMET MINING PROJECT AND LAND EXCHANGE SDEIS

USDA, Forest Service

The purpose for the United States Forest Service (USFS) is to meet desired conditions in the Superior National Forest Land and Resource Management Plan (Forest Plan), including ensuring the proposed land exchange Proposed Action eliminates existing conflict and ensuring mineral resources are produced in an environmentally sound manner contributing to economic growth.

In regards to desired conditions for land exchange and mineral development, the Superior National Forest's Forest Plan includes the following direction:

“D-LA-1 – The amount and spatial arrangement of National Forest System land within the proclamation boundary of the Forest are sufficient to protect resource values and interests, improve management effectiveness, eliminate conflicts, and reduce the costs of administering landlines and managing resources.” (Forest Plan, Land Adjustment, pg. 2-51)

“D-MN-2 – Ensure that exploring, developing, and producing mineral resources are conducted in an environmentally sound manner so that they may contribute to economic growth and national defense.” (Forest Plan, Minerals, pg. 2-9)

PolyMet intends to exercise private mineral rights that were reserved when lands were conveyed to the United States and has proposed the development of a surface mine. This land was purchased by the USFS, for National Forest purposes, under the authority of the Weeks Act (16 USC 515). The USFS has taken the position that the mineral rights that were reserved do not include the right to surface mine as proposed by PolyMet.

In addition, allowing private surface mining would be inconsistent with USFS legal mandates for acquiring and managing these lands. The USFS needs to resolve this fundamental conflict.

U.S. Army Corps of Engineers

The Purpose and Need of the Proposed Action is to produce base and precious metals precipitates and flotation concentrates from ore mined at the NorthMet Deposit by uninterrupted operation of the former LTVSMC processing plant. The processed resources would help meet domestic and global demand by sale of these products to domestic and world markets.

Minnesota Department of Natural Resources

The Purpose and Need of the Proposed Action is to produce base and precious metals precipitates and flotation concentrates from ore mined at the NorthMet Deposit by uninterrupted operation of the former LTVSMC processing plant. The processed resources would help meet domestic and global demand by sale of these products to domestic and world markets.

Appendix C

APPENDIX C – TRIBAL AGENCY POSITION SUPPORTING MATERIALS

Following this page, Appendix C is identical to Appendix C provided in the Supplemental Draft Environmental Impact Statement for the NorthMet Mining Project and Land Exchange.

C1 INTRODUCTION

Appendix C contains Tribal Cooperating Agencies' comments and supporting documentation that represent major differences of opinion with the analyses as presented in the SDEIS. The information was submitted by the Bois Forte, Grand Portage, Fond du Lac, Great Lakes Indian Fish & Wildlife Commission, and the 1854 Treaty Authority. All materials in this appendix are Tribal views provided verbatim and have not been validated or approved by the Co-lead Agencies.

See Chapter 8, Major Differences of Opinion, in the SDEIS for a complete listing of the 18 Tribal issues and summaries, and the Co-lead Agency responses.

Hydrology Section:

The hydrology section of the Tribal SDEIS Appendix consists of documents and reports related to three topics:

- 1. Baseflow predictions by XPSWMM vs. measurements of baseflow in the upper Partridge River.**
The data reported and analysis contained in the five letters and memos in this sub-section highlight the lack of agreement between the low baseflow predicted by the surface water model XPSWMM and the baseflows measured in the field and by continuous stream gauging. Estimates of impacts to the Partridge River and estimates to other surface and groundwaters in the mine site area are dependent on accurate information on river baseflow.
- 2. The inability of the GoldSim model to accurately predict current water quality at the mine site or the plant site.**
The results of the Goldsim modeling highlighted in the email and figure of this sub-section demonstrate that Goldsim does a poor job in predicting current ground and surface water quality. In some cases GoldSim mis-predicts water quality by more than 400%. Accurate prediction of current water quality by a model such as GoldSim is an easier task than predicting future water quality, given the uncertainty of input variables in the future. GoldSim's inability to accurately predict current water quality indicates it is poorly suited for predicting future water quality.
- 3. The lack of inclusion of reasonably foreseeable events in the SDEIS No-Action Alternative modeling.**
The documents and email in this sub-section highlight the CEQ requirement that "where a choice of "no action" by the agency would result in predictable actions by others, this consequence of the "no action" alternative should be included in the analysis." The no-action alternative analysis of future water quality used in the SDEIS includes nothing except continuation of the current water quality. This SDEIS No-Action alternative is so extremely unrealistic so as to not even include the dilution effects of precipitation on existing tailings basin water when predicting future water quality.

Re: Partridge River baseflow, draft analysis of new data suggest XP-SWMM estimate inaccurate

We remain concerned that the basic hydrology of the mine site is mis-characterized as being very non-conductive. The baseflow in the Partridge is a fundamental parameter to which many flow and contaminant transport models are calibrated. Unfortunately the baseflow at the site used in impact prediction is an estimate made by XP-SWMM. XP-SWMM appears to do a poor job of predicting baseflow at the mine site, possibly because it is based on a data set collected 17 miles downstream.

As we note in our recently submitted PSDEIS comments, the MDNR winter flow measurements in the PSDEIS (Table 4.2.2-9) indicate substantially higher baseflow in the Partridge than predicted by XP-SWMM. This is true even when the flow data is corrected for any possible Northshore (NS) discharge to the Partridge by subtracting the farthest upstream measurement from measurements taken farther downstream.

Even more compelling than the winter MDNR flow measurements is the flow data that has been recorded at the Dunka Road gage over the last 2 years. I have again calculated some statistics on the flow measurements taken at the Partridge River & Dunka Road, also known as monitoring site SW003. (http://www.dnr.state.mn.us/waters/csg/site_report.html?mode=get_site_report&site=03155002)

Earlier comments on this topic are attached and previous analysis was submitted to the lead agencies by email on 2012-06-12, 2012-06-18, and on 2008-09-28 (attached).

The stage and flow values measured by stream gage are available at 15 minute intervals. Based on 66,581 stage records collected between May 2011 and April 2013 and the DNR rating curve, I found:

Q90 at SW003 = 2.32 cfs (90% of the time flow was greater than 2.32 cfs) Q90 is sometimes used as an indicator of baseflow

Using 586 daily average flows from 2011-05-26 to 2012-12-31 calculated by the DNR and accounting for winter ice conditions, I found:

Q90 at SW003 = 1.9 cfs

Given that Northshore Peter Mitchel (PM) pit intermittently discharges to the Partridge River, I also analyzed 3 months in 2011 (Jul, Aug, Sep) and 3 months in 2012 (Feb, Mar, Apr) when Northshore (NS) discharged zero (0) gallons into the Partridge River.

Based on average daily flows calculated by the DNR:

In the 3 months of no NS pit discharge in 2011 Q90 at SW003 = 1.8 cfs

In the 3 months of no NS pit discharge in 2012 Q90 at SW003 = 1.1 cfs

Given that both these 3-month periods are typically low flow times, it seems that a baseflow estimate for site SW003 of 1 - 2 cfs would be reasonable.

While analysis based on only 6 months of flow data is not ideal, it should be noted that the XP-SWMM model is calibrated to only 2 months when Northshore did not discharge to the Partridge in 1985 (PSDEI S page 4.2.2-44, 1st paragraph).

Neither the direct field observations (minimum of 3.4 cfs) nor the values calculated from the DNR rating curve, support the **baseflow predicted by XP-SWMM at SW003 of 0.51 cfs** (Water Modeling Data package Vol.1-Mine Site, ver12, p.130 and PSDEI S Table 4.2.2-8). XP-SWMM's low estimates of baseflow are used in calibration of the MODFLOW model and thus influence many aspects of the site characterization and impact prediction, including pit inflow, dewatering impacts to the Partridge River, water treatment needs, groundwater flow rates, contaminant transport times and concentrations, and contaminant dilution in the Partridge watershed.

Although it is now an unfortunate time in the NEPA process to try to adequately characterize basic site hydrology, it appears that predictions of effects of the project may be far from accurate. It is not easy to say how the mis-characterization of river baseflow would affect compliance predictions because, although more baseflow might mean more dilution of contaminants, it could also mean transport of greater quantities of pollutants to the river and more drawdown of the Partridge River. We have repeatedly asked that the data at the Dunka Road gage be formally analyzed for baseflow as a check of the accuracy of the XP-SWMM modeling. If that analysis indicates that the XP-SWMM predictions under-represents baseflow, as our draft analysis suggests, that result should be incorporated into all project model calibration and prediction.

Thank you in considering this issue when revising the SDEI S.

The watershed upstream of SW-004 makes up 22% of the SW-006 watershed (23 of 103 sq.miles), yet XP-SWMM predicts that the watershed contributes only 17% (0.92 of 5.3 cfs) of the baseflow.

Using a ratio of watershed areas to extrapolate baseflow up from the USGS gage (SW-006) would suggest that baseflow at SW-004 is 1.2 cfs (5.3 X .22).

While using the watershed ratio technique is uncomplicated compared to XP-SWMM, it appears to give a prediction of baseflow at SW-004 closer to the flows actually observed at the site.

It seems that the Partridge River may be over-modeled with the use of XP-SWMM. Such a parameter-heavy model as XP-SWMM needs substantially more data from near the mine site in order to be justified. A more parsimonious approach appears to be a better fit.

To: "Hingsberger, Thomas J MVP" <thomas.j.hingsberger@usace.army.mil>

As a contribution to the discussion tomorrow, I calculated some statistics on the flow measurements taken so far at the the Partridge River & Dunka Road. (http://www.dnr.state.mn.us/waters/csq/site_report.html?mode=get_site_report&site=03155002)

The stage and flow values are available at 15 minute intervals starting in February of 2012. Based on 10,300 records I found Flow stats of:

Q70 = 6.9 cfs (70% of the time flow was greater than 6.9 cfs) Q70 is sometimes used as an indicator of baseflow

Q90 = 2.8 cfs (90% of the time flow was greater than 2.8 cfs) Q90 is sometimes used as an indicator of baseflow

Q10 = 28.3 cfs (10% of the time flow was greater than 28.3 cfs)

Q99 = 0.4 cfs (99% of the time flow was greater than 0.4 cfs)

minimum 7day average flow was 2.37 cfs (this is sometime also used as an indicator of baseflow)

These flow values are based on a rating curve that is still being developed and cover less than a year, but neither the direct observations (minimum of 3.8 cfs) nor the values calculated from the rating curve support the XP-SWMM predicted baseflow 4 miles downstream of the gage (i.e. 0.76 cfs) and used in modeling.

Memorandum

To: Thomas Hingsberger USACE
Erik Carlson Minnesota DNR

From: John Coleman, Environmental Section Leader

Re: Polymet model calibration to Partridge River low flows

The hydrologic models for the Polymet mine site have been calibrated to targets that under-represent true baseflow. Models should be calibrated to a strong set of observational data. Construction of the site's basic hydrologic model to unrealistically low baseflows has ramifications for all the flow and contaminant modeling at the site.

Under-representation of Partridge River baseflow.

Review of the winter baseflow measurements and comparison to predictions made by XP-SWMM indicate that XP-SWMM substantially underpredicts baseflow (Barr June 9, 2011, Comparison of MDNR winter flow gauging to Partridge River XP-SWMM model). This has ramifications throughout the parameter sets being used in models characterizing hydrology at the Polymet mine site.

In the above referenced memo, Barr points out that the average measured baseflow at Dunka Rd. was 5.0 cfs while the XP-SWMM predicted baseflow is 0.4 cfs. Even when discharge from Northshore Mining was taken into account, the average baseflow measured at Dunka is 4.3 cfs while XP-SWMM predicts 0.42 cfs.

In its memo, Barr correctly points out that: "At all locations along the main stem of the Partridge River, the XP-SWMM-estimated baseflow is less than the MDNR-measured baseflow. The XP-SWMM model provides a conservative estimate of Partridge River baseflow for the purposes of modeling water quality impacts (e.g., less dilution of loads from the Mine Site)." What is not acknowledged in the Barr memo is that calibration of hydrologic models to an underestimate of baseflow produces models that characterize the groundwater hydrologic system as moving an unrealistically small quantity of water.

Additional flow measures over the last 9 months on the Partridge River at the Dunka Road (site SW-003) further support the position that baseflow predicted by XP-SWMM under-represents true baseflow. The least flow measured at the Dunka Road site was 3.8 cfs. While there have so far been only 7 measurements taken at that site, the flow measured and the stage recorded by the gauge do not appear to support XP-SWMM's low baseflow predictions for the upper Partridge River.

Mis-calibration of groundwater flow models.

The calibration of the Modflow model to a Partridge River baseflow of 0.76 cfs predicted by XP-SWMM results in a model that moves very little water through the groundwater system. This can result in low predicted rates of inflow to the mine pit and slow movement of contaminants from sources (stockpiles or reflooded pits) to points of evaluation. More generally, an incorrect baseflow calibration target results in excessively low estimates of recharge and likely incorrect estimates of horizontal and vertical conductivity. These hydrologic parameters are interrelated and getting one wrong, as appears to be the case with baseflow, will almost certainly result in the other parameters being incorrectly estimated. Although there has been little sensitivity analysis conducted in the Polymet modeling efforts, flow models tend to be sensitive to these interrelated parameters.

Based on Modflow model calibration to a baseflow of 0.76 cfs and recharge values set at 0.3 and 1.5 in/yr (see page 61 of Water Modeling Data Package Vol 1-Mine Site v9 DEC2011.pdf and page 11 of RS22, Appendix B), some horizontal and vertical conductivities (K) were calculated by Barr using PEST (see Table 1 of Attachment B of Water Modeling Data Package Vol 1-Mine Site v9 DEC2011.pdf). These K values are likely to be inaccurate since they are calculated with a model that is calibrated to a baseflow that appears to be almost an order of magnitude too low. It is unlikely that any accurate predictions of water movement, transport of contaminant mass, or contaminant levels can be made when the characterization of the hydrologic system is so out-of-kilter.

Unusually low recharge and vertical K:

The low values used for recharge (0.3 and 1.5 in/yr) and the low wetland and till vertical K (0.0000033 ft/day [1.16×10^{-9} cm/s]) used in the Modflow model are a reflection of a model constructed and calibrated to move an unrealistically small amount of water through the hydrologic system. For context, note that engineered clay liners in landfills typically aim for 1.0×10^{-7} cm/s hydraulic conductivity. I was unable to find any reference in the literature to wetland soil vertical conductivity as low as is used in the Modflow model. The lower end of the spectrum I found for wetland soil vertical conductivity was 1×10^{-6} cm/s.

Our long standing concern that the mine site hydrologic models incorporate incorrect assumptions about recharge are supported by Fred Marinelli's comment on line 39 and elsewhere of: "Agency Responses MS and PS WP and Waste Characterization Data package V7 2-7-12.xls". His comment states that "A net infiltration (recharge) range of 0.3 to 1.5 in/yr represents 1.1 to 5.4 percent of mean annual precipitation (MAP). This range for local net infiltration is unrealistically low for this area of the US." These low recharge values and the low

vertical K values are related to calibration of the Modflow model to low baseflow. Until Modflow, and by extension the other related models XP-SWMM and GoldSim, are calibrated to data from the site (e.g. observed baseflow and an adequate number of observed heads) and incorporate reasonable recharge rates, the results from the models are unlikely to accurately simulate current or future conditions.

Recalibration of models needed:

The Modflow model, in particular, needs to be calibrated with targets based on observed baseflow and observed well water heads. Calibration to projections by XP-SWMM, that appear to be incorrect, means that the fundamental characterization of the site hydrology is likely to be faulty. In the document referenced above (Agency Responses ...) Barr Engineering states that many hydrologic model parameters were “discussed as part of the IAP process and will not be considered further at this time.” While some parameters were discussed in the groundwater IAP process, the discussion was almost exclusively concerning water quality parameters, not flow model parameters such as recharge, baseflow and K_v and K_h . The focus on water quality parameters to the near exclusion of hydrologic flow parameters is reflected in the Groundwater IAP summary memo of June 2011. Groundwater flow modeling underpins contaminant transport modeling and is interrelated to surface flow models. Without adequate vetting of flow model parameters and predictions, it is impossible to have confidence in predictions of contaminant movement and water quality.

Now that the hydrologic models have been more fully articulated by Barr and additional data are available, the models must be calibrated to observed baseflow and well water levels. This should include the new water level data from the newly installed mine site wells. PEST can then be used to more reasonably estimate values for recharge and conductivity. The observed baseflow and the PEST estimated recharge and conductivity values should then be used in the XP-SWMM and GoldSim modeling efforts. Modeling efforts that are based on faulty initial assumptions and not on field observations will not be able to reasonably predict impacts. The current Polymet modeling effort needs to be well founded on a strong base of observations of the physical conditions at the site.

References:

Stuart,
Here are additional issues related to RS22-Appen.B and RS73

1) The Kv of the wetland and drift materials are unrealistically low:

The Modflow model in RS22 Appen.B uses vertical conductivity values for wetland and glacial drift soils that are unrealistic to the extreme. Table 3-3 of RS22 Appen.B indicates that the hydraulic conductivity values used in the local-scale model are 0.0000033 ft/day (1.16X10⁻⁹ cm/s), for comparison, engineered clay liners in landfills typically aim for 1.0X10⁻⁷ cm/s hydraulic conductivity. I was unable to find any reference in the literature to wetland soil vertical conductivity as low as is used in the Modflow model. The lower end of the spectrum I found for wetland soil vertical conductivity was 1X10⁻⁶ cm/s. These low Kv values have effects on predicted recharge, mine pit inflow, groundwater drawdown, river baseflow impacts, and contaminant transport to the Partridge River.

2) No recharge to the Giant's Range or Biwabik Iron Formations is specified. These are material types in the Modflow layer one. Were they zero or just not reported?

3) The recharge for wetlands and drift (0.3 and 1.5 in/yr) are unusually low.

MODFLOW of Crandon project in an area of glacial drift and wetlands used 9 in/yr.

The Polymet MODFLOW mode for the plant/tailings site uses 8in/yr for wetland/drift areas.

The MODFLOW report supports the choice of 0.3 and 1.5 in/yr or recharge by citing the RS73A SWMM model "groundwater recharge coefficient". These are not equivalent parameters and the baseflow predicted by SWMM is most likely underestimated as explained below.

4) The 1.43 cfs of baseflow at SW-004 that the Modflow model is calibrated to (RS22 Appen.B, page 13) is a predicted value from the SWMM model which is calibrated to USGS gage 04015475 baseflow of 5.47 cfs, estimated from 1978-1988 flow data (RS73A). The USGS gage (near the inlet to Colby Lake) is 17 miles downstream of SW-004 and 26 miles downstream of the headwaters. Flow data collected in 2004 during 3 periods (see RS63) of low flow show significantly greater flows in the river at SW-004 and SW-003 than at the station (SW-005) 17 miles downstream near Colby Lake inlet (RS63). During these periods, SW-003 showed flows of 6 to 8.6 cfs while the downstream station (SW-005) showed flows of 2.7 to

7.6 cfs. In addition there was one measurement at SW-003 in 1978 that overlaps with the USGS gage 04015475. On 11/15/1978 flow at SW-003 was recorded as 25 cfs and at the USGS gage 23 cfs. The higher flows in the upper reaches of the Partridge River indicate that the river is gaining in its upper reaches and is losing in its lower reaches. This is not at all surprising given the drop in elevation of 320 feet above SW-003. Below SW-003 there is only another 100 ft of drop over the 20 miles to the USGS gage.

The flow data from 2004 and 1978 appear to indicate that baseflow at SW-003 and SW-004 is approximately 1 to 2 times the baseflow in the Partridge River near the inlet to Colby Lake. Given the 1978 and 2004 data, it appears that the Modflow would more reasonably be calibrated to a baseflow of approximately 7-8 cfs at SW-003 and 4 cfs at SW-004. Calibration to higher baseflows in the Partridge River would likely produce a model with higher recharge, more flow to the pits, different contaminant transport results, and different drawdown and baseflow impact predictions.

Note: measurement stations in RS22, RS73, RS74 and RS63 have multiple names.

Re: Goldsim inaccurately predicts existing conditions, unlikely to accurately predict future project conditions

While we feel that modeling of the existing conditions is an inadequate substitute for a realistic No-Action Alternative model and does not follow CEQ guidelines, it appears that Goldsim does not even accurately model existing conditions. As we noted in our spreadsheet comments submitted June 25th, for many parameters at several water bodies the No-Action P50 model of annual average value is substantially different than the observed average existing conditions. Because of the inaccuracy of the Goldsim predictions of current conditions it is not clear that use of the Goldsim estimates of project impacts are adequate to ensure protection of water resources.

For example:

- -PSDEIS Table 4.2.2-18 reports Colby Lake as currently having an observed mean Arsenic of 0.78 to 1.4 ug/L (depending on the data set), whereas Figure 5.2.2-35, the No-Action (continuation of current conditions) P50 model for Colby Lake Arsenic shows annual maximum values of 0.5 ug/L.
- -PSDEIS Table 4.2.2-34 reports PM-10 (seep at the basin north toe) as having an observed mean Mn value of 100,192 ug/L, whereas Figure F-01-18.1 (Water Modeling Data Package Vol 2-Plant Site v9 MAR2013) shows the No-Action (continuation of existing conditions) P50 as an annual maximum Mn of 390 ug/L. at the north toe.
- -PSDEIS Table 4.2.2-34 reports PM-10 as having an observed mean Aluminum of 39.6 ug/L yet Figure F-01-02.1 (Water Modeling Data Package Vol 2-Plant Site v9 MAR2013) shows an annual maximum for No-Action (continuation of existing conditions) at the north toe as 11 ug/L.
- -PSDEIS Table 4.2.2-14 shows that observed average SO4 at SW-005 (9.11 mg/L) is nearly identical to the Goldsim P50 predicted current annual maximum for that site (PSDEIS Fig. 5.2.2-27, 9 mg/L). This suggests that Goldsim is under-predicting SO4 at SW-005. (The authors of the text on page 5.2.2-125 of the PSDEIS seem to misinterpret the P50 of the figure as a predicted annual average. This is not the case. The P50 of that figure is the "best" estimate of the annual maximum. The Goldsim model estimate of the annual average at SW-005 is shown as the P50 in Mine Site Data Package Attachment K Figure K-06-24.2, i.e. 6 mg/L) Again this suggests that Goldsim is underpredicting SO4 at SW-005.
- - PSDEIS Table 4.2.2-29 shows that observed average Al at PM-13 is 221 ug/L. This observed average is much higher than the modeled No-Action (continuation of existing conditions) P50 annual maximum (PSDEIS Table 5.2.2-47, 159-166 ug/L). The modeled No-Action P50 annual average for Al at PM-13 of 75 ug/L (attached Fig.I -05-02.2, Water Modeling Data Package Vol 2-Plant Site v9 MAR2013) is only 1/3 of the observed average.

The tables below compare the observed existing conditions values found in various PSDEIS tables to the P50 existing conditions predicted by Goldsim. While a very few of these model predictions are presented in the PSDEIS, many are not and therefore, the tables below refer back to the underlying data packages from which the PSDEIS was written.

Observed existing conditions in the Partridge River vs. annual average existing conditions predicted by Goldsim.

Parameter (ug/L)	Average existing water quality (PSDEI S Table 4.2.2-14)	Annual average P50 existing conditions predicted by Goldsim (Mine Site Data Package Attach.K)
Mn	SW-002 = 142	SW002 = 80 (Fig.K-01-18.2)
TI	SW-002 = 0.6	SW002 = 0.11 (Fig.K-01-25.2)
Mn	SW-003 = 147	SW003 = 85 (Fig.K-02-18.2)
B	SW-004a = 126.5	SW004a = 30 (Fig.K-04-05.2)
K	SW-004a = 2,700	SW004a = 1,600 (Fig.K-04-16.2)
SO4	SW-004a = 15,900	SW004a = 8,000 (Fig.K-04-24.2)
Pb	SW-005 = 1.3	SW005 = 0.26 (Fig.K-06-21.2)
SO4	SW-005 = 9,110	SW005 = 6,000 (Fig.K-06-24.2)
TI	SW-005 = 0.4	SW005 = 0.05 (Fig.K-06-25.2)

Observed mean existing conditions in Colby Lake vs. annual average existing conditions predicted by Goldsim.

Parameter (ug/L)	Colby Lake mean existing water quality (PSDEI S Table 4.2.2-18, Barr data)	Colby Lake Annual average P50 existing conditions predicted by Goldsim (Mine Site Data Package Attach.K)
Al	108	75 (Fig.K-08-02.2)
As	0.78	0.4 (Fig.K-08-04.2)
Cu	2.4	0.7 (Fig.K-08-13.2)
Ni	2.5	1.1 (Fig.K-08-20.2)
SO4	33,800	~10,000 (Fig.K-08-24.2)
TI	0.1	0.025 (Fig.K-08-25.2)

Observed mean existing conditions at the tailings basin toe vs. annual maximum existing conditions predicted by Goldsim. (Goldsim predicted mean concentrations are not provided in Modeling Data Package Vol 2-Plant Site v9 MAR2013)

Parameter (ug/L)	Mean seep measured value at Basin Toe (Table 4.2.2-34)	Annual <u>maximum</u> P50 existing condition predicted by Goldsim (Plant Site Data Package Attach.F)
Al	PM-8 = 25.7	West toe = 14 (Fig.F-04-02.1)
AL	PM-9 = 29.9	NW toe = 13 (Fig.F-02-02.1)
AL	PM-10 = 39.6	North toe = 11 (Fig.F-01-02.1)
Mn	PM-8 = 3,039	West toe = 1,250 (Fig.F-04-18.1)
Mn	PM-10 = 100,192	North toe = 380 (Fig.F-01-18.1)
F	PM-8 = 2,900	West toe = 1,100 (Fig.F-04-14.1)
As	PM-8 = 3	West toe = 2 (Fig.F-04-04.1)
B	PM-10 = 379	North toe = 330 (Fig.F-01-05.1)

The above examples are not an exhaustive list of discrepancies between observed existing water quality data and the Goldsim P50 prediction of the No-Action alternative (continuation of existing conditions) but highlight some of the most notable discrepancies. What the discrepancies demonstrate is that the Goldsim model is a relatively poor predictor of current conditions. If a model is unable to accurately predict current conditions it is even less likely to accurately predict future Project conditions. The Goldsim models need to be better calibrated to existing conditions (the calibration effort reported in "Calibration of the Existing Natural Watershed at the Plant Site v4 MAR2012" only compared model output to upstream site PM-12 and apparently did a poor job of preparing the models to predict either the lower reaches of the Embarrass or the Partridge River.) and model results recalculated.

Thank you for considering this issue while revising the PSDEIS.

Re: Continuation of Existing Conditions an inappropriate No-Action alternative

According to CEQ guidelines (attached):

"No action" in such cases would mean the proposed activity would not take place, and the resulting environmental effects from taking no action would be compared with the effects of permitting the proposed activity or an alternative activity to go forward.

Where a choice of "no action" by the agency would result in predictable actions by others, this consequence of the "no action" alternative should be included in the analysis. For example, if denial of permission to build a railroad to a facility would lead to construction of a road and increased truck traffic, the EIS should analyze this consequence of the "no action" alternative.

Based on the above CEQ guidelines, it is clear that activities that will occur under the Cliffs Consent Decree should be included in modeling of a No Action alternative. Unfortunately not only are the consent decree activities not included, but the fact that it will be precipitating on the tailings basins for the foreseeable future has not been included in the No Action modeling. This is evident by the model results that show stable levels of Chloride coming from the basins for the next 200 years (Figure attached) when there is no ongoing source for Chloride. With no source for new Chloride, rainwater will gradually dilute the residual Chloride in the basin and levels will drop. The PSDEIS claims that the basins water quality has stabilized and that the current conditions will not change over time. The claim of chemical stability is based on basin pond water sampling for only 4 years (2001 - 2004, PSDEIS Table 4.2.2-23).

Since there has been no water quality data collected in the basin pond for 9 years it is reasonable to assume that the past 9 years of precipitation has diluted the water chemistry in the basin pond and that eventually the more dilute water will work its way through the basins and be discharged at the toe. If chemical stability is to be assumed, more recent data on basin pool water chemistry is needed. While the CEQ makes it clear that a blind "continuation of existing conditions" model is inappropriate as a No Action alternative, a "continuation of existing conditions" model that ignores simple environmental processes such as precipitation is even less appropriate.

Thank you for considering this issue.

COUNCIL ON ENVIRONMENTAL QUALITY
Executive Office of the President

Memorandum to Agencies:

**Forty Most Asked Questions Concerning
CEQ's National Environmental Policy Act Regulations**

SUMMARY: The Council on Environmental Quality, as part of its oversight of implementation of the National Environmental Policy Act, held meetings in the ten Federal regions with Federal, State, and local officials to discuss administration of the implementing regulations. The forty most asked questions were compiled in a memorandum to agencies for the information of relevant officials. In order efficiently to respond to public inquiries this memorandum is reprinted in this issue of the Federal Register.

Ref: 40 CFR Parts 1500 - 1508 (1987).

March 16, 1981

**MEMORANDUM FOR FEDERAL NEPA LIAISONS, FEDERAL, STATE,
AND LOCAL OFFICIALS AND OTHER PERSONS INVOLVED IN THE
NEPA PROCESS**

Subject: Questions and Answers About the NEPA Regulations

During June and July of 1980 the Council on Environmental Quality, with the assistance and cooperation of EPA's EIS Coordinators from the ten EPA regions, held one-day meetings with federal, state and local officials in the ten EPA regional offices around the country. In addition, on July 10, 1980, CEQ conducted a similar meeting for the Washington, D.C. NEPA liaisons and persons involved in the NEPA process. At these meetings CEQ discussed (a) the results of its 1980 review of Draft EISs issued since the July 30, 1979 effective date of the NEPA regulations, (b) agency compliance with the Record of Decision requirements in Section 1505 of the NEPA regulations, and (c) CEQ's preliminary findings on how the scoping process is working. Participants at these meetings received copies of materials prepared by CEQ summarizing its oversight and findings.

Great Lakes Indian Fish and Wildlife Commission (GLIFWC) Mercury Section

Below are comments from the Great Lakes Indian Fish and Wildlife Commission (GLIFWC) related to mercury issues in the “NorthMet Mining Project and Land Exchange: Preliminary Supplemental Draft Environmental Impact Statement” (PSDEIS). Detailed rationale and comments follow the summary.

Summary

The understanding of mercury dynamics in the St. Louis River watershed is very limited and is insufficient to lead to the conclusion reached in the PSDEIS that “the NorthMet Project Proposed Action would not exceed applicable environmental evaluation criteria.” This lack of scientific information is explicitly stated throughout the PSDEIS and is what led the Minnesota Pollution Control Agency (MPCA) early this year to delay the establishment of a St. Louis River TMDL until further mercury cycling data could be collected.

Further, the conclusion that “the NorthMet Project Proposed Action would not exceed applicable environmental evaluation criteria” is based on a number of flawed assumptions. Specifically, we do not agree with the following assumption in the PSDEIS (rationale provided below):

- The tailings basin will function as a mercury sink.
- Mercury methylation will not increase because the amount of sulfate being released to the environment will actually be reduced by the project.
- the NorthMet project would have minor effects on flows in the Partridge and Embarrass Rivers or their tributaries and is thus not expected to result in increases in flow fluctuations that promote mercury methylation.

Many lakes and rivers in the area are already classified as “impaired waters” by the MPCA due to elevated fish mercury. All additional increases in mercury contributions to the environment therefore constitute a risk to human and ecosystem health. The proposed project will result in increased mercury releases to the environment both via air and water, increasing human and ecosystem risk. All increases in mercury releases into the Lake Superior watershed are contrary to the goals of the 1991 “Binational Program to Restore and Protect the Lake Superior Basin” to establish a Zero Discharge Demonstration Program for nine critical pollutants, including mercury. These increased emissions are expected to have a measureable effect on mercury levels in fish and the subsequent health risk to recreational and subsistence fishers. Any additional mercury releases to the environment are exacerbating an already unacceptable risk situation in the area. Increased fish mercury levels fish will also have direct impacts on both the cultural and recreational resources of the region.

In addition, there are a several concerns related to mercury that are not addressed in the PSDEIS. These concerns are summarized here, with more detailed comments and rationale provided in the comments below. There is no discussion of the potential for the constructed wetlands over the East Pit and at the perimeter of the tailings basin to serve as a significant source of mercury methylation or as a route of mercury exposure to waterfowl and water birds that may utilize this habitat. The potential for the West Pit overflow to exceed the Great Lakes Initiative standard of 1.3 ng/L mercury is ignored. There is no consideration of the likely mercury pulse to the Partridge River resulting from placement of the stripped peat and unsaturated overburden into the unlined Overburden Storage and Laydown Area. It is not apparent whether mercury monitoring is included within the water quality monitoring of the Mine Site or Plant Site. The estimate of air emissions of mercury as a result of the project does not take into account emissions from electricity generation for the site or from the burning of fuel by mining vehicles or other equipment. Wetland monitoring following restoration is only vegetative and hydrologic in nature, but should include total and methyl mercury to collect information on mercury levels and methylation rates and identify any necessary remedial actions. The Wildlife Section does not discuss mercury contamination despite the fact that there are a number of fish- or aquatic invertebrate-eating species [such as the bald eagle (state listed and protected by federal law), otter, and wood turtle (state listed), and various amphibians] that may be impacted by increased methyl mercury in the food web. Flow to the Partridge River, Embarrass River, or their tributaries may be sufficient to impact habitat leading to alterations of species composition, food web structure, and ultimately mercury bioaccumulation.

Comment 1

The PSDEIS concludes that "Based on the results of the modeling and impacts analysis, the NorthMet Project Proposed Action would not exceed applicable environmental evaluation criteria." Due to a general lack of understanding of mercury dynamics, particularly in the St. Louis River (SLR) watershed, this conclusion is not defensible with regard to mercury. The PSDEIS explicitly points out this knowledge gap in a number of sections. For example:

- Section 5.2.2.1.2: indicates that even though mercury in fish tissue is relevant to water resources evaluation criteria considerations, the modeling did not attempt a numeric analysis of NorthMet Project Proposed Action-specific effects on mercury in fish tissue. In addition, the ability of numeric models to predict concentrations of mercury in fish tissue in response to changes in mercury-loading is currently inadequate due to gaps in scientific knowledge. Finally, the relationship of inorganic mercury-loading to uptake of methylmercury in fish is inherently complex and subject to numerous chemical, physical, and biological parameters, which vary geographically and are only partially understood.

- Sections 6.2.3.3.4 and 5.2.2.3.4: indicate that mercury was not included in the GoldSim model as insufficient data and a general lack of definitive understanding of mercury dynamics prevented modeling mercury like the other solutes.
- Section 5.2.2.3.4: indicates that current scientific understanding of the factors and mechanisms affecting mercury methylation and bioaccumulation is limited.

Further, the Minnesota Pollution Control Agency (MPCA) has concluded that a SLR mercury Total Maximum Daily Load (TMDL) is not feasible at this time due to a lack of understanding of mercury dynamics in the watershed. They have delayed completing the mercury TMDL process pending the collection of additional mercury data in the watershed. This brings into doubt the possibility that the PSDEIS could adequately assess mercury impacts from the proposed action to conclude there will be no exceedances of applicable environmental criteria related to mercury.

Comment 2

The conclusion that mercury will not increase in the environment or exceed applicable environmental evaluation criteria is based on several assumptions. One such assumption is that the tailings basin will function as a mercury sink (Section 5.2.2). This assumption is not justified for a number of reasons.

The assumption that the tailings basin will serve as a mercury sink is based only on a small-scale bench top study of tailings from the site of the NorthMet project, providing minimal information. Details of the study are not provided. Further, field conditions were not accurately simulated in the study. For example, the experiment used process water that was 3.3 ng/L to test the adsorption capacity of the tailings. But, the PSDEIS states that a pilot study found the process water from the project would contain an estimated 11.2 ng/L of mercury (3.4 times higher than the experimental concentration). Thus, the concentrations used in the experiment were not environmentally relevant to the anticipated conditions at the mine site. Process water with a much higher mercury concentration might not experience mercury reductions to the same degree as was seen in the small-scale bench top study.

In addition, the conclusions drawn from the bench top study are backed up in the PSDEIS by earlier Minnesota Department of Natural Resources (MDNR) research on taconite tailings. There are inherent differences in composition between taconite tailings and the tailings that would come from the NorthMet PGM type project. These differences are likely to affect metallic binding potential. Therefore it is not appropriate to apply conclusions from this research to the current project.

Also lacking from the discussion of the potential for mercury to be adsorbed by the mine tailings is a discussion of potential saturation of the tailings with mercury (or other metals) and whether the tailings could shift from a mercury sink to a source in the future. This information is not presented for the NorthMet tailings or for the taconite tailings already present on site. The time scale on which the experiments were conducted are not adequate for predicting the long-term behavior of mercury and its interactions with tailings materials. Questions that should be addressed include:

- Are there conditions under which the tailings would shift from a sink to a source (e.g., temperature or pH alterations as a result of mining activities or global climate change, oversaturation after a significant time period)?
- Is the mercury permanently and irreversibly adsorbed to the tailings?
- The PSDEIS indicates in section 5.2.7.2.5 that about 95 percent of the mercury originating in the ore is expected to remain within—or be adsorbed to—the tailings and the hydrometallurgical residue, where it would remain isolated from further transport to the environment. Has this been proven with regards to potential tailings saturation and changing environmental conditions?

Comment 3

The conclusion that mercury will not increase in the environment or exceed applicable environmental evaluation criteria is based on several assumptions. One such assumption is that mercury methylation will not increase because the amount of sulfate being released to the environment will actually be reduced by the project. This assumption is not justified. The MPCA 2006 strategy to address effects of sulfate on MeHg production focuses on avoiding discharges to “high risk” situations such as wetlands, low (<40 mg/L) sulfate waters where sulfate may be a limiting factor in the activity of sulfur-reducing bacteria, and waters that flow downstream to a lake that may stratify. As indicated in the PSDEIS (Section 5.2.2.3.4), most or all of these conditions apply to the area downstream of the tailings basin and waste water treatment facility (WWTF). As a result, sulfate releases from the mine site and subsequent impacts on mercury methylation are a critical consideration.

The assumption that mercury methylation will not increase because the amount of sulfate being released to the environment will actually be reduced by the project only holds true if water is captured and treated in perpetuity. The assumption no longer holds if this onsite water treatment ceases or is reduced. Further, there are concerns regarding the conclusion that sulfate releases will be decreased by the project. This may not be true in all instances (see GLIFWC hydrology attachment for comments related to sulfate releases). Finally, as the PSDEIS indicates (5.2.2.3.4), the current scientific understanding of the factors and mechanisms affecting mercury methylation and bioaccumulation is limited. It is known that the response of mercury

methylation to sulfate concentrations is non-linear and complex. It is not defensible to state that the mercury/sulfate cycle is not well understood and then conclude that the projected levels of sulfate releases are expected to result in a decrease on mercury methylation in the watershed. It is apparent that there is not sufficient scientific knowledge to assess the impact of any change in sulfate concentration, positive or negative, on mercury methylation and the subsequent impact on mercury levels in fish and throughout the aquatic food web.

Comment 4

The conclusion that mercury will not increase in the environment or exceed applicable environmental evaluation criteria is based on several assumptions. One such assumption is that the NorthMet project would have minor effects on flows in the Partridge and Embarrass Rivers or their tributaries and is thus not expected to result in increases in flow fluctuations that promote mercury methylation. As indicated in the PSDEIS, The methylation of environmental mercury by sulfate-reducing bacteria is also stimulated by drying and rewetting associated with hydrologic changes and water level fluctuations (Gilmour et al. 2004; Selch et al. 2007). Drying (and subsequent increase in exposure to oxygen) of substrate containing reduced sulfur species (sulfides and organic sulfur) oxidizes those species into sulfate, which is remobilized and available to sulfate-reducing bacteria upon rewetting of the substrate. The PSDEIS also indicates that this mechanism stimulates production of methylmercury in sediments exposed to wetting and drying cycles (Gilmour et al. 2004) and is likely to account for some of the elevated methylmercury concentrations seen in discharge from wetlands during high flow events (Balogh et al. 2006). Thus, hydrologic changes and water level fluctuations are known to stimulate mercury methylation and enhance its bioaccumulation.

We do not accept the conclusion that the project will not significantly impact flow and water level fluctuations. Therefore, it is possible, if not likely, that the project will lead to increased mercury methylation and bioaccumulation. GLIFWC comments regarding hydrology effects (e.g. perched vs. connected wetlands, old and inaccurate hydrology data for the Partridge River, water level fluctuations exposing riparian wetlands, and groundwater drawdown are provided in the wetlands attachment).

Comment 5

In year 21, the East Pit backfill will be completed and a mitigation wetland will be constructed over the back filled material and another wetland will be constructed at the perimeter of the tailings pond (Section 5.2.2.3.1). There is no discussion of the impact that these constructed wetlands could have on mercury methylation and bioaccumulation. Wetlands are known to promote enhanced mercury methylation. The methylation process is dependent on many factors, including the concentrations of mercury and sulfate present in the water and sediment of the

wetland. The East Pit and the tailings basin are regions of potentially elevated mercury and sulfate. Therefore, there is a reasonable potential for the constructed wetlands to be significant sources of methylmercury to the aquatic foodweb. This has not been accounted for in the assessment of mercury related impacts by the mining project.

Comment 6

There is a potential for the overflow from the West Pit (after year 40) to exceed the Great Lakes Initiative (GLI) standard for mercury of 1.3 ng/L (Section 5.2.2.3.4). This has not been considered when concluding the Proposed Action would not exceed applicable environmental evaluation criteria. The mercury concentration in the West Pit was estimated based on concentrations in other natural and mine pit lakes as well as by a mass balance approach.

Of the 16 mine pit lakes examined, two (12.5%) had average mercury concentrations >1.3 ng/L (1.61ng/L in Pit 2W and 1.87 ng/L in Pit 9S). Individual samples were as high as 2.55 ng/L, double the acceptable level. It is not stated how many of the 16 lakes had individual samples that exceeded the GLI standard. This result shows that there is a significant possibility that, based on comparisons with other similar mine pit lakes, the West Pit of the project may exceed the GLI standard for mercury of 1.3 ng/L.

The mass balance approach included an estimate that 3% of the mercury is lost via volatilization. Air emissions of mercury are known to be the primary source of mercury deposition to surface waters. This volatilized mercury then needs to be accounted for in the air emissions inventory since it will presumably primarily redeposit within the watershed.

Comment 7

There is no consideration of the likely mercury pulse to the Partridge River resulting from placement of the stripped peat and unsaturated overburden into the unlined Overburden Storage and Laydown Area. While the surface runoff will be collected, monitored and potentially routed to the WWTF, any potential water seepage into the ground below the Overburden Storage and Laydown Area will flow directly into the Partridge River. The result is a potentially unaccounted for and unquantified mercury pulse into the Partridge River.

Comment 8

It is not apparent whether mercury monitoring is included within the water quality monitoring of the Mine Site or Plant Site (Tables 5.2.2-52 and 5.2.2-53). If it is, this should be specified. If it is not, it should be added to the monitoring activities.

Comment 9

Air emissions of mercury are known to be the primary source of mercury deposition to surface waters. The estimate of air emissions of mercury as a result of the project (4.6 lbs/yr) does not take into account emissions from electricity generation for the site or from the burning of fuel by mining vehicles or other equipment (Section 5.2.7.2.5). This should be quantified and included in the analysis.

Comment 10

It appears that wetland monitoring following restoration is only vegetative and hydrologic in nature. Total and methyl mercury should be monitored pre-project through post-reclamation to collect information on mercury levels and methylation rates and identify any necessary remedial actions.

Comment 11

The Wildlife Section (5.2.5) does not discuss mercury contamination. There are a number of fish- or aquatic invertebrate-eating species [such as the bald eagle (state listed and protected by federal law), otter, and wood turtle (state listed), and various amphibians] that may be impacted by increased methyl mercury in the food web. The only fish-eating non-fish species considered in the PSDEIS is humans. Similarly the Aquatic Species Section (5.2.6) does not discuss direct health impacts to aquatic species due to mercury contamination. Presumably, these omissions are due to the fact that the PSDEIS concludes that mercury methylation in the watershed will actually be reduced due to reduced sulfate releases, mercury adsorption to tailings, and minimal resulting water level fluctuations. But, we do not accept these conclusions (see Comments 2, 3 and 4 in this document).

Comment 12

The PSDEIS dismisses the possibility of waterfowl and waterbirds utilizing the tailings basin despite the fact that common waterfowl and waterbirds have been observed at the LTVSMC tailings basin during migration (Section 5.2.5.2.3). We believe that this is a possibility and that it represents a significant potential pathway of mercury exposure to these individuals. The rationale given for the conclusion in the PSDEIS is that states this is not an issue because the tailings basin is <0.01% of the available open water in the area and because it does not contain any high quality foraging habitat. One aspect of this issue not considered is that wetlands will be constructed over the East Pit and adjacent to the tailings basin. If these wetlands are properly constructed they will represent potential waterfowl and/or waterbird habitat that is likely to result in increased mercury exposure and bioaccumulation (see Comment 5 of this document).

Comment 13

PSDEIS states there will be effects on flow in the Partridge R. and Embarrass R. tributaries, but that they are not expected to influence habitat (Section 5.2.6). We feel that the water level fluctuations may be sufficient to impact habitat (see GLIFWC hydrology attachment for comments on water fluctuations). Habitat alteration is likely to lead to changes in species composition or relative abundance. This in turn has an impact on food availability and the structure of the food web. Mercury bioaccumulation is highly influenced by the structure and length of the food web. Therefore, the project has a reasonable potential to impact mercury food web dynamics with the possibility of ultimately causing increased mercury levels in fish and exposure to fish-eating humans and wildlife.

Comment 14

Many lakes and rivers in the area are classified as “impaired waters” by the MPCA due to elevated fish mercury. All additional increases in mercury contributions to the environment therefore constitute a risk to human and ecosystem health. There are a number of aspects of the proposed action cited in the PSDEIS that will lead to increased mercury releases to the environment, increasing human and ecosystem risk. For example:

- There will be a predicted net increase in mercury loading to Embarrass River (22.3 to 22.9 g/year) due to redirection of flow and construction of east dam (Section 5.2.6.22). The PSDEIS concludes that despite this increase in mercury loading, mercury in fish would decrease because of reduced sulfate inputs. We do not agree with the conclusion that sulfate inputs would be reduced by the project in all instances (see Comment 3 of this document).
- There will be estimated air emissions of mercury of 4.6 lbs/yr from plant site (Section 5.2.7.2.5).

These increased emissions are expected to have a measureable effect on mercury levels in fish and the subsequent health risk to recreational and subsistence fishers. This will compound the facts that (1) many sport and subsistence fish species already have mercury concentrations exceeding acceptable threshold criteria, (2) background risk quotients (RQ) for all human populations analyzed already exceed 1, and (3) the mercury levels in the St. Louis River watershed have been deemed high enough that the statewide mercury TMDL will not be sufficient to remove fish consumption restrictions in this region. Therefore, any additional mercury releases to the environment are exacerbating an already unacceptable risk situation in the area.

All increases in mercury releases are contrary to the goals of the 1991 “Binational Program to Restore and Protect the Lake Superior Basin” to establish a Zero Discharge Demonstration Program for nine critical pollutants, including mercury.

Comment 15

According to the PSDEIS, the MPCA conducted a review of the NorthMet Project Proposed Action mercury emissions and determined that it will not impede the reduction goals (Section 5.2.7.2.5). The mercury TMDL for the St. Louis River has not yet been established due to insufficient understanding of mercury dynamics in the watershed. It is known that the statewide TMDL is insufficient for reducing mercury to acceptable levels in fish of the SLR. Since there is no SLR mercury TMDL available, the impact of the project’s mercury emissions on reduction goals in the area cannot be adequately assessed.

Comment 16

Increased mercury, especially in fish, could negatively impact cultural resources, especially for local Native American tribes who rely on fish as a major source of subsistence food and who view fishing and fish consumption as vitally important cultural and spiritual activities. This is not acknowledged in the PSDEIS. Further, fish harvest is a treaty reserved right of these tribes. The presence of mercury in fish at levels that restrict consumption threatens the ability of the tribes to exercise this treaty right.

Wild Rice Section

Wild Rice Sulfate Standard

The State of Minnesota has promulgated a 10 mg/l sulfate standard for Wild Rice waters. There is extensive scientific support for the fact that sulfate negatively affects wild rice. Tribal cooperating agencies, the 1854 Treaty Authority, and GLIFWC have commented numerous times on this issue and provided extensive background information to support the need to protect wild rice from sulfate. Additional scientific support is available through the MPCA document *The Sulfate Standard to Protect Wild Rice Study Protocol* (MPCA 2011).

Yet, the PSDEIS, like the 2009 DEIS, continues to prevaricate on the issue of sulfate impacts to wild rice. It is puzzling that this error remains after all the information and perspectives provided to the lead agencies and their contractor.

The point is simply this. A 10 mg/l sulfate standard applies in wild rice waters. All extraneous discussion that attempt to minimize the validity or applicability of that standard should be removed from the PSDEIS.

Seasonal Application of the Sulfate Standard

The MPCA has determined that the 10 mg/l standard can be applied seasonally; essentially during winter months when the plant is not growing. We fundamentally disagree with this interpretation because there is no scientific basis for stating that seed is not affected by high sulfate levels while it lays dormant over the winter or that the effects of high sulfate water would not remain into the summer. It is GLIFWC staff position that the sulfate standard should apply all year.

The PSDEIS states the NorthMet is not seeking a seasonal application of the wild rice sulfate standard. This position is supported by an email from Bill Johnson of the MNDNR dated 6-19-2013 that states “Finally please note that PolyMet is not seeking the application of the seasonal wild rice standard at this time. They intend to meet the 10 mg/l standard year round.” We believe this statement is misleading. The PSDEIS indicates in several sections that the goal is to transition from mechanical water treatment to passive water treatment systems. These passive water treatment systems are described in the Adaptive Water Management Plan v5 (March 2013). Descriptions in the AWMP as well as page 5.5.2-200 of the PSDEIS state:

“The West Pit overflow non-mechanical treatment system would be designed to discharge only during September and October in order to comply with the seasonal sulfate discharge criterion for wild rice downstream of the Mine Site. The 2-month discharge period would result in a higher flow rate and larger treatment system than would be required for continuous discharge.”

The above statement is in contradiction of other sections of the PSDEIS and the MNDNR statements that the applicant is not seeking a seasonal application of the standard. This contradiction should be addressed.

Embarrass River Watershed

Historic Data and Information

We are aware of the MPCA determination on waters that are defined as supporting the production of wild rice. We believe that the process used to inform this determination must incorporate historic information of wild rice presence, abundance and habitat. The following section provides historic information on wild rice that, when viewed in combination with other more recent information, suggests that the Embarrass River produces or has produced wild rice in several areas upstream of the current point of compliance. Therefore, we suggest that the compliance point for the wild rice sulfate standard should be upstream of the current location at all areas where rice is growing.

Manoomin or Wild Rice can be found throughout the Great Lakes but the areas of greatest concentration are in Minnesota and Wisconsin (Figure 1) (Peter David, GLIFWC wild rice biologist, personal communication, Jenks 1901, Moyle 1944, MRC 1969). The areas of greatest concentration, which are defined as wild rice districts by Jenks, encompass lakes and streams within the region covered by glacial outwash. Jenks' description of the wild rice district is often cited in other publications that describe the range of wild rice (GLIFWC, 1999). Jenks provides additional information on wild rice distribution by stating that within the wild rice district, rice is found wherever there is suitable habitat. Specifically:

“Farther south the St. Louis River system tells the same tale – the streams all bear abundant stores of wild rice” (Jenks, 1901, page 1035)

This publication supports the accounts of tribal members from the tribes acting as cooperating agencies for this project. The draft Cultural Landscape Report prepared as part of the Polymet SDEIS dated September 15, 2011 states, “With the potential for wild rice in the shallow margins of lakes and streams, and abundant wild plant, fishing and hunting habitats, portions of the Preliminary Project APE may have been very attractive to the Ojibwe” (pg. 48). That report also includes an account from a Bois Forte tribal member indicating that harvest occurred on the Embarrass River. Another tribal member stated that she knows of a family that harvested wild rice in the vicinity of the LTV tailings dam on the Embarrass River. These specific descriptions would indicate harvest occurring upstream of Embarrass Lake and upstream of Wynne and Sabin Lakes. This supports the notion of abundant wild rice stands in areas where only smaller stands now remain.

Another corroborating piece of information is the presence of a wild rice farm straddling the Embarrass River. This wild rice farm operated from 1957 until 1993 when the operation went bankrupt (Barr, 1995). Aerial Photos taken in the spring of 1991 and 1992 show the flooded rice paddies and some ditches connecting the farm to the Embarrass River (Figure 2). The use of water from the river in the farm operation clearly defines the Embarrass River as used for the production of wild rice. Figure 2 also shows that Unnamed Creek (Labeled Rice Farm Creek in Figure 2) was likely a source of water for the farm. This creek currently originates at the northwest corner of the LTV tailings basin (Figure 3). According to the Clean Water Act (CWA) this use of water for production of wild rice is a designated use. As such, the sulfate standard applies for the Embarrass River.

Wild Rice Habitat

Field data collected by Barr Engineering (Barr, 2011) indicates that mine related sulfate effluent has already impacted the river to the point of exceeding the wild rice standard. The Draft Staff Recommendation does not provide information on how the MPCA considered the existing water quality in its recommendation and to what extent the high sulfate values have already impacted wild rice on the Embarrass River. This basic analysis should be part of describing existing conditions in the PSDEIS. A description of how the issues of wild rice habitat protection and existing elevated sulfate levels in the Embarrass River water were treated in the development of the recommendation is needed. Wild rice in this area is a degraded resource. As such, all remnant populations are in need of protection. This need is further emphasized by the designation of the Embarrass River as impaired in the 2012 draft 303d list (Figure 4)

The current wild rice standard language clearly states that wildlife use of wild rice is an important factor in protecting the plant. It is not clear how MPCA staff determined that the number of wild rice plants upstream of the current point of compliance is not enough to be used as a food source by wildlife. GLIFWC staff is not aware of research that defines the number of plants or the density of a rice bed that would make it usable to blackbirds, muskrat, geese, or other wildlife. A single plant can provide nutrition to wildlife. Furthermore, browsing by wildlife is one of the reasons that wild rice fluctuates in abundance and density from year to year (Peter David, GLIFWC wild rice biologist, personal communication). The variability that is observed in the wild rice survey data on the Embarrass River may well be the result of wildlife use. Finally, Barr Engineering field notes indicate wildlife is using the wild rice stands in the area. These observations of browsing include small stands that are classified in the lowest density and lowest abundance categories (Barr, 2013). This supports the tribal position that all locations where rice is growing should be points of compliance for the 10 mg/l sulfate standard.

Summary and Conclusion.

Based on available information the GLIFWC staff believes that productive wild rice waters on the Embarrass River are where wild rice is currently growing and is confirmed to have been present in the past. The basis for this view is:

- Wild Rice has been present at these locations during at least one of the four survey years (2009 – 2012).
- The wild rice sulfate standard is 10 mg/l. Language attempting to cast doubt of the current applicability of this standard should be removed. Further, there is no scientific support for the seasonal application of the standard.
- Wild Rice is food for wildlife regardless of its density and the observed inter annual fluctuation in abundance of wild rice in the Embarrass River is consistent with the ecology of wild rice. Barr field notes support this position.
- Historic information from tribal sources indicates past harvest in this area and non-tribal sources support the assertion that this is an area where wild rice was found.
- The existence of a rice farm in this area is consistent with the assertion that the Embarrass River water quality was supportive to wild rice prior to mining impacts.
- Wild rice in the Embarrass River endures despite degraded water quality. It is likely that the degraded water quality has decreased the abundance of wild rice in this river.

It is important to note that this view is based on current information and field data. Should new information be developed or field data be collected, this view may change.

Underground Mine and West Pit Backfill Alternatives

GLIFWC staff believes that the underground mine and west pit backfill alternatives have been prematurely eliminated from consideration in the PSDEIS for the NorthMet project. We believe that there is potential for significant environmental benefits to these alternatives when compared to the proposed action. This document will provide questions and discussion on each of these alternatives. However, we believe that these alternatives are related to one another in terms of the issue of inferred ore deposits at depth and foreseeable future actions at this site. This issue impacts the accuracy of information in the PSDEIS and is discussed below.

Underground Mine Alternative

The Underground Mining Alternative Assessment for the NorthMet Mining Project and Land Exchange Environmental Impact Statement document dated February 5th 2013 provides the lead agency rationale for eliminating the alternative from further analysis in the SDEIS. The document states that for an alternative to be evaluated it must meet 5 screening criteria:

1. be technically feasible
2. be available
3. offer significant environmental benefits over the proposed project
4. meet the purpose and need
5. be economically feasible

The lead agency position paper correctly states that the underground alternative would offer significant environmental benefits over the proposed action. In some areas these benefits would be substantial. The roughly 1000 acre wetland fill could be almost completely eliminated and the amount of tailings and waste rock generated by the project would be significantly reduced. The water quality and quantity impacts on surface and groundwater would be mitigated. This is particularly important given the probability that the NorthMet project will violate water quality standards and the certainty that the project would require perpetual water treatment. In addition to the environmental benefits the document correctly states that underground mining is technically feasible and available at the site. It is important to note that with underground mining the land exchange with the Superior National Forest would not be needed therefore environmentally sensitive areas like the 100 mile swamp and essential Lynx habitat would remain in the federal estate.

The only rationale that is used to eliminate the alternative is economic feasibility. All other objectives of the purpose and need statements in section 1.3.2.1 of the PSDEIS are met. Therefore, the question on further analysis is determined by the applicants' assessment of the economics of the alternative. This leads to several questions.

Section 1.2 of the Underground Mining Alternative Assessment describes the assessment as a semi-quantitative screening analysis. Section 1.2.2 of the Underground Mine Alternative Assessment states "The information provided by PolyMet was reviewed by technical staff at the MNDNR and was determined to be sufficient for a screening level review of the feasibility of underground mining at the NorthMet Deposit". What is the accuracy of a screening level review? The determination that a project is economic or not necessarily relies on rather detailed analysis. The following are some descriptions of the accuracy that can be expected for different types of analysis:

- **Conceptual Studies - Desktop/Order of Magnitude:** Conceptual/Strategic studies are conducted early in the project life cycle to assist exploration strategy and to identify fatal flaws and development opportunities. These studies are typically used to support the decision to progress to Preliminary Economic Assessment. **Order of Magnitude (+/- 50%) estimating accuracy** is typical for this level of study.
- **Preliminary Economic Estimates:** The Preliminary Economic Assessment (PEA) is a scoping-level study which relies on information from disciplines such as geotechnical, environmental, infrastructure and markets in addition to the core inputs from mining, geology and metallurgy. Capital and operating cost **estimates for the project will typically be estimated to +/-30%.**
- **Preliminary Feasibility Studies:** The Preliminary Feasibility Study (PFS) develops the concepts and work completed in scoping-level studies, examines necessary trade-offs or optimizations, and may progress resources into reserves. Multi-disciplinary technical teams will improve the accuracy of capital estimates through the completion of additional engineering. Disciplines such as geotechnical, environmental, infrastructure and markets are utilized in addition to the core inputs from mining, geology and metallurgy. Capital and operating cost estimates for the project **will typically be estimated to 20-25% overall accuracy.** Engineers and geologists have experience in the completion of Pre-Feasibility Studies and can manage the resources required for such work.

A description of the error term in the economic assessment needs to be developed and clearly explained in the SDEIS.

Section 2.0 of the Underground Mining Alternative Assessment states that the project should “(provide sufficient income to cover: operating capital and other costs with an adequate return to investors). If an adequate rate of return is to be included in the economic feasibility it should be defined. What do the authors ascertain is an adequate return to investors? Is the underground mine alternative excluded because of a net negative return to investors or a positive return that is not deemed adequate? The November 2012 PolyMet power point presented by Douglas Newby projects an after tax Internal Rate of Return (IRR) of 30.6% for the open pit mine. Is the same assumption made for an underground mine?

Section 2.1 discusses the significant environmental and/or socioeconomic benefits. However, no economic data was presented related to the environmental benefits related to the underground mining alternative. For example:

- There is no mention that an underground mine would not require a \$4 million land exchange with the United States Forest Service.
- No mention of the economic benefits (environmental goods and services) provided by wetlands
- No mention of the economic impact of perpetual maintenance and water treatment at the site. Of note, there is no discussion on the cost of wetland mitigation activities that are needed with an open pit mine. An underground mine would not require extensive wetlands mitigation costs for wooded swamp and bog sites that could reach between

\$35,460,000-\$110,205,000 (i.e. 1200 acres x 1.5 rate x \$19,700/acre ACOE source and 1200 acres x 1.5 rate x \$61,225/acre MN Department of Transportation – (i.e. - Mitigation of Impacts to Fish and Wildlife Habitat: Estimating Costs and Identifying Opportunities, Environmental Law Institute, October 2007, Corps District, St. Paul, Corps District Data Average \$19,700 and Wetland Mitigation in Abandoned Gravel Pits, Minnesota Department of Transportation, Research Services, Office of Policy Analysis, Research & Innovation, March 2010, Final Report#2010-11, Executive Summary page 3)

The Underground Mining Alternative Assessment relied heavily on an InfoMine model to determine economic feasibility. However there is no detail on the model itself, the model assumptions or how the model calculates its results. For a complete evaluation of the alternative, a review of this model should have been done by the lead agencies.

Finally, it appears likely that the project as proposed will violate applicable water quality standards. This means that the current proposal is not likely to be permitted. Because of this, it seems reasonable that an underground alternative be considered as an additional mitigation measure.

West Pit Backfill Alternative

Based on the lead agency memorandum titled Co-lead Agencies' Consideration of a West Pit Backfill Alternative dated April 11, 2013 it is clear that this alternative meets the purpose and need, is available, is technically feasible and is economically feasible. The document argues that environmental benefits are unclear. However, because of the screening level analysis used by the lead agencies the full effect of the alternative on the environment is not known. Page 3 indicates that there is no information to determine water quality projections under this alternative. Therefore the primary potential benefit of this alternative is not addressed. Until this information is developed, GLIFWC staff maintain that backfill of the west pit may provide long term water quality benefits. Given that the current project is expected to violate water quality standards, additional mitigation is needed and this alternative should be more fully analyzed.

Inferred Ore Deposits at Depth and Reasonably Foreseeable Future Actions

The proposed NorthMet project proposes to mine a relatively small portion of the ore body. Figure 3.2-10 of the PSDEIS indicates that an upper mineralization zone and a portion of the Unit 1 mineralization are the targets. This mine plan appears to leave behind a substantial portion of ore. GLIFWC staff has argued that the remaining ore could be accessed through underground mining methods. According to the Co-lead Agencies' document "Consideration of a West Pit Backfill Alternative" dated April 11, 2013, a major reason for the development of an open pit mine plan is that there is a lease agreement between PolyMet and the owners of mineral rights immediately southwest of the toe of NorthMet's west pit. These private lease agreements apparently include using the west pit as a portal for future mining activities. In addition, tribal cooperating agencies have provided the lead agencies with power point presentations from PolyMet staff to their investors that tout the potential for future mining of these mineral resources southwest of the west pit.

If the west pit is to be used as a portal for this future mining, then that should be described in the PSDEIS and the environmental consequences assessed. The Evaluation of Backfilling the NorthMet West Pit (December 2012) states on page 2 “mineralization on the western end is much more flat laying, dipping at about 15 degrees and could be developed in the future via expansion of the proposed open pit mining operation and/or underground mining from the base of the west pit.” It appears that the PSDEIS is describing a project that is not complete in that future mining is not included. What are the implications of developing an underground mine that extends from the west pit to surface and groundwater resources of the Partridge River watershed?

Another stated reason for avoiding backfill for the west pit is the lease requirement of not encumbering the mineral resources to the southwest. The lead agencies have also noted this goal in the PSDEIS. The assertion that backfilling the west pit would encumber minerals is ludicrous. We disagree with the notion that the only way to access minerals at depth is through the bottom of the west pit. These minerals could be accessed through other standard underground mining techniques from other locations. In fact, these minerals are accessible now and would continue to be accessible even if the NorthMet project is never built. Taking advantage of an existing pit may provide economic benefits to a mining company but it is unclear why a regulatory agency would prefer this method without first conducting an analysis. If the lead agencies are taking the position that the preferred alternative of a future underground project includes a portal through the west pit, then they need to provide a scientifically defensible reason for that decision.

Finally, the titled Co-lead Agencies’ Consideration of a West Pit Backfill Alternative dated April 11, 2013 provides several reasons for the conclusion that backfill would not provide significant environmental and socioeconomic improvements over the proposed action. Page 3 of the document clearly states that there has been no analysis done to support these conclusions.

It appears that economic considerations of a future mine expansion are the only concrete reasons for not conducting an analysis of the environmental and socioeconomic benefits of backfilling the west pit. The NorthMet project as proposed is a perpetual maintenance and water treatment facility. It seems logical that every available option that might improve the long term impacts of the project should be explored regardless of the commitments that applicant may have made on their mineral lease. GLIFWC staff suggests that this alternative has been eliminated prematurely and that a full analysis is needed.

GLIFWC Wetlands Attachment

Analysis of Indirect Wetland Impacts from Groundwater Drawdown

Enclosed please find an analysis of indirect impacts to wetlands due to drawdown at the NorthMet mine site developed by the Great Lakes Indian Fish and Wildlife Commission (GLIFWC). GLIFWC is an intertribal agency exercising delegated authority from 11 federally recognized Ojibwe (or Chippewa) tribes in Wisconsin, Michigan and Minnesota.¹ Those tribes have reserved hunting, fishing and gathering rights in territories ceded in various treaties with the United States. GLIFWC's mission is to assist its member tribes in the conservation and management of natural resources and to protect habitats and ecosystems that support those resources.

As you know, the proposed Polymet mine is located within the territory ceded in the Treaty of 1854. GLIFWC member tribes have expressed concern about the potential impacts of sulfide mining, whether those impacts occur within the 1854 ceded territory, in the 1842 ceded territory, which includes portions of Lake Superior, or the 1837 ceded territory. The following analysis is submitted by GLIFWC staff with the explicit understanding that each GLIFWC member tribe or any other tribe may choose to submit analysis and information from its own perspective.

Potential impacts to wetlands due to groundwater drawdown at the NorthMet mine site are described in the NorthMet Project Wetland Data Package Version 7 dated March 1, 2013 and summarized in the 2013 PSDEIS. Potential impacts due to drawdown are assessed using an analog method where information from another site is used to provide a best guess as to how wetlands surrounding NorthMet might be affected. The data package states that this method came out of the Wetlands IAP process however it does not state that GLIFWC and other cooperating and reviewing agencies have objected to using this method. The objections are detailed in the comments that GLIFWC provided within the IAP process (Attachment A).

GLIFWC continues to believe that the analog method can be informative in the process. We also reiterate that the lead agencies' reliance on analogs as the only source of information to gauge impacts from pit dewatering is not a rigorous approach to impact estimation. However, because of the lead agencies insistence that this method be used in the SDEIS, GLIFWC is providing an independent analysis using information from other mine pits located on the Mesabi Range.

1 GLIFWC member tribes are: in Wisconsin -- the Bad River Band of the Lake Superior Tribe of Chippewa Indians, Lac du Flambeau Band of Lake Superior Chippewa Indians, Lac Courte Oreilles Band of Lake Superior Chippewa Indians, St. Croix Chippewa Indians of Wisconsin, Sokaogon Chippewa Community of the Mole Lake Band, and Red Cliff Band of Lake Superior Chippewa Indians; in Minnesota -- Fond du Lac Chippewa Tribe, and Mille Lacs Band of Chippewa Indians; and in Michigan -- Bay Mills Indian Community, Keweenaw Bay Indian Community, and Lac Vieux Desert Band of Lake Superior Chippewa Indians.

Analog Data Used

- Randal Property Wells T3 and T4 (Source: Crotteau, 2013), Rhino and Highway 7 wells in the vicinity of the Canisteo pit. (Source: Adams and Liljegren 2011)
- MNDNR observation well, in the vicinity of Hibtac pits (Source: Crotteau, 2013).
- Dom-ex and Pinto wells north of Hibbing in the vicinity of Hibtac (Source: Crotteau, 2013).
- Keewatin City wells #1 and #2 in the vicinity of the Keetac pit (Source: Liesh and Associates Technical Memorandum, 2009).

Contour lines showing the analog well information in relation to the proposed NorthMet mine site are provided in Figure 1.

Wetland Analog Impact Zones and Significance Criteria

GLIFWC objections to the impact zones developed by the lead agencies are presented in Attachment A. We believe these distance zones are somewhat arbitrary and continue to have concerns regarding their use. Despite these concerns, we are using similar impact zones so that the results we present can be compared to the analysis that is presented in the NorthMet Project Wetland Data Package Version 7.

GLIFWC impact zones (Figure 2) are:

- Zone 1 – 0 to 1000 feet from the mine pit edge.
- Zone 2 – 1000 to 2000 feet from the mine pit edge.
- Zone 3 – 2000 to 5000 feet from the mine pit edge.
- Zone 4 – 5000 to 10000 feet from the mine pit edge.

For impact assessment, this analysis applies the significance criteria outlined in large table 8 of the NorthMet Project Wetland Data Package Version 7. However, GLIFWC does not automatically exclude wetlands that have been classified as ombrotrophic in the data package from being considered impacted by drawdown. Literature indicates that ombrotrophic wetlands can and are impacted by drawdown. Several studies document vegetation changes at ombrotrophic bogs in Finland (Murphy et al, 2009, Grootjans et al 2009, Jaatinen et al 2006, Vassander 1995). In general, groundwater drawdown beneath these ombrotrophic bogs leads to increases in the root mass of woody vegetation species as well as greater dominance of woody species at the surface. The functions and values changes resulting from the drawdown induced change in vegetation in ombrotrophic bogs are not characterized in the PSDEIS.

The analysis in the NorthMet Project Wetland Data Package Version 7 relies on surface observations of plant communities to classify bog wetlands as ombrotrophic or minerotrophic. GLIFWC agrees that this is useful information but we maintain that it is not a substitute for detailed understanding of the relationship of the water table and wetlands at the site. NorthMet Project Wetland Data Package Version 7 states that hydraulic conductivity in the unconsolidated deposits around the mine site can range between 0.012 to 31 feet per day. This range of values indicates that substantial water movement within the aquifer can occur. Therefore unless there is information on whether the unconsolidated deposits that underlie wetlands are saturated or not it

is not possible to know the degree to which groundwater supports wetland hydrology. Despite the assumption in the wetlands section of perched conditions for over 50% of wetlands at the mine site, Section 4.2.2-5 of the PSDEIS states that saturated conditions exist within the unconsolidated deposits and the underlying bedrock. It also states that recharge to the bedrock comes from leakage from the overlying surficial aquifer. Given these statements describing vertical movement of water in the mine site area, it does seem reasonable to also assume a vertical hydrologic connection between ombotrophic wetlands and the surficial aquifer.

The data package and PSDEIS assume that wetlands deemed to be ombotrophic are not connected to groundwater and therefore are not impacted by drawdown. This assumption is based mostly on plant lists and surface observations. We believe that this assumption is not supportable. Instead, GLIFWC assumes that there is at least a partial connection between ombotrophic wetlands and groundwater. Therefore, if groundwater under these “perched” wetlands is drawn down by several feet, this new head pressure would lead to impacts to the wetlands because of a “bathtub effect”. In other words, water would seep out of ombotrophic wetlands in areas where there is a hydrologic connection to the saturated layer. This assumption is the support for assigning significance criteria for Deep Marsh/Shallow Marsh and Open bog wetlands for the Crandon project. It is this project that is the basis for the significance criteria used in the PSDEIS (large table 8 of the NorthMet Project Wetland Data Package Version 7).

Finally, the data package ignores the fact that the proposed NorthMet pits would be over twice the depth of a typical pit located up on the Mesabi Range and double the depth of the Canisteo pit analog. Thus the hydrologic effects on the surrounding aquifer will likely be greater for the NorthMet project.

Zone 1 Impacts (0 – 1000 Feet)

Wetlands within Zone 1 are depicted in Figure 3. Information provided by MNDNR Mining Hydrologist Michael Crotteau indicates that 2 wells at the Randall property (Wells T3 and T4) were artesian before a drain tile was installed to reduce groundwater levels in the area. This indicates a strong hydrologic connection between these wells and the Canisteo pit approximately 700 feet from the edge of the pit (Figure 4). The basement of the Randall residence was built when the Canisteo pit was dewatered is at an elevation of 1300 feet above sea level. The surface elevation at the site is 1310.73 feet above sea level. This indicates at least an 8 to 10 foot increase in the elevation of the water table 792 feet away from a reflooded Canisteo pit.

Based on these analog wells, a drawdown of up to 10 feet could affect wetlands in zone 1. We believe it is reasonable to assume that 5 to 10 feet of drawdown would occur throughout zone 1. In addition, these wetlands are often remnants of wetlands directly impacted by the pits and stockpiles, are surrounded by roads and ditches, and directly border the pits. Therefore, all wetlands in zone 1 are assessed as severely impacted (Table 1).

Table 1. Zone 1 impact assessment.

Zone 2 Impacts (1000 – 2000 Feet)

Wetlands within zone 2 are depicted in Figure 5. The Dom-ex well is located on the north side of the city of Hibbing is 1320 feet from the nearest dewatered pit at Hibtac. According to Mr. Crotteau this well experienced a drop of 3.07 feet in response to pit dewatering. Because wells in zone 3 (discussed below) indicate drawdown values ranging between 1 and 3 feet, and wells in zone 1 indicate dewatering of up to 10 feet, this analysis assumes that drawdowns in zone 2 are on the order of 3 to 5 feet. In addition to drawdown, wetlands in zone 2 are remnants of wetlands directly impacted by the project are surrounded by roads, ditches and other mine features, or have sections in zone 1. These wetlands can also be impacted by aerial deposition of mine related contaminants. The impact assessment for wetlands in zone 2 is outlined in Table 2.

It is important to note that a section of the upper Partridge River is located within Zone 2. Drawdowns of 3 to 5 feet under a river could severely reduce baseflow leading to reductions in flow in the river channel. Reductions in flow could indirectly impact riparian wetlands downstream.

Table 2. Zone 2 impact assessment.

Zone 3 Impacts (2000 – 5000 Feet)

GLIFWC has modified Zone 3 in response to available data (from 2000 to 3500 feet in data package to 2000 to 5000 feet). Wetlands within zone 3 are depicted in Figure 6. The Rhino and Highway 7 wells are 2150 and 2625 feet respectively from the Canisteo pit. In response to reflooding in the pit, the Rhino well responded with a greater than 1 foot increase and the Highway 7 well responded with a greater than 2 foot increase. Two additional wells provide analog information for this zone. First, the Pinto well north of Hibbing is 2112 feet from the nearest active pit shows a drop of at least 3.55 feet in response to pit dewatering. Second, a MNDNR observation well located 4224 feet from the nearest active pit at Hibtac shows a 3.5 foot drop in water level. Attachment B is a slide from a presentation given by Mr. Crotteau outlining the water level drop at this well.

In addition to these wells, the city of Keewatin has been greatly impacted by pit dewatering. Well #2 at approximately 4220 feet from the Mesabi Chief pit dropped 75 feet in response to a 150 foot drop in water levels in the pit. Water levels in Well #1 at approximately 4750 feet from the pit are also correlated with pit dewatering at the pit although the report indicates that the amount of water drop was less than at well #2. The correlations between pit

dewatering and water level drop at the wells were also supported by chemical characterization of the water in the pit (Attachment C).

These two wells are drilled into the bedrock and therefore it is not clear how those large water level drops in bedrock wells are expressed in the surficial aquifer and in wetlands. However, as previously stated, the PSDEIS does document vertical movement of water between the surficial aquifer and the bedrock aquifer. Regardless, this information fits with the analog approach of the lead agencies for NorthMet and illustrates that pit induced groundwater drawdowns can be expected to extend well into zone 3. The analog information suggests that drawdowns of 1 to 3.5 feet can be expected throughout zone 3. The impact assessment for zone 3 wetlands is provided in Table 3.

Zone 3 wetlands on the north side of the mine pits are also subject to impacts related to the dewatering of the Northshore pit. Figure 8 illustrates the possible extent of drawdown impacts at the Northshore pit based on the Hibtac well data provided by the MNDNR Mining Hydrologist Michael Crotteau. This cumulative effect is not included in version 7 of the data package or the PSDEIS. This analysis should be conducted.

It should also be noted that there are wetlands that fall within Zone 3 that have not been delineated by PolyMet. These wetlands should be delineated and the impacts of the combined Northshore and NorthMet drawdown on these wetlands should be assessed by the applicant.

Most of the east west reach of the Partridge River on the north side of the mine pits is within zone 3. As previously suggested, 1 to 3.5 feet of drawdown could be a significant impact to the hydrology of the river. In addition, the City of Kewaatin wells indicate that groundwater drawdown of tens of feet in the bedrock aquifer below the Partridge River are likely. This potential hydrologic impact should be assessed as part of the NEPA process. Finally, reductions in flow to the Partridge River could indirectly impact riparian wetlands downstream.

Table 3. Zone 3 impact assessment.

Zone 4 Impacts (5000 – 10000)

Wetlands within zone 4 are depicted in Figure 7. There is no well data that can be used to draw conclusions about mine pit related drawdown in this zone. Based on Zone 3, it is reasonable to assume that 0 to 1 feet of drawdown would occur under wetlands within this zone.

As discussed above zone 4 wetlands on the north side of the proposed mine pits are also subject to impacts related to the dewatering of the Northshore pit (Figure 8).

Table 4. Zone 4 impact assessment.

Impacts to Riparian Wetlands along the Partridge River

The applicant and lead agencies have ignored repeated requests by cooperating agencies to better characterize the hydrology of the mine site through a robust surface and groundwater data collection program. Therefore reliable data with which to assess the effects of drawdown in the surficial and bedrock aquifers to riparian wetlands along the Partridge River are not available. Based on pit dewatering induced drawdowns at other sites described in this report, it is reasonable to assume that flow in the Partridge River would be significantly reduced if the NorthMet project proceeds as currently designed. This would have an effect on riparian wetlands far downstream. These effects are highly important because of the potential for increased methylation of mercury that is released by the project. To date, these potential impacts have not been characterized.

Summary

GLIFWC disagrees with the use of the Canisteo pit analog as the only method for estimating drawdown impacts for the NorthMet project. Repeated requests for a robust approach have not been successful. Therefore, this analysis uses the lead agencies own analog approach with data that is not included in the PSDEIS analysis. It is important to note that this analysis also uses the impact criteria developed for the Crandon project in Wisconsin which is the basis for impact criteria in the PSDEIS.

The assumption that ombrotrophic bogs are completely separated from the surficial aquifer is not supportable. The extent of the hydrologic connection should be investigated.

Based on GLIFWCs analysis, wetlands severely impacted by drawdown total 3188.62 acres in zone 1; 2458.12 acres in zone 2; and 273.01 acres in zone 3. Severe indirect impacts to wetlands from mine pit drawdown total 5719.75 acres. All wetlands potentially impacted by drawdown are depicted in Figure 9. The Corps should require up front mitigation for all severely impacted wetlands. At a minimum, up front mitigation for all wetlands in zone 1 should be required. Additional up front mitigation should be considered for wetlands that are classified in the moderate to severe category. Robust monitoring is required for wetlands in the moderate category.

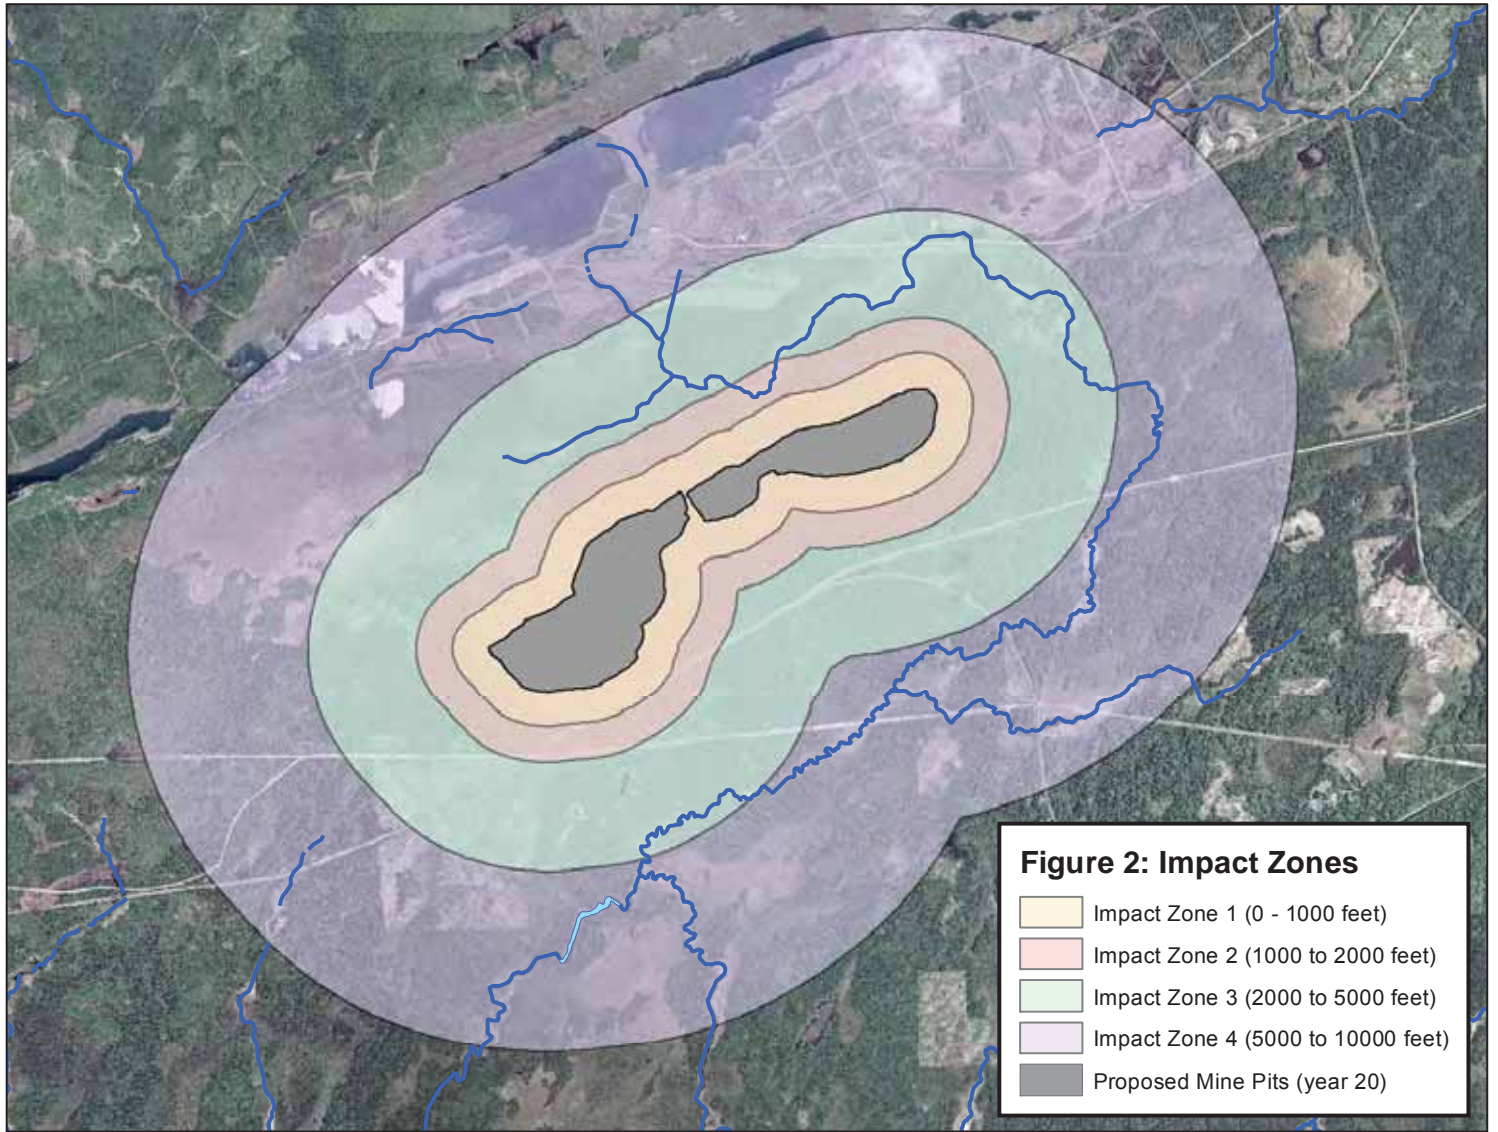

Impacts for wetlands suffering the cumulative effect of NorthMet and Northshore projects should be assessed and mitigation required. Un-delineated wetlands south of the Northshore pits should be delineated and included in the analysis. Impacts to riparian wetlands cannot be discounted given the shortcomings of the analog method and the inadequate characterization of surface and groundwater hydrology for the mine site area.

Wetland Resources IAP Draft Summary Memo

Line Number	Comments
General Comments (per line number)	<i>[insert your name]</i>
105	The Co-lead position described here is unchanged from the 2009 DEIS. This position is contrary to standard analysis that mining companies have to conduct as part of sulfide mine EIS processes across the country.
118	This characterization requires further detail. According to our meeting notes, the need for a quantitative assessment of drawdown at the mine site was a unanimous position among the tribal cooperating agencies, the EPA, and the Fish and Wildlife Service. This position also received strong support from the PCA. This is why the original request by the wetland workgroup for a quantitative method of assessing drawdown impacts at the mine site was described as a "consensus". This should be clarified in the summary memo. See attached comment letter for additional detail on the groundwater modeling issue.
143	GLIFWC staff concur with Margaret Watkins that the cumulative impact assessment should be conducted for the same area that is used in the cultural resource assessment (Wetland area of potential effect).
148	As discussed during the Wetland IAP call of May 13th 2011, baseline data for water quality in wetlands are essential to this analysis. We support the Corps request that the applicant provide a list of available baseline data that will be assessed for adequacy in describing the existing condition and no action alternative. We request that this be specifically included in the workplan.
PolyMet NorthMet Project Co-Lead Agency Workplan Preparation Guidance for Wetland Assessment General Comments	
032	GLIFWC staff maintains that the analogue method proposed by the Army Corps does not provide sufficient information to base the indirect wetland impact analysis for the entire project.
078	GLIFWC staff believe that the analysis area for cumulative impacts is not adequate. See comment on line 143 of the summary memo. In addition, the cumulative impact assessment should cover topics that were not part of the 2009 DEIS. Climate change in the region is a stressor for wetlands. This additional factor should be assessed. Cumulative impacts of Iron Range mine projects on water quality of wetlands should be described.
085	GLIFWC staff do not agree with the Corps' definition of "reasonably foreseeable project". Several mine projects to the east and northeast of Polymet are likely to be proposed, some as early as this summer. A mining company interested in the Dunka deposit will be installing a stream gauge on the upper Partridge River this spring. Because this project will likely impact some of the same areas as Polymet (Partridge River watershed), this project should be included in the analysis.

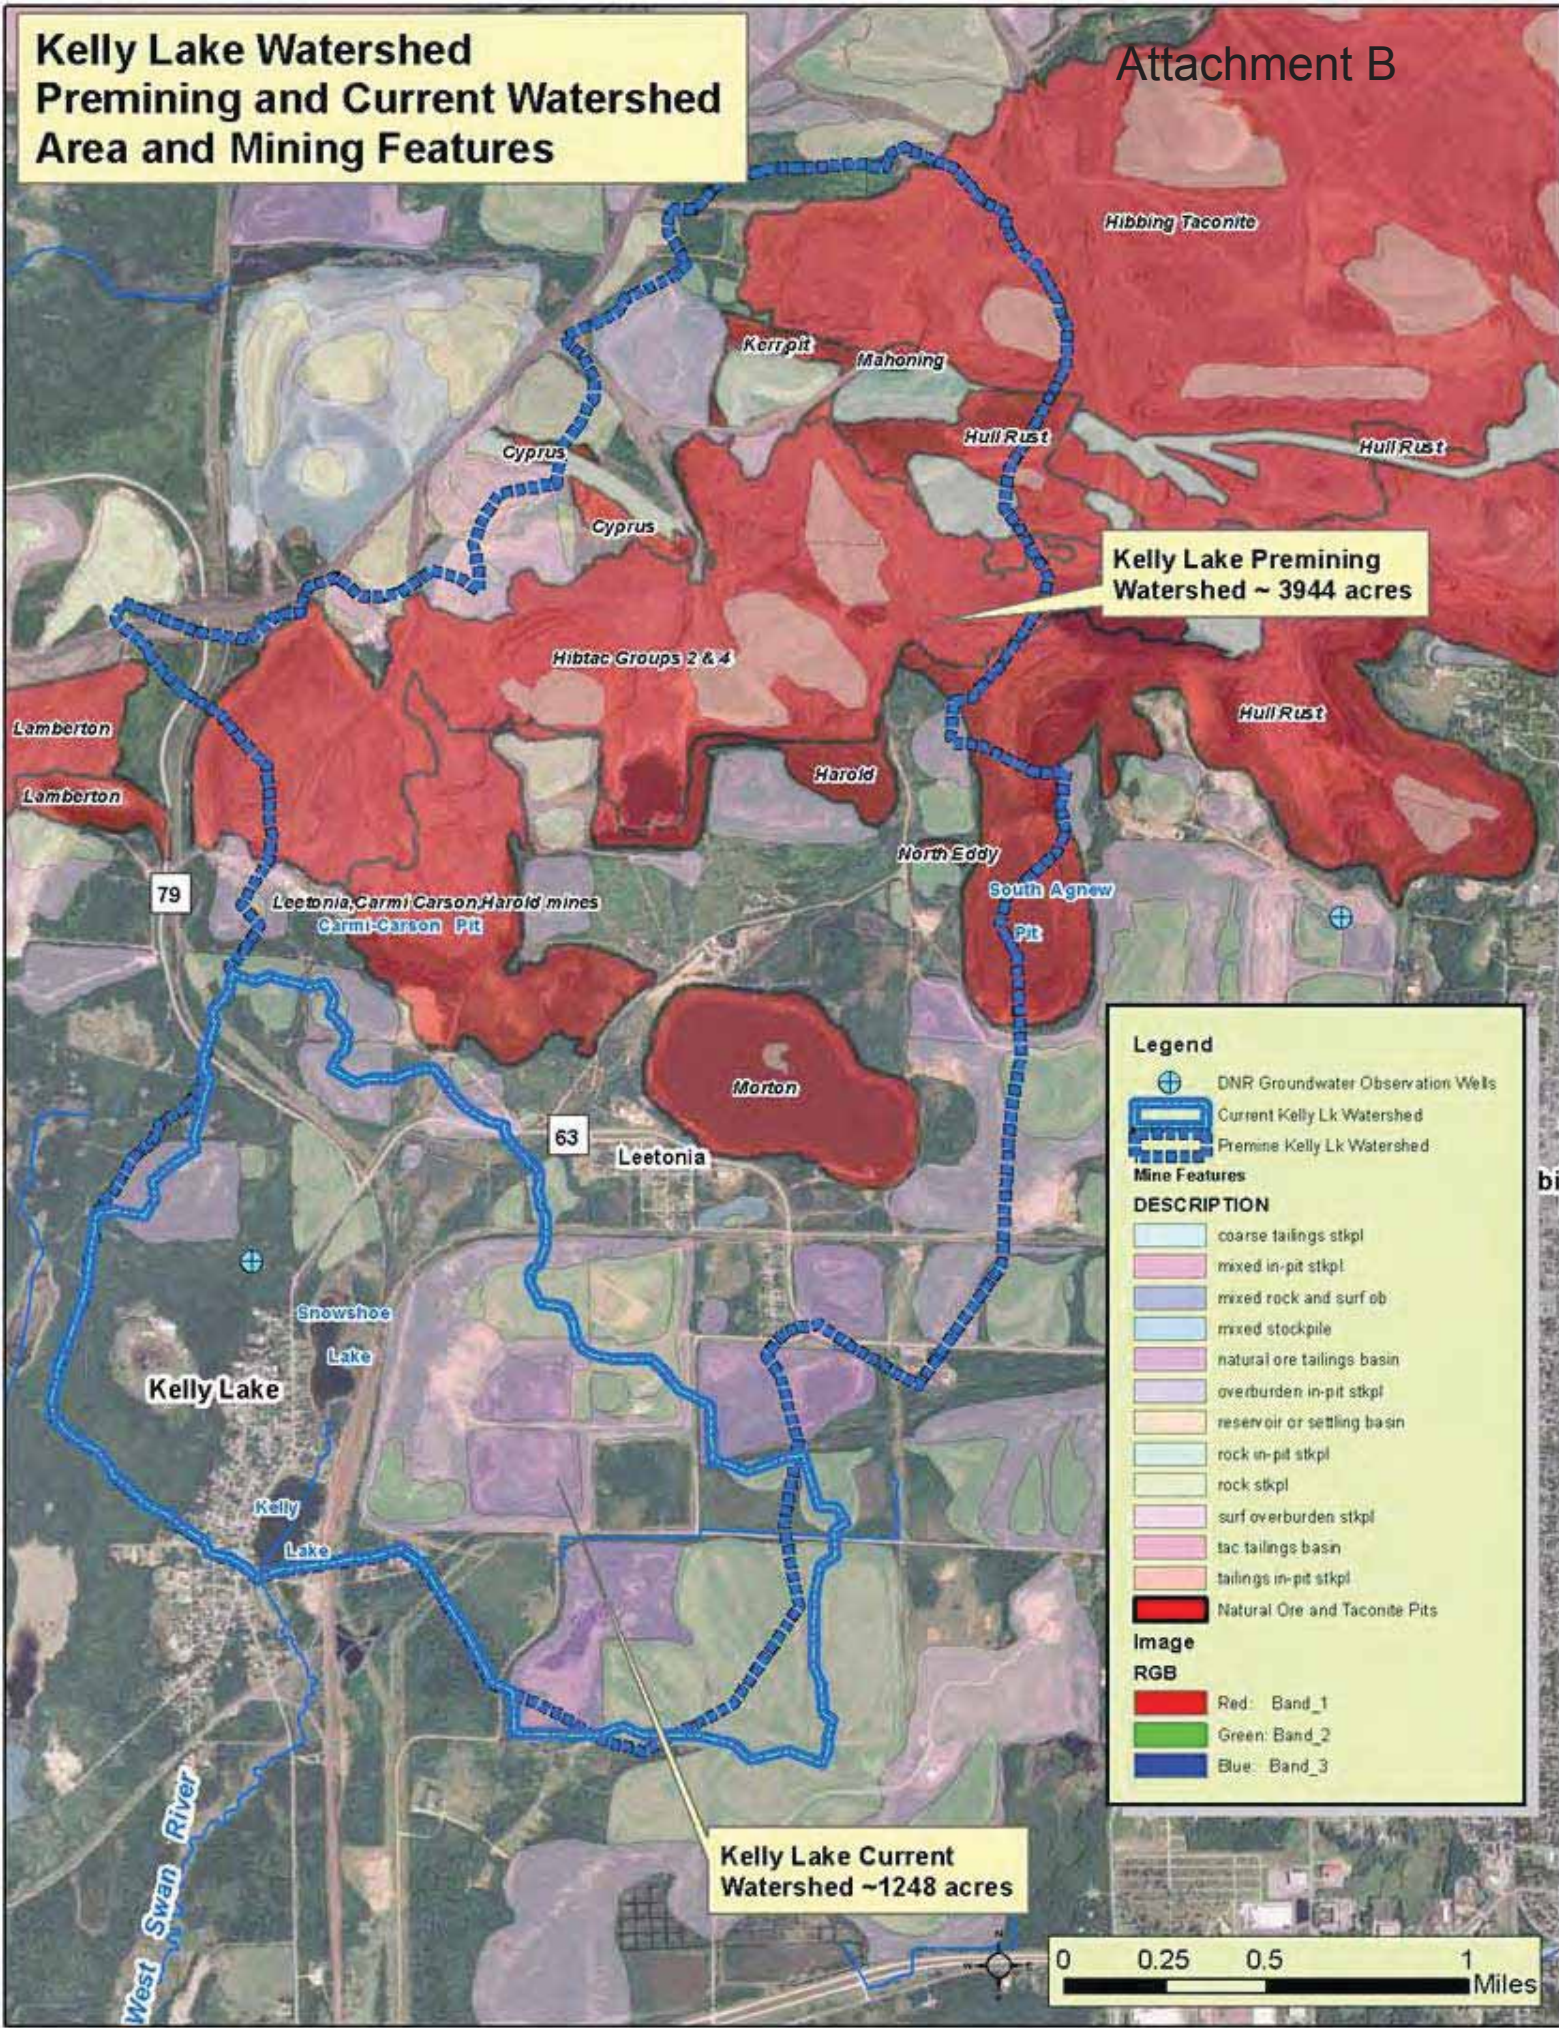

090 GLIFWC staff agree that the analogue data prepared by John Adams can be used as part of the indirect impact analysis. We remain concerned that this analysis is being used as the sole data source for the discussion of indirect wetland impacts at the Polymet mine site. As discussed during the wetland IAP call of May 13th 2011, a detailed report that includes all data and assumptions used by John Adams to assess the Canisteo Pit data should be developed and reviewed by the wetlands IAP group. After that review, a determination on the adequacy of the analysis as an analogue to Polymet can be made.

102 GLIFWC staff believe that these distances are open to a great deal of interpretation. We do not believe that the distance categories listed in this document are conservative interpretations of the Canisteo pit data.
118 The Canisteo Pit data indicated that water levels at a well 2300 feet from the pit were correlated with water fluctuations in the pit. Therefore it is inappropriate to exclude the "high likelihood" category from this distance category.

123 For the same reason stated in the comment on line 118, it is not appropriate to exclude the "high likelihood" or "moderate likelihood" of impact from this distance category.

TECHNICAL MEMORANDUM

TO: Mike Johnson, PE - Liesch Associates, Inc.

FROM: Jim de Lambert, PG - Liesch Associates, Inc.

DATE: February 18, 2009

RE: Water Supply Contingency Plans for Keewatin and Nashwauk

U.S. Steel – Minnesota Ore Operations (US Steel) is proposing to increase production at the US Steel Corporation Keewatin Taconite Facility under a project known the Keetac Expansion Project (the “Project”). The Project involves continuous dewatering operations that are ongoing and will continue in current and future mining areas. These planned activities are expected to generate drawdown in the aquifer locally and potentially at the water supply wells for the Cities of Keewatin and Nashwauk.

This memorandum is intended to provide background on the City water supplies and the Biwabik Iron Formation and to outline a plan to monitor the effects of mine pit dewatering on the aquifer so that appropriate steps can be taken to maintain the water supplies.

Relatively little information exists concerning the hydrogeology of the Biwabik Iron Formation (BIF) and the City water supplies. The Minnesota Department of Health (MDH) has assisted both Cities with Wellhead Protection activities and the results of this work probably represent the most comprehensive source of information concerning the source of water discharging at the City wells. In conducting this work it was apparent that traditional groundwater flow models would not be appropriate tools to estimate capture zones in the fractured BIF Aquifer. Instead, MDH utilized isotopic and chemical characteristics of water from the wells and nearby surface water bodies to estimate the source of water discharging at the wells. This work is summarized in separate reports titled Wellhead Protection Plan for the City of Keewatin - Part I (Walsh 2003) and Wellhead Protection Plan for the City of Nashwauk - Part I (Walsh 2007). Each report includes a delineation of the Wellhead Protection Area (WHPA), determination of the Drinking Water Supply Management Area (DWSMA) and assessments of Well and DWSMA Vulnerability. In addition, the reports include a summary of the hydrogeologic

conditions concerning the city water supplies. Additional information used in preparing this memorandum includes various published maps and reports and personal communication with representatives from MDH, Department of Natural Resources and the Cities.

Keetac Mine Hydrogeology

The Keetac Mine extracts iron ore from the Biwabik Iron Formation (BIF) of the Mesabi Iron Range. The BIF is Precambrian in age, was deposited under marine conditions and is composed primarily of chert and iron minerals. Its subcrop area extends along strike for a distance of at least 100 miles generally from Grand Rapids to Babbitt and varies in width from one to three miles. The BIF has an overall thickness 350 to 750 feet and dips generally to the south at three to twelve degrees (Grout 1951). Information provided by the MDH from a deep test hole drilled near Keewatin suggests a BIF thickness of 590 feet in this area.

According to a suggestion by J. F. Wolf in 1917, and elaboration by J. W. Gruner in 1946 (Grout 1951), the BIF is generally divided into four members. From top to bottom, these are Upper Slaty, Upper Cherty, Lower Slaty, and Lower Cherty. The low grade magnetic iron ores, known as taconite, are mined from the Upper Cherty and Lower Cherty members. The Upper Cherty Member has a thickness ranging from 80 to 250 feet. The Lower Cherty ores are typically 120 to 425 feet thick. The slaty units can alter to form a sticky, clayey rock that generally exhibits low permeability including the Intermediate Slate which is a thin bedded silicate taconite, also known as paint rock that occurs at the base of the Lower Slaty Member. This is an important marker horizon for water supply purposes as it marks the contact with the Lower Cherty Member. Borehole logs suggest that the more productive zones for water supply wells may occur below this contact in the Lower Cherty Member.

In addition to being an important source of iron ore the BIF is also an important aquifer locally. Both Nashwauk and Keewatin, and numerous other range Cities and water users, utilize the BIF Aquifer. Depending on the amount of water desired and other factors, BIF aquifer wells are typically constructed by drilling a casing to solid rock, usually the top of the BIF Formation, and then drilling an open hole to a sufficient depth to obtain the required quantity of water. Yields in the 300 to 600 gallon per minute (gpm) range have been reported from existing wells. For Nashwauk and Keewatin, geochemical work conducted by MDH has indicated that a significant percentage of the water discharging at some of the wells originates from nearby mine pits.

The BIF Aquifer consists primarily of fine grained chert and iron minerals, exhibiting very little primary porosity. Groundwater movement appears to be restricted to zones of secondary permeability controlled by fractures and joints particularly in the cherty portions of the BIF. The MDH has conducted a suite of borehole logs at available wells constructed in the BIF Aquifer in an attempt identify preferred flow paths and to further characterize the hydrogeology of the formation. This information suggests the occurrence of preferred flow zones in both of the cherty members.

The Virginia Formation immediately overlies the BIF while the Pokegama Formation and the Giants Range Batholith underlay the BIF. These bedrock formations generally do not yield significant volumes of water to wells and are generally not considered important aquifers. Up to 200 feet of glacial drift lies above the consolidated bedrock near the Mesabi Range. Where these deposits include saturated granular outwash they may provide a potential source for significant volumes of water.

Little information is available regarding groundwater flow fields in the BIF due to a lack of available wells and detailed water level measurements over time. Mining operations conducted to date have undoubtedly altered natural flow patterns and planned mine dewatering activities in the Mesabi Range will continue to influence flow patterns.

Keewatin Water Supply

In recent years the City of Keewatin has obtained its water supply from two wells, designated Well 1 and Well 2. The City has indicated that it drilled an additional well in 2007, designated Well 3, in response to increasing manganese concentrations at Well 2. All wells are shown on the attached **Figure 1** (Attachment 1). Keewatin Well 3 has been added to the City’s water supply system and Well 2 has been removed from service.

Basic information concerning Keewatin’s wells is summarized on **Table 1** below and logs for each well are included in Attachment 2.

Table 1

Well Name	Well Number	Casing		Open Hole, Elevation (ft msl)		Status	Notes
		Diameter	Depth (ft.)	Top	Bottom		
1	192359	8-inch	249	1224	867	Active	Drilled in 1952/1982
2	228828	10-inch	344	1113	984	Observation	Drilled in 1951
3	751520	12-inch	198	1274	857	Active	Drilled in 2007

Water level information contained in Keewatin’s Part 1 WHP plan shows a direct correlation between the dewatering of the Mesabi Chief Pit which was initiated in 1995 and Keewatin Well 2. As of 2002, the water level was lowered approximately 150 feet at the Mesabi Chief Mine while the static water level fell approximately 75 feet at Keewatin Well 2. Water levels were not collected at Keewatin Well 1 after 1998, however, the earlier measurements at Keewatin Well 1 also showed water level declines but somewhat less than those observed at Well 2. The WHP plan shows a correlation between water levels at select existing mine pits within the footprint of the proposed Project during dewatering and the water level at Well 2. The correlation was also supported by chemical characterization of water from the mine pits and well.

Details of the connection between mine dewatering, water levels and water chemistry at the City Wells are not clear. Long term monitoring is recommended to obtain additional

information concerning the connection and to provide a mechanism to determine whether additional steps are needed to maintain the City's source of water supply.

Keewatin Water Use

The City of Keewatin is currently operating under Minnesota Department of Natural Resources (DNR) Appropriations Permit number 1972-2192. This permit allows Keewatin to pump up to 75 million gallons of water per year (mgy) at a permitted rate not to exceed 350 gallons per minute. The yearly reported pumping volumes submitted to the DNR are provided on **Table 2**. The reported values illustrate that the City's annual water use has increased from 45 to approximately 65 mgy in recent years.

Table 2

Permit	Well	Unique Well No.	Permit Vol (mgy)	Permit Rate (gpm)	2007	2006	2005	2004	2003	2002	2001	2000	1999	1998
					1979-2192	1	192359	75.0	350.0	54.6	49.5	44.0	43.7	24.3
	2	228828	8.8	14.5	16.2	16.9	29.2			15.8	17.1	22.8	25.8	18.2
	3	751520	0.0	0.0	0.0	0.0	0.0			0.0	0.0	0.0	0.0	0.0
Ten Year Average = 52.8 mgy				Total:	63.4	64.1	60.2	60.5	53.5	45.0	45.9	46.6	44.1	44.4

Nashwauk Water Supply

The water supply for the City of Nashwauk is obtained from two bedrock wells located within the City limits of Nashwauk as shown on **Figure 1**. Like Keewatin, both of Nashwauk's wells tap portions of the BIF Aquifer. Basic information concerning Nashwauk's wells is summarized on **Table 3** below and logs for each well are included in Attachment 2. Less information is available concerning Nashwauk's wells and some discrepancies exist regarding well numbering and depths. The well names and unique numbers used here are as presented in the MDH Wellhead Protection Plan Part 1, prepared for the City. The log for Well 3 indicates a casing depth of 40 feet in combination with a depth to bedrock of 110 feet. This is an unlikely scenario as the casing would typically extend at least to the top of the rock.

Table 3

Well Name	Well Number	Casing		Open Hole, Elevation (ft msl)		Status	Notes
		Diameter	Depth (ft)	Top	Bottom		
3	241017	8-inch	40	1449	1075	Active	Drilled in 1930
4	228819	16-inch	150	1289	899	Active	Drilled in 1947

The northern portion of the City of Nashwauk and the City's Well 3 are situated directly between two former natural ore pits, the Larue to the northeast and the Hawkins to the southwest. Well 4 is situated in the southern portion of the City approximately 3200 feet south of Well 3. Geochemical information provided in the MDH WHP report suggests that a significant percentage of water discharging at the wells originates at the Larue Pit. It is also likely that a connection exists between the levels in nearby mine pits and the

City wells. To the northeast, the nearest mining proposed under the Keetac Project is more than two miles away. The effects of mine pit dewatering under this Project on the City wells will likely depend on the effects at the former natural ore pits between the Project and the City. Anecdotal evidence suggests that the former natural ore pits are separated by “land bridges” that may serve to reduce the effects of dewatering at the City wells.

To the southwest of Nashwauk, Minnesota Steel also has plans for taconite extraction, including mine pit dewatering and water supply pumping that could also affect water levels in nearby natural ore pits and the City wells.

Nashwauk Water Use

Nashwauk is currently operating under Minnesota Department of Natural Resources (DNR) Appropriations Permit number 1975-2151. This permit allows the City of Nashwauk to pump up to 70 million gallons of water per year (MGY) at a permitted rate not to exceed 1,100 gallons per minute. The yearly reported pumping volumes submitted to the DNR are provided on **Table 4**. Pumping in recent years has ranged from approximately 45 to 65 mgy.

Table 4

Permit	Well	Unique Well No.	Permit Vol (mgy)	Permit Rate (gpm)	2007	2006	2005	2004	2003	2002	2001	2000	1999	1998
1975-2151	4	228819	70.0	1,100.0	25.1	25.9	27.7	34.0	33.3	32.9	25.5	23.6	22.1	23.7
	3	241017			27.2	20.1	29.3	29.5	30.6	23.1	26.4	21.6	21.4	22.1
Ten Year Average = 52.5 mgy				Total:	52.3	46.0	57.1	63.6	63.9	55.9	52.0	45.2	43.4	45.8

Proposed Monitoring Plan

Monitoring is proposed to establish baseline conditions, to monitor changes in the BIF Aquifer that could impact the existing water supply wells for the Cities of Keewatin and Nashwauk and to assess potential measures to mitigate impacts, if necessary. Development and implementation of the Keetac Project will take place in stages over a period of several years. Sufficient time exists to monitor the resources in question and to develop a mitigation plan, if required. Impacts could include interference drawdown from dewatering activities or water supply pumping and/or changes in water quality that make use of the water undesirable. Therefore, the monitoring program should include both water quantity and quality components.

Water Quality

Existing water quality from both Cities supply wells should be obtained from the City and MDH. Additional baseline samples should be taken from existing wells for dissolved mineral constituents and general chemistry. Annual sampling of the wells should continue for select parameters to detect changes over time. Wells to be sampled include Nashwauk Wells 3 and 4 and Keewatin Wells 1 and 3. Parameter lists for

baseline and annual sampling are included in Attachment 3.

The MDH has recommended that the Cities sample for stable isotopes of water, chloride and sulfate as part of their ongoing WHP efforts. MDH has indicated that they will conduct the analysis but the City would be responsible for obtaining the samples. US Steel representatives responsible for sample collection will contact MDH prior to sampling to coordinate collection of MDH samples with the sampling recommended here. The results could assist the Cities in their WHP efforts and provide useful information concerning the hydrogeology of the BIF Aquifer and the source of water discharging at the City wells.

Water Quantity

Long term water level monitoring points are required to assess drawdown in the aquifer. A search should be conducted to identify potential monitoring points including wells and surface water locations. MDH and DNR staff have expressed an interest in long term monitoring and noted a lack of available points in the BIF aquifer.

We understand that not all of the City wells involved are accessible for water level measurements. Arrangements should be made for the wells to be accessible and for City utility personnel to make regular measurements of static levels, pumping levels, pumping rates and volume.

Former Well 2 at Keewatin is now out of service and could serve as a useful monitoring point. We understand that the DNR has recently conducted logging procedures at the well and that both the DNR and MDH are interested in data from this location. The City has indicated that this well is available for long term monitoring by US Steel. A data logger and transducer will be installed and maintained by US Steel for well water level measurement at this location.

At present we are not aware of a suitable BIF Aquifer well for long term monitoring near Nashwauk. A new observation well is proposed for use as a dedicated monitoring point generally between the City and the Keetac project. This well should also be equipped with a transducer and data logger. Transducers and data loggers will be visited quarterly to verify operation, collect data and to reset the instruments to correct for drift.

Measurements of water levels from select mine pits, should also be collected as part of the Monitoring Plan. This includes water levels from pits within the Keetac Project, the LaRue pit complex and data collected by Minnesota steel for their operations southwest of Nashwauk. This information will be useful for correlating mine pit water levels with the City wells and the BIF Aquifer water levels in general.

Reporting

All data should be collected and summarized in a report format annually. The report should include a summary of the data collected during the previous year, a description of any changes to the monitoring network, recommended changes to the monitoring network and a determination as to any effects of the dewatering activities on the Cities well water supplies. If the results of the planned monitoring suggest significant changes in well water quality or level that may be related to Keetac mining activities, additional

monitoring activities may be recommended. The annual report will be prepared by US Steel no later than February 15th for the previous calendar year and distributed to the Cities, DNR and MDH for review.

Potential Mitigation Measures

In the event that mine dewatering activities have an adverse impact on the production or quality of the City water supply additional monitoring, treatment, augmentation or replacement of the impacted supply may become necessary. The hydrogeology of the Keewatin/Nashwauk area limits the available options to the following:

- Increased monitoring or changes to the monitoring plan if suspected impacts do not immediately threaten the City's ability to supply water.
- Modification of existing facilities including lowering, or replacing, existing pumps and deepening wells.
- New wells drilled in the BIF Aquifer in areas where interference effects are not as great.
- New wells drilled in the glacial outwash if areas of sufficient saturated thickness and favorable water quality can be identified.
- A new water treatment system to treat surface water, mine water or affected well water.

The extent of potential interference effects associated with the Project cannot be predicted with certainty at this time. The BIF Aquifer is utilized throughout the area and has the potential to supply adequate amounts of water to satisfy municipal needs. However, a better understanding of the effects of pumping on the BIF Aquifer is required to assess the potential for ongoing use and locations for additional BIF wells.

Glacial outwash deposits are utilized as municipal water sources throughout Minnesota. Although historical publications suggest that glacial outwash deposits are present between Keewatin and Nashwauk, glacial outwash deposits can change significantly over very short distances and specific investigations would be required to identify and assess the suitability for use as sources of water supply.

There are surface water resources in the area that could potentially provide a source of water including lakes that fill old mine pits and underground workings. It is anticipated that such a system would require construction of a surface water treatment plant.

Tribal Cooperating Agencies Cumulative Effects Analysis

NorthMet Mining Project and Land Exchange

Prepared by staff from the Bois Forte Band of Chippewa, the Fond du Lac Band of Lake Superior Chippewa, the Grand Portage Band of Lake Superior Chippewa, the Great Lakes Indian Fish and Wildlife Commission, and the 1854 Treaty Authority

September 2013

Tribal Cooperating Agencies Cumulative Effects Analysis

NorthMet Mining Project and Land Exchange

In Chapter 6 of the *Preliminary Supplemental Draft Environmental Impact Statement (PSDEIS) for the NorthMet Mining Project and Land Exchange*, the co-lead agencies present a resource-specific cumulative effects analysis (CEA) for the NorthMet Project Proposed Action and Land Exchange Proposed Action that may result when combined with effects from other activities. It acknowledges that in addition to additive effects, cumulative effects may be further magnified by synergisms or cross-interactions in the environment. The analysis was developed by the co-lead agencies and their third-party contractor with consideration of the 1997 CEQ guidance *Considering Cumulative Effects under the National Environmental Policy Act* and EPA's 1999 NEPA review guidance *Consideration of Cumulative Impact in EPA Review of NEPA Documents*. However, despite specific and repeated requests from tribal cooperating agencies, the co-lead agencies did not elect to utilize a tool developed in 2011 by the EPA in cooperation with tribes, *Applying Cumulative Impact Analysis Tools to Tribes and Tribal Lands*, in order to discern potential cumulative effects to resources important to the tribes who retain usufructuary rights within the 1854 Ceded Territory. The NorthMet Project Proposed Action and Land Exchange Proposed Action are both located entirely within the boundaries of the 1854 Ceded Territory (Figure 1).

Figure 1.1854 Ceded Territory.

The Fond du Lac, Bois Forte, and Grand Portage Bands, as well as the 1854 Treaty Authority (1854) and the Great Lakes Indian Fish & Wildlife Commission (GLIFWC), have consistently advocated for a more robust, comprehensive CEA for the PolyMet NorthMet project and other mining projects. We have observed that current, historic, and ‘reasonably foreseeable’ mining activities have profoundly and, in many cases permanently, degraded vast areas of forests, wetlands, air and water resources, wildlife habitat, cultural sites and other critical treaty-protected resources within the 1854 Ceded Territory. As we have engaged with the lead federal and state agencies for the environmental review process under NEPA and the tribal consultation process under §106 of the National Historic Preservation Act (NHPA), we have clearly expressed our concerns for the incompleteness and inadequacy of their CEA.

In the 2008 CPDEIS section 2.2, Issues Identified During the EIS Scoping Process, it is stated that "The MnDNR and USACE determined that the following topics are not expected to present significant impacts, but would be addressed in the EIS using limited information beyond that provided in the Scoping EAW commensurate with the anticipated impacts: Cover Types; Vehicle Related Air Emissions; Air Emissions; Noise; Archeology; Visibility; Compatibility with Plans and Land Use Regulations; Infrastructure; Asbestiform Fibers; and 1854 Ceded Territory". Yet none of these resource categories or issues was fully evaluated from the standpoint of describing cumulative effects at spatial or temporal scales that the tribes find relevant, either in the earlier environmental impacts analysis or the current SDEIS process. The tribal cooperating agencies’ perspectives on the resource-specific temporal and spatial boundaries for the CEA are significantly different from the co-lead agencies. Additionally, many of the tribal cooperating agencies’ assumptions regarding predicted effects of the proposed actions (both the project and the land exchange) and the predicted success of proposed mitigations are significantly different from the co-lead agencies. Therefore, the tribal cooperating agencies have undertaken an alternative cumulative effects analysis, considering impacts to multiple resource categories to the extent we were able to do in the brief time within which we have been able review the draft PSDEIS, provide comments, and identify major differences of opinion.

In this CEA, we will be presenting major differences of opinion regarding cumulative effects to the 1854 Ceded Territory, Tribal Historic District (Figure 2) and the St. Louis River watershed. In addition, our analysis of the No-Action Alternative assumes current legal and regulatory requirements to remediate pollution from previous mining activities will, if implemented and enforced, lead to resource conditions that are substantially improved from their current degraded condition.

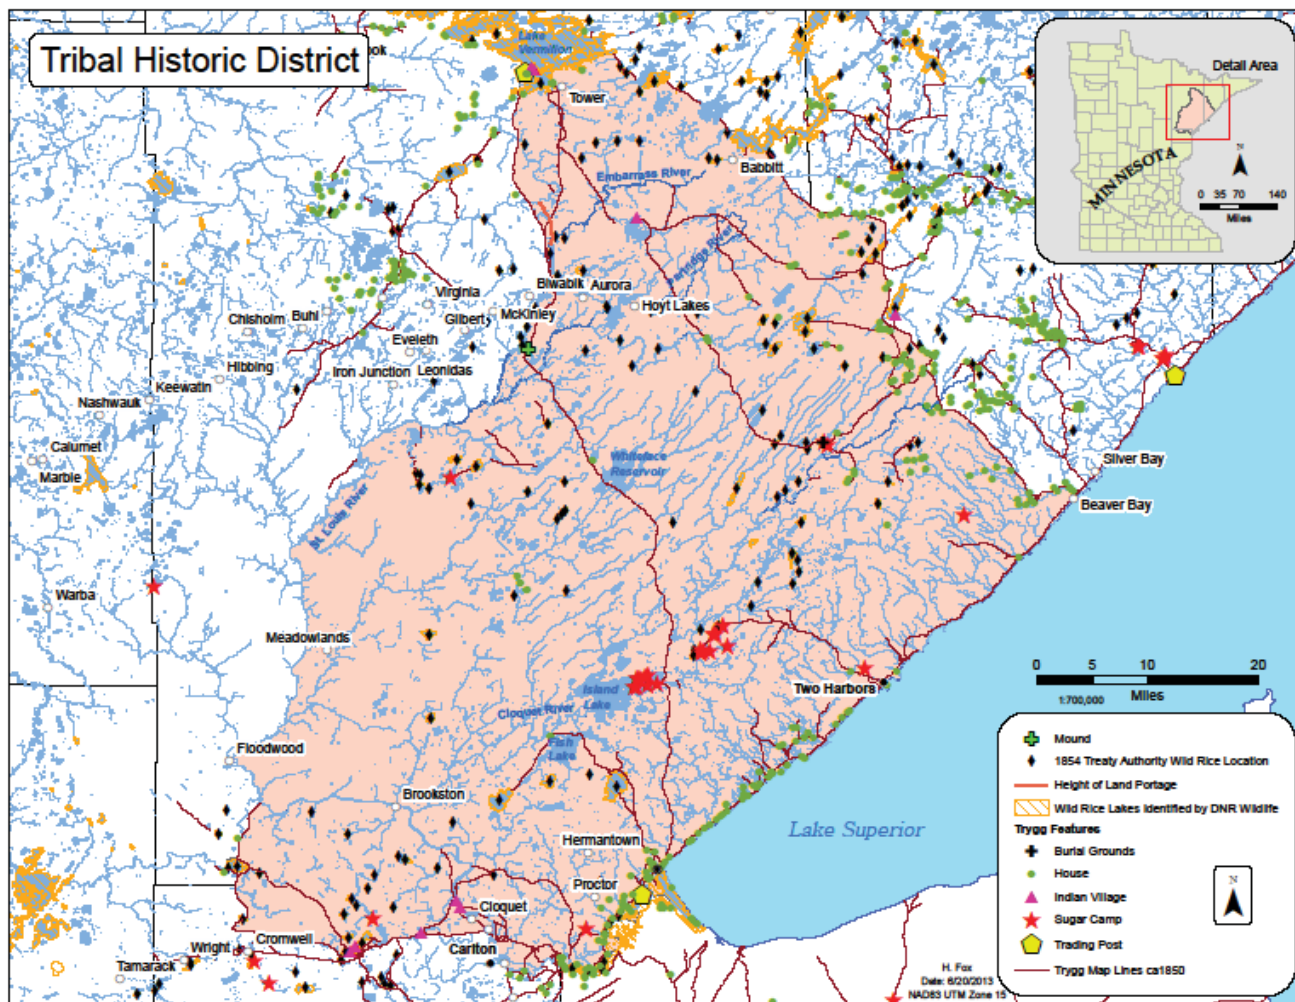

Figure 2. Tribal Historic District.

The tribal cooperating agencies use a resource-specific GIS-based approach as defined in the 2011 guidance to generate an alternative CEA that more accurately accounts for cumulative impacts to resources of tribal significance. From: *Applying Cumulative Impact Analysis Tools to Tribes and Tribal Lands*:

The National Environmental Policy Act (NEPA) requires Federal agencies to evaluate the environmental impacts of their major projects. The scope of a federal Environmental Impact Statement (EIS) is spelled out in the NEPA legislation, in guidance documents published by the Council on Environmental Quality (CEQ) and EPA, and in various federal agencies' promulgated rules for implementing NEPA. An EIS evaluates the project's impacts to natural resources, the human environment, historical properties, and cultural properties. EIS documents are submitted for public review. Under Section 309 of the Clean Air Act, EPA is required to review and publicly comment on the environmental impacts of major federal actions including actions which are the subject of EISs.

The assessment of cumulative impacts in NEPA documents is required by CEQ regulations. A cumulative impact is "the impact on the environment which results from the incremental impact of the action when added to other past, present, and reasonably foreseeable future actions regardless of what agency (Federal or non-Federal) or person undertakes such other actions. Cumulative impacts can result from individually minor but collectively significant actions taking place over a period of time." (Title 40 Code of Federal Regulations (CFR) Section 1508.7, CEQ Regulations for Implementing NEPA, 1987). Only resources that are directly impacted or indirectly affected by an action are subject to a cumulative impacts analysis....

In 1984, EPA issued its Indian Policy stressing two related themes: EPA will (1) pursue the principle of Indian self-government and (2) work directly with tribal governments on a government-to-government basis. Consistent with this Indian Policy and other EPA's statutory and regulatory authorities, EPA will identify and consider potential effects to reservation environments and take these potential effects into account as the Agency fulfills its regulatory duties. As a regulatory agency, EPA does not manage tribal trust resources or treaty resources in ceded territory. The U.S. Department of Interior, Bureau of Indian Affairs, does manage tribal trust resources. However, the Agency acknowledges its general trust responsibility to tribal governments which derives from the historical relationship between the Federal government and Indian tribes as expressed in certain treaties and Federal Indian laws, and understands that its regulatory activities can affect tribes.

Tribal lands are fixed; that is the reservations, Indian lands, and ceded territories are specific places, defined by treaty, and tribes may hold certain rights within these areas. In addition, tribal cultural identity may be tied to specific areas, cultural properties, natural resources found within these areas or properties, and traditions and uses involving these places and resources. For this reason, tribes are not considered mobile. For these

reasons, many tribes have expressed interest and concern about cumulative impacts of actions relative to the areas they govern and/or use....

Tribal concerns about impacts to natural and cultural resources and properties and to their particular uses may include, but are not limited to the following:

- Water with naturally high quality and impacts involving -
 - Changes in concentrations of unregulated substances
 - Synergistic effects of multiple individually unregulated or regulated substances
 - Changes to water that make it unsuitable for cultural uses
- Lakes, rivers, wetlands, and other water bodies where plants of significance to tribes grow (e.g., wild rice)
- Water quality and quantity and soil quality that enable wild rice to grow
- Water quality necessary to support fish populations
- Plants and wildlife (e.g., moose, grouse, deer) of significance to tribes
- Sufficient wildlife populations and habitat to support traditional hunting, fishing, and gathering
- Fish and wildlife without contaminants that preclude their frequent consumption
- Archeological locations or areas
- Traditional or historic properties, locations or areas (e.g., traditional locations for hunting, fishing, and gathering; springs and ceremonial sites; other places where historic events occurred)
- Sacred locations or areas (e.g., gravesites, spiritual sites) without visual or noise impacts that would make them unsuitable for traditional activities
- Habitats that host culturally important resources (e.g., pipestone, sage, other culturally important plants)
- Access to areas where tribes have hunting, fishing, or gathering rights and to lands where off-reservation harvest under treaty rights occurs, including trails or passageways that link tribal use areas.
- Cultural items as defined by the Native American Graves Protection and Repatriation Act, 25 United States Code (USC) 3001, including funerary objects, sacred objects, and cultural patrimony
- Social bonds associated with traditional activities
- Tribal jurisdiction and control over reservation lands, thus improving or maintaining quality of life for residents of the reservations

An EIS that addresses cumulative impacts with respect to tribal uses and practices related to natural and cultural resources and properties should consider an analysis approach that uses:

1. A geographic area that is relevant to the tribe, for which information is collected and evaluated,
2. Information that reflects and describes tribal uses and tribal rights, and
3. A timeframe that is relevant to tribal uses.

In short, considering cumulative impacts to tribes may require a wider focus area and a discussion of direct and indirect impacts of all projects in an area, relative to tribal traditions, values, and concerns that involve using the resources affected by the project.

Regarding the geographic scope for a tribally relevant cumulative effects analysis:

- Scale is a central issue in the ecosystem approach.
- The appropriate boundary is one that ensures adequate consideration of all resources that are potentially subject to non-trivial impacts.
- For some resources, that boundary can be very large. For example, the long-range atmospheric transport of nutrients and contaminants into water bodies such as the Great Lakes and Chesapeake Bay transcends even the boundaries of their vast watersheds.
- At the other end of the spectrum, significant contributions to biodiversity protection can be made by identifying and avoiding small sensitive areas, such as rare plant communities.
- Determining relevant boundaries for assessment is guided by informed judgment, based on the resources potentially affected by an action and its predicted impacts.

The 1997 CEQ document notes that, for a project-specific analysis, it is often sufficient to analyze impacts within the immediate area of the proposed action. When analyzing the proposed action's contribution to cumulative impacts, however, the geographic boundaries of the area should almost always be expanded. Project-specific analyses are usually conducted on the scale of forest management units, or facility footprints, or mixing zone in a waterbody pursuant to a discharge permit. Cumulative impacts analysis should be conducted in the scale of human communities, landscapes, watersheds, or airsheds.

Finally, EPA's 1999 document notes that the EPA reviewer can determine an appropriate spatial scope of the cumulative impact analysis by identifying a geographic area that includes resources potentially affected by the proposed project and extending that area, when necessary, to include the same and other resources affected by the combined impacts of the project and other actions. Furthermore:

- Geographical boundaries should not be extended to the point that the analysis becomes unwieldy and useless for decision-making.
- The analysis should use an ecological region boundary that focuses on the natural units that constitute the resources of concern.
- For non-ecological resources, other geographic areas, such as historic districts (for cultural resources) or metropolitan areas (for economics), should be used.

Cultural Resources

During the EIS scoping process for the NorthMet Project (see Section 2.1 of the Final Scoping Decision Document), no cumulative impact issues associated with cultural resources were identified. Tribes were not invited to participate in scoping. However, Tribal comments on the June 2008 PDEIS, the 2009 CPDEIS and the 2009 DEIS noted this cumulative impact and the need for analysis. The tribal cooperating agencies have repeatedly stated and commented in writing that there likely will be substantial impacts to cultural resources, and impacts to cultural resources need to be fully integrated into evaluation of potential impacts to cultural sites and cultural resources. However, there appears to be a concerted effort to diminish any and all comments on this subject and simply revert back to decisions made during the scoping phase.

The Traditional Use Survey conducted in 2011 (Latady and Isham 2011) focused on identifying and evaluating significance of places of importance to the Bands within the area to be affected by the proposed mine. Identification and evaluation is the first step before assessing adverse effects and integral to the development of a cultural resource management plan to facilitate preservation and management of cultural resources including traditional use areas. Beyond identification, the intent of the survey highlighted the potential to bridge the past and future in terms of native culture, history and natural resources.

Tribal cooperating agencies consider a 216,300 acre area bounded by the St Louis River, Lake Superior, Lake Vermilion and the Beaver Bay to Vermilion Trail to be a Tribal Historic District, and the pertinent area for consideration of cumulative effects to cultural resources. In addition to the St Louis River, the area supports three major drainage systems, the Cloquet, Embarrass and Pike Rivers. Trygg maps (1966), historic documents (Brownell 1967, Carey 1936, Chester 1902, Lancaster 2009, Trygg 1969, Van Brunt 1922, Jenks 1901, Moyle 1941) and information contained in site files located at the Bois Forte Tribal Historic Preservation Office were used to determine the extent of the district. Additional information on Historic places and properties are available at SHPO, Superior National Forest Headquarters and Duluth Archaeology Center. Included within the proposed historic district are the headwaters of the St. Louis River, the site of ongoing mineral exploration.

Ancestors of present day Band members resided in this area for centuries and many Band members followed traditional practices extensively until about a generation ago when the effects of mining devastated the rice beds in the Embarrass and St. Louis River watersheds and closed access to large tracts of public (USFS) land where traditional harvest and collection areas occur. This proposed Tribal Historic District encompasses complex trail systems, Indian villages, trading posts, encampments for fishing, hunting, wild rice harvest

and processing, sugar bush, and other traditional subsistence practices. It includes what was essentially a ‘water highway’ used by the Ojibwe at the time of European contact, and subsequently by Voyageurs during the era of heavy fur trading. In addition, numerous medicinal plant gathering sites, Midewewin lodges, vision quest locales and other sacred places occur.

Land Use

The co-lead agencies define the CEAA for land use to include effects associated with the NorthMet Project Proposed Action combined with other industrial (including mining) or public works projects located within the portion of the Mesabi Iron Range encompassed by St. Louis County”. Tribal cooperating agencies believe the CEA for land use should encompass the 1854 Ceded Territory, as the signatory Bands have lost access to substantial portions of the 1854 CT and the resources within (Figure 3). The 1854 Ceded Territory encompasses 6,283,836 acres in North Eastern Minnesota. Of that, 4,095,146 acres are public land ranging from Federal to CRP lands. The remaining 2,188,578 is private to private industrial land¹. Band members generally do not exercise usufructuary rights on private lands without landowner permission, although the treaty does not hold that restriction. Lands within the 1854 Ceded Territory that have experienced urban and/or industrial development are permanently ‘lost’ as a source of treaty resources.

¹ http://deli.dnr.state.mn.us/data_catalog.html using GAP Stewardship 2008 – all Ownership Types shape file and database

Figure 3. Public Lands within the 1854 Ceded Territory

Water Resources

The co-lead agencies evaluated cumulative impacts to surface water within the Partridge and Embarrass River watersheds only. From the preliminary SDEIS: “The St. Louis River was considered for inclusion in the cumulative effects assessment. The NorthMet Project Proposed Action is predicted to meet all water quality evaluation criteria or not make concentrations worse. Further, concentrations of sulfate and mercury, two key constituents of concern, are predicted to decrease as a result of the NorthMet Project Proposed Action. The NorthMet Project Proposed Action would also result in only minor changes in hydrology within the Partridge River and Embarrass River. Therefore, the NorthMet Project Proposed Action is not considered to have the potential for cumulative effects on hydrology and water quality in the St. Louis River. As a result, the CEAA for surface water is defined by the Partridge River and Embarrass River watersheds as shown on Figure 6.2.3-1.”

The tribal cooperating agencies believe the relevant spatial scale for water quality and hydrologic cumulative effects analysis is the entire St. Louis River watershed. This watershed has experienced substantial historic, current and proposed expanded mining activities, as well as other industrial, agricultural and urban development. In addition to the direct surface water and wetland impacts (loss and/or degradation) from these activities, nearly half of the watershed has experienced hydrologic alteration from extensive ditching. It is reasonably foreseeable that an additional 3000 acres of wetlands within the watershed will be directly impacted by proposed new mining projects and expansions that are in active permitting and/or environmental review: the PolyMet NorthMet project, Mesabi Nugget Phase II, US Steel Minntac expansion, US Steel Keetac expansion, United Taconite Tailings Basin 3 construction. To date, virtually all required wetland mitigation for mining impacts has been implemented out of the basin, representing a permanent loss of high quality ecological resources and functions.

Modeling

The tribal cooperating agencies’ review of the water modeling data packages for the NorthMet Project Proposed Action led to our conclusion that Goldsim did not accurately predict existing conditions, and cannot be relied upon to accurately predict future project conditions. While we feel that modeling of the existing conditions is an inadequate substitute for a realistic No-Action Alternative model and does not follow CEQ guidelines, it appears that Goldsim does not even accurately model existing conditions. As noted in spreadsheet comments submitted June 25, 2013, for many parameters at several waterbodies the No-Action P50 model of annual average value is substantially different than the observed average existing conditions. Because of the inaccuracy of the Goldsim predictions of current conditions it is not clear that use of the Goldsim estimates of project impacts are adequate to ensure protection of water resources. For example:

- PSDEIS Table 4.2.2-18 reports Colby Lake as currently having an observed mean Arsenic of 0.78 to 1.4 ug/L (depending on the data set), whereas Figure 5.2.2-35, the No-Action (continuation of current conditions) P50 model for Colby Lake Arsenic shows annual maximum values of 0.5 ug/L

- PSDEIS Table 4.2.2-34 reports PM-10 (seep at the basin north toe) as having an observed mean Mn value of 100,192 ug/L, whereas Figure F-01-18.1 (Water Modeling Data Package Vol 2-Plant Site v9 MAR2013) shows the No-Action (continuation of existing conditions) P50 as an annual maximum Mn of 390 ug/L. at the north toe.
- PSDEIS Table 4.2.2-34 reports PM-10 as having an observed mean Aluminum of 39.6 ug/L yet Figure F-01-02.1 (Water Modeling Data Package Vol 2-Plant Site v9 MAR2013) shows an annual maximum for No-Action (continuation of existing conditions) at the north toe as 11 ug/L.
- PSDEIS Table 4.2.2-14 shows that observed average SO4 at SW-005 (9.11 mg/L) is nearly identical to the Goldsim P50 predicted current annual maximum for that site (PSDEIS Fig. 5.2.2-27, 9 mg/L). This suggests that Goldsim is under-predicting SO4 at SW-005. (The authors of the text on page 5.2.2-125 of the PSDEIS seem to misinterpret the P50 of the figure as a predicted annual average. This is not the case. The P50 of that figure is the "best" estimate of the annual maximum. The Goldsim model estimate of the annual average at SW-005 is shown as the P50 in Mine Site Data Package Attachment K Figure K-06-24.2, i.e. 6 mg/L) Again, this suggests that Goldsim is underpredicting SO4 at SW-005.
- PSDEIS Table 4.2.2-29 shows that observed average Al at PM-13 is 221 ug/L. This observed average is much higher than the modeled No-Action (continuation of existing conditions) P50 annual maximum (PSDEIS Table 5.2.2-47, 159-166 ug/L). The modeled No-Action P50 annual average for Al at PM-13 of 75 ug/L (attached Fig.I-05-02.2, Water Modeling Data Package Vol 2-Plant Site v9 MAR2013) is only 1/3 of the observed average.

Tables 1-3 below compare the observed existing conditions values found in various PSDEIS tables to the P50 existing conditions predicted by Goldsim. While a very few of these model predictions are presented in the PSDEIS, many are not and therefore, the tables below refer back to the underlying data packages from which the PSDEIS was written.

Parameter (ug/L)	Average existing water quality (PSDEIS Table 4.2.2-14)	Annual average P50 existing conditions predicted by Goldsim (Mine Site Data Package Attach.K)
Mn	SW-002 = 142	SW002 = 80 (Fig.K-01-18.2)
Tl	SW-002 = 0.6	SW002 = 0.11 (Fig.K-01-25.2)
Mn	SW-003 = 147	SW003 = 85 (Fig.K-02-18.2)
B	SW-004a = 126.5	SW004a = 30 (Fig.K-04-05.2)
K	SW-004a = 2,700	SW004a = 1,600 (Fig.K-04-16.2)
SO4	SW-004a = 15,900	SW004a = 8,000 (Fig.K-04-24.2)
Pb	SW-005 = 1.3	SW005 = 0.26 (Fig.K-06-21.2)
SO4	SW-005 = 9,110	SW005 = 6,000 (Fig.K-06-24.2)
Tl	SW-005 = 0.4	SW005 = 0.05 (Fig.K-06-25.2)

Table 1. Observed existing conditions in the Partridge River vs. annual average existing conditions predicted by Goldsim.

Parameter (ug/L)	Colby Lake mean existing water quality (PSDEIS Table 4.2.2-18, Barr data)	Colby Lake Annual average P50 existing conditions predicted by Goldsim (Mine Site Data Package Attach.K)
Al	108	75 (Fig.K-08-02.2)
As	0.78	0.4 (Fig.K-08-04.2)
Cu	2.4	0.7 (Fig.K-08-13.2)
Ni	2.5	1.1 (Fig.K-08-20.2)
SO4	33,800	~10,000 (Fig.K-08-24.2)
Tl	0.1	0.025 (Fig.K-08-25.2)

Table 2. Observed mean existing conditions in Colby Lake vs. annual average existing conditions predicted by Goldsim.

Parameter (ug/L)	Mean seep measured value at Basin Toe (Table 4.2.2-34)	Annual <u>maximum</u> P50 existing condition predicted by Goldsim (Plant Site Data Package Attach.F)
Al	PM-8 = 25.7	West toe = 14 (Fig.F-04-02.1)
AL	PM-9 = 29.9	NW toe = 13 (Fig.F-02-02.1)
AL	PM-10 = 39.6	North toe = 11 (Fig.F-01-02.1)
Mn	PM-8 = 3,039	West toe = 1,250 (Fig.F-04-18.1)
Mn	PM-10 = 100,192	North toe = 380 (Fig.F-01-18.1)
F	PM-8 = 2,900	West toe = 1,100 (Fig.F-04-14.1)
As	PM-8 = 3	West toe = 2 (Fig.F-04-04.1)
B	PM-10 = 379	North toe = 330 (Fig.F-01-05.1)
Pb	PM-10 = 1.3	North toe = 1 (Fig.F-01-21.1)

Table 3. Observed mean existing conditions at the tailings basin toe vs. annual maximum existing conditions predicted by Goldsim. (Goldsim predicted mean concentrations are not provided in Modeling Data Package Vol 2-Plant Site v9 MAR2013).

The above examples are not an exhaustive list of discrepancies between observed existing water quality data and the Goldsim P50 prediction of the No-Action alternative (continuation of existing conditions) but highlight some of the most notable discrepancies. What the discrepancies demonstrate is that the Goldsim model is a relatively poor predictor of current conditions. If a model is unable to accurately predict current conditions it is even less likely to accurately predict future Project conditions. The Goldsim models need to be better calibrated to existing conditions (the calibration effort reported in "Calibration of the Existing Natural Watershed at the Plant Site v4 MAR2012" only compared model output to upstream site PM-12 and apparently did a poor job of preparing the models to predict either the lower reaches of the Embarrass or the Partridge River.) and model results recalculated.

Surface water quality

Evaluation Criteria that are used by the Project Proponent to evaluate the impacts of pollutants that are currently exceeding WQS do not comply with the Clean Water Act. 40 CFR § 122.44 (d) requires that all effluents be characterized to determine the need for a

Water Quality Based Effluent Limit (WQBEL). If a projected concentration of a specific pollutant exceeds the applicable numeric WQS, there is a reasonable potential that the discharge may cause or contribute to an excursion above WQS. Where existing data demonstrates an excursion from WQS, a WQBEL may be imposed without facility-specific effluent monitoring. In order to calculate a WQBEL, a Waste Load Allocation (WLA) for each permitted discharge must be established. The WLA is the portion of a Total Maximum Daily Load that is allowed for each point source to ensure compliance with WQS. However, it is very difficult to determine based on the information that has been provided by PolyMet if the additional contribution of each pollutant that currently exceeds WQS will exceed the load limit that would be required by a WLA to ensure compliance with WQS. And, the additional loading of pollutants that already exceed WQS demonstrates cumulative water quality impacts from the Project. Therefore, the Area of Potential Effect for water quality extends from the Embarrass and Partridge rivers to the mouth of the St. Louis River.

The Embarrass River, Partridge River and Colby Lake already have several constituents including sulfate, manganese, and mercury in concentrations that already exceed Minnesota Water Quality Standards ("WQS"). The existing large number of water-quality exceedances and the suite of constituents, particularly trace metals, exceeding WQS indicate the site has not been remediated from previous mining activities, and that the required reclamation was not adequate to ensure compliance with WQS. Concentrations of sulfate, specific conductance, manganese, mercury and arsenic that exceed MN WQS have been measured for NPDES permit Data Monitoring Reports and by the PolyMet project proponent demonstrate both water quality contamination issues and cumulative water quality impacts.

Specific conductance

Tribal staff have noted that elevated specific conductance is a water chemistry 'signature' for mining discharges. Specific conductance is the ability of a material to conduct an electric current measured in microSiemens per centimeter ($\mu\text{S}/\text{cm}$) standardized to 25°C. Specific conductance reflects concentrations of dissolved solids, including metal and other contaminants from mining, other industrial activities, and agriculture.

Tribal staff conducted analysis of specific conductance downstream of mine discharges using agency monitoring data (1990-2013). Analysis of specific conductance downstream of mine discharge sites indicated that specific conductance was highest nearest to mine discharge sites, and tended to only gradually decrease downstream of mine discharge sites. Linear regressions demonstrated that specific conductance was significantly negatively related to distance across all sample sites ($P < 0.01$, $R^2 = 0.15$; $n = 123$ sites; Fig. 4) and within the St. Louis River and Swan River systems ($P < 0.05$, $R^2 = 0.18$ and 0.52 , respectively; Fig. 5). This analysis included stream and river monitoring only (not lakes). The regression suggests that specific conductance could drop to 150 $\mu\text{S}/\text{cm}$ only 203 km (126 mi) downstream of the nearest upstream mine discharge site.

Specific conductance downstream of mine point discharges (1990-2013)

Figure 4. Mean specific conductance measurements at monitoring stations downstream of mine point discharges were inversely related to distance downstream from mine point discharge sites.

Figure 5. Linear regression indicated that mean specific conductance (± 1 SE) was significantly negatively related to distance of the monitoring location downstream of the nearest mine discharge in two of the main downstream river systems, with highest specific conductance nearest to mine discharges and decreasing relatively gradually downstream (St. Louis River system $P < 0.01$, $R^2 = 0.18$, $n = 85$; and the Swan River system ($P < 0.05$, $R^2 = 0.52$, $n = 9$).

These analyses demonstrate that existing mining discharges result in elevated concentrations of pollutants that persist far downstream in the St. Louis River, which is consistent with the findings of the USEPA in their assessment report on the effects of mountaintop removal and valley fill mining².

Manganese

The Health Risk Limit (HRL) for manganese is 100 micrograms per liter ($\mu\text{g/l}$) because it is a potent neurotoxin known to cause brain damage when formula fed infants are exposed to high concentrations, and can cause Parkinsons-like symptoms in adults exposed to high concentrations. The average measured concentration of manganese in Wyman Creek between April 2005 and December 2012 was 1383 $\mu\text{g/l}$. Water discharging from Area Pit 5 to Spring Mine Creek, a tributary to the upper Embarrass River, between July 2010 and

² U.S. EPA (Environmental Protection Agency). 2011. The Effects of Mountaintop Mines and Valley Fills on Aquatic Ecosystems of the Central Appalachian Coalfields. Office of Research and Development, National Center for Environmental Assessment, Washington, DC. EPA/600/R-09/138F.

October 2011, had an average measured concentration of 804 µg/l. Test results from sixteen private drinking water wells located between the proposed project and the Embarrass River in 2008 revealed concentrations of manganese that exceeded the HRL in eight wells. The range of manganese concentrations from all of the wells was 0.66 – 4710 µg/l. The PolyMet project will contribute additional manganese to the groundwater from tailings basin water that is not captured and treated, and the water that seeps through fractures in the mine pit walls once the pit has filled with water.

In the Partridge river watershed, measured concentrations of manganese increase dramatically from the most upstream measurements to the furthest downstream measurements (Figure 6).

In the Embarrass River watershed, high concentrations of manganese are associated with mining features. SD033 is the discharge from Area Pit 5, and the former LTV tailings basin appears to be the source of pollution for monitoring locations MLC-2, PM-19, and PM-11 (Figure 7).

Figure 6. Partridge River Watershed Manganese Concentrations.

Figure 7. Embarrass River Watershed Manganese Concentrations.

Arsenic

Arsenic is a known carcinogen. The drinking water standard for arsenic is 10 $\mu\text{g/l}$, based on both human health and the economics of treating drinking water to meet the standard. Based on human health alone, the standard for arsenic is less than 2 $\mu\text{g/l}$ ³. Arsenic concentrations measured in sixteen private drinking water wells between the proposed project and the Embarrass River in 2008 ranged from less than the detection limit of 2 to 7.5 $\mu\text{g/l}$. Arsenic concentrations are projected to increase as a result of the PolyMet project⁴.

In the Partridge River watershed, measured maximum arsenic concentrations exceed Class 2A and 2Bd water quality standards at all but three locations (Figure 8). The locations where the maximum measured concentration of arsenic does not exceed the Class 2A and 2Bd water quality standards are in the upper portion of the watershed.

Figure 8. Partridge River Arsenic Concentrations.

³ 40 CFR 131.36

⁴ PolyMet Water Modeling Data Package

In Colby Lake, which is the City of Hoyt Lakes drinking water source, the increase in arsenic from the PolyMet project would be 38.5% (5.2.2-127 Table 5.2.2-33 Maximum Modeled Monthly P90 Surface Water Concentrations for the Colby Lake). This is significant because the US EPA's Priority Toxic Pollutants rule suggests that this level of arsenic would be more than an order of magnitude higher than what would prevent cancer in humans. The increased arsenic in the Partridge River — up to 55% at SW-004b are even more striking (p. 5.2.2-113, Table 5.2.2-29 Maximum Modeled Monthly P90 Surface Water Concentrations for the Mine Site), which may affect humans through fish consumption, even if the water isn't used for drinking.

Aluminum

The Class 2A chronic standard for total aluminum, applicable to Wyman Creek, is 87µg/l. The quality of Class 2Bd surface waters shall be such as to permit the propagation and maintenance of a healthy community of cool or warm water sport or commercial fish and associated aquatic life and their habitats. These waters shall be suitable for aquatic recreation of all kinds, including bathing, for which the waters may be usable. The Class 2Bd standard for aluminum is 125µg/l, applicable to the Embarrass River, Partridge River and St. Louis River. As Figure 9 below demonstrates, at every site where data is available the maximum aluminum concentrations exceed WQS, except at SW-001. The average aluminum concentration exceeds WQS at one quarter of the sites where monitoring data is available for aluminum.

Figure 9. Partridge River Watershed Aluminum Concentrations.

Aquatic Species

Within the CEA area defined by the co-leads for impacts to aquatic species (the Partridge and Embarrass Rivers from their headwaters to a point approximately 15.5 miles downstream of the NorthMet Project Proposed Action activities, where the rivers form the St. Louis River), the MPCA has assessed and identified waterbodies that are impaired for fish and/or benthic macroinvertebrate communities, based upon recent monitoring data (since 2009). The draft 2012 §303(d) list prepared by the MPCA includes more headwaters streams and rivers in the St. Louis River watershed that are also impaired for aquatic communities (Figure 10). It is likely that the state-led stressor identification process underway will identify historic and existing mining operations as major causal factors for these impairments. The tribal cooperating agencies believe that the appropriate spatial scale for considering cumulative impacts to aquatic species is the St. Louis River watershed.

Figure 10. Impaired Waters (§303(d) Listed) within the St. Louis River and other mining-impacted watersheds.

The co-lead agencies conclude that, since the NorthMet Project Proposed Action is not predicted to result in any short- or long-term exceedances of surface water chronic standards in the Partridge River, Colby Lake, or the Embarrass River, even under extreme low-flow conditions during operations, no cumulative effects on aquatic resources are predicted within the CEAA. The co-lead agencies also conclude that there will be no effects on current baseline habitat conditions (as defined by hydrologic changes) from the NorthMet Project Proposed Action; therefore, no cumulative effects are anticipated. Both of these assumptions are major differences of opinion between the co-lead agencies and the tribal cooperating agencies. Clearly there are already adverse effects of mining operations and other development within these subwatersheds.

Mercury

From the PSDEIS: “The NorthMet Project Proposed Action is predicted to result in a net decrease in mercury loadings to the Partridge River from 24.2 grams per year to 23.0 grams per year. This would primarily be a result of a decrease in natural runoff (with a total mercury concentration of 3.6 ng/L) and a proportional increase in water discharged from the West Pit via the WWTF (with a total mercury concentration of 1.3 ng/L).”

The understanding of mercury dynamics in the St. Louis River watershed is very limited and is insufficient to lead to the conclusion reached in the PSDEIS that “the NorthMet Project Proposed Action would not exceed applicable environmental evaluation criteria.” This lack of scientific information is explicitly stated throughout the PSDEIS and is what led the Minnesota Pollution Control Agency (MPCA) early this year to delay the establishment of a St. Louis River TMDL until further mercury cycling data could be collected.

The PSDEIS also states that the current fish tissue concentration in the five local lakes results in Hazard Quotients (HQs) that exceed 1 (page 6-58), but gives no further information. The *Cumulative Impacts Analysis, Local Mercury Deposition and Bioaccumulation in Fish (July 2012)* (Barr report) showed modeled contributions from both the Mesabi Nugget LDSP and PolyMet; this information should be included in the SDEIS for public review. The Barr report provides the actual HQs, rather than just saying “they exceed 1”. The SDEIS should state clearly that in one case, the existing HQ equals 46.2, which is 46 times as high as the number where action is recommended.

The Barr report also states that “the existing health risk under Scenario 1 and 2 to subsistence/tribal and subsistence anglers eating three pounds or more per week of fish from these lakes would be significantly higher – up to fifteen times the EPA assumed safe risk intake level for a pregnant mother or child under the age of 15”. While the incremental risk from the project may be small, the existing risk is large and has not yet been addressed through a total maximum daily load (TMDL) or other reduction program. Table 5 and Figure 9 from the Barr report should be included to give the public a clear idea of the existing condition of the local waters and why the tribes believe that no additional mercury should be added at this time. The SDEIS does not provide any rationale for more mercury to be added to a system that is already so high in mercury, but rather only suggests that the TMDL should take care of this.

Mercury is potent neurotoxin, with the primary human and wildlife route of exposure through consumption of fish. The Embarrass River, Wyman Creek, Whiteface Reservoir, Stony Creek, West Two River, numerous lakes, and the entire St. Louis River all have fish consumption advisories in place for recreational fishing. These advisories do not consider subsistence fishing. Mercury concentrations in fish from these impaired waters will require additional load reductions beyond the emissions reductions required by the statewide mercury TMDL.

Mercury levels in Lake Superior lake trout remain higher than the other Great Lakes, despite significant reductions in the amount of mercury being released from sources around the lake. The largest source of mercury from within the Lake Superior basin is the mining sector, at 63% of total emissions.⁵ There has not been significant “ground-truthing” of mercury deposition rates that were used in the modeling assessment. Tribal cooperating agencies note that no studies have been conducted within this region of active mining to determine why fish tissue mercury concentrations are so high if the local sources mainly emit ‘non-locally polluting’ forms of mercury.

⁵ Lake Superior Lakewide Management Plan Annual Report 2012, Catalogue No.: En161-9/2012E-PDF

A 2011 Minnesota Department of Health study⁶ of infants in the Lake Superior basin found that 1 in 10 infants are born with unsafe mercury levels in blood. Blood spot mercury concentrations in infants from Minnesota were significantly higher than infants born in the Lake Superior basin in Wisconsin and Michigan.

Increased sulfate concentrations increase bioaccumulation of mercury. Additionally, mercury loadings to surface waters from the project is expected to increase from removing peat and storing peat in the overburden storage layout area without a cover or liner. Stormwater run-off containing concentrations of mercury that exceed MN WQS have been well documented (Aitkin AgriPeat). The Laskin Energy Center NPDES permit MN000990-SD-2 has a permit limit of 19.1 ng/l⁷, even though the aquatic life WQS for the Lake Superior basin is 1.3 ng/l. Other existing permitted facilities contribute mercury loadings to the Partridge and Embarrass Rivers, in addition to the local atmospheric deposition (Figures 11, 12).

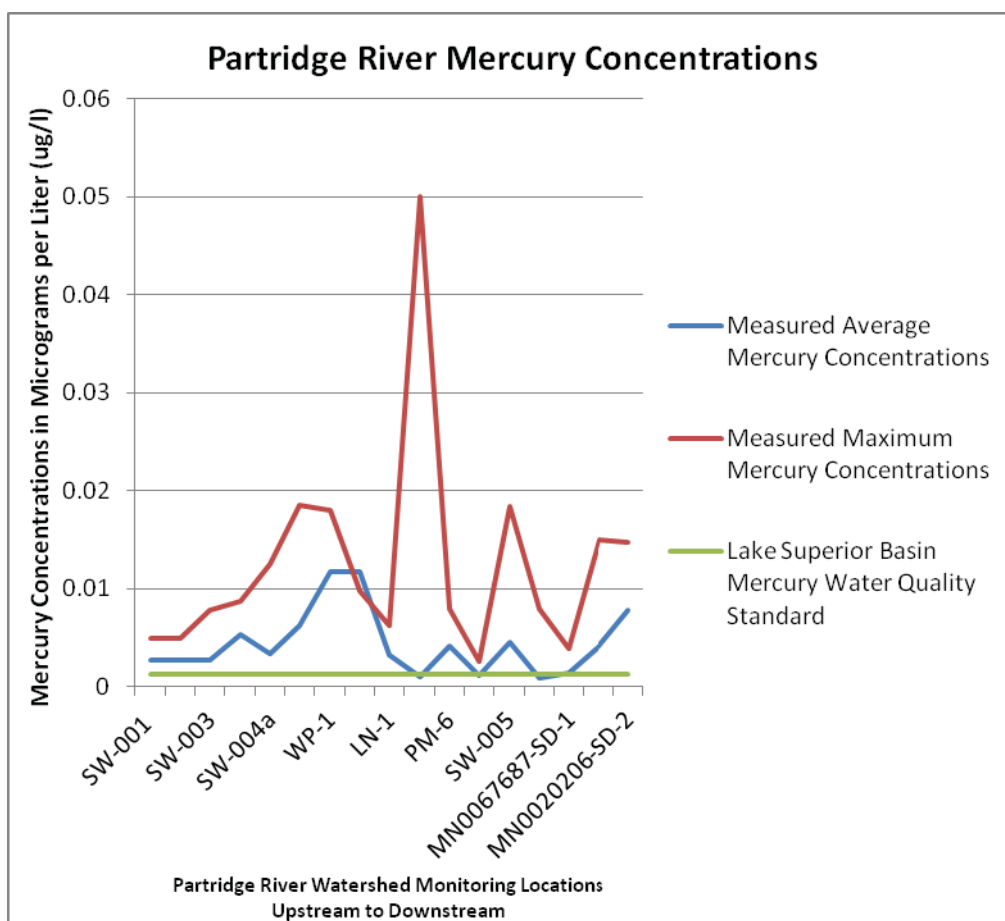

Figure 11. Partridge River Mercury Concentrations

Figure 12. Embarrass River Mercury Concentrations.

Cumulative effects associated with mercury deposition and increased mercury methylation (mediated by increased sulfate loading and hydrologic alteration of peatlands) therefore extend from the plant site down the Embarrass River to the St. Louis River estuary. Additional analyses of predicted mercury impacts from the NorthMet Project Proposed Action have been provided by GLIFWC⁸.

Sulfate

From the preliminary SDEIS: “Sulfate concentrations increase to an average of approximately 150 mg/L downstream of the confluence with Second Creek at the County Road 110 bridge (Mesabi Nugget monitoring location MNSW12). The wild rice surveys found sulfate concentrations as high as 289 mg/L below Second Creek during a relatively dry period. The baseline sulfate concentrations found in the Partridge River reflect the effects of discharges from existing activities within the watershed. The NorthMet sulfate load to the Partridge River would total an average of about 41 kg/d, which represents a 0.1 percent

⁸ Great Lakes Indian Fish and Wildlife Commission (GLIFWC) Comments Related to Mercury on the “Northmet Mining Project and Land Exchange: Preliminary Supplemental Draft Environmental Impact Statement”

increase over existing loads. Therefore, the NorthMet Project Proposed Action should not adversely affect downstream waters that support the production of wild rice.”

Sulfate concentrations in Trimble Creek, the Embarrass River, and the Partridge River currently exceed the wild rice standard of 10 mg/l. The drinking water standard and the cold water fisheries standard for sulfate is 250 mg/l. Discharge from Area Pit 5 near the proposed PolyMet tailings basin has measured sulfate concentrations that range from 170 to 2520 mg/l, averaging 1,083 mg/l between 2001 and 2013⁹. Sulfate concentrations measured in the discharge from the Peter Mitchell Pit to the upper Partridge River for NPDES permit MN0046981-SD-9 ranged from 14-37 mg/l. Sulfate concentrations measured in the discharge from the LTV Tailings basin to Second Creek for NPDES permit MN0042536-SD026 ranged from 118-360 mg/l in the period between 2008 - 2013¹⁰. Sulfate impaired wild rice waters, for the first time ever, will be included in the MPCA impaired waters list in 2014. The Bands believe that the Embarrass River, Second Creek, the Partridge River, Dunka River, and Bobs Bay of Birch Lake should be included on that list. In addition, the Swan River, Swan Lake, Sand River and the Twin Lakes (Sandy and Little Sandy Lakes, adjacent to the US Steel Minntac tailings basin) are all impaired wild rice waters due to concentrations of sulfate that exceed the MN wild rice sulfate standard.

The wild rice sulfate WQS is exceeded at almost every point where data is available in the Embarrass River watershed (Figure 12), and the drinking water standard is exceeded at half of the monitoring locations. In the Partridge River watershed, the wild rice sulfate WQS is exceeded at fourteen of seventeen locations (Figure 13). And, the sulfate drinking water standard is exceeded at two locations in the Partridge river watershed. The NorthMet Project Proposed Action will contribute additional sulfate to the groundwater from tailings basin water that is not captured and treated, water that seeps through fractures in the mine pit walls once the pit has filled with water, and stockpile infiltration and run-off.

¹⁰ MPCA DMR data for NPDES permit MN0042536-SD026 2008 -2013.

Figure 12. Embarrass River Watershed Sulfate Concentrations.

Figure 13. Partridge River Watershed Sulfate Concentrations.

Tribal staff did additional analysis of sulfate concentrations throughout the St. Louis River watershed. Analysis of sulfate concentrations downstream of mine discharge sites indicated that sulfate concentrations were highest nearest to mine discharge sites, and tended to only gradually decrease downstream of mine discharge sites. Linear regressions demonstrated that mean sulfate was significantly negatively related to distance across all sample sites ($P < 0.01$, $R^2 = 0.14$, $n = 92$) and within the Saint Louis River system ($P < 0.01$, $R^2 = 0.17$, $n = 73$; Figure 14). This analysis included stream and river monitoring only (not lakes).

The regression suggests that sulfate concentrations could drop to less than 10 mg/L only 170 km (105 mi) downstream of the nearest upstream mine discharge site (Figure 15).

Sulfate concentrations downstream of mine point discharges (1990-2013)

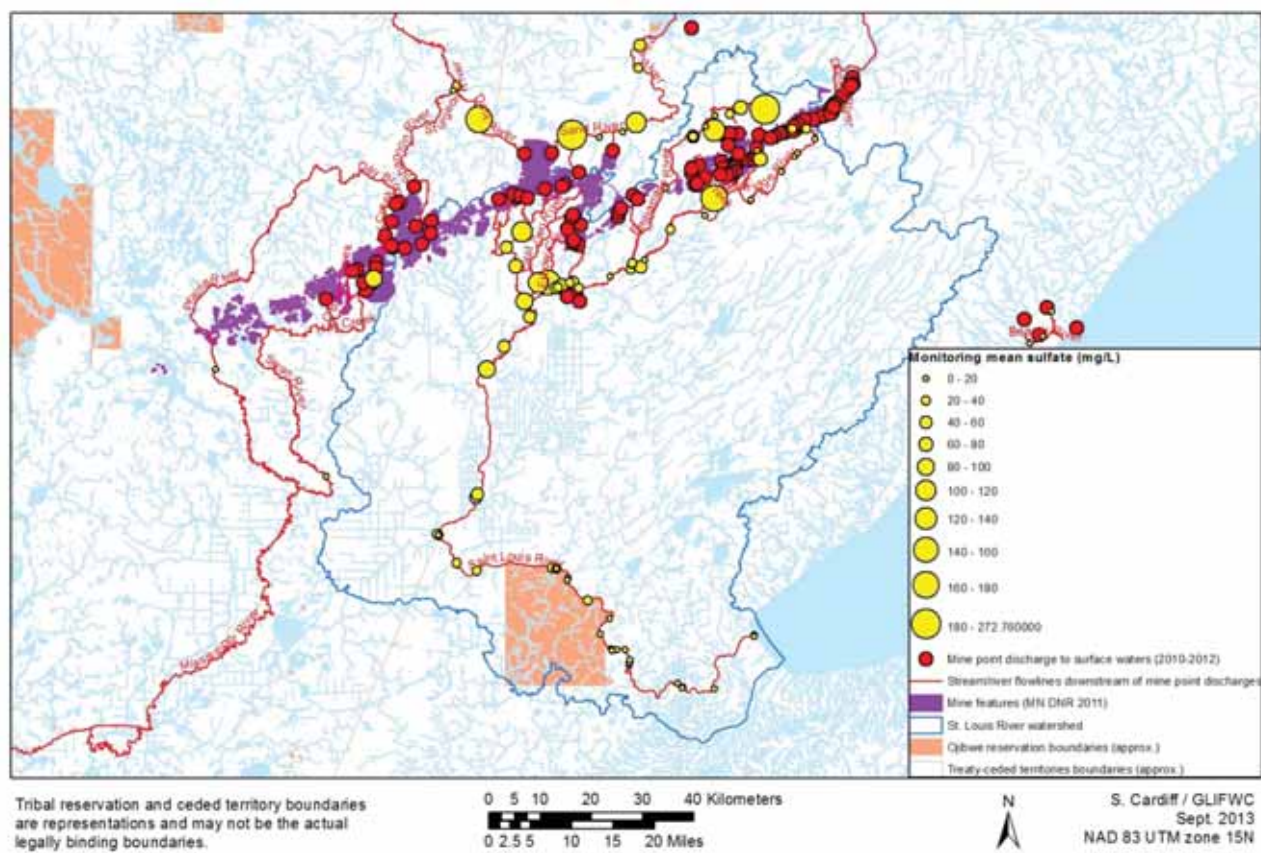

Figure 14. Mean sulfate concentrations at monitoring stations downstream of mine point discharges was inversely related to distance downstream from the discharge sites.

Figure 15. Linear regression indicated that mean sulfate (± 1 SE) was significantly related to distance of the monitoring location downstream of the nearest mine discharge in the St. Louis River with highest sulfate concentrations nearest to mine discharges and decreasing relatively gradually downstream ($P < 0.01$, $R^2 = 0.17$, $n = 73$).

Ground water quality

From the PSDEIS: “Neither the Scoping Decision Document nor the SDEIS identified potential cumulative effects on groundwater. Although the NorthMet Project Proposed Action would affect groundwater levels, this effect would be very limited geographically and temporally (e.g., groundwater levels would be restored once pit dewatering ceases) and not subject to any off-site cumulative effects. The effects of mine dewatering are considered in terms of effects on surface water flows.”

The cumulative effect of blasting ore, or vibration, has not been mentioned in the SDEIS, or even considered. It is evident that effect of blasting ore will increase fractures in the Virginia Formation and the Duluth Complex in the vicinity of the Project¹¹. And, that

¹¹ ISEE Presentation Wesley L. Bender, Understanding Blast Vibration and Airblast, their Causes, and their Damage Potential (updated 2009), available at <http://www.iseegoldenwest.org/Blast%20Effects.pdf> (last visited 9/5/13)

fractures have already hydrologically connected the Biwabik Iron Formation with the Virginia Formation and Duluth Complex, as a result of blasting in the Peter Mitchell Pit. The increase in fractures from blasting has likely hydrologically connected some of the known and inferred faults in the vicinity of the Peter Mitchell Pit, too. And, there will be a cumulative impact on water quality and water quantity resulting from blasting ore in the proposed PolyMet mine pit because the fractures from blasting in the Peter Mitchell Pit will overlap fracturing resulting from blasting in the PolyMet Pit. The area where most of the new fractures are likely to be created lie within the Virginia formation between the two pits. The Virginia Formation is known to have the highest sulfur content of the three bedrock formations found within the area between the proposed PolyMet mine pit and the Peter Mitchell mine pit, and the second highest transmissivity rate.

The PolyMet SDEIS section on vibration (Chapter 5.2.8) does not discuss impacts of blasting in creation of fractures. However, fractures created by blasting and shoveling ore would extend far beyond the pit walls. Section 5.2.8-9 **Vibration** of the preliminary SDEIS states: “permanent ground displacement occurs close to the blast. For heavily confined rocks, ground vibrations of 25.4 mm/sec will occur as far away as 1,581 meters. For free face average rock, ground vibrations of 25.4 mm/sec will occur as far away as 627 meters.” “Permanent ground displacement” is a discreet way to refer to the creation of new fractures without having to discuss the resulting increase in groundwater flow and connectivity to surface waters. In fact, all of the PolyMet predictions regarding discharge from the mine pits and waste rock piles, including the more reactive waste rock piles and the ore surge pile as well as the unlined permanent Category 1 waste rock pile, are made without considering the effects of fractures on discharge to groundwater and surface water.

Excerpts from three reports produced for the PolyMet project regarding groundwater/surface water interactions include the following:

“Groundwater samples were collected from three of the deep borings at the site. Two of the samples were collected from 6-in diameter exploratory boreholes. The remaining sample was collected from the water supply well (Unique Well Number 717972). This well is open to both the Duluth Complex (20-150 feet below ground surface) and the Virginia Formation (150-200 feet below ground surface)...The water sample from well MW-05-02 exceeded criteria for ammonia (240 ug/l), pH (10),aluminum (322 ug/l), and copper (11.2 ug/l). The sample from MW-05-08 exceeded criteria for aluminum (1,040 ug/l), copper (10 ug/l), and mercury (0.0053 ug/L). The sample from MW-05-09 exceeded criteria for aluminum (4,640 ug/L), chromium (28.6 ug/l), cobalt (5.4 ug/l), copper (72.2 ug/l), lead (5.6 ug/l), and mercury (0.0181 ug/l)... The presence of ammonia in the deep boreholes may indicate that the water in the borehole came from the shallow surficial deposits. Ammonia is not typically found in deep bedrock systems but is common in wetland environments.”¹²

¹² Hydrogeologic Investigation- PolyMet NorthMet Mine Site report RS-02. Barr Engineering. 2006

“The water samples from wells P-2 and P-4 exceeded the nitrogen (ammonia as N) criteria (270 ug/L and 110 ug/L respectively). The presence of ammonia nitrogen in the samples likely indicates that there is a hydraulic connection between the bedrock aquifer and the surficial aquifer; however, the nature of this connection cannot be determined at this time.”¹³

“The samples from pumping well P-2 all contained measurable tritium, indicating that at least a portion of the source water is post-1952 water.”¹⁴

The Peter Mitchell Pit lies approximately one mile north of the proposed PolyMet mine pit. Taconite production began in 1955 at the Peter Mitchell Pit. Based on the review of the Peter Mitchell NPDES permit MN0046981 at various discharge locations, unionized ammonia nitrogen has exceeded permit limits on numerous occasions¹⁵. Unionized ammonia nitrogen is used to blast rock. Though PolyMet did not determine what the source unionized ammonia or tritium found in the deep boreholes was, it seems likely that because of the Peter Mitchell Pit’s close proximity to the proposed PolyMet mine site, the Peter Mitchell Pit is the source of contamination. The approximate fifty- year travel time of the pollutants found in the P-2 bore hole from the Peter Mitchell Pit were not used to estimate travel time for pollutants leaving the PolyMet mine pit and reaching the Partridge River, or even to calibrate the model.

In fact, bedrock groundwater flow paths have not been determined using standard methods for hydrogeologic investigations. Instead, a model has been developed that uses extremely low baseflows in the Partridge River in order to suggest that peak concentrations of contaminants will not reach surface water features for hundreds or even thousands of years. Even though data collected for PolyMet in the three hydrologic investigations between 2006 and 2007 demonstrate a strong connection between boreholes in the bedrock aquifer and the surficial aquifer and surface water (including wetlands). This information, and the results from winter flow monitoring have not been incorporated into the PolyMet project projections for surface and groundwater quality and quantity.

Groundwater contamination from the previous mining activities is still an issue near the LTV tailings basin and mine pits more than twenty years after operations have ceased. The above evidence suggests that, whatever the degree of fractures now existing in the rock, blasting at the levels proposed by PolyMet will create damage to rock masses and rock fractures over an extensive area, including the entire mine site and extensive adjacent wetlands areas (Figure 16). This evidence requires that the impacts of fractures on propagation of pollutants from all mine sources be analyzed in detail and calls into question PolyMet's claims that discharge of sulfates and toxic metals from the mine site will not impact wetlands and exceed water quality standards. The impacts of vibrations and airblast on slope stability of waste rock piles are not discussed in the SDEIS either.

¹³ Hydrogeologic Investigation – Phase II PolyMet NorthMet Mine Site RS-10. Barr Engineering. 2006

¹⁵ MPCA DMR data for MN0046981 from website “What’s in My Neighborhood”

(<http://www.pca.state.mn.us/index.php/data/wimn-whats-in-my-neighborhood/whats-in-my-neighborhood-text-search.html>) (last visited 9/4/13)

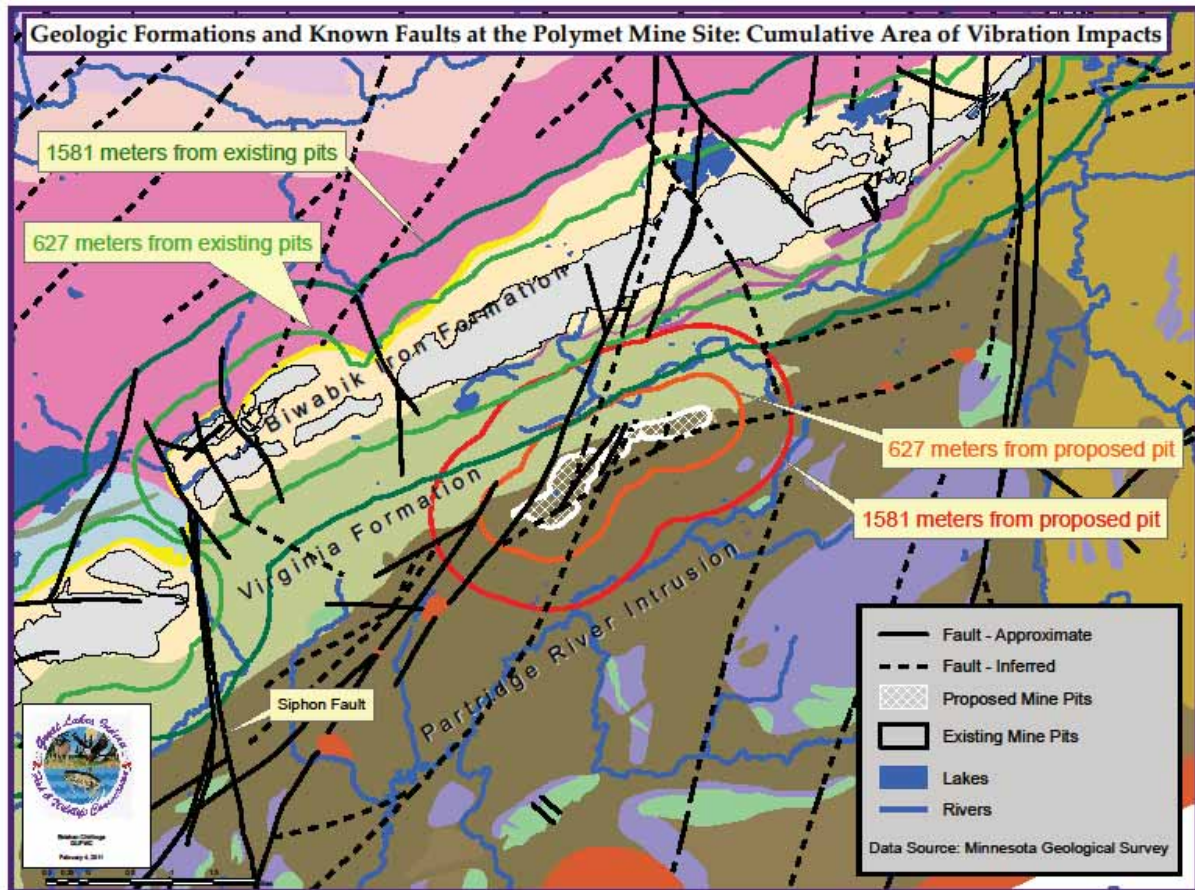

Figure 16. Cumulative Area of Vibration Impacts.

Impacts to water quality in the immediate vicinity of the project area from mining activities include:

Peter Mitchell Pit: Expansion of the Peter Mitchell Pit to the South towards the proposed PolyMet project and the in-pit disposal of Virginia Formation waste rock.

Former LTV Site (Cliffs): Dunka Pit, Area Pit 5, Tailings Basin, Area Pit 2, Area Pit 3

Mesabi Nugget: Area Pit 1, Area Pit 9, Area Pit 9S, Area Pit 6, Area Pit 2WX, Stevens Pit

Considering there are domestic wells south of the property, and pit 2WX will likely overflow to surface water features when mining has ceased, contaminant transport models for surface and groundwater need to be developed if pit 2WX or pit 6 are mined due to the presence of the Virginia Formation and the Aurora Sill.

Wetlands

The co-lead agencies confined their cumulative effects analysis for wetlands to the Partridge and Embarrass River watersheds, simply quantifying the wetland acreage change from pre-settlement conditions to the present, then projecting the estimated acres in the future based upon impacts due to the NorthMet Proposed Project. The co-lead agencies, relying upon the XP-SWMM model developed for the Partridge River, conclude that “changes in annual flow (and therefore stage) in the Partridge River would be within the naturally occurring annual variation for the Partridge River. Therefore, no potential indirect cumulative wetland effects are identified for the wetlands abutting the Partridge River.

The PSDEIS states: “The St. Louis River is located downstream of the Partridge River. Effects on flows (and, by extension, water surface elevations) generated by the NorthMet Proposed Action are anticipated to be less than those estimated for the Partridge River and within the natural variation of flow within the St. Louis River. Therefore, no potential indirect cumulative wetland effects are identified for the wetlands within the St. Louis River below the ordinary high water mark from its confluence with Embarrass River to Lake Superior.”

The tribal cooperating agencies take a different approach to quantifying cumulative wetland impacts for the NorthMet Proposed Action. Referencing the alternative indirect wetland impacts analysis provided by GLIFWC for the PolyMet mine site, tribal cooperating agencies believe that cumulative wetland impacts within the St. Louis River watershed should be the scale of the analysis, and that direct and indirect wetland impacts due to hydrologic modification (ditching) should be included (Figure 17). There are 1,387,630 acres of wetlands in the St. Louis River watershed, with 1732 individual wetlands impacted by ditching, totaling 198,989 acres. Ditching has occurred in 14.3% of the wetlands in the watershed. Approximately 50% of the subwatersheds have had some degree of impact from ditching, while some have experienced ditching in nearly 100% of their wetlands. Clearly, this has a profound impact to the connected surface waters, and impacts to specific stream reaches should be assessed.

There are direct impacts to wetlands that occurred when the ditches were constructed. Those impacts depend on the length and width of each ditch. The second, and larger, set of impacts is indirect. The ditches have converted some percentage of the wetlands to upland, and changed the functions and values of another percentage of wetlands.

Figure 17. St. Louis River Watershed Hydrologic Impacts from Ditching

Tens of thousands of acres of high quality wetlands within the St. Louis River watershed have been entirely and permanently lost to historic and current mining operations, prior to regulatory requirements for mitigation. Since the initiation of state and federal wetland mitigation requirements for permitting wetland dredge and fill activities, most mitigation has taken place outside the St. Louis River watershed and has not replaced the wetland types and functions that have been lost. Nearly 3000 additional wetland acres will be directly impacted under several reasonably foreseeable mining projects within the watershed (Figure 18).

Figure 18. Cumulative Hydrologic Impacts: Expected Wetland Losses within the St. Louis River watershed

When all impacts to water quality, aquatic communities, wetlands, and hydrology are considered in a comprehensive manner, the cumulative effects on water resources are extensive (Figure 19).

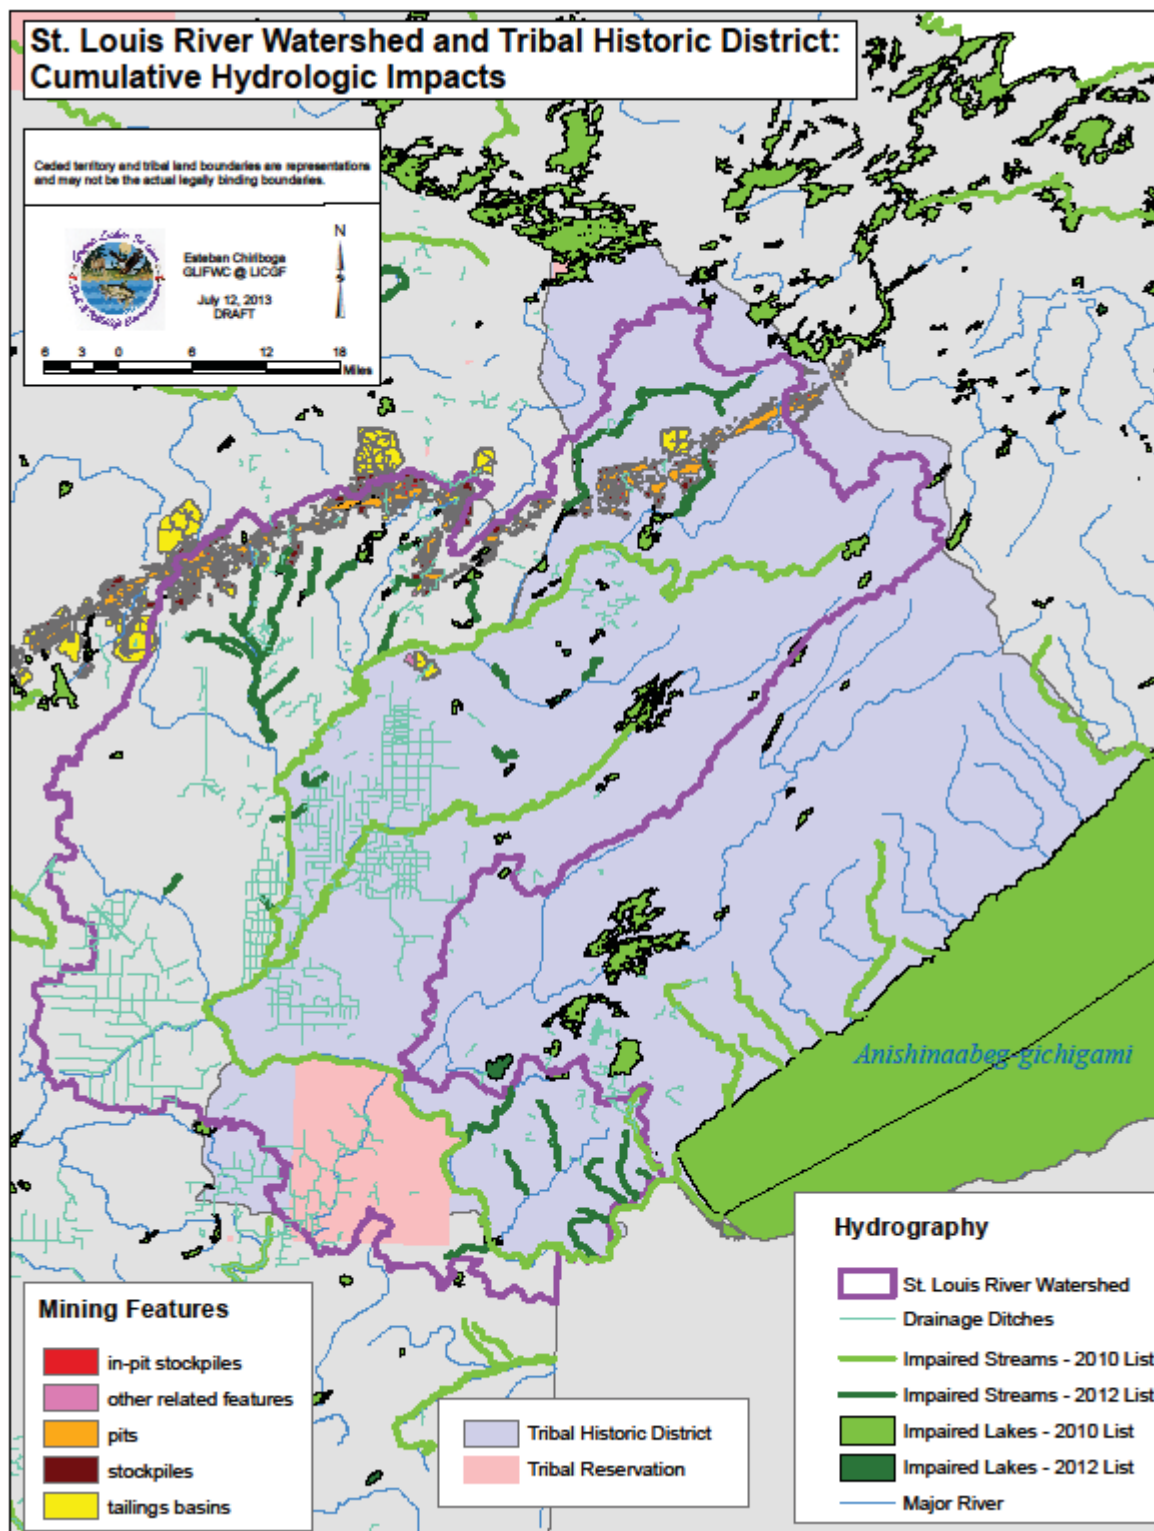

Figure 19. St. Louis River Watershed and Tribal Historic District: Cumulative Hydrologic Impacts.

Vegetation

The co-lead agencies evaluated cumulative effects on vegetation within the portion of the Mesabi Iron Range encompassed by the Nashwauk Uplands and Laurentian Uplands ecological subsections. From the preliminary SDEIS:

“Minnesota Biological Survey

The MDNR operates the MBS program, which includes spatial information from survey reports on native plant communities and rare species. Sites of Biodiversity Significance are designated and ranked by the MDNR based on the environmental conditions present, including native plant communities, rare species, and unique habitat. The MBS utilizes a four-tiered ranking system: Outstanding, High, Moderate, and Below (from highest to lowest). Sites of High Biodiversity Significance contain very good-quality occurrences of the rarest species, high-quality examples of rare native plant communities, and/or important functional landscapes (MDNR 2008a). The entire 3014.5-acre Mine Site has been characterized by the MBS as various Sites of High Biodiversity Significance due to the presence of the One Hundred Mile Swamp site, which covers 15 percent of the Mine Site, and the Upper Partridge River site, which is 85 percent of the Mine Site (MDNR 2008a).”

The tribal cooperating agencies believe a more relevant spatial reference for cumulative effects to vegetation would include the One Hundred Mile Swamp and the Headwaters Site. Additionally, the “Contributing Past, Present and Reasonably Foreseeable Actions should include the extensive mineral exploration taking place within the headwaters of the St. Louis River. The degradation and destruction of this landscape and the vegetation that provides forage and habitat for culturally important species, as well as sustenance and medicine for band members, has been a cumulative impact to cultural and natural resources since the signing of the treaty.

From Danielson and Gilbert (2002):

“The Ojibwe gather over 350 wild plant species for food, utilitarian, medicinal, ceremonial, and commercial purposes (Meeker, Elias and Heim 1993; Densmore 1928). Examples include sweet grass (*wiingashk*), white sage (*mashkiki*), basswood (*wiigob*), yellow birch (*wiinizik*), paper birch (*wiigwaas*), wintergreen (*wiinisiibag*) red-osier dogwood (*miskoobimizh*), bearberry (*miskwaabiimag*), wild sarsaparilla (*waaboozojiibik*), white water lily (*akandamoo*), bluebead lily (*odotaagaans*), Canada mayflower (*agongosimin*), swamp milkweed (*bagizowin*), wood lily (*mashkodepin*), rue anemone (*biimaakwad*), wild ginger (*namepin*), blue cohosh (*beshigojiibik*) bloodroot (*meskwijjibikak*), black ash (*aagimaak*), yarrow (*ajidamoowaanow*), wild rose (*oginiiminagaawanzh*), Labrador tea (*waabashkikiibag*), sweet flag (*wiikenh*), wild black current (*amikomin*), wild blackberry (*odatagaagominagaawanzh*), blueberry (*miinagaawanzh*), nannyberry (*aditemin*), and highbush cranberry (*annibiminagaawashk*). Tribal members may gather wild plants, as guaranteed by their treaty rights, on all public lands within the ceded territories.

The Ojibwe have been “managing” (e.g., respecting, observing and utilizing) the land and its resources since time immemorial. However, tribal members seldom use the term “managing.” Through the sharing of stories and spiritual beliefs, elders transfer a wide spectrum of skills and information to younger generations. Some scholars refer to this

information as traditional ecological knowledge and wisdom (TEKW). Berkes (1999) defines TEKW as “a cumulative body of knowledge, practice, and belief, evolving by adaptive processes and handed down through generations by cultural transmission, about the relationship of living beings (including humans) with one another and with their environment. TEKW does not reflect a stagnant inventory of information but rather, without disregarding past wisdom, continues to transform through time.

TEKW and contemporary ecosystem management, though not identical, share common characteristics. A report published by the Ecological Society of America Committee on the Scientific Basis for Ecosystem Management states: “Ecosystem management is management driven by explicit goals, executed by policies, protocols, and practices, and made adaptable by monitoring and research base on our best understanding of the ecological interactions and processes necessary to sustain ecosystem composition, structure, and function. In additions, “ecosystem management assumes intergenerational sustainability as a preconditions for management rather than an afterthought” (Christensen et al. 1996). Clearly, shared principles include adaptive management through observation and monitoring and an intergenerational sustainability, including the relationship and dependence of humans and all life on each other.

The tribes remind (these) land managers that, as necessitated by trust responsibility and treaty law, they must ensure the availability and sustainability of wild plant harvest. Irrevocably, the Ojibwe worldview teaches values based on an understanding that humans depend on all other earth beings (Johnston 1976).”

Further documentation of the high quality and ecological function of this landscape is found in *An Evaluation of the Ecological Significance of the Headwaters Site, Northern Superior Uplands Ecological Land Classification System Section; Laurentian Uplands Subsection Lake and St. Louis Counties, Minnesota, March 2007*):

“The Headwaters Site straddles the continental divide, with water from the Site flowing both east through the Great Lakes to the Atlantic Ocean and north to the Arctic Ocean. Paradoxically, the divide runs through a peatland. Although the peatland appears flat, water flows out of it from all sides, forming the ultimate source of rivers that eventually reach two different oceans. The Site is the headwaters of four rivers: Stony River, Dunka River, South Branch Partridge River, and the St. Louis River, which is the second largest tributary to Lake Superior...

The Headwaters Site encompasses vast peatlands on its eastern side, unfragmented upland forests in the west, and broad transition zones between them. Within the Site are two distinct areas, referred to in the document as the “Extensive Peatlands” and the “Big Lake Area,” which are linked hydrologically as part of the Upper St. Louis River watershed. The Extensive Peatlands area is a mosaic of open and forested wetland communities and includes forested upland islands and peninsulas. The Big Lake Area, in the southwestern quarter of the Site, includes Big Lake and surrounding unfragmented upland forest interspersed with small wetlands.

The Headwaters Site is unique in northeastern Minnesota in several ways. The size and complexity of the peatlands in the Extensive Peatlands are unmatched in the Northern Superior Uplands Ecological Land Classification System (ECS) Section. The Sand Lake Peatland Scientific and Natural Area (SNA), established by the Wetlands Conservation Act of 1991, protects one of the 15 most significant peatlands in the state, and it is by far the largest SNA in the Section (MNDNR 1984).

The Nature Conservancy's (TNC) Superior Mixed Forest (SMF) Ecoregion Plan identifies the Sand Lake/Seven Beavers (SL7B) conservation area, including the entire Headwaters Site, as one of 51 conservation areas in the Ecoregion that best represent the ecosystems and species of the Ecoregion, and serve as a blueprint for conservation action...According to the SMF Ecoregion Plan, these conservation areas are the best opportunities for conserving the full diversity of terrestrial and aquatic ecosystems and globally rare or declining species. The SMF Ecoregion Plan identifies these areas as critical places for conserving biodiversity...and outlines the threats to conservation and conservation targets for these areas...recognizing that more detailed site planning is needed to address how to implement conservation efforts...

The Minnesota Pollution Control Agency has ranked the Upper St. Louis River watershed in the second highest category in the Lake Superior Basin for watershed integrity (Minnesota Pollution Control Agency 2003). The Headwaters Site is among the highest quality areas within the watershed. The upland forest surrounding Big Lake is among the largest, if not the largest, unfragmented, predominantly upland forest in the North Shore Highlands, Toimi Uplands, and Laurentian Uplands (NTL) ECS Subsections. The upland forest area covers 7,920 acres (including 788-acre Big Lake). This high-quality, fire-dependent forest has not been logged in recent decades, except for two stands totaling 140 acres, along the northern edge of the Site.

Covering an area roughly 11 to 12 miles (from northeast to southwest) by 7 to 8 miles (from northwest to southeast), the Headwaters Site is a mosaic of high-quality native plant communities that have functioned under relatively undisturbed conditions since the nineteenth and early twentieth century, when parts of the Site were logged and then burned by wildfires. A corridor containing a railroad grade and power line crosses this vast area, representing the only major permanent conversion of the natural landscape. Minnesota County Biological Survey (MCBS) sites bordering about two-thirds of the Site's boundary have been assigned High or Moderate statewide Biodiversity Significance (Figure 4, page 85). The lack of roads, absence of recent large-scale logging, and large size of the Site allow for natural functioning of ecological processes. These processes include disturbances such as wind, fire, and flooding, as well as plant species competition, nutrient cycling, and hydrology. Natural landscape patterns, such as patch size of the various plant communities, have not been altered, in comparison with most other parts of northeastern Minnesota (White and Host 2003). Minimal recent human disturbance also results in a landscape with very few populations of exotic or invasive species.

The predominant upland forest native plant community in the Big Lake Area is Aspen – Birch Forest [FDn43b], with inclusions of Upland White Cedar Forest [FDn43c] and White Pine – Red Pine Forest [FDn43a] (Figure 5, page 87). Isolated wetlands within the Big Lake

Area's upland forest support a variety of native plant communities, including Northern Poor Conifer Swamp [APn81], Northern Rich Spruce Swamp (Basin) [FPn62], White Cedar Swamp (FPn63a), Northern Alder Swamp [FPn73a], and Black Ash - Conifer Swamp [WFn64a]...

The Extensive Peatlands are composed of a complex of native plant communities, including Northern Cedar Swamp [FPn63]; Northern Rich Spruce Swamp (Basin) [FPn62]; Northern Alder Swamp [FPn73]; Northern Rich Tamarack Swamp (Water Track) [FPn81]; Northern Rich Fen (Water Track) [OPn91]; Northern Rich Fen (Basin) [OPn92]; Northern Shrub Shore Fen [OPn81]; Northern Spruce Bog [APn80]; Northern Poor Conifer Swamp [APn81]; Northern Open Bog [APn90]; and Northern Poor Fen [APn91]. The many upland islands in this portion of the Site provide additional native plant community diversity, supporting community types in the Northern Dry-Mesic Mixed Woodland [FDn33] and White Pine-Red Pine Forest [FDn43] classes...

The Headwaters Site supports healthy known populations of eight state-listed plant species, all of which are listed as Special Concern (SPC) in Minnesota: coastal sedge (*Carex exilis*), Michaux's sedge (*Carex michauxiana*), English sundew (*Drosera anglica*), bog rush (*Juncus stygius*), small green wood orchid (*Platanthera clavellata*), Lapland buttercup (*Ranunculus lapponicus*), sooty-colored beak rush (*Rhynchospora fusca*), pedicelled woolgrass (*Scirpus cyperinus*/*S. pedicellatus*), and Torrey's mannagrass (*Puccinellia pallida*)...The unfragmented complex of high-quality native plant communities within and across the Site's landforms provide excellent habitat for a wide variety of animal species distinctive of the landscape, including moose, gray wolf, sandhill cranes, American bitterns, boreal and great gray owls, and numerous amphibians, butterflies, and small mammals.

In 2005 and 2006 the Minnesota County Biological Survey of the MN DNR conducted rare plant and native plant community fieldwork, mapped the native plant communities and completed this Ecological Evaluation of the Headwaters Site. Based on the natural features and conditions revealed through this recent work and that of others since the 1980s, MCBS recommends the primary management objective for the Headwaters Site be to protect, enhance, or restore ecological processes and native plant community composition and structure. In accordance with this objective, the site or portions of the site may be identified by landowners or land management agencies for conservation activities such as special vegetation management, including ecologically based silviculture and forest development activities, or for designation as a park (city, county, state, or private), research natural area, non-motorized recreation area, scientific and natural area, or other reserve. This Ecological Evaluation has been written to characterize the ecological significance of the MCBS Site as a whole and to serve as a guide for conservation action by the various landowners.

MANAGEMENT RECOMMENDATIONS

Overview

The Headwaters Site is a large, natural area with features of widely recognized statewide ecological and biological significance. These include:

- one of the 15 most significant peatlands in the state (MN DNR 1984, Wright et al. 1992);
- the largest SNA in the Northern Superior Uplands Section;

- one of the largest, unfragmented, predominantly upland forest patches in the Laurentian Uplands,
- Toimi Uplands, and North Shore Highlands subsections;
- an ecologically functional mosaic of high quality native plant and animal communities;
- a concentration of excellent occurrences of rare species populations;
- support of species with large home ranges;
- six state-designated old-growth stands;
- remote, undeveloped lakes.

The documented condition and quality of the aquatic and vegetation resources within this headwaters region of the St. Louis River watershed meet the resource-based threshold of an Aquatic Resource of National Importance, under the Memorandum of Agreement reached by the EPA and the US Army Corps of Engineers in 1992¹⁶.

Wildlife

The word “moose” does not appear at all in the SDEIS cumulative effects analysis, despite consistent concerns raised by tribal cooperating agency staff to co-lead agency staff during the environmental review process. As of August 19, 2013, moose are now proposed to be listed as a MNDR species of concern.

The tribal profile for the Grand Portage Band, states the unique importance of this species:

“Moose are the primary subsistence species for the Grand Portage Band and define the subsistence culture.”

http://www4.nau.edu/tribalclimatechange/tribes/greatlakes_lschippewa.asp

From the Fond du Lac Wildlife Biologist: “In my experience at FDL, moose have always had a loyal core of hunters who pursue moose every year. Primarily for meat, but some for hide, bone and antler related crafts. I think also for the camaraderie, family traditions, etc – same as the rest of us for deer or duck camp. For the last couple of years at least, FDL has been supplying other bands with moose hides for drums.

Until very recently, the demand for moose hunting opportunities at FDL has always been greater than the supply. It’s unique among locally hunted or trapped wildlife species that way. As the moose population has rapidly dwindled in the last couple of years, I believe more and more potential moose hunters are deciding it’s not worth the effort.

Of all wildlife species, moose has required the most back and forth discussions between staff, legal counsel and the DNR regarding co-management of resources within the 1854 Ceded Territory. This again is a supply and demand issue, and reflects the relatively low density at which moose populate the landscape – even when times were good. -My program invests more effort and money in annual population surveys of moose than any other wildlife species.”

¹⁶ Clean Water Act Section 404(q) Memorandum of Agreement, Part IV (August 11, 1992)

The rationale for a comprehensive cumulative impacts analysis for moose can be found in the MDNR SONAR proposing listing of moose as a species of special concern:

(p. 21) “Between 1990 and 2000, the northwestern Minnesota Moose population underwent a substantial decline, and a 2007 Minnesota DNR aerial survey determined that as of that date, fewer than 100 Moose comprised the northwestern population. Aerial surveys currently estimate the northeastern Minnesota population at roughly 4,230 individuals. The northwestern Minnesota Moose population decline occurred in less than a decade. Recent surveys document a slow decline in the northeastern Minnesota Moose population.

“Increased temperatures are likely to increase heat stress and lead to increased mortality within the state’s remaining Moose populations. Changes in land ownership and changes in forest management practices within the state’s Moose range may be having a significant adverse effect on the quantity and quality of the species’ habitat within the state, and particularly on thermal refuges in warmer weather. The state’s northeastern Moose population has not shown as rapid a decline, but is very likely to be dramatically impacted by rising temperatures resulting from climate change. This will likely lead to a marked decline in this population within the foreseeable future.”

From the *Report to the Minnesota Department of Natural Resources(DNR) by the Moose Advisory Committee (18 August 2009)*:

“In MN, moose habitat can be characterized as young forest stands, older forest stands with gaps of regenerating forest, wetlands, muskeg, marsh, riparian areas and brushlands with abundant deciduous browse within reach of moose and adequate winter and summer thermal cover. Functionally, habitat provides forage and cover. Moose forage has a primarily deciduous browse component and a seasonal aquatic component. Cover has several potential components for moose: protection from heat, protection from deep snow, moderation of cold temperatures, predator avoidance and presence of calving locations. In addition to the functional aspects of habitat, spatial distribution of habitat must also be considered at a variety of scales (from subhome range to the landscape level).

“As moose are increasingly challenged by warmer temperatures and changing precipitation patterns due to climate change, changes in land ownership and changes in forest management practices that occur within MN moose range have the potential to significantly affect the quantity, quality, and distribution of moose habitat. Examples include but are not limited to: habitat fragmentation due to expected and occurring ownership changes and shifting landowner objectives, changes in the extent of forest management due to national and state economic effects on the primary wood- using industry in Minnesota, and increased harvesting of smaller diameter trees and brush used by moose for browse as the demand for woody biomass increases. Focused management to provide high quality habitat (forage and cover) may be necessary to slow population declines and maintain or recover moose in appreciable numbers in Minnesota.”

A cumulative impacts analysis must be done for this species of concern that it is of particular cultural importance to the Bands.

Air

Fugitive dust:

The tribal cooperating agencies believe that wind-blown dust particles containing sulfate compounds that are emitted from mining and beneficiation activities could contaminate wetlands, lakes, and streams near the project site and could cause harm to the Species of Special Concern that have been found in this area and to the animals that depend on these plants for food. While the PSDEIS attempts to address this issue, this is the first time details of this analysis have been available for review, and the tribes have identified some areas that require more work. The tribes do not agree with the assumption that only those areas showing model-estimated deposition rates greater than 100% of background deposition will be impacted. The choice of the “100% of background” level of deposition appears to be arbitrary and is not supported by any documentation. Further, the modeled deposition rates do not include the effects of contamination to wetlands and water bodies that may occur through other mechanisms, such as pit leaks and seepage, nor how additional sulfate will impact waters that are already experiencing elevated sulfate levels, with regard to the growth of wild rice. The work that has been done so far in this section does not meet the definition of a cumulative review.

The text describing this analysis is also unclear in places, as described below. In addition, tribal cooperating agency air staff members were not consulted regarding the impact of fugitive dust on historic properties and the definition of intra-property APE, especially with regard to mercury or acid dust (See page 4.2.9-9 of the PSDEIS).

All figures and page numbers cited below refer to the PSDEIS.

Misleading Description

- While areas of fugitive dust deposition may not exceed the ambient air quality standard beyond the property boundary, as stated in the PSDEIS, this information is irrelevant with regard to the tribes’ concerns regarding sulfide dust, because there is no ambient air quality standard that is applicable to sulfide dust. Therefore, statements of this nature should be removed.

Acid and Metallic Dust

- Figure 5.2.3-23 (PSDEIS) shows that there are indeed potential indirect impacts to wetlands outside of the ambient air boundary due to deposition of dust. Figure 4.2.9-3 corroborates this claim by showing that the Fugitive Dust Area of Potential Effects extends well beyond the plant site.

- Page 5.2.3-6 lists the fugitive sources that were modeled for deposition. Rail cars and tailings basins were not included. Section 5.2.3.2.2 (page 5.2.3-58) states that the air IAP group determined that emissions from railcars would be coarse in nature and would not be dispersed to any great extent; therefore these emissions were not modeled. The section also states that “Based on this conclusion, air modeling of potential release of dust from railcars will not be performed because the potential wetlands effects would not be significant”. The analysis also assumes “that all spillage of the coarse material would occur in a 2-meter-wide strip on both sides of the center line of the railway over the entire haul distance.” While the dust may settle near the tracks, there is no evidence that it will not subsequently disperse and cause impacts. The dust can easily be spread through run-off.
- Tailings basin emissions were not modeled. Pages 5.2.3-50 and 5.2.3-51 and page 5.2.3-74 discuss fugitive dust somewhat, but do not make it clear whether “dust” is meant to address the acidic composition of the dust, or some other component. There are also contradictory statements on page 5.2.3-51: “All of the receptor nodes with the highest model-estimated deposition rates were located within the ambient air boundary” versus “Of the 234 acres of wetlands, 228 acres (97%) would be located within the Mine Site ambient air boundary”. “97%” does not equal “all”; apparently 6 acres of wetlands with the highest model-estimated deposition rates are outside of the ambient air boundary.
- Figure 5.2.3-17 indicates that the Partridge River could be impacted by fugitive dust, however this is not stated or addressed in the text.
- From page 5.2.3-51 “The potential release of dust from railcars transporting ore from the Mine Site to the Plant Site was addressed in an Air Quality IAP Workgroup that concluded potential wetland effects would not be significant and, therefore, air modeling was not performed (PolyMet 2013b). The tribal cooperating agencies have not been provided with any report that was generated by that workgroup, nor do they have any information about how that conclusion was reached. Also, “Of the 19,914 acres of wetlands identified within the Mine Site receptor grid, deposition modeling results indicated that 234 acres of wetlands could be potentially indirectly affected (modeled metal deposition rates greater than 100% of the background”. It is unclear whether modeling was performed for both metals and sulfide dust, and whether the results discussed on page 5.2.3-74 are for metals or sulfide dust. While Figures 5.2.3-16, 5.2.3-17, 5.2.3-22, and 5.2.3-23 differentiate between metals or dust modeling results, the discussion needs to be clearer.

- There are a number of unclear or incorrect statements under the heading *Fugitive Dust/Metals and Sulfide Dust Emissions* on page 5.2.3-74. Initially, the section states that “all receptors have model-estimated dust deposition of 50% or less of the effects-level background of 365 g/m²/yr” but the next sentence states that “at the Plant Site, there would be two locations showing model-estimated deposition rates greater than 100% of background deposition”. These two statements are contradictory.
- It is not clear which metals were modeled and whether the background concentrations mentioned (365 g/m²/yr) was for metals or sulfide dust. There is no explanation for the origin of this background concentration and how the metals concentrations in dust were obtained. There is also no explanation of why 100% of background deposition was chosen as an indicator of whether potential effects could occur. To our knowledge, no discussion of this modeling or the assumptions contained within it was conducted with tribes or the co-leads before the PSDEIS was released.
- This section also indicates that the “southern and western two-thirds of the basin” shows model-estimated deposition rates greater than 100% of background deposition (exactly what constituent is being discussed is not clear). However, this same paragraph goes on to state that only 193.9 acres of wetland out of 25,846 could be potentially indirectly affected. These two statements appear to contradict one another. Without knowing what constituent is being discussed, it is hard to know which figure (5.2.3-16, 5.2.3-17, 5.2.3-22 or 5.2.3-23) corresponds to the text. Also, the yellow highlighted area on Figure 5.2.3-23, which indicates the “extent of the highest estimated deposition receptors with deposition of 100% of background”, appear to cover a much larger area than 193.9 acres out of 25,846 total acres.
- The paragraph also states that “approximately 90% of the receptor nodes with the highest model estimated deposition rates are located within the ambient air boundary”. It is impossible to verify this statement, because a map showing the location of the receptor nodes does not seem to have been included. If this statement is true, it overlooks that fact that 90% of the *area* predicted to be impacted does not lie within the ambient air boundary - only about 60% does, judging from Figure 5.2.3-23.
- The tribal cooperating agencies do not agree with the statement that “no potential indirect wetland effects from fugitive dust to Second Creek would occur” (page 5.2.3-74). A portion of Second Creek appears within the area predicted to experience deposition of 100% of background.

- Chapter 5's discussion of fugitive sulfide dust calls for future wetlands monitoring where predicted deposition will exceed 100% of the background value (first full paragraph on page 5.2.3-51). This monitoring should look at water chemistry, hydrology, soil color, texture, and composition and should take place annually for the first three years of operation and then every five years afterward. Baseline numbers should be obtained before construction starts.
- Page 5.2.4-4, *Indirect Effects* calls for water spraying areas of fugitive dust release during dry periods. Page 5.2.7-8 also calls for watering haul roads and other unpaved roads. In the case of dust that may have high acidic content, this would be a poor option, as the addition of water to the dust could simply create problems with run-off. The fugitive dust control plan also lists several monitoring options that "could" be done. These are left as vague ideas, but are not required. These options should be made more concrete.

Fibers

The tribes believe that the cumulative impacts of mineral fibers are not adequately addressed in the PSDEIS. In fact, no cumulative impact analysis of mineral fibers was performed because the PSDEIS asserts that mineral fibers will not be contacted in this project. This is a reckless assumption to make, with little evidence provided for justification, and it leaves a potentially harmful situation completely unaddressed. For example, the distance of the PolyMet project to known deposits of mineral fibers should be given in the PSDEIS. Rates of mesothelioma on the Iron Range are already alarmingly high, making it irresponsible for potential cumulative impacts to remain unaddressed. Although preliminary results from the University of Minnesota indicate that exposure to dust from today's taconite operations is "generally within safe exposure limits", it is possible that exposure to additional dust could lead to more cases of mesothelioma 30-40 years in the future, after the mine has closed. This is an issue that should unquestionably have received a cumulative impacts analysis. While the mine is expected to close in 20 years, this is not a timeframe that is relevant to either tribal concerns or to the development of mesothelioma. Tribal members live and recreate in areas close enough to the mine for this to be a source of concern. The proximity of fish, game, and culturally significant plants to the project site cause this issue to be an item of concern.

Only one year of mineral fiber monitoring in Hoyt Lakes is proposed in the PSDEIS, which the tribes believe is insufficient for detecting the potential release of fibers from portions of the formation that will be encountered during later years of operation. It is also not clear why Hoyt Lakes was chosen as a monitoring site, or if this where air dispersion modeling predicts maximum impacts. The tribes would expect to see monitoring performed for the entire life of the mine, at the site of maximum predicted impact. Since no "safe" mineral fiber concentration level has yet been specified, the tribal cooperating agencies urge the State of Minnesota to move forward to set this limit as soon as possible.

Noise

The co-lead agencies simply state that there are no other past, present, or reasonably foreseeable actions that would interact in such a way as to have a cumulative effect on the receptors identified in Sections 4 and 5 and no further evaluation of cumulative noise effects has been conducted. The tribal cooperating agencies believe it is indefensible to conclude that, amidst a “mining district” with multiple active mine facilities operating in close proximity, that there is no cumulative effect of 24 hour/day, seven days/week of heavy industrial and blasting noise on sensitive wildlife and on traditional cultural practices.

Cumulative Impacts of Noise, Vibration and Airblast Overpressure

Tribal cooperating agencies note that the noise information presented in the PSDEIS will be replaced with new data in the SDEIS. We have not been afforded the opportunity to review this information and must withhold detailed comment on the noise analysis for a later date.

With respect to cumulative impact analysis, tribal cooperating agencies do not believe that an adequate analysis has been done. Meeting ambient noise standards is a different question than assessing impacts. Impacts should be fully characterized in this document and contour maps showing overlapping noise pollution from different projects provided. Without this information, it is not possible for the public to review the cumulative impacts of noise. In addition, the cumulative impacts of mine related vibration have not been assessed. As shown in Figure 20, the cumulative effects of vibration are spatially extensive.

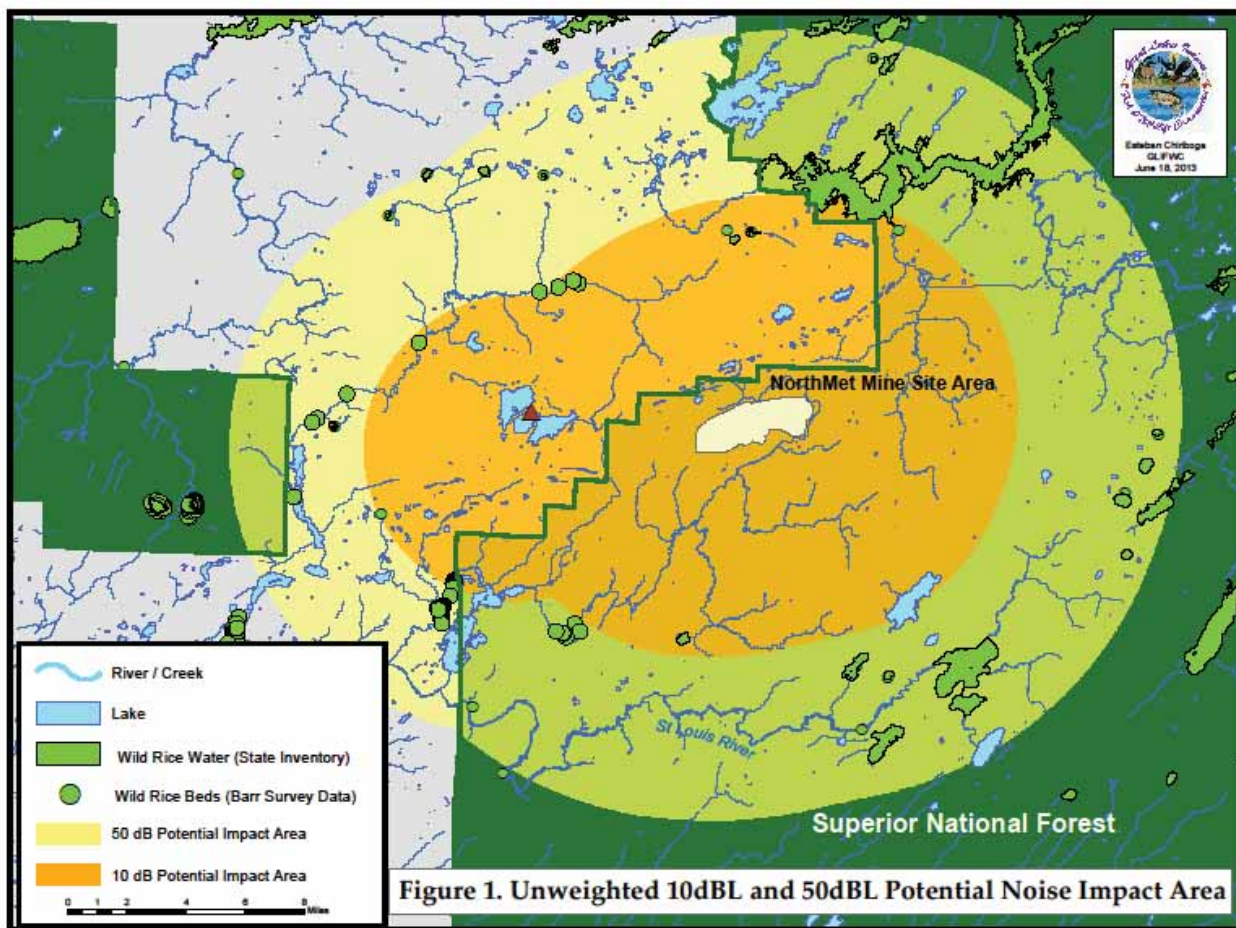

Figure 20. Unweighted 10 dBL and 50 dBL Potential Noise Impact Area

Tribal cooperating agencies also note that the noise, vibration, and airblast overpressure analysis confuses baseline noise levels with existing conditions and assumes they are the same thing. Baseline noise levels in the SDEIS should be natural noise levels that do not include existing mine operations such as Northshore. In other words, baseline is the pre-mining condition. Existing conditions are the noise levels currently recorded at the site of the proposed mine which include any contributions from the Northshore mine, the Dunka road, etc. The analysis would then use both of these pieces of information to assess the effects of the project as a single entity and in combination with other projects in the cumulative section. The lead agencies have indicated that they are using existing conditions (currently measured noise levels) as background. This is not appropriate and should be corrected.

The noise data presented in the SDEIS used A-weighted decibel data (dBA). This is appropriate when considering the effects of noise on humans because it focuses on the frequencies that the human ear can perceive. However, this weighting is not appropriate when assessing the effects on animals because they can perceive different, and often greater, ranges of frequencies than humans. The United States Department of Transportation (USDOT) has

developed a document¹⁷ describing the effects of noise on animal populations. In general the document indicates that the sensitivities of various groups of wildlife can be summarized as:

- Mammals < 10 Hz to 150 kHz ; sensitivity to -20 dB
- Birds (more uniform than mammals) 100 Hz to 8-10 kHz; sensitivity at 0-10 dB
- Reptiles (poorer than birds) 50 Hz to 2 kHz; sensitivity at 40-50 dB
- Amphibians 100 Hz to 2 kHz; sensitivity from 10-60 dB

Figure 21 indicates the noise area of impact for wildlife. The noise contours are unweighted decibel values (dB). A more complete analysis of these impacts in the SDEIS document for the NorthMet project is needed. Known locations of wild rice are included in the map because it is an important source of food for waterfowl. We also note that the entire area of impact is important habitat for Canada Lynx.

As illustrated in Figures 21 and 22, the impacts of noise, airblast and ground vibration overlap in a large area surrounding the mine site. Figure 21 (Cumulative Impacts on Wildlife) also provides the location of the remaining wildlife corridors in the area. The wildlife corridor immediately northwest of the mine site would be cumulatively affected by noise (10dBL and 50 dBL) airblast overpressure and ground vibration. These impacts when thought of in the context of its proximity to the mine site, wetland destruction and fragmentation of the 100 mile swamp lead to a conclusion of a severe and significant impact to this corridor. Figure 22 (Cumulative Impacts on Humans) indicates areas of tribal significance that are affected.

No Action Alternative

A December 3, 2008 memo from NTS to the MPCA regarding the Area of Concern (AOC) Summary for the VIC Projects on the Cliffs Erie Property shows twenty-nine AOCs within the Project area. Only three AOCs have been remediated. Twenty of the remaining twenty-six sites' status is listed as "Area within property under Contract for Sale with PolyMet. No actions have been taken with regard to this site."

Some of those sites include: "Oily Waste Disposal Area, Private Landfill, Dunka WTP Sludge, Tailings Basin Reporting, Transformers, Emergency Basin, Cell 2W Salvage Area, Hornfels..." It also appears that there has not been a brownfield/superfund site investigation for the properties PolyMet intends to acquire for the Project area to assess existing contamination. Therefore, critical information to determine cumulative impacts at the site are not included in the SDEIS, and natural background water quality cannot be differentiated from existing contamination requiring remediation.

According to CEQ guidelines:

"No action" in such cases would mean the proposed activity would not take place, and the resulting environmental effects from taking no action would be compared with the effects of permitting the proposed activity or an alternative activity to go forward.

Where a choice of "no action" by the agency would result in predictable actions by others, this consequence of the "no action" alternative should be included in the analysis. For example, if denial of permission to build a railroad to a facility would lead to construction of a road and increased truck traffic, the EIS should analyze this consequence of the "no action" alternative."

Based on the above CEQ guidelines, it is clear that activities that will occur under the Cliffs Consent Decree should be included in modeling of a No Action alternative. Unfortunately not only are the consent decree activities not included, but the fact that it will be precipitating on the tailings basin for the foreseeable future has not been included in the No Action modeling. This is evident by the model results that show stable levels of chloride coming from the basin for the next 200 years (Figure 23) when there is no ongoing source for chloride. With no source for new chloride, rainwater will gradually dilute the residual chloride in the basin and levels will drop. The PSDEIS claims that the basin's water quality has stabilized and that the current conditions will not change over time. The claim of chemical stability is based on basin pond water sampling for only 4 years (2001 – 2004, PSDEIS Table 4.2.2-23).

Since there has been no water quality data collected in the basin pond for 9 years it is reasonable to assume that the past 9 years of precipitation has diluted the water chemistry in the basin pond, and that eventually the more dilute water will percolate through the basins and be discharged at the toe. If chemical stability is to be assumed, more recent data on basin pool water chemistry is needed. While the CEQ makes it clear that a blind "continuation of existing conditions" model is inappropriate as a No Action alternative, a "continuation of existing conditions" model that ignores simple environmental processes such as precipitation is even less appropriate.

Figure 23. Annual Maximum of Concentration Statistics: Chloride at the North Toe.

Proposed Transport of Ore

GLIFWC staff disagrees that the amount of ore that could escape from rail cars would be “small.” Taconite pellets currently litter the railroad right-of-way between the plant site and the proposed mine site, confirming that spillage from rail cars does occur (attached Figure 1). Second, fugitive dust escaping through these gaps is also a concern. Given the duration of this proposed project and the large quantity of materials to be moved, approximately 228 million tons of ore and 394 million tons of waste rock, there will be tracking, dusting, and spillage of material that has been demonstrated to leach contaminants when exposed to air and water. Even a loss of only one thousandth of one percent (0.001%) of the extracted material to tracking, dusting or spillage would result in 6,220 tons of fine leachable material being released into the environment. Our experience with a much smaller, shorter duration, sulfide mine in Wisconsin (Flambeau Mine) indicates that tracking and dusting of ore and waste rock, even at a level that is unnoticed during operations, can result in soil and runoff contamination that exceeds standards.

Transport of ore between mine site and processing plant would be done by rail using the rail cars previously used by LTV. These cars are not sealed and will readily spill a fraction of the approximately 228 million tons of ore they are transporting. Attached are pictures of the cars proposed for transporting the sulfide ore (Figures 2 and 3). The rail line between the mine and the processing plant is approximately 8 miles long, 1 mile of which is over wetlands, and crosses over at least 3 creeks. The current proposal to use existing rail cars for ore haulage raises concerns about impacts to biotic endpoints along the rail corridor. Given the design and current condition of the rail cars proposed for transport an ecologically significant amount of spillage could occur into these streams, wetlands and their watersheds. Because transport will deposit some level of ore and ore dust along the rail line, methods for control of contaminated runoff from along the rail line must be developed and implemented in the mine plan.

The PSDEIS states that rail maintenance crews can collect spilled debris along the rail track. The material of significant concern would be too small to pick up. GLIFWC staff is unsure how ore debris can be visually distinguished by rail track maintenance crews from other rocks and ore that litter the embankments. In addition, spillage of fine ore pieces and dust (the most leachable sizes) into the wetlands and creeks that are located along the rail line could not be easily identified and recovered. It is reasonable to assume that some acid drainage and metal leaching would occur along the waterbodies located along the rail line.

GLIFWC staff does not believe that the method described in the PSDEIS to segregate fines in the center of the rail car is realistic. GLIFWC has suggested incorporating new rail cars with sealed compartments as a mitigation measure but that alternative has not been included in the PDEIS.

Finally, The PSDEIS states that monitoring of the creeks that could be affected by ore dust deposition will be done. We agree that this is important. However, monitoring would only detect impacts after that have already occurred. The example of the Flambeau mine illustrates that cleanup of ore dust contamination in an aquatic environment is a long and difficult process. A serious examination of the issue of fugitive dust from rail cars should be conducted and included in the DEIS and mitigation options that require the use of sealed rail cars to transport ore from the mine site to the plant site are needed.

Figure 1. Spilled taconite pellets on a bridge above the Partridge River.

Figure 2. Gap in the side hinge of the rail car.

Figure 3. Rail cars proposed for use at the NorthMet project.

Perpetual Maintenance and Water Treatment at the NorthMet Project

The lead agencies position on post closure maintenance and water treatment needs in the SDEIS states:

“Both mechanical and non-mechanical treatment will require periodic maintenance and monitoring activities. Modeling predicts that treatment activities will be a minimum of 200 years at the mine site and 500 years at the plant site. While long term, these time frames for water treatment are not necessarily perpetual. The owning company would be held accountable to maintenance and monitoring required under permit and would not be released until all conditions have been met”

GLIFWC staff disagrees with the characterization of long term maintenance for the NorthMet project. The notion of water treatment and maintenance for hundreds of years, supported by financial assurance instruments that must also be available for hundreds of years, is illogical. Specific flaws in the rationale presented by the lead agencies in the SDEIS follow.

The NorthMet Project is a Perpetual Water Treatment and Maintenance Project

In the statement above, the lead agencies attempt to say that the proposed project does not necessarily require perpetual treatment. That statement is only true if a narrow definition of “perpetual” is used. The term perpetual is used in several ways. These are:

per·pet·u·al

adj.

1. Lasting for eternity.
2. Continuing or lasting for an indefinitely long time.
3. Instituted to be in effect or have tenure for an unlimited duration: a treaty of perpetual friendship.
4. Continuing without interruption.
5. Flowering throughout the growing season.

In the SDEIS the lead agencies are strictly using the term as defined in #1 above. While it is true that it is not likely that water treatment and maintenance needs of the NorthMet project will last for eternity, we believe that definition #2 above is a more realistic use of the term. The project has predicted minimum water treatment timeframes (200 years at the mine site and 500 years at the plant site), but no modeling has been done that would give an indication of when water quality standards would be met without treatment. It could be hundreds of years or thousands. In fact, water treatment needs for the NorthMet project will be required for an indefinite period of time.

The lead agency rationale also ignores a part of the project that will require perpetual maintenance under definition #1 above. The hydrometallurgical residue facility is proposed to

contain tailings generated from the hydrometallurgical beneficiation process. These tailings are the most heavily contaminated materials that would be produced at the site and must be separated from the surrounding aquatic environment. This facility has a double liner and cover system that will likely be an effective containment system in the short term. But, given time, this containment system, like all human-made structures, will degrade and fail. No human-made structure has lasted forever, so it is illogical to assume that this facility will. Therefore, this facility will need maintenance, repair and monitoring in perpetuity.

There are many engineered features that will be needed to be maintained in perpetuity (as defined in #2 above). These include the water treatment plants at the mine and plant sites, the water capture and pumpback systems at the flotation tailings basin, the category 1 stockpile cover system, the hydrometallurgical tailings facility, the overflow control structure at the west pit lake, etc. The SDEIS also includes a goal to transition from mechanical water treatment (water treatment plant using reverse osmosis) to non-mechanical methods such as constructed wetlands, permeable reactive barriers, etc. The SDEIS does not provide detail on the passive systems, because it states that their effectiveness would have to be demonstrated at a later date. However, available literature indicates that non-mechanical systems require periodic maintenance as well. Therefore, the hypothetical transition to a non-mechanical treatment method does not eliminate the need for perpetual maintenance.

Minnesota Rule 6132.3200, regarding closures and postclosure maintenance of mines, states that the goal of closure and reclamation is that "[t]he mining area shall be closed so that it is stable, free of hazards, minimizes hydrologic impacts, minimizes the release of substances that adversely impact other natural resources, and is maintenance free." Because perpetual maintenance will be required at the hydrometallurgical residue facility, as well as at the numerous engineered features listed above, the position of GLIFWC staff is that this project does not meet this goal.

The Assumption that PolyMet Will Exist Decades or Centuries after Closure is Not Logical

The lead agency statement above assumes that the mining company will exist for decades or centuries after closure. This is not a realistic assumption. Historically, mining companies are temporary entities that disband soon after a mine project comes to an end. The most reasonable scenario for long term closure is that a state or federal agency will be responsible for monitoring, maintenance, and cleanup activities because a mining company cannot be held accountable if it no longer exists. Similarly, the assumption that financial assurance instruments can be developed to ensure that funds will be available centuries from now is not logical. The State of Minnesota has existed for 155 years. The United States of America has existed for 237 years. The notion that a mining company and financial assurance instruments will be available to work on a mine site 500 years from now is not believable.

The Assumption that Water Quality Standards will be met is Not Logical

Throughout the SDEIS, the Co-Lead agencies state that they expect the proposed project to meet all applicable water quality standards. This expectation is based on modeling and GLIFWC does not believe that the modeling is robust enough to support such a statement. However, even assuming that the modeling accurately represents the real future of the project, it is illogical to assume that standards will be met because the modeling assumes effective operation of water capture and treatment facilities. As stated above, the idea that water treatment plants will operate for hundreds of years is not believable. Therefore, the statement that water quality standards will be met is also not believable.

Executive Summary

Comment_No.	Agency	Section	Comment	Co-Lead Disposition	GLIFWC Response
GLIFWC 1	GLIFWC	ES Executive Summary-NorthMet Project Proposed action	As with the first 2 bullets, the third bullet should indicate the length of time that post-closure maintenance and water treatment would last. Therefore, it should indicate that water treatment and maintenance of permanent facilities would be required in perpetuity.	Text edited to reflect that the closure objective is to provide mechanical and non-mechanical treatment for as long as necessary to meet regulatory standards at evaluation locations in groundwater and surface water. Both mechanical and non-mechanical treatment will require periodic maintenance and monitoring activities. Modeling predicts that treatment activities will be a minimum 200 years at the Mine Site and a minimum of 500 years at the Plant Site. While long-term, these time frames for water treatment are not necessarily perpetual. The owning company would be held accountable to maintenance and monitoring required under permit and would not be released until all conditions have been met.	GLIFWC does not agree with the language in the co-lead disposition. Provide a link to the Perpetual care language in the appendix.
GLIFWC 2	GLIFWC	ES Executive Summary	The description of the history of the 2009 DEIS and the need for the SDEIS is not accurate. The reason for the development of a supplemental document and the continuation of the NEPA process is the the EPA gave the 2009 DEIS the lowest possible rating. The EPA found the project to have unacceptable environmental consequences and found that the DEIS failed in its purpose of accurately describing the project and the potential environmental impacts.	The EU-3 rating is discussed in section 1.2.2. "This process culminated in October 2009, with the publication of the NorthMet Project Draft EIS (DEIS) that analyzed the project as it was then designed proposed by PolyMet. After issuing the DEIS, the Co-lead Agencies, responding to public, other federal (including US EPA) and state agency and tribal comments and concerns, analyzed an alternative design that sought to resolve several major environmental concerns and permitting barriers."	ok
GLIFWC 3	GLIFWC	ES Executive Summary	Map is misleading. The area labeled Mesabi Iron Range / Historic mining district encompasses areas that have never been mined and are outside the geologic formations where iron mines have operated. It suggests that the NorthMet mine site is part of a mined area which is not correct. The GIS layer depicting all the mine features on the range (pits, tailings basins, etc) should be used instead.	Text edited. This is now called "General Mesabi Iron Range-Historic Mining".	GLIFWC staff disagree with the disposition. We maintain that the figure is misleading.
GLIFWC 4	GLIFWC	ES Executive Summary	Describes the NorthMet deposit as low-medium quality. We disagree with this characterization. The deposit had a low ore grade compared to most other ore bodies in the Great Lakes region. It should be characterized only as low quality.	It is ERM's professional judgment that the NorthMet Deposit should be classified as low-medium grade. Classification of the ore-body in simplified terms is relative and subjective and does not have any implications to the economic viability of the resource, nor does it influence the environmental evaluation presented in Chapter 5. Full description of the mineral resource may be found in PolyMet's 43-101 document. No text edit.	We disagree. In GLIFWC's professional judgement the deposit should only be described as low quality.

Comment_No.	Agency	Section	Comment	Co-Lead Disposition	GLIFWC Response
GLIFWC 5	GLIFWC	ES Executive Summary - Closure and Post-Closure Maintenance	Text should state that water treatment would be perpetual .	Text edited to reflect that the closure objective is to provide mechanical and non-mechanical treatment for as long as necessary to meet regulatory standards at evaluation locations in groundwater and surface water. Both mechanical and non-mechanical treatment will require periodic maintenance and monitoring activities. Modeling predicts that treatment activities will be a minimum 200 years at the Mine Site and a minimum of 500 years at the Plant Site. While long-term, these time frames for water treatment are not necessarily perpetual. The owning company would be held accountable to maintenance and monitoring required under permit and would not be released until all conditions have been met. Text clarified.	GLIFWC does not agree with the language in the co-lead disposition. Provide a link to the Perpetual care language in the appendix.
GLIFWC 6	GLIFWC	ES Executive Summary - Closure and Post-Closure Maintenance	Should state that because water treatment would be perpetual, maintenance and monitoring needs would also be perpetual.	Text edited to reflect that the closure objective is to provide mechanical and non-mechanical treatment for as long as necessary to meet regulatory standards at evaluation locations in groundwater and surface water. Both mechanical and non-mechanical treatment will require periodic maintenance and monitoring activities. Modeling predicts that treatment activities will be a minimum 200 years at the Mine Site and a minimum of 500 years at the Plant Site. While long-term, these time frames for water treatment are not necessarily perpetual. The owning company would be held accountable to maintenance and monitoring required under permit and would not be released until all conditions have been met. Text Clarified.	GLIFWC does not agree with the language in the co-lead disposition. Provide a link to the Perpetual care language in the appendix.
GLIFWC 7	GLIFWC	ES Executive Summary	What are environmental evaluation criteria? We assume that in many instances these criteria are also standards (eg. Water quality, noise, etc.) When legal standards are the same as environmental evaluation criteria, the term "standard" should be used throughout the document.	Environmental evaluation criteria is the framework selected for use in this NEPA EIS. Discussion of "standards" is a part of the regulatory/permitting process. No text edit.	GLIFWC disagrees with the disposition. We maintain that the language in the SDEIS should be clarified
GLIFWC 8	GLIFWC	ES Executive Summary - NorthMet project effects on water resources section	We disagree that current operating mines are subject to strict environmental rules. Historically, enforcement of water quality standards on these mines has been lax. Sentence should be removed.	Paragraph deleted. The stringency of environmental rules is open to interpretation. Edited as requested.	ok

Executive Summary

Comment_No	Agency	Section	Comment	Co-Lead Disposition	GLIFWC Response
GLIFWC 9	GLIFWC	ES Executive Summary - NorthMet project effects on water resources section	This discussion is misleading. Compliance with water quality standards for this project is only possible with successful operation of water capture and treatment facilities in perpetuity. The section should state that without perpetual treatment, water quality standards would be exceeded. In addition the decreases in concentrations for some solutes after the project is built may be artifacts of incorrect modeling assumptions. We will provide more detail in the water sections.	See response for GLIFWC 5 & 6. Will consider revisions to text accordingly.	GLIFWC does not agree with the language in the co-lead disposition. Provide a link to the Perpetual care language in the appendix.
GLIFWC 10	GLIFWC	ES Executive Summary	The PSDEIS discussion on mercury states that there is a great deal of uncertainty on these mercury issues. Therefore it is not appropriate for the executive summary to present these results as definitive. See GLIFWC mercury attachment for more information.	No text edit recommended because ES consistent with text in body of SDEIS.	GLIFWC disagrees with the disposition. Provide a link to the mercury section in the appendix.
GLIFWC 11	GLIFWC	ES Executive Summary - NorthMet project effects on water resources section	There are wetlands within the mine project area that will be severely impacted by several different types of mine related effects (fragmentation+drawdown+air deposition). While these wetlands will not be filled, the Corps should require up-front mitigation for them. More information is in GLIFWC wetland attachment.	A wetland monitoring plan would be developed and implemented if the NorthMet project is permitted. The plan would require wetland hydrology monitoring, vegetation monitoring, and wetland water quality monitoring to identify if indirect wetland impacts occur during implementation of the project. If indirect wetland impacts resulting from the project are determined by the monitoring program, compensatory wetland mitigation would be required for those indirect wetland impacts. Fragmented wetlands are classified as indirect impact; however, fragmented wetlands are included in upfront mitigation. Total upfront mitigation is for the 912.5 acres of direct effects and 26.4 acres of fragmented wetlands (indirect effect). Tables have been revised to reflect this. Text clarified.	GLIFWC disagrees with the disposition. Provide a link to the wetland section of the appendix.
GLIFWC 12	GLIFWC	ES Executive Summary - NorthMet project effects on water resources section	Disagree with this paragraph. The conclusions written here are based on fatally flawed modeling of surface and groundwater hydrology for the Partridge River watershed. The statements in the paragraph are unsupported.	No change to SDEIS text recommended because subject experts believe that the hydrology for the Partridge River watershed was properly characterized. No text edit.	GLIFWC disagrees with the disposition. Provide a link to the hydrology section of the appendix.
GLIFWC 13	GLIFWC	ES Executive Summary - NorthMet project effects on water resources section	We disagree with the assumption that constituents exceeding water quality standards in the Embarrass River area are natural in origin. It is an accepted fact that tailings basin seepage water has saturated the aquifer in the area. Therefore, the constituent loads exceeding standards are the result of historic mining operations and seepage from the LTV tailings basin.	There is no mention of constituents natural in origin, so no change warranted. No text edit.	ok

Executive Summary

Comment_No	Agency	Section	Comment	Co-Lead Disposition	GLIFWC Response
GLIFWC 14	GLIFWC	ES Executive Summary - NorthMet project effects on biological resources section	The discussion on restoration of Lynx habitat at the mine site is misleading. The open water feature at the mine site is the re-flooded west pit. The water in the pit is expected to be contaminated and in need of treatment for centuries. In addition, there will be fencing around the pit lake. The speculative language about restoring lynx habitat should be removed.	Edited as requested. "Restoration of disturbed areas as part of mine closure would potentially create lynx habitat, although this successional process could take decades."	ok
GLIFWC 15	GLIFWC	ES Executive Summary- NorthMet project effects on cultural and socioeconomic resources section	Just because a site is not eligible for listing does not mean that it will not be impacted. The conclusion of no impact should be removed or rewritten.	Deleted second half of the second sentence. Text clarified.	ok
GLIFWC 16	GLIFWC	ES Executive Summary- NorthMet project effects on cultural and socioeconomic resources section	A paragraph discussing natural resources as cultural resources from the tribal perspective is needed in this section. Impacts to natural resources are an impact to Ojibwe culture.	Added sentence where appropriate. "Natural resources and the lands on which they are gathered are important to the Bands for a number of reasons, including cultural, spiritual, and/or historic meanings, and will be considered under federal agency tribal trust responsibilities as outlined above and also as cultural resources under NEPA."	ok
GLIFWC 17	GLIFWC	ES Executive Summary- NorthMet project effects on cultural and socioeconomic resources section	Information on the negative socioeconomic effects of mining is conspicuously absent. Extensive information has been provided as part of the socioeconomic IAP. A fair representation of possible benefits AND possible negative effects of mining is expected in the executive summary.	See discussion in Section 5.2.10.14.	Additional detail is needed for section 5.2.10.14. Incorporation of the Freidenburg mining article is needed.
GLIFWC 18	GLIFWC	ES Executive Summary - Environmental Consequences of the Land Exchange section	Modeling in this PSDEIS assumes that the no action alternative is a continuation of existing conditions. Therefore, the statements in this paragraph are not carried forward into the modeling. This should be stated here.	Text to be clarified per response to GLIFWC comment 144.	The co-lead disposition does not provide enough information for us to remove our comment. Provide a link to hydrology section in the appendix.
GLIFWC 19	GLIFWC	ES Executive Summary - Environmental Consequences of the Land Exchange section	The phrase "smaller net gains in environmental resources" is not a supported assumption. The Superior N.F. has indicated that the land exchange is a real estate transaction only and that specific environmental resources are not necessarily a part of that transaction. The assumption of environmental gain should be removed.	Edited as requested. "In comparison to the combined Proposed Action, the combined Alternative B (NorthMet Project Proposed Action and Land Exchange Alternative B) would have the same direct impacts from the NorthMet Project Proposed Action, but would convey fewer lands through the land exchange. Removed "resulting in similar net gains in environmental resources". "	ok
GLIFWC 20	GLIFWC	ES Executive Summary - Table 1	99.9% water capture number is not supportable. Other areas of the document say 90% or 93% based on the location where water is captured. In all cases, there should be a range describing water capture ammounts. 99.9% is neither correct not plausible.	Edited as requested. "Greater than 90% of water would be captured and treated to meet effluent limits set to protect water quality standards."	ok
GLIFWC 21	GLIFWC	ES Executive Summary - Table 1	The conclusion that mercury loading will decrease is not supportable. See GLIFWC mercury attachment.	The aquatic species summary points in the SDEIS table have been revised and does no longer include the mercury loading conclusion commented on.	ok
GLIFWC 22	GLIFWC	ES Executive Summary - Table 1	Need additional bullet stating: loss of carbon sink and release of stored carbon through wetland destruction. For proposed action and alternative B.	Acknowledge partial loss of carbon sink and release of stored carbon from wetlands destruction. Suggested text change. "Wetland mitigation plan will be implemented to offset increased carbon dioxide emissions to extent practicable." Text clarified.	Disagree. Wetland mitigation will not offset the emission of carbon from the peat rich wetlands at the 100 mile swamp.

Executive Summary

Comment_No	Agency	Section	Comment	Co-Lead Disposition	GLIFWC Response
GLIFWC 23	GLIFWC	ES Executive Summary - Table 1	For noise and vibration bullet delete text describing effects to nearest receptors. Using receptors limits the impact analysis - see GLIFWC noise attachment.	Edited as requested. "Noise, ground vibration, and air blast impact area/zone would be limited to 11,456, 11,469, and 11,334 acres, respectively. The BWCAW, which is 20 miles away, is outside the maximum area of audibility (247,613 acres)."	GLIFWC has concerns about the analysis. Provide a link to the cumulative impact section in the appendix.
GLIFWC 24	GLIFWC	ES Executive Summary - Table 1	add: increase in cumulative destruction of trail network and Mesabe Widju	No text edit. The existing text address the Mesabe Widju	The comment applies to a cumulative effects analysis which is, in our opinion, inadequate in the PSDEIS. Provide a link to the cumulative effects section of the appendix
GLIFWC 25	GLIFWC	ES Executive Summary	The PSDEIS concludes that "Based on the results of the modeling and impacts analysis, the Northmet Project Proposed Action would not exceed applicable environmental evaluation criteria." Due to a general lack of understanding of mercury dynamics in the St. Louis River watershed, this conclusion is not defensible with regard to mercury. See the supplemental document "Great Lakes Indian Fish and Wildlife Commission (GLIFWC) Comments Related to Mercury" [Comment 1] for additional rationale.	Text clarified in SDEIS. See response to GLIFWC 195	GLIFWC disagrees with the co-lead disposition. Provide a link to the mercury section in the appendix.
GLIFWC 26	GLIFWC	ES Executive Summary	The executive summary should clearly state that the proposed NorthMet project requires perpetual water treatment and perpetual maintenance. Therefore, the proposed project violates Minnesota Rule 6132.3200 regarding closure and postclosure maintenance of mines. This rule states that the goal of closure and reclamation is that "The mining area shall be closed so that it is stable, free of hazards, minimizes hydrologic impacts, minimizes the release of substances that adversely impact other natural resources, and is maintenance free." This language should be inserted into the executive summary. In addition Rule 6132.3200 states that "No release from the permit to mine under part 6132.4800 shall be granted for those portions of the mining area that require postclosure maintenance until the necessity for maintenance ceases." Since maintenance would never cease under the project, the executive summary should indicate that the applicant would never be released from the permit to mine.	Text edited to reflect that the closure objective is to provide mechanical and non-mechanical treatment for as long as necessary to meet regulatory standards at evaluation locations in groundwater and surface water. Both mechanical and non-mechanical treatment will require periodic maintenance and monitoring activities. Modeling predicts that treatment activities will be a minimum 200 years at the Mine Site and a minimum of 500 years at the Plant Site. While long-term, these time frames for water treatment are not necessarily perpetual. The owning company would be held accountable to maintenance and monitoring required under permit and would not be released until all conditions have been met.	GLIFWC does not agree with the language in the co-lead disposition. Provide a link to the Perpetual care language in the appendix.
GLIFWC 27	GLIFWC	ES Executive Summary- NorthMet project effects on cultural and socioeconomic resources section	The NorthMet Project Proposed Action would create up to an estimated 500 full-time direct jobs during peak construction and 360 full-time direct jobs during operations. Estimates for full-time employment were provided by NorthMet. " *It is essential that throughout the SDEIS authors need to repeatedly state that direct employment estimates for both construction and during operations were provided by NorthMet.	Text edited. It should be noted that these employment estimates were provided by PolyMet.	ok

Executive Summary

Comment_No.	Agency	Section	Comment	Co-Lead Disposition	GLIFWC Response
GLIFWC 28	GLIFWC	ES Executive Summary- NorthMet project effects on cultural and socioeconomic resources section	"These direct jobs would generate additional indirect and induced employment, estimated to be 332 additional construction phase jobs and 631 additional operations phase jobs." Indirect and Induced Effect employment numbers are calculated by IMPLAN and may be temporary, part-time, full-time, long-term or short term jobs, as IMPLAN does not differentiate between these. **It is essential that throughout the SDEIS authors need to repeatedly state that Indirect and Induced Effect employment numbers are calculated by IMPLAN and may be temporary, part-time, full-time, long-term or short term jobs. See GLIFWC socioeconomic attachment for additional information.	Text edited. It should be noted that indirect and induced effect employment numbers are calculated by IMPLAN and may be temporary, part-time, full-time, long-term or short term jobs.	ok
7/	GLIFWC	ES Executive Summary- NorthMet project effects on cultural and socioeconomic resources section	The Draft Environmental Impact Statement (DEIS) prepared in 2009 stated, "Due to the estimated 20-year operating life of the facility, it is estimated that approximately 55% of labor for the operations would be non-local and would be relocated to the east range: 20% would commute daily or weekly from centers such as Duluth; and the remaining labor would be local" DEIS (page 4.10-15). The Executive Summary needs to clearly identify the number of jobs projected to be filled by "local residents" in St. Louis County rather than the broad Arrowhead Region. See GLIFWC socioeconomic attachment for additional information.	The DEIS definition of "local" appears to be limited to the East Range, essentially the nearby towns and cities in St. Louis County alone. By comparison, the PSDEIS clearly states that "local" workers--those who would commute daily or weekly--would come from a very wide commute shed, given the willingness of workers in this region to commute relatively long distances. The definitions of "local" are very different; therefore, no change is needed.	ok

Chapter 1

Comment No.	Agency	Section	Comment	Co-Lead Disposition	GLIFWC Response
GLIFWC 30	GLIFWC	1.1.2 Land Exchange	Map is misleading. The area labeled Mesabi Iron Range / Historic mining district encompasses areas that have never been mined and are outside the geologic formations where iron mines have operated. It suggests that the NorthMet mine site is part of a mined area which is not correct. The GIS layer depicting all the mine features on the range (pits, tailings basins, etc) should be used instead.	Map is intended to show general area of the Mesabi Iron Range. Figure Key edited to now read, "General Mesabi Iron Range - Historic Mining"	GLIFWC staff disagree with the disposition. We maintain that the figure is misleading.
GLIFWC 34	GLIFWC	1.2.2 Cooperating Agencies	Please insert the following text for GLIFWC participation: GLIFWC staff did not participate in the development of the language in the SDEIS or the referenced technical documents.	Text edit made. New text reads "The Great Lakes Indian Fish and Wildlife Commission (GLIFWC) and the 1854 Treaty Authority have assisted the Bands in their roles as Cooperating Agencies"	ok
GLIFWC 31	GLIFWC	1.3 Purpose And Need	The first 4 bullets are the mining companies' purpose and need and not the purpose and need of the agencies involved. A title is needed making this clear. Question: This is a document from the lead agencies. Does the applicants purpose belong here?	The Co-lead Agencies developed this language for insertion into the SDEIS. As such, it is appropriately placed.	ok
GLIFWC 32	GLIFWC	1.7 Pollutants Of Interest	There is absolutely no scientific doubt that GHG in the atmosphere have, and will continue to change climate conditions. Text should be corrected.	Text not edited, use of "may" and "can" is intended to be consistent with the rest of this section.	GLIFWC staff disagree with the disposition. The text may be consistent with the section but it is inconsistent with accepted scientific knowledge.
GLIFWC 33	GLIFWC	1.7 Pollutants Of Interest	There is absolutely no scientific doubt that sulfate has, and will continue to negatively impact wild rice. There is absolutely no scientific doubt that sulfate has, and will continue to contribute to mercury methylation. Correct the text. The text may be consistent with the section but it is inconsistent with accepted scientific knowledge.

Chapter 3

Comment_No.	Agency	Section	Comment	Co-Lead Disposition	GLIFWC Response
GLIFWC 35	GLIFWC	3.1.1.3 Mine Operations Overview	Describes the NorthMet deposit as low-medium quality. We disagree with this characterization. The deposit had a low ore grade compared to most other ore bodies in the Great Lakes region. It should be characterized only as low quality.	It is ERM's professional judgment that the NorthMet Deposit should be classified as low-medium grade. Classification of the ore-body in simplified terms is relative and subjective and does not have any implications to the economic viability of the resource, nor does it influence the environmental evaluation presented in Chapter 5. Full description of the mineral resource may be found in PolyMet's 43-101 document. No changes to text.	We disagree. In GLIFWC's professional judgement the deposit should only be described as low quality.
GLIFWC 46	GLIFWC	3.2.2.4 Financial Assurance	EPA recommends that 10 to 25% of financial assurance be made available as cash. This should be added to the section. In addition, an explanation of how the state will financially assure a perpetual treatment project is required. Specifically, the state must financially assure in perpetuity: 2 RO water treatment plants, perpetual monitoring of water quality for the 2 tailings basins, west pit outflow, and groundwater points of compliance. Perpetual maintenance would be required at both tailings facilities for water quality, water capture, flow augmentation system, and geotechnical stability, the Cat 1 stockpile and the water level controls at the west pit.	Financial assurance costs, instruments, and duration will be determined in the MDNR Permit to Mine permitting process. Financial assurance can be required indefinitely and can include self-sustaining instruments such as trust funds.	The co-lead disposition is not realistic. Provide a link to the perpetual care language in the appendix.
GLIFWC 37	GLIFWC	3.1.2 Land Exchange Overview	Information in this paragraph is incorrect. As previously commented, federal lands are not within the historic mesabi range. Federal lands are not surrounded by private lands. Rather they are connected to other Superior National Forest lands on the south and east. Finally, the land exchange would unite surface and mineral rights for the mine site lands but not for the parcels that would enter the federal estate. Those surface and mineral ownerships would still be severed. The text should be clarified.	Edited sentences... "The federal lands are located adjacent to historic mining projects on the Mesabi Iron Range and are almost surrounded by privately held land used for mining and other industrial purposes; portions of the east and southwest areas of the federal lands are bordered by Superior National Forest lands." "in the area" to "on the federal lands"	ok
GLIFWC 40	GLIFWC	3.2.2.1.9 Water Management	Information on the length of time that the facility would need to operate should be included	This section is specific to the operational phase of mining. Long term management is discussed in section 3.2.2.1.10	ok

Chapter 3

Comment_No.	Agency	Section	Comment	Co-Lead Disposition	GLIFWC Response
GLIFWC 38	GLIFWC	3.2.2.1.7 Overburden And Waste Rock Management	Should state that Cat 1 stockpile will require some maintenance in perpetuity.	Table 3.2-7 states that from Year 20+ there would be maintenance. Maintenance activities would continue throughout reclamation and post-reclamation, for as long as necessary to meet regulatory standards.	GLIFWC believes the disposition is incomplete. Provide a link to perpetual care section in the appendix.
GLIFWC 39	GLIFWC	3.2.2.1.8 Engineered Water Controls	Throughout the section, information on post closure maintenance needs and length of time operation is needed should be included for all engineering controls.	This section is specific to the operational phase of mining. Long term management is discussed in section 3.2.2.1.10	ok
GLIFWC 42	GLIFWC	3.2.2.1.10 Reclamation And Long-term Closure Management	Last paragraph should explicitly state that erosion repair, and removal of woody species from the stockpile cover system would need to be perpetual. This would also include monitoring and inspections of the facility.	Maintenance activities would continue throughout reclamation and post-reclamation, for as long as necessary to meet regulatory requirements.	GLIFWC believes the disposition is incomplete. Provide a link to perpetual care section in the appendix.
GLIFWC 50	GLIFWC	3.2.2.1.10 Reclamation And Long-term Closure Management	Insert text stating that water quality modeling suggests water treatment would need to occur for over 500 years in order to meet water quality standards.	The Closure objective is to provide mechanical and non-mechanical treatment for as long as necessary to meet regulatory requirements at evaluation locations in groundwater and surface water. Both mechanical and non-mechanical treatment will require periodic maintenance and monitoring activities. Modeling predicts that treatment activities will be a minimum 200 years at the Mine Site. While long-term, this time frame for water treatment is not necessarily perpetual. Added text to section 3.2.2.1.10 to this effect.	GLIFWC does not agree with the language in the co-lead disposition. Provide a link to the Perpetual care language in the appendix.
GLIFWC 51	GLIFWC	3.2.2.2.4 Use During Operations	We disagree with the characterization that ore dust releases from rail cars is not a significant issue. See GLIFWC rail car attachment.	Air quality for the NorthMet Project is evaluated in Section 5.2.7. Due to the size of the ore rock being transported, the design of the railcars, and the short distance of transport from the Mine Site to the Plant Site, the ore fines are expected to be coarse in nature. Thus, no significant reactive airborne fugitive dust from the rail transport is expected	GLIFWC does not agree with the language in the co-lead disposition. Provide a link to the rail car section in the appendix.

Chapter 3

Comment_No.	Agency	Section	Comment	Co-Lead Disposition	GLIFWC Response
GLIFWC 36	GLIFWC	3.1.1.7 Project Closure Overview	This section states that post closure monitoring and maintenance would continue until features were "deemed environmentally acceptable in a self sustaining and stable condition" Water treatment and facility maintenance at the site are perpetual. Therefore this statement would never happen. It is misleading to suggest otherwise.	Text edited to reflect that the closure objective is to provide mechanical and non-mechanical treatment for as long as necessary to meet regulatory standards at evaluation locations in groundwater and surface water. Both mechanical and non-mechanical treatment will require periodic maintenance and monitoring activities. Modeling predicts that treatment activities will be a minimum 200 years at the Mine Site and a minimum of 500 years at the Plant Site. While long-term, these time frames for water treatment are not necessarily perpetual. The owning company would be held accountable to maintenance and monitoring required under permit and would not be released until all conditions have been met.	GLIFWC does not agree with the language in the co-lead disposition. Provide a link to the Perpetual care language in the appendix.
GLIFWC 53	GLIFWC	3.2.2.3.9 Transport Of Consumables And Products	There is no information provided on outgoing rail routes from the mine site. A map of these rail routes is requested.	The railway between the Mine Site and Plant Site is shown in Figure 3.2-4 and 3.2-20. Railway beyond the project area is outside of the scope of the SDEIS	GLIFWC disagrees. Regional transportation routes have been raised as issues in the past and there is the potential for environmental impacts along those routes based on impacts at other mine sites.
GLIFWC 54	GLIFWC	3.2.2.3.10 Engineered Water Controls	Section indicates that a water containment system exists on the south side. Please add that system to figure 3.2-27	Removed south side containment system from text.	ok
GLIFWC 55	GLIFWC	3.2.2.3.10 Engineered Water Controls - figure 3.2-28	Legend should be updated to describe the red and yellow lines on the outside of the berm.	The red and yellow lines do not add value to the figure and have been removed	ok

Chapter 3

Comment_No.	Agency	Section	Comment	Co-Lead Disposition	GLIFWC Response
GLIFWC 44	GLIFWC	3.2.2.3.12 Reclamation And Long-term Closure Management	It should be clearly stated that inspection and periodic water collection at the hydrometallurgical residue facility would need to be perpetual.	The Closure objective is to provide mechanical and non-mechanical treatment for as long as necessary to meet regulatory standards at evaluation locations in groundwater and surface water. Both mechanical and non-mechanical treatment will require periodic maintenance and monitoring activities. Modeling predicts that treatment activities will be a minimum 200 years at the Mine Site and a minimum of 500 years at the Plant Site. While long-term, these time frames for water treatment are not necessarily perpetual. Text has been added to section 3.2.2.3.12 to reflect this.	GLIFWC does not agree with the language in the co-lead disposition. Provide a link to the Perpetual care language in the appendix.
GLIFWC 45	GLIFWC	3.2.2.3.12 Reclamation And Long-term Closure Management - post-reclamation activities	A clear statement that perpetual water treatment, either active or passive, is required for the project to comply with water quality standards. In addition, the section should state that passive treatment is speculative.	The Closure objective is to provide mechanical and non-mechanical treatment for as long as necessary to meet regulatory standards at evaluation locations in groundwater and surface water. Both mechanical and non-mechanical treatment will require periodic maintenance and monitoring activities. Modeling predicts that treatment activities will be a minimum 200 years at the Mine Site and a minimum of 500 years at the Plant Site. While long-term, these time frames for water treatment are not necessarily perpetual. Text has been added to section 3.2.2.3.12 to reflect this.	GLIFWC does not agree with the language in the co-lead disposition. Provide a link to the Perpetual care language in the appendix.

Chapter 3

Comment_No.	Agency	Section	Comment	Co-Lead Disposition	GLIFWC Response
GLIFWC 56	GLIFWC	3.2.2.3.12 Reclamation And Long-term Closure Management	Include information about long term maintenance needs and length of time that water treatment is needed.	The Closure objective is to provide mechanical and non-mechanical treatment for as long as necessary to meet regulatory standards at evaluation locations in groundwater and surface water. Both mechanical and non-mechanical treatment will require periodic maintenance and monitoring activities. Modeling predicts that treatment activities will be a minimum 200 years at the Mine Site and a minimum of 500 years at the Plant Site. While long-term, these time frames for water treatment are not necessarily perpetual. Text has been added to section 3.2.2.3.12 to reflect this.	GLIFWC does not agree with the language in the co-lead disposition. Provide a link to the Perpetual care language in the appendix.
GLIFWC 47	GLIFWC	3.2.2.4.3 Cessation Of Financial Assurance	The NorthMet project is a perpetual maintenance and water treatment project. This should be clearly stated in this section. Therefore, there is a significant financial assurance component that the applicant will never be able to recover. Finally, a clear statement that the state of Minnesota will ultimately be responsible for conducting any long term maintenance and/or cleanup because it is not realistic to assume that this mining company will exist past closure.	The Closure objective is to provide mechanical and non-mechanical treatment for as long as necessary to meet regulatory standards at evaluation locations in groundwater and surface water. Both mechanical and non-mechanical treatment will require periodic maintenance and monitoring activities. Modeling predicts that treatment activities will be a minimum 200 years at the Mine Site and a minimum of 500 years at the Plant Site. While long-term, these time frames for water treatment are not necessarily perpetual. Text has been added to section 3.2.2.3.12 to reflect this. Financial assurance can be required indefinitely and can include self-sustaining instruments such as trust funds.	GLIFWC does not agree with the language in the co-lead disposition. Provide a link to the Perpetual care language in the appendix.
GLIFWC 41	GLIFWC	3.2.2.1.10 Reclamation And Long-term Closure Management	Description of long term maintenance needs for the west pit lift station is needed.	The West Pit Lift station would be maintained as per needed in accordance with the reclamation plan, similarly as the WWTF would. Appropriate details would be provided for permitting	GLIFWC does not agree with the language in the co-lead disposition. Provide a link to the Perpetual care language in the appendix.

Chapter 3

Comment_No.	Agency	Section	Comment	Co-Lead Disposition	GLIFWC Response
GLIFWC 49	GLIFWC	3.2.2.1.10 Reclamation And Long-term Closure Management	Describe long term maintenance and monitoring needs for the stormwater ponds and outlet control structures next to the Dunka Rd.	The detailed maintenance and monitoring needs for outlet structures would be provided in the Reclamation Plan as required for permitting	GLIFWC does not agree with the language in the co-lead disposition. Provide a link to the Perpetual care language in the appendix.
GLIFWC 52	GLIFWC	3.2.2.1.10 Reclamation And Long-term Closure Management	A table describing in detail the long term maintenance, monitoring, and treatment needs is requested.	The following section provide more detail that what could be portrayed in a table. Please refer to the text.	GLIFWC does not agree with the language in the co-lead disposition. Provide a link to the Perpetual care language in the appendix.
GLIFWC 43	GLIFWC	3.2.2.3.10 Engineered Water Controls	How long would the tailings basin water collection and treatment system operate in post closure?	The Closure objective is to provide mechanical and non-mechanical treatment for as long as necessary to meet regulatory standards at evaluation locations in groundwater and surface water. Both mechanical and non-mechanical treatment will require periodic maintenance and monitoring activities. Modeling predicts that treatment activities will be a minimum 200 years at the Mine Site and a minimum of 500 years at the Plant Site. While long-term, these time frames for water treatment are not necessarily perpetual. Text has been added to section 3.2.2.3.12 to reflect this.	GLIFWC does not agree with the language in the co-lead disposition. Provide a link to the Perpetual care language in the appendix.

Chapter 3

Comment_No.	Agency	Section	Comment	Co-Lead Disposition	GLIFWC Response
GLIFWC 48	GLIFWC	3.2.3.3 Development Of The Northmet Project Proposed Action - table 3.2-16	"capture and treatment of virtually all groundwater..." is not realistic or correct. Change to capture and treatment of "most" groundwater...	Groundwater containment with slurry walls and permeable trenches has been routinely performed at mine and industrial sites over the last 50 years. There are hundreds of currently operating systems. When geologic conditions are favorable (particularly the presence of a low permeability basal unit that can be keyed into), it is typical to achieve greater than 90 percent groundwater capture. At the Mine and Plant Sites, the geologic conditions are favorable due to the presence of low permeability bedrock. Performance modeling of the containment systems performed by PolyMet and reviewed by the Co-Leads provides strong evidence that the capture efficiency will be greater than 90 percent. the bullet point has been updated to reflect this.	ok
GLIFWC 59	GLIFWC	3.2.3.4.1 Underground Mining Alternative	GLIFWC staff disagree with the lead agency position paper on the underground alternative. See GLIFWC underground mining attachment for more information (will be provided by July 3rd)	The Co-leads have eliminated the Underground Mining Alternative based on the rationale provided in section 3.2.3.4.1.	GLIFWC does not agree with the language in the co-lead disposition. Provide a link to the underground mine alternative section in the appendix.
GLIFWC 60	GLIFWC	3.2.3.4.2 West Pit Backfill	GLIFWC staff disagree with the lead agency position paper on the west pit backfill alternative. See GLIFWC backfill attachment for more information (will be provided by July 3rd)	The Co-leads have eliminated the West Pit Backfill Alternative based on the rationale provided in section 3.2.3.4.2.	GLIFWC does not agree with the language in the co-lead disposition. Provide a link to the west pit backfill section in the appendix.

Chapter 3

Comment_No.	Agency	Section	Comment	Co-Lead Disposition	GLIFWC Response
GLIFWC 57	GLIFWC	3.3.2.1 Federal Lands Proposed For Exchange	As previously commented, the mine site is not located within the historic mesabi iron range and the property is not surrounded by industrial lands. Correct the text.	Edited sentences... "The federal lands are located adjacent to historic mining projects on the Mesabi Iron Range and are almost surrounded by privately held land used for mining and other industrial purposes; portions of the east and southwest areas of the federal lands are bordered by Superior National Forest lands." "in the area" to "on the federal lands"	ok
GLIFWC 61	GLIFWC	3.3.2.1 Federal Lands Proposed For Exchange	As previously commented, the federal lands are not within the historic mining district and are not surrounded by private land used for mining	Edited sentences... "The federal lands are located adjacent to historic mining projects on the Mesabi Iron Range and are almost surrounded by privately held land used for mining and other industrial purposes; portions of the east and southwest areas of the federal lands are bordered by Superior National Forest lands." "in the area" to "on the federal lands"	ok
GLIFWC 58	GLIFWC	3.3.2.2 Non-federal Lands Proposed For Exchange	Section should indicate that all lands that would enter the federal estate have severed mineral and surface ownership.	Added sentence... "All of the non-federal lands except Tract 4 have severed mineral and surface ownership."	ok
GLIFWC 62	GLIFWC	3.3.2.2 Non-federal Lands Proposed For Exchange	Section should state that the lands entering the federal estate would still have severed surface and mineral ownership and therefore future mining cannot be ruled out.	Added sentence... "All of the non-federal lands except Tract 4 have severed mineral and surface ownership."	ok
GLIFWC 63	GLIFWC	3.3.3.6 Underground Mining Alternative	GLIFWC disagrees with the elimination of the underground alternative for further consideration in the SDEIS. The only reason for a land exchange is the fact that the applicant has chosen a surface mining operation. The development of an underground project that takes advantage of the entire mineralized zone should be analyzed. See GLIFWC underground mine attachment for more detail.	Feasibility analysis of an underground mining alternative was based on the mineralized zone as defined in accordance with National Instrument 43-101. The Underground Mining Alternative was eliminated from further analysis because it would not be economically viable and would not meet the purpose and need.	GLIFWC does not agree with the language in the co-lead disposition. Provide a link to the underground mine alternative section in the appendix.

Chapter 4.2

Comment No.	Agency	Section	Comment	Co-Lead Disposition	GLIFWC Response
4.2.2 Water Resources					
GLIFWC 104	GLIFWC	4.2.2 Water Resources - Table 4.2.2-29	The values in this table for PM-12 are different than the values used in "Calibration of the Existing Natural Watershed at the Plant Site v4 MAR2012", why? For example SO4 in Table 4.2.2-29 gives average So4 as 6.9 mg/L while "Calibration of the Existing Natural Watershed at the Plant Site v4 MAR2012" page 38 reports 4.34 mg/L. Manganese in Table 4.2.2-29 reports an average of 365 mg/L while "Calibration of the Existing Natural Watershed at the Plant Site v4 MAR2012" page 36 reports 158 mg/L. Why?	The values in Table 4.2.2-29 will be confirmed and updated as appropriate in the SDEIS.	Will the Goldsim model be recalibrated with the updated data in Table 4.2.2-29? If not, why?
GLIFWC 72	GLIFWC	4.2.2.3.2 Surface Water Resources Embarras River WQ section	The first section is not correct. The river is on the draft 2012 303d list. See GLIFWC figure 3 in wild rice attachment. The section should also indicate that the wild rice standard is being exceeded in the Embarras river because of effluent from the tailings basin and area 5 pits.	Text revised to clarify the current status of 303(d) listings.	ok
GLIFWC 68	GLIFWC	4.2.2.2.2 Surface Water	The XP-SWMM modeling is fatally flawed because it is incapable of predicting even current baseflow conditions. If it is incapable of predicting current water quantity it will not accurately predict future water quantity conditions, a much more difficult task. It is therefore, not suitable for use in the SDEIS to predict future conditions. See GLIFWC hydrology attachment.	We believe the XP-SWMM modeling is acceptable for use in the SDEIS. The 20 year old data is acceptable as there haven't been any significant changes within the watershed. We believe the assumptions used were reasonably conservative. Additional detail is provided in the water sections of the SDEIS, and further rationale is provided in the Water Data Packages.	GLIFWC disagrees with the co-lead disposition. The portion of the comment in bold has not been answered. Provide a link to the hydrology section in the appendix.
GLIFWC 69	GLIFWC	4.2.2.2.2 Surface Water	Section states that the old gauge represents current flows. We disagree. The hydrology of the Partridge river is incorrectly characterized because of the fatal flaws of XP-SWMM.	We believe the XP-SWMM modeling is acceptable for use in the SDEIS. The 20 year old data is acceptable as there haven't been any significant changes within the watershed. We believe the assumptions used were reasonably conservative. Additional detail is provided in the water sections of the SDEIS, and further rationale is provided in the Water Data Packages.	GLIFWC disagrees with the co-lead disposition. Provide a link to the hydrology section in the appendix.
GLIFWC 96	GLIFWC	4.2.2 Water Resources	Yes, as stated in the SDEIS text Northshore dewater into partridge. So simply subtracting the flow at the Northshore RR tracks from the flow measures further downstream will give the gain in groundwater between the RR tracks and downstream sites. Result at SW-003: 2.3 cfs, not the 0.51cfs predicted by XP-SWMM. In additionaTable 4.2.2-9 values from XP-SWMM are obsolete values (see table 4.2.2-8).	We believe the XP-SWMM modeling is acceptable for use in the SDEIS. The 20 year old data is acceptable as there haven't been any significant changes within the watershed. We believe the assumptions used were reasonably conservative. Additional detail is provided in the water sections of the SDEIS, and further rationale is provided in the Water Data Packages. XP-SWMM values in Table 4.2.2-9 have been revised.	GLIFWC disagrees with the co-lead disposition. The portion of the comment in bold has not been answered. Provide a link to the hydrology section in the appendix.

Chapter 4.2

Comment No.	Agency	Section	Comment	Co-Lead Disposition	GLIFWC Response
GLIFWC 100	GLIFWC	4.2.2 Water Resources	high SO4 water of Wyman Cr. is entering the rice waters of the Partridge river. Given that the Partridge is already 9.1 mg/L at SW-005 the addition of high sulfate water by Wyman Cr. almost certainly causes the Partridge R. to exceed 10 mg/L. Does this exceedance influence the Polymet project in any way?	No. Under Minnesota Rules chapter 7050 discharges, either direct or indirect, must not cause violation of water quality standards in the immediate receiving waters, but also must not cause exceedances in downstream waters that have more stringent water quality standards. No discharges are planned from the Mine Site during operations and reclamation. During long-term closure, West Pit water will be pumped to the Mine Site WWTF, the effluent from which will require an NPDES/SDS permit to discharge to the Partridge River. The WWTF, when it starts discharging to the PR, will be designed to meet an effluent target of <10 mg/L SO4 (RC)	ok
GLIFWC 101	GLIFWC	4.2.2 Water Resources	Tailings pond water quality was measured in 2001-2004 and has not been measured since 2004. The claim, used in the No-Action or Current Condition models that water level and quality at the basins has stabilized, can not be confirmed or refuted with such a limited & old data set. Current data on water quality in the tailings pond must be collected to verify if the tailings basins are currently hydrologically stable. It seems unlikely that the pond water quality would stay the same over the last 9 years given that the only water input to the system has been rainwater.	Additional water quality samples will be taken from the LTV tailings pond to confirm its water quality and the results included in the EIS.	Is water quality sampling of the tailings ponds being conducted this summer. If not when will sampling be conducted?
GLIFWC 102	GLIFWC	4.2.2 Water Resources - Legacy Groundwater Quality Issues	the title of these two paragraphs suggest that it is a discussion of general contamination, yet the text only addresses organics. The text must be expanded to discuss groundwater contamination of all types.	The discussion under Legacy Groundwater Quality Issues will be expanded to include other constituents.	ok
GLIFWC 64	GLIFWC	4.2.2.1.3 Wild Rice	There is no question that wild rice is affected by sulfate. The text should state that healthy and natural stands of wild rice are found in waters of 10 ppm sulfate or less. See GLIFWC wild rice attachment.	The text already states that 'Some research has indicated that natural wild rice thrives better in low sulfate waters.'. No text edit.	The text in the co-lead disposition is misleading. It implies that there is doubt about the negative effects of sulfate on rice by using the word "some". Provide a link to the wild rice section in the appendix.
GLIFWC 65	GLIFWC	4.2.2.1.3 Wild Rice	States that "current scientific understanding of its habitat requirements is limited". This is not correct, the habitat requirements are well known. Correct your work.	Text clarified.	ok

Chapter 4.2

Comment No.	Agency	Section	Comment	Co-Lead Disposition	GLIFWC Response
GLIFWC 93	GLIFWC	4.2.2 Water Resources	"consequently, the 10 mg/L water quality standard for sulfate would not apply to this portion of the river (MPCA 2011b)." the "not" appears to be incorrect	Disagree. According to MPCA 2011a, the 10 mg/L water quality standard would not apply to this portion of the river.	GLIFWC does not agree with the MPCA determination for wild rice waters. Provide a link to the wild rice section of the appendix.
GLIFWC 94	GLIFWC	4.2.2 Water Resources	A 2010 field survey is mentioned. The pH and "salinity" data reported in Eggers 2011a, I believe to be data GLIFWC collected. No "salinity" measures were collected. The data appears to have been misunderstood. Please contact GLIFWC concerning this data.	Text revised to remove reference to salinity and be more consistent with Eggers 2011a.	GLIFWC collected the data. Please contact GLIFWC for proper interpretation of the data, as requested.
GLIFWC 98	GLIFWC	4.2.2 Water Resources - table 4.2.2-14	SW-005 shows a mean value of 9.11 mg/l of SO4. an average of 9.11 indicates that at times the SO4 10mg/L standard is exceeded at SW-005. The underlying data needs to be referenced and available.	The surface water quality data used to support the water quality modeling is in Barr 2013b (Technical Memorandum: Ongoing data collection for the NorthMet water quality modeling, aka Data Sufficiency Document, Version 3. February 25, 2013), as stated under the table.	ok
GLIFWC 99	GLIFWC	4.2.2 Water Resources - many data tables	Need sample size for the averages. otherwise the averages communicate very little information.	Tables 4.2.2-12, 4.2.2-14, 4.2.2-15, and 4.2.2-29 have been revised to include columns with detection and range data. The surface water quality data used to support the water quality modeling is in Barr 2013b (Technical Memorandum: Ongoing data collection for the NorthMet water quality modeling, aka Data Sufficiency Document, Version 3. February 25, 2013), as stated under the table.	ok
GLIFWC 103	GLIFWC	4.2.2 Water Resources - Table 4.2.2-29	Sulfate exceeds the 10mg/L standard for a substantial stretch of the Embarrass between Hwy 135 to Sabin Lake. Average SO4 at PM-13 is 31.8. Again sample size is needed in order to evaluate the information in the table. This reported average is very different than the modeled P50 (existing condition) value in figure 5.2.2-49, why?	Table 4.2.2-29 has been modified to include the number of samples for both locations. Original data is available in Barr 2013b. The calibrated water quality model PM-13 (Embarrass R. below all Mine Site loads) overestimates mean sulfate concentrations for existing conditions relative to measured values, apparently because the model does not incorporate removal of sulfate by chemical reduction processes (Barr 2012), Section 2.2). The overall calibration of the No Action Model was approved by the Co-lead Agencies.	ok

Chapter 4.2

Comment No.	Agency	Section	Comment	Co-Lead Disposition	GLIFWC Response
GLIFWC 105	GLIFWC	4.2.2 Water Resources - table 4.2.2-29	The existing water quality at PM-13 reported in this table is substantially different than the P50 values reported as (continuation of existing conditions) in chapter 5 (e.g. fig. 5.2.2-49) and substantially different from the P50 values reported as No-Action model in the modeling data package (Water Modeling Data Package Vol 2-Plant Site v9 MAR2013.pdf). This suggests that the model is poorly calibrated and unlikely to accurately predict project impacts.	The surface water quality model was calibrated to conditions in the Embarrass River at a location above where mining had effected water quality (i.e., location PM-12), and conditions at down-stream locations were then estimated by adding known loads (for existing conditions model) and/or possible new loads (for Proposed Action model). The predicted model range for monthly concentrations over the 200-year simulation in the Embarrass R. below all Plant Site Area loads (i.e., minimum P10 to maximum P90 concentrations at location PM-13) brackets average measured concentrations for most constituents reported in Table 4.2.2-49. The model does overestimate mean sulfate concentrations for existing conditions at PM-13 relative to measured values, apparently because the model does not incorporate removal of sulfate by chemical reduction in the river and wetlands (Barr 2012j, Section 2.2). The accuracy of this Embarrass River water-quality model, as calibrated to existing conditions, was approved by the Co-lead Agencies as adequate to support the NorthMet SDEIS.	GLIFWC disagrees with the co-lead disposition. Provide a link to the hydrology section in the appendix.

Chapter 4.2

Comment No.	Agency	Section	Comment	Co-Lead Disposition	GLIFWC Response
GLIFWC 106	GLIFWC	4.2.2 Water Resources - table 4.2.2-1	The existing water quality in the Partridge reported in this table is substantially different than the P50 values reported as "continuation of existing conditions" in chapter 5 and substantially different from the P50 values reported as No-Action model in the modeling data package (e.g. Fig. K-06-24.2[SO4] and Fig. K-06-25.2 [Thallium], Water Modeling Data Package Vol 2-Plant Site v9 MAR2013.pdf . This suggests that the model is poorly calibrated and unlikely to accurately predict project impacts.	The surface water quality model was calibrated to conditions in the Embarrass River at a location above where mining had effected water quality (i.e., location PM-12), and conditions at down-stream locations were then estimated by adding known loads (for existing conditions model) and/or possible new loads (for Proposed Action model). The predicted model range for monthly concentrations over the 200-year simulation in the Embarrass R. below all Plant Site Area loads (i.e., minimum P10 to maximum P90 concentrations at location PM-13) brackets average measured concentrations for most constituents reported in Table 4.2.2-49. The model does overestimate mean sulfate concentrations for existing conditions at PM-13 relative to measured values, apparently because the model does not incorporate removal of sulfate by chemical reduction in the river and wetlands (Barr 2012j, Section 2.2). The accuracy of this Embarrass River water-quality model, as calibrated to existing conditions, was approved by the Co-lead Agencies as adequate to support the NorthMet SDEIS.	GLIFWC disagrees with the co-lead disposition. Provide a link to the hydrology section in the appendix.
GLIFWC 116	GLIFWC	4.2.2 Water Resources - Table 4.2.2-34	The means shown here for seeps at the toe of the basins are very different from the No-Action (continuation of existing conditions) values modeled in Water Modeling Data Package Vol 2-Plant Site v9 MAR2013.pdf. For example, Table 4.2.2-34 reports PM-10 (on the north toe) as having a mean Mn value of 100,192 mg/L, whereas Figure F-01-18.1 shows "continuation of existing conditions" as an annual maximum of 390 ug/L. at the north toe. Aluminum is reported in Table 4.2.2-34 as a mean of 39.6 ug/L at PM-10 yet reported as a maximum for existing conditions at the north toe as 11 ug/L in Figure F-01-02.1. These discrepancies between observed values at the north toe and the modeled existing conditions at the north toe suggests that the GoldSim model is poorly calibrated and unlikely to accurately predict project impacts.	The NorthMet Plant Site water-quality model used the composition of water in monitoring locations GW001, GW006, GW007, GW012, SD004, and SD026 as concentration targets for the GoldSim model (and PolyMet 2013L, Section 10.2.1 and Large Figure 5; see Figure 4.2.2-13 in this SDEIS). The overall calibration of the No Action Model was approved by the Co-lead Agencies.	GLIFWC disagrees with the co-lead disposition. Provide a link to the hydrology section in the appendix.
GLIFWC 66	GLIFWC	4.2.2.1.3 Wild Rice - Regulations section	we disagree with the MPCA's interpretation of the points of compliance. See GLIFWC wild rice attachment.	All information provided was considered when the MPCA made their recommendation.	GLIFWC does not agree with the MPCA determination for wild rice waters. Provide a link to the wild rice section of the appendix.

Chapter 4.2

Comment No.	Agency	Section	Comment	Co-Lead Disposition	GLIFWC Response
GLIFWC 67	GLIFWC	4.2.2.2.1 Groundwater Resources	The 2010 field survey of wetlands focused on vegetation and plant lists. This information does not yield conclusive information on the effects that groundwater drawdown would have on a wetland. See GLIFWC wetland attachment.	No change to SDEIS text.	GLIFWC does not agree with the co-lead disposition. Provide a link to the wetland section in the appendix.
GLIFWC 70	GLIFWC	4.2.2.2.2 Surface Water	The section should state that Wyman creek has elevated sulfate at PM-5 which is likely a direct result of past mine impact. What is the effect of Wyman creek water on the wild rice standard compliance?	The fact that Wyman Creek drains an area previously mined by LTVSMC is discussed in the text preceding Table 4.2.2-15.	ok
GLIFWC 71	GLIFWC	4.2.2.3.1 Groundwater Resources	There is no question that historic contamination from the LTV tailings basin has been the most important factor in water quality in the area. Discussing natural processes and ignoring the tailings basin effluent in the discussion of existing water quality values is not appropriate.	Water quality affected by the LTV tailings is listed in Table 4.2.2-3. The baseline water quality sought wells that displayed minimal effect of LTV tailings seepage so that effects of the proposed action could be most easily compared to pre-mining conditions.	ok
GLIFWC 73	GLIFWC	4.2.2.3.2 Surface Water Resources	Uses an outdated point of compliance for the wild rice sulfate standard. Correct the text	The text will be consistent with the most recent MPCA recommendation.	ok
GLIFWC 74	GLIFWC	4.2.2.3.2 Surface Water Resources	same comment as above.	The text will be consistent with the most recent MPCA recommendation.	ok
GLIFWC 90	GLIFWC	4.2.2 Water Resources	"the portion of Upper Partridge River from river mile approximately 22 just upstream of the railroad bridge near Allen Junction, " from where to where?	Text edited.	ok
GLIFWC 92	GLIFWC	4.2.2 Water Resources - Table 4.2.2-14	The text states that the values in Table 4.2.2-14 are referenced to (Barr 2008f) i.e. "PolyMet averaged available ambient water quality data to document existing conditions (Barr 2008f) " Barr 2008f is RS74A but in that document "Table 5-3: Average baseline concentrations observed in the Partridge River" in that document shows different values. RS63 (Draft PolyMet Mining Baseline Surface Water Quality Information Report) shows individual values from 2004 but these are yet different. Where did the values in Table 4.2.2-13 come from?	Table 4.2.2-14 references Barr 2013b (Technical Memorandum: Ongoing data collection for the NorthMet water quality modeling, aka Data Sufficiency Document, Version 3, February 25, 2013), which is the cumulative repository for surface and groundwater quality data measured for the NorthMet Project. Table 4.2.2-13 cites as its source" MPCA, 2013a," http://www.pca.state.mn.us/index.php/water/index.html , which is the MPCA's web site to access water quality data.	Please clean up the text to clarify which is the source for the existing conditions.
GLIFWC 91	GLIFWC	4.2.2 Water Resources - table 4.2.2-12	sulfate is nearly exceeded by the mean at station SW-005, some readings exceed the standard. The rice standard applies there but no numeric rice standard is shown in the table	Agree. Text is revised	ok

Chapter 4.2

Comment No.	Agency	Section	Comment	Co-Lead Disposition	GLIFWC Response
GLIFWC 95	GLIFWC	4.2.2 Water Resources	Yes, there is inadequate flow data for the upper Partridge. however there has been a gage on the upper Partridge at the Dunka Rd. (http://www.dnr.state.mn.us/waters/csg/site_report.html?mode=get_site_report&site=03155002) for over 2 years now. The spot flow measurements and data from that gage help clarify flow in the Partridge. Those measures show substantially more baseflow than that predicted by XP-SWIMM. The recent data needs to be used and the models (SP-SWIMM, Modflow & Goldsim) need to be calibrated to the more accurate flow data now available. (see GLIFWC Hydrology attachment for more information)	The difference in the base flows are very small (indistinguishable from a stage standpoint). We believe the assumptions used were reasonably conservative in terms of water quantity.	GLIFWC believes that a difference in baseflow of 200% to 300% is not "small". Provide a link to the hydrology section in the appendix.
GLIFWC 97	GLIFWC	4.2.2 Water Resources	Yes, there is uncertainty in the Northshore discharges. The DNR must require better reporting or else install a gage near Northshore's discharge. The lack of adequate reporting of discharges and flows in the upper Partridge prevents the adequate evaluation of upper Partridge hydrology.	Northshore is meeting the statutory requirements.	Inadequate data for this project has been a chronic problem. In particular our, and others' repeated requests for flow measurement on the Partridge River has been ignored. Why is the EIS being written with <u>no</u> data collected by Polymet on flows on the upper portion of the river?
4.2.3 Wetlands					
GLIFWC 75	GLIFWC	4.2.3 Wetlands - table 4.2.3-1	Text discussing limitations of the classification system should be provided. In particular, the issue of "lumping" different bog wetland types together in the Eggers and Reed system overlooks the range of connectivity that bog wetlands have with the aquifer. This oversimplification leads to masking of the effects of drawdown on bog wetlands. See GLIFWC wetland attachment.	Footnote added: All wetland classification systems have some limitations; however, wetlands identified as open bogs or coniferous bogs under the Eggers and Reed (1997) classification system were further subcategorized as either ombrotrophic (hydrology and mineral inputs entirely from direct precipitation) or somewhat minerotrophic (some degree of mineral inputs from groundwater and/or surface water runoff) (Eggers 2011a; PolyMet 2013b). Please refer to Section 4.2.3.1.2 and Section 5.2.3 for more information.	The co-lead disposition is incomplete. Provide a link to the wetland section in the appendix.
GLIFWC 76	GLIFWC	4.2.3.1.2 Hydrology Wetland Vegetation And Community Types	We disagree with the first sentence. The effect of construction, operations, reflooding and subsequent dewatering of the Northshore pits have never been investigated. Therefore the conclusion in the first sentence is not supportable.	Vegetation types at the site are indicative of pre-settlement conditions and lack hydrologic disturbance, the wetlands at mine site are stable. Following sentence was added: The vegetation types located at the Mine Site are indicative of pre-settlement conditions and lack hydrologic disturbance.	GLIFWC disagrees with the co-lead disposition. Vegetation is not a robust indicator of groundwater hydrology.

Chapter 4.2

Comment No.	Agency	Section	Comment	Co-Lead Disposition	GLIFWC Response
GLIFWC 77	GLIFWC	4.2.3.1.2 Hydrology Wetland Vegetation And Community Types	There is no hydrologic data that shows that wetlands are perched. The lead agencies and the applicant have resisted suggestions by tribal agencies that the connectivity between wetland hydrology and surficial aquifer be assessed.	ERM, USACE, and Barr held a conference call to talk about the data. ERM also reviewed the source documents and added additional text on the connectivity question.	There is not enough information for us to remove our comment.
GLIFWC 78	GLIFWC	4.2.3.1.2 Hydrology Wetland Vegetation And Community Types	The "stability" of the wetlands not affected by the Northshore pits may be due to the factors listed. However the main reason for the stability is the absence of major hydrologic stressors - such as mine pits.	We disagree as groundwater would need to flow uphill for Northshore Pits to impact the surficial aquifer. Furthermore, this section is on existing conditions and the potential impact from NM project to wetlands is discuss in Chapter5.	Information developed by the MNDNR mining hydrologist show that impacts from mine pits affect can affect surficial aquifer by pirating water that would otherwise enter an unimpacted system and flow downgradient. Groundwater would <u>not</u> need to flow uphill for Northshore Pits to impact the surficial aquifer. Please consult a qualified hydrologist before providing further response.
GLIFWC 79	GLIFWC	4.2.3.1.2 Hydrology Wetland Vegetation And Community Types	The last sentence is not necessarily true and is an unsupported assumption. While groundwater may not be an important part of the hydrology at the surface of some wetlands at this time, that could change once stressors are introduced into the system.	Text added to refer reader to chapter 5.2.3	GLIFWC disagrees with the co-lead disposition. Provide a link to the wetland section in the appendix.
GLIFWC 80	GLIFWC	4.2.3.1.2 Hydrology Wetland Vegetation And Community Types	We disagree with the conclusion in the last sentence. There has been no data collected in these wetlands that looks at the connectivity of the surficial aquifer to the water at the surface. It is not defensible to assume that all ombotrophic wetlands at the site are perched and/or would remain perched under mine induced drawdown conditions.	See comment GLIFWC 77 According to Eggers 2011a memo, ombrotrophic peatlands (hydrology entirely from direct precipitation) would likely not be impacted by groundwater drawdown associated with mining operations. No text edit.	GLIFWC disagrees with the co-lead disposition. Provide a link to the wetland section in the appendix.

Chapter 4.2

Comment No.	Agency	Section	Comment	Co-Lead Disposition	GLIFWC Response
GLIFWC 81	GLIFWC	4.2.3.1.2 Hydrology Wetland Vegetation And Community Types	The first sentence is not supported. As indicated in the paragraph, the pump test did show some connectivity. Furthermore, a 30 day pump test does not produce the same degree of drawdown pressure as a 20 year mine project with 600 feet deep pits. Finally, the effects are likely to differ from one wetland to another. The sweeping conclusions in the bullet should be removed.	Edit bullet point... "• There is a general lack of connectivity between the shallow water table in the wetlands and the deeper bedrock aquifer. The depth of soil and till overlying the bedrock ranges up to 33 ft, with bedrock outcrops present that alter local groundwater flow paths. A pumping and isotope test conducted in 2006 indicated that the majority of the groundwater pumped during a 30-day pump test from a 610-ft-deep well drilled into the Virginia Formation was derived from aquifer recharge rather than surface water seepage from surface water features such as the Northshore Pit or wetlands. The variability of the bedrock and soil surface, along with the location of the surface water divide, creates localized, short, surficial groundwater flow paths within the watersheds on the Mine Site." Also see information provided in GLIFWC 77 that was added to beginning of section.	There is not enough information for us to remove our comment.
GLIFWC 82	GLIFWC	4.2.3.1.2 Hydrology Wetland Vegetation And Community Types	The discussion in these bullets represent observations of current conditions in wetlands that are not under hydrologic stress from mine induced drawdown. Once dewatering of the aquifer occurs, the situation is likely different. The text should be clarified.	This is existing conditions being discussed and not the potential effects of the project. No text edits.	ok
GLIFWC 83	GLIFWC	4.2.3.1.2 Hydrology Wetland Vegetation And Community Types	It should be noted in the text that according to scientific literature, ombotrophic wetlands can be affected by groundwater drawdown. See GLIFWC wetlands attachment.	Following sentence was added: Wetlands can be either groundwater or precipitation fed.	ok
4.2.6 Aquatic Species					
GLIFWC 84	GLIFWC	4.2.6.4 Mercury Concentrations In Fish	The discussion of 303d listing is not correct because the Embarrass River is on the 2012 303d list. See GLIFWC map of 303d waters in the wild rice attachment (figure 3). Sulfate has a link to mercury methylation which is directly related to mercury contamination in fish. This should be noted here.	Text revised to clarify the current status of 303(d) listings. The Embarrass River is on the 303d list as impaired for Fishes Bioassessment, a category not related to mercury.	ok. However it should be noted that the Embarrass river is expected to be impaired for sulfate in the next draft list. Language regarding changes to 303d lists should be added.
4.2.8 Noise and Vibration					

Chapter 4.2

Comment No.	Agency	Section	Comment	Co-Lead Disposition	GLIFWC Response
GLIFWC 85	GLIFWC	4.2.8.2 Mine Site	As with the 2009 DEIS, this document relies on assessing noise impacts on a few receptors instead of discussing the overall area that would be affected. A discussion of noise impacts to all publicly accessible areas in the Superior National Forest is needed. See GLIFWC noise attachment.	A discussion of noise impacts to all publicly accessible areas in the Superior National Forest has been included. As indicated above, the USFS has provided shapefiles for all recreational sites within the project vicinity (family camp grounds, camp sites, boating, fishing, swimming, and family picnic areas). In addition to the residential areas, BWCAN, and wildlife corridors already discussed in the SDEIS, we have also included recreational sites, trails, and closest State wildlife waters (used by tribal members for harvesting purposes) in all the noise and vibration contour maps. A discussion of noise impacts to all publicly accessible areas in the SNF has been included in the text in Section 4.2.8.2. Though not depicted on the noise and vibration figures due to sensitivity regarding cultural resources and locations, a discussion of the nearest archaeological sites (e.g., Spring Lake Sugarbush and Mesabe Widjiu [Laurentian Divide]) within the Project vicinity has been included in the text.	GLIFWC has concerns about the analysis. Provide a link to the cumulative effect section in the appendix.
4.2.9 Cultural Resources					
GLIFWC 86	GLIFWC	4.2.9.2.3 Area Of Potential Effects	Text asserts that compliance with standards suggests there would be no impacts to vegetation or soils. This assumption is incorrect. Significant effects and changes from unimpacted conditions can occur without violation of a standard.	No change. The assumption is based on meeting ambient air quality standards.	GLIFWC stands by the comment.
GLIFWC 87	GLIFWC	4.2.9.2.3 Area Of Potential Effects	The discussion on water quality standards is not complete. The project may not exceed any evaluation criteria but that assumes successful implementation of perpetual water treatment and perpetual maintenance of the features that are left behind (hydromet and flotation tailings basins, cat 1 stockpile). This information should be included anytime the SDEIS makes the claim that all evaluation criteria are met. In addition, evaluation criteria are different from water quality standards. The PSDEIS indicates that water quality standards will not be met for several constituents.	Refer to chapter 5.2 for the environmental analysis of effects of the NorthMet Project Proposed Action.	GLIFWC disagrees with the co-lead disposition. Provide a link to the perpetual maintenance section in the appendix.
GLIFWC 88	GLIFWC	4.2.9.2.3 Area Of Potential Effects	We disagree with the conclusion that there would be no impacts due to groundwater drawdowns. See GLIFWC wetland attachment.	Refer to chapter 5.2 for the environmental analysis of effects of the NorthMet Project Proposed Action.	GLIFWC disagrees with the co-lead disposition. Provide a link to the hydrology section in the appendix.
GLIFWC 89	GLIFWC	4.2.9.2.3 Area Of Potential Effects	The visual area of potential effect should be the viewshed of the existing tailings basin. See GLIFWC map.	Text has been revised for clarity.	There is not enough information for us to remove our comment.

Chapter 4.2

Comment No.	Agency	Section	Comment	Co-Lead Disposition	GLIFWC Response
4.2.10 Socioeconomics					
GLIFWC 107	GLIFWC	4.2.10 Socioeconomics - "The study area for socioeconomics extends beyond the area of direct potential project effects to include all of Cook, Lake, and St. Louis counties (see Figure 4.2.10-1)."	IMPLAN modeling played a key role in the SDEIS's socio-economic assessment. IMPLAN modeling and the employment figures derived from the model (i.e. direct, indirect and induced) were for St. Louis County (i.e. NorthMet Economic Impact 2011 Update: Economic Impact of PolyMet's NorthMet Project on St. Louis County, Minnesota Revised April 2012 for PolMet Mining Inc.). The socio-economic study area (i.e. 3 counties) is not consistent with IMPLAN modeling (one county). See GLIFWC socioeconomics attachment for additional information.	Section 5.2.10.1.3 explains why the IMPLAN model focuses on St. Louis County, and how this is consistent with the remainder of the Socioeconomic section. No text edit.	We disagree. The comment stands.
GLIFWC 108	GLIFWC	4.2.10 Socioeconomics - Jobs Held by residents section, Table 4.2.10-9 Employment Status of Study Area Communities, 2009	This table illustrates unemployment rates in 2009 during the worse of the recession. Tables should be updated with unemployment figures for the Counties in 2010, 2011, and 2012 to ascertain impacts of business cycles on regional employment. See GLIFWC socioeconomics attachment for additional information.	No change. Will revisit updating all data (including IMPLAN) for the Final SEIS.	We disagree. The comment stands.
GLIFWC 109	GLIFWC	4.2.10 Socioeconomics - Education Section	A table is needed to provide number of graduates from Mesabi Range Community and Technical College (Virginia and Eveleth); Vermilion Community College (Ely); Hibbing Community College; Fond du Lac Tribal and Community College (Cloquet); and Lake Superior College (Duluth) for the following job categories: 1) Management, 2) Mine Operations - Contract supervision, operators, maintenance, 3) Mine Technical - Geology, grade control, planning, 4) Railroad Operations, 5) Plant Operations, 6) Sample Preparation and analytical laboratory, and 7) Finance, purchasing, marketing, environmental, HR. See GLIFWC socioeconomics attachment for additional information.	Sufficient assumptions have been made about availability of the workforce. No change.	We disagree. The comment stands.

Chapter 5.2

Comment_No.	Agency	Section	Comment	Co-Lead Disposition	GLIFWC Response
5.2.2 Water Resources					
GLIFWC 195	GLIFWC	5.2.2.3.4 Mercury	There is a general lack of understanding of mercury dynamics in the St. Louis River Watershed. See the supplemental document "Great Lakes Indian Fish and Wildlife Commission (GLIFWC) Comments Related to Mercury" [Comment 1] for details.	The Co-leads agree that the mercury dynamics are complex; however, the analysis as presented indicated that there was minimal potential for a downstream increase in mercury loading.	GLIFWC disagrees with the co-lead disposition. Provide a link to the mercury section in the appendix.
GLIFWC 197	GLIFWC	5.2.2.3.4 Mercury - Throughout the section	The conclusion that mercury will not increase in the environment or exceed applicable environmental evaluation criteria is based on several assumptions. One such assumption is that mercury methylation will not increase because the amount of sulfate being released to the environment will actually be reduced by the project. This assumption is not justified. See the supplemental document "Great Lakes Indian Fish and Wildlife Commission (GLIFWC) Comments Related to Mercury" [Comment 3] for details.	Text will be edited to remove this statement. Similar sentences will also be removed.	ok
GLIFWC 198	GLIFWC	5.2.2.3.4 Mercury	The conclusion that mercury will not increase in the environment or exceed applicable environmental evaluation criteria is based on several assumptions. One such assumption is that the Nothmet project would have minor effects on flows in the Partridge and Embarrass Rivers or their tributaries and is thus not expected to result in increases in flow fluctuations that promote mercury methylation. This assumption is not justified. See the supplemental document "Great Lakes Indian Fish and Wildlife Commission (GLIFWC) Comments Related to Mercury" [Comment 4] for details.	The modeling does not suggest that flow fluctuations should be any greater than existing conditions.	GLIFWC disagrees with the co-lead disposition. Provide a link to the hydrology section in the appendix.
GLIFWC 200	GLIFWC	5.2.2.3.4 Mercury - Throughout the section	There is a potential for the overflow from the West Pit (after year 40) to exceed the Great Lakes Initiative (GLI) standard for mercury of 1.3 ng/L. This has not been considered when concluding the Proposed Action would not exceed applicable environmental evaluation criteria. See the supplemental document "Great Lakes Indian Fish and Wildlife Commission (GLIFWC) Comments Related to Mercury" [Comment 6] for details.	Both an analog approach and a mass balance were conducted for evaluating the potential for the West Pit lake water quality to exceed the GLI standard for mercury of 1.3 ng/L. Both analyses concluded the potential for an exceedance was unlikely. Further, West Pit overflow water is first treated at the WWTF before discharge, which would further reduce mercury concentrations in the effluent.	Comment stands. Provide a link to the mercury section in the appendix.

Chapter 5.2

Comment_No.	Agency	Section	Comment	Co-Lead Disposition	GLIFWC Response
	GLIFWC	5.2.2	The GOLDSIM model is not able to reproduce the existing water quality conditions that are observed at the site. This indicates that the model is poorly calibrated to existing conditions. Therefore, it is doubtful that GOLDSIM will be able to accurately predict future water quality which is a much more difficult task. Provide a link to the hydrology section.		Provide a link to the hydrology section in the appendix
GLIFWC 173	GLIFWC	5.2.2.3.5 Proposed And Recommended Mitigation Measures	The section on proposed action design changes and fixed engineering controls are no longer mitigation measures as they are now part of the proposed project. These changes have already been described in other sections of the PSDEIS. It appears that the list of mitigations is being padded. These sections should be removed.	This section acknowledges measures taken to avoid, minimize, or mitigate impacts to water resources. Just because a measure is included as part of the proposed project does not mean it does not serve to mitigate impacts.	ok
GLIFWC 174	GLIFWC	5.2.2.3.5 Proposed And Recommended Mitigation Measures	The notion of fine material being segregated in the center of the rail cars is not credible. See GLIFWC rail car attachment.	Discussion of fine material being segregated in the center of rail cars has been removed.	While that language has been removed, the overall conclusion regarding rail cars remains. Provide a link to the rail car information in the appendix.
GLIFWC 175	GLIFWC	5.2.2.3.5 Proposed And Recommended Mitigation Measures	Because the hydrology of surface and groundwater for the Partridge River is poorly understood, this section should give information on the maximum capacity for the WWTF. GLIFWC staff believe that this facility will have to treat significantly greater amounts of water than the applicant proposes based on field baseflow data.	As stated on page 5.2.2-109, "The WWTF equalization basins are designed for the spring snowmelt when the Mine Site would be at its maximum area. In the event of an extreme event (e.g., 100-year storm), excess water would remain in the mine pits, which essentially have unlimited storage capacity, with mine operations in the pits temporarily shut down (see Mine Site Water Management Plan)." The WWTF is being designed such that additional capacity may be added if required as per the adaptive water management plan	ok

Chapter 5.2

Comment_No.	Agency	Section	Comment	Co-Lead Disposition	GLIFWC Response
GLIFWC 176	GLIFWC	5.2.2.3.5 Proposed And Recommended Mitigation Measures	Says that the Category 1 stockpile cover design could be updated but it does not say how. The rest of the text is simply a restatement of the proposed project.	Text added. Design options, which would need to be approved by the MPCA and MDNR, include: increased or decreased thickness of the geomembrane material to modify the potential for defects to be created during installation and to modify the life of the geomembrane; increased or decreased soil cover thickness above the geomembrane material to modify water storage capacity; increased or decreased soil hydraulic conductivity of the granular drainage layer above the geomembrane to modify lateral drainage capacity; increased or decreased uninterrupted slope length to modify lateral drainage capacity; modified soil type and/or thickness below the geomembrane to modify leakage rate through potential geomembrane defects; and/or including a geosynthetic clay liner below the geomembrane to modify leakage rate through potential geomembrane defects. After installation of the cover system, post-installation adjustments, such as modifying vegetation density and erosion of the cover system, could be made if approved by the MPCA and MDNR (PolyMet 2013g).	ok
GLIFWC 177	GLIFWC	5.2.2.3.5 Proposed And Recommended Mitigation Measures	This is a restatement of the bentonite cover that is part of the proposed project. This is not a mitigation measure. How exactly can the cover system be modified? What part of the cover design is adaptive?	Text added to clarify. Prior to installation, the design of the pond bottom cover system could be adjusted to modify performance. Design options include: increasing or decreasing the thickness of the bentonite amendment, and/or increasing the percent of bentonite, and/or a combination of increasing/decreasing the thickness and increasing/decreasing the percent bentonite. After installation, the design of the installed pond bottom cover system could also be adjusted to modify performance by these same methods. In addition, the bentonite amended layer could be excavated from portions of the pond bottom. Any design modifications would need to be approved by the MPCA and MDNR (PolyMet 2013g).	ok
GLIFWC 178	GLIFWC	5.2.2.3.5 Proposed And Recommended Mitigation Measures	Describe the long term maintenance needs for PRB's including replacement frequency (expected effective timeperiod)	The Proposed Action relies on mechanical treatment to achieve water quality objectives. Non-mechanical treatment (including PRBs) is described as a goal, but is not specifically part of the Proposed Action. It is beyond the scope of the SEIS to describe non-mechanical systems in detail. For interested readers, information on non-mechanical systems is referenced in the SDEIS (PolyMet, 2013g).	GLIFWC staff disagree with the co-lead disposition. Provide a link to the perpetual maintenance section in the appendix.

Chapter 5.2

Comment_No.	Agency	Section	Comment	Co-Lead Disposition	GLIFWC Response
GLIFWC 179	GLIFWC	5.2.2.3.5 Proposed And Recommended Mitigation Measures	As previously commented, other sections of the PSDEIS state that the applicant is not seeking a seasonal application of the wild rice standard. Yet, the west pit overflow non mechanical treatment system relies on a seasonal discharge to comply with the standard. This non-mechanical treatment option should be eliminated from the project as it does not meet the stated goals of compliance with water quality standards.	The Proposed Action relies on mechanical treatment to achieve water quality objectives. Non-mechanical treatment (including PRBs) is described as a goal, but is not specifically part of the Proposed Action. It is beyond the scope of the SEIS to describe non-mechanical systems in detail. For interested readers, information on non-mechanical systems is referenced in the SDEIS (PolyMet, 2013g).	GLIFWC staff disagree with the co-lead disposition. Provide a link to the perpetual maintenance section in the appendix.
GLIFWC 202	GLIFWC	5.2.2.3.6 Monitoring - Throughout the section	It is not apparent whether mercury monitoring is included within the water quality monitoring of the Mine Site or Plant Site. If it is, this should be specified. If it is not, it should be added to the monitoring activities.	Water quality monitoring would be finalized during permitting, but in general, mercury monitoring would be included within the water quality monitoring.	ok
GLIFWC 180	GLIFWC	5.2.2.4 Northmet Project No Action Alternative	This section describes the flaw in the PSDEIS of assuming that the no action alternative is equivalent to existing conditions. We agree that they are not the same thing. A true no action alternative should be modeled as required by NEPA. See GLIFWC hydrology attachment for more information.	Description of the No Action Alternative will be clarified.	There is not enough information for us to remove the comment. Provide a link to the hydrology section of the appendix.
GLIFWC 117	GLIFWC	5.2.2 Water Resources	As previously commented, the mine site is not located within the historic iron/taconite mining district. It is in a separate geology altogether in an mostly undisturbed area known as the 100 mile swamp. Correct the text.	Text edited.	ok
GLIFWC 118	GLIFWC	5.2.2 Water Resources	The negative effects of sulfate on wild rice are well understood and scientifically documented. Edit the text as outlined in the GLIFWC wild rice attachment.	All information provided was considered when the MPCA made its recommendation. The text already states that 'Some research has indicated that natural wild rice thrives better in low sulfate waters.'. No text edit.	GLIFWC staff disagree with the co-lead disposition. Provide a link to the wild rice section in the appendix.
GLIFWC 119	GLIFWC	5.2.2 Water Resources	There is a discussion comparing the NorthMet project to other sulfide mines. The goal appears to be the minimization of impact discussion prior to any information presented on the impact analysis itself. If this type of information is to be presented, additional discussion about the water quality contamination that these other mines have caused, their location and ore grade is necessary.	No change to SDEIS text.	Comment stands.
GLIFWC 120	GLIFWC	5.2.2 Water Resources	why is the term wild rice bed in quotes? Remove the quotes.	Quotes removed.	ok

Chapter 5.2

Comment_No.	Agency	Section	Comment	Co-Lead Disposition	GLIFWC Response
GLIFWC 121	GLIFWC	5.2.2 Water Resources	The discussion on water treatment should state that both active and passive treatment systems would need to operate successfully in perpetuity.	Text edited to reflect that the Closure objective is to provide mechanical and non-mechanical treatment for as long as necessary to meet regulatory standards at evaluation locations in groundwater and surface water. Both mechanical and non-mechanical treatment will require periodic maintenance and monitoring activities. Modeling predicts that treatment activities will be a minimum 200 years at the Mine Site and a minimum of 500 years at the Plant Site. While long-term, these time frames for water treatment are not necessarily perpetual. The owning company would be held accountable to maintenance and monitoring required under permit and would not be released until all conditions have been met.	GLIFWC does not agree with the language in the co-lead disposition. Provide a link to the Perpetual care language in the appendix.
GLIFWC 122	GLIFWC	5.2.2 Water Resources	The discussion of model results and compliance with evaluation criteria assumes perpetual water treatment and perpetual maintenance of the facilities. This should be clearly stated. Also, evaluation criteria are different from standards. The PSDEIS does say that standards would be exceeded for several constituents.	Text edited. As described in the SDEIS, the evaluation criteria do use the standards, but interpret the standards from a probabilistic perspective. The P90 approach is a reasonable method for applying the results of probabilistic modeling for EIS impact assessment. In this context, it is not appropriate to say that "a constituent will exceed a water quality standard". It is more accurate to say that "there is at least a 90 percent probability that a constituent will not exceed a standard (or up to a 10 percent probability that it will)". These quoted statements are very different.	GLIFWC does not agree with the language in the co-lead disposition. Provide a link to the Perpetual care language in the appendix.
GLIFWC 196	GLIFWC	5.2.2 Water Resources	The conclusion that mercury will not increase in the environment or exceed applicable environmental evaluation criteria is based on several assumptions. One such assumption is that the tailings basin will function as a mercury sink. This assumption is not justified. See the supplemental document "Great Lakes Indian Fish and Wildlife Commission (GLIFWC) Comments Related to Mercury" [Comment 2] for details.	Co-leads disagree. Tailings Basins in general are a sink for mercury.	GLIFWC does not agree with the language in the co-lead disposition. Provide a link to the mercury section in the appendix.
GLIFWC 221	GLIFWC	5.2.2 Water Resources	The No-Action, P50 model (continuation of current conditions) for As shows annual maximum values (~0.5 ug/L), substantially less than those shown as mean existing water quality in Table 4.2.2-18 (mean As is 0.78 to 1.4 ug/L depending on the data set).	Baseline data is presented in Table 4.2.2-18 which is different to what was modeled for the Continuation of Existing Conditions Scenario.	"Continuation of Existing Conditions" is supposed to represent a model of existing conditions. If baseline for Colby Lake in Table 4.2.2-18 is not existing conditions then what is it?

Chapter 5.2

Comment_No.	Agency	Section	Comment	Co-Lead Disposition	GLIFWC Response
GLIFWC 222	GLIFWC	5.2.2 Water Resources	the travel times to the Partridge River depend on the basic hydrology of the mine site. As we comment elsewhere, the baseflow assumed for the Partridge is not supported by data from the Dunka Rd. gage. Incorporating the higher baseflow indicated by the gage data into modeling assumptions and calibration would result in a more conductive site and therefore, faster transport times.	Groundwater travel times are related to river baseflow estimates. We believe the baseflow estimates are reasonable. Higher baseflows would likely result in a more conductive site and faster transport times, but this would not necessarily result in higher solute concentrations in either groundwater or surface water; in fact we believe higher baseflows would result likely result in lower concentrations. The GoldSim model duration was 200 years, which was sufficient to capture the peak concentration of all solutes along all surficial groundwater flow paths; therefore, the GoldSim model does not need faster transport times to capture peak solute concentrations.	A more conductive site would, as you agree, result in faster transport times but would also result in great loss of groundwater to pit dewatering. The interaction between site conductivity and contaminate transport is not a simple relationship that can fully captures by a "belief" on your part.
GLIFWC 223	GLIFWC	5.2.2 Water Resources	The evaluation point at the toe of the basins is omitted from the table. Without that information it is impossible to evaluate the need for and the effectiveness of the seep capture system. Given that the seep capture system can not be operated indefinitely, it is important to report the character of the water that will be exiting the basins. A figure showing the water character at the toe of the basins should be added. Figures from Water Modeling Data Package Vol 2-Plant Site v9 MAR2013.pdf such as Figure F-01-04.1 or Figure F-01-18.1 or Figure F-01-24.1 would be suitable.	Although we agree that the evaluation locations at the toe of the tailings basin are valuable in terms of ongoing monitoring and early warning of potential water quality issues, we do not see any real benefit to including these additional evaluation locations in the SDEIS as the GoldSim model was run for sufficient durations that the peak of seepage from all contamination sources reaches the evaluation locations currently included in the SDEIS.	Given dilution of contamination between the basin and the reported evaluation points, the modeled peak is not the same as the concentration at the toe of the basin. Toe of basin concentrations should be reported.
GLIFWC 123	GLIFWC	5.2.2.1.1 Groundwater	The conclusion that there are no significant hydrologic affects of the project cannot be supported. It is based on fatally flawed modelling in XP-SWMM using antiquated data from far downstream. See GLIFWC hydrology attachment.	We believe the XP-SWMM modeling is acceptable for use in the SDEIS. The 20 year old data is acceptable as there haven't been any significant changes within the watershed. We believe the assumptions used were reasonably conservative. Additional detail is provided in the water sections of the SDEIS, and further rationale is provided in the Water Data Packages.	GLIFWC does not agree with the co-lead disposition. Provide a link to the hydrology section in the appendix.

Chapter 5.2

Comment_No.	Agency	Section	Comment	Co-Lead Disposition	GLIFWC Response
GLIFWC 124	GLIFWC	5.2.2.1.1 Groundwater	The discussion of groundwater evaluation criteria is incomplete. The evaluation point at the Dunka road needs to be discussed and all results displayed in a table. This is because there are 2 alternatives for the land exchange and a preferred alternative is not yet chosen. This section, and all other sections of chapter 5 must not assume a property boundary in the text. Finally, figure 5.2.2-4 appears to depict the Dunka Rd. evaluation point. the text should also.	Although we agree that the evaluation locations along Dunka Road are valuable in terms of ongoing monitoring and early warning of potential water quality issues, we do not see any real benefit to including these additional evaluation locations in the SDEIS as the GoldSim model was run for sufficient durations that it captures the peak solute concentrations along all flow paths at the evaluation locations currently included in the SDEIS.	The Dunka road should be included because Alternative B of the land exchange would use that evaluation point as the point of compliance should that alternative be chosen.
GLIFWC 125	GLIFWC	5.2.2.1.1 Groundwater- figure 5.2.2-4	The location of the groundwater evaluation point for the ore surge pile flowpath should be moved to the section of the property boundary closest to the pile itself. Does the modeling use this incorrect evaluation point?	The evaluation point for the OSP is the Partridge River because the river is located slightly further upgradient (northwest) than the mine property boundary. The distance from the OSP to the evaluation point is about 1100 meters which is consistent with Figure 5.2.2-4.	We suggest you look at the figure again. The river is <u>not</u> closer than the property boundary to the OSP source. NOTE - Map corrected in later version.
GLIFWC 126	GLIFWC	5.2.2.1.2 Surface Waters - Hydrologic Alterations	The evaluation criteria values for the project are taken from XP_SWMM modeling That model is fatally flawed and produces results that conflict with measured data. The results cannot be used. See GLIFWC hydrology attachment	We believe the XP-SWMM modeling is acceptable for use in the SDEIS. The 20 year old data is acceptable as there haven't been any significant changes within the watershed. We believe the assumptions used were reasonably conservative. Additional detail is provided in the water sections of the SDEIS, and further rationale is provided in the Water Data Packages.	GLIFWC does not agree with the co-lead disposition. Provide a link to the hydrology section in the appendix.
GLIFWC 127	GLIFWC	5.2.2.1.2 Surface Waters	GLIFWC disagrees with MPCA interpretation of areas of wild rice production. See GLIFWC wild rice attachment.	The SDEIS uses MPCA's draft determination regarding the locations of water used for the production of wild rice.	GLIFWC does not agree with the MPCA determination of points of compliance. Provide a link to the wild rice section in the appendix.
GLIFWC 128	GLIFWC	5.2.2.1.2 Surface Waters	GLIFWC disagrees with MPCA seasonal application of the wild rice standard. See GLIFWC wild rice attachment.	The SDEIS uses MPCA's draft determination regarding the seasonal application of the wild rice standard.	GLIFWC does not agree with the MPCA seasonal application of the wild rice sulfate standard. Provide a link to the wild rice section in the appendix.
GLIFWC 129	GLIFWC	5.2.2.1.2 Surface Waters	Section states that PolyMet is not seeking application of a seasonal wild rice standard. This is in conflict with other sections of the PSDEIS. See GLIFWC wild rice attachment.	All information provided was considered when the MPCA made their recommendation. Should the application of the standard change, it will be addressed at that time.	GLIFWC does not agree with the MPCA determination of points of compliance. Provide a link to the wild rice section in the appendix.
GLIFWC 194	GLIFWC	5.2.2.1.2 Surface Waters	There is a general lack of understanding of mercury dynamics in the St. Louis River Watershed. See the supplemental document "Great Lakes Indian Fish and Wildlife Commission (GLIFWC) Comments Related to Mercury" [Comment 1] for details.	The Co-leads agree that the mercury dynamics are complex; however, the analysis as presented indicated that there was minimal potential for a downstream increase in mercury loading.	GLIFWC does not agree with the co-lead disposition. Provide a link to the mercury section in the appendix.

Chapter 5.2

Comment_No.	Agency	Section	Comment	Co-Lead Disposition	GLIFWC Response
GLIFWC 130	GLIFWC	5.2.2.2.3 Water Quality Modeling (goldsim)	There is a comparison of sulfur content with other mines. Fundamentally, it does not matter if S levels are lower or higher compared to other mines. NorthMet would be located in a wet environment with complex hydrology where other mines are located in arid or arctic environments with little hydrologic connectivity. All mines are different and this language makes the attempt to minimize the risks of this particular mine. Remove the language.	Caveat added to discussion.	There is not enough information for us to remove the comment.
GLIFWC 131	GLIFWC	5.2.2.2.3 Water Quality Modeling (goldsim)	XP-SWMM model is fatally flawed and should not be used in impact assessment. See GLIFWC hydrology attachment	The difference in the baseflows are very small (indistinguishable from a stage standpoint). We believe the XP-SWMM modeling is acceptable for use in the SDEIS. The 20 year old data is acceptable as there haven't been any significant changes within the watershed. We believe the assumptions used were reasonably conservative. Additional detail is provided in the water sections of the SDEIS, and further rationale is provided in the Water Data Packages.	GLIFWC does not agree with the co-lead disposition. Provide a link to the hydrology section in the appendix.
GLIFWC 132	GLIFWC	5.2.2.2.3 Water Quality Modeling (goldsim)	There is a statement that the no action alternative is a continuation of existing conditions. GLIFWC staff fundamentally disagree with this approach. This flawed assumption leads to errors in water quality model outputs. NEPA requires an analysis of the no action alternative so that the effects of the proposed action can be understood in a larger context. See GLIFWC hydrology attachment.	We believe the assumptions used were reasonably conservative. The description of the No Action Alternative and Continuation of Existing Conditions will be further clarified in the SDEIS.	GLIFWC does not agree with the co-lead disposition. Provide a link to the hydrology section in the appendix.
GLIFWC 133	GLIFWC	5.2.2.3.1 Northmet Project Proposed Action Water Budget Overview - figure 5.2.2-15	This map, or a new map are needed with the location of the west pit level control structure, the outfall location, and the potential location of facilities described in the AWMP.	Figure 5.2.2-15 will be edited to include the west pit level control structure & the outfall location.	ok
GLIFWC 134	GLIFWC	5.2.2.3.1 Northmet Project Proposed Action Water Budget Overview	Section states that figure 5.2.2-15 has the location of a wetland and outlet control structure OS-5. It does not. Figure should also include the tributary channel that would connect the outfall to the Partridge River.	Figure 5.2.2-15 will be edited to include the west pit level control structure & the outfall location.	ok

Chapter 5.2

Comment_No.	Agency	Section	Comment	Co-Lead Disposition	GLIFWC Response
GLIFWC 135	GLIFWC	5.2.2.3.1 Northmet Project Proposed Action Water Budget Overview	Discussion on the hydromet tailings facility should clearly state that the periodic pumping and water collection activities would be perpetual.	The Closure objective is to provide water management activities at the Hydrometallurgical facility for as long as necessary to meet regulatory standards at evaluation locations in groundwater and surface water. While described as long-term, the time frame for these activities is not necessarily "perpetual". Chapter 3 describes closure of the Hydrometallurgical Residue Facility. Once the facility is drained and reclaimed (covered), no further pumping would be required. As such, there would not be periodic or perpetual pumping of water from the Hydrometallurgical Residue Facility post closure.	GLIFWC does not agree with the language in the co-lead disposition. Provide a link to the Perpetual care language in the appendix.
GLIFWC 136	GLIFWC	5.2.2.3.1 Northmet Project Proposed Action Water Budget Overview - Mine Site section	The section should clearly state for how long water collection and treatment of Category 1 stockpile seepage would be needed. It should also state that the length of time the WWTP would operate in order to comply with water quality standards is perpetual	Text edited to reflect that the Closure objective is to provide mechanical and non-mechanical treatment for as long as necessary to meet regulatory standards at evaluation locations in groundwater and surface water. Both mechanical and non-mechanical treatment will require periodic maintenance and monitoring activities. Modeling predicts that treatment activities will be a minimum 200 years at the Mine Site and a minimum of 500 years at the Plant Site. While long-term, these time frames for water treatment are not necessarily perpetual. The owning company would be held accountable to maintenance and monitoring required under permit and would not be released until all conditions have been met.	GLIFWC does not agree with the language in the co-lead disposition. Provide a link to the Perpetual care language in the appendix.
GLIFWC 137	GLIFWC	5.2.2.3.1 Northmet Project Proposed Action Water Budget Overview	States that the goal is to transition to non mechanical water treatment. The fact that all water treatment (mechanical and/or non mechanical) would need to occur in perpetuity. It should also clearly state that a transition to non mechanical treatment may not be possible.	Text edited (see GLIFWC 136: maintenance and monitoring long term required)	GLIFWC does not agree with the language in the co-lead disposition. Provide a link to the Perpetual care language in the appendix.
GLIFWC 138	GLIFWC	5.2.2.3.1 Northmet Project Proposed Action Water Budget Overview	First paragraph should state that treatment and capture of water needs are perpetual.	Text edited (see GLIFWC 136: maintenance and monitoring long term required)	GLIFWC does not agree with the language in the co-lead disposition. Provide a link to the Perpetual care language in the appendix.

Chapter 5.2

Comment_No.	Agency	Section	Comment	Co-Lead Disposition	GLIFWC Response
GLIFWC 139	GLIFWC	5.2.2.3.1 Northmet Project Proposed Action Water Budget Overview	States that long term closure activities will continue until the various facility features are deemed environmentally acceptable, in a self sustaining and stable condition. This is a misleading statement because the maintenance and water treatment needs are perpetual. A stable and self sustaining site will never occur.	Text edited to reflect that the Closure objective is to provide mechanical and non-mechanical treatment for as long as necessary to meet regulatory standards at evaluation locations in groundwater and surface water. Both mechanical and non-mechanical treatment will require periodic maintenance and monitoring activities. Modeling predicts that treatment activities will be a minimum 200 years at the Mine Site and a minimum of 500 years at the Plant Site. While long-term, these time frames for water treatment are not necessarily perpetual. The owning company would be held accountable to maintenance and monitoring required under permit and would not be released until all conditions have been met.	GLIFWC does not agree with the language in the co-lead disposition. Provide a link to the Perpetual care language in the appendix.
GLIFWC 140	GLIFWC	5.2.2.3.1 Northmet Project Proposed Action Water Budget Overview	Non mechanical treatment options would still require maintenance and monitoring in perpetuity to ensure effectiveness.	Text edited to reflect that the Closure objective is to provide mechanical and non-mechanical treatment for as long as necessary to meet regulatory standards at evaluation locations in groundwater and surface water. Both mechanical and non-mechanical treatment will require periodic maintenance and monitoring activities. Modeling predicts that treatment activities will be a minimum 200 years at the Mine Site and a minimum of 500 years at the Plant Site. While long-term, these time frames for water treatment are not necessarily perpetual. The owning company would be held accountable to maintenance and monitoring required under permit and would not be released until all conditions have been met.	GLIFWC does not agree with the language in the co-lead disposition. Provide a link to the Perpetual care language in the appendix.
GLIFWC 199	GLIFWC	5.2.2.3.1 Northmet Project Proposed Action Water Budget Overview	There is no discussion of the impacts on mercury from the construction of wetlands over the East Pit and at the perimeter of the tailings basin during reclamation. See the supplemental document "Great Lakes Indian Fish and Wildlife Commission (GLIFWC) Comments Related to Mercury" [Comment 5] for details.	These wetlands are not expected to be sources of mercury nor have elevated mercury concentrations. The water used to augment flows north of the tailings storage facility would have significantly lower sulfate concentrations than current conditions. Therefore we do not expect these wetlands to function as any more of a source of methyl mercury than the current wetlands found in these locations.	The answer addresses only one part of the comment. There are other factors besides sulfate that generate methylmercury in a wetland. Wetlands in general, whether they are high in sulfate or not have the potential to generate methylmercury. Please add a link to the mercury section of the appendix.
GLIFWC 141	GLIFWC	5.2.2.3.2 Partridge River Watershed	The entire section is fatally flawed because it relies on the Canisteo Pit analog method. GLIFWC staff have objected to the use of this method since it was proposed (See GLIFWC wetland attachment). This analog approach is not scientifically defensible.	The analog approach is considered a reasonable method for evaluating the extent of pit drawdown considering the heterogeneous nature of glacial till and the underlying low-permeability bedrock. Even when the pit water level is well below the top of bedrock, the low-permeability bedrock limits the amount of surficial groundwater that can drain downward into the pit and there is sufficient recharge to the surficial unit to generally maintain water levels.	GLIFWC does not agree with the co-lead disposition. Provide a link to the wetland section in the appendix.

Chapter 5.2

Comment_No.	Agency	Section	Comment	Co-Lead Disposition	GLIFWC Response
GLIFWC 142	GLIFWC	5.2.2.3.2 Partridge River Watershed table 5.2.2-18	Chemical mechanisms column for the west pit should include water level fluctuations in the pit with wetting and drying of pit walls. This fluctuation is likely if a non-mechanical treatment option is used in order to meet the MPCA seasonal wild rice standard.	This factor will be addressed in future analysis of the passive system.	If the passive systems are not to be analyzed at all, they should be removed from the SDEIS.
GLIFWC 143	GLIFWC	5.2.2.3.2 Partridge River Watershed	Placing peat and unsaturated overburden in an unlined area would create a significant pulse of mercury. This mercury release does not seem to be accounted for in the mercury sections. The mercury, once released would travel the groundwater flow path and constitute an untreated discharge into the Partridge River. This is a particular concern because of the applicants failure to model mercury.	Surface runoff from the Overburden Storage and Laydown Area is considered "Process Water," and would be captured in an unlined pond (Pond PW-OSLA) and monitored for quality, including mercury. If the Overburden Storage and Laydown Area water was of sufficient quality, it would be pumped to the CPS and discharged to the East Pit or the Tailings Basin. If water in Pond PW-OSLA required treatment, it would be pumped to the WWTF for treatment prior to delivery to the CPS. The potential release of mercury from the decomposition of overburden materials is included in the mercury mass balance (Section 5.2.2.3.4).	ok
GLIFWC 144	GLIFWC	5.2.2.3.2 Partridge River Watershed	The no action alternative is not the same as existing conditions. An accurate no action alternative needs to be modeled in order to compare impacts under NEPA.	The SDEIS text regarding the No Action Alternative and "Continuation of Existing Conditions" will be clarified.	GLIFWC does not agree with the co-lead disposition. Provide a link to the hydrology section in the appendix.
GLIFWC 145	GLIFWC	5.2.2.3.2 Partridge River Watershed	All statements indicating that evaluation criteria would be met must include the caveat that perpetual water capture and treatment must be done to make that happen. We disagree that all water quality standards would be met. Water quality will be exceeded for several constituents.	Text edited. As described in the SDEIS, the evaluation criteria do use the standards, but interpret the standards from a probabilistic perspective. The P90 approach is a reasonable method for applying the results of probabilistic modeling for EIS impact assessment. In this context, it is not appropriate to say that "a constituent will exceed a water quality standard". It is more accurate to say that "there is at least a 90 percent probability that a constituent will not exceed a standard (or up to a 10 percent probability that it will)". These quoted statements are very different.	GLIFWC does not agree with the language in the co-lead disposition. Provide a link to the Perpetual care language in the appendix.
GLIFWC 146	GLIFWC	5.2.2.3.2 Partridge River Watershed	Title is not correct because there is no property boundary yet. In addition, the table should provide the 90th percentile concentration values for both land exchange alternatives.	Table title will be revised. In this section, the SDEIS is evaluating the Proposed Action. See Section 5.3.2 for a discussion of the land exchange alternative.	ok

Chapter 5.2

Comment_No.	Agency	Section	Comment	Co-Lead Disposition	GLIFWC Response
GLIFWC 147	GLIFWC	5.2.2.3.2 Partridge River Watershed	The first paragraph is not correct. The Copper Nickel study from 1979 states "Highly saline groundwater has been encountered in some bedrock areas in the study area...The source and spatial distribution of this water in the Study Area is unknown. The Superior National Forest technical memorandum No. 4 Brackish Groundwater within the SNF states that In 1976, brackish waters were encountered at the AMAX site which is in the same geology as the NorthMet project. In 2012 elevated chloride levels were found at mineral exploration drill locations near the South Kawishiwi River. The text should be corrected in light of available data from the SNF.	We disagree - applicable data is discussed.	Comment stands.
GLIFWC 148	GLIFWC	5.2.2.3.2 Partridge River Watershed	XP-SWMM model is fatally flawed and should not be used in imoact assessment. See GLIFWC hydrology attachment.	We believe the XP-SWMM modeling is acceptable for use in the SDEIS. The 20 year old data is acceptable as there haven't been any significant changes within the watershed. We believe the assumptions used were reasonably conservative. Additional detail is provided in the water sections of the SDEIS, and further rationale is provided in the Water Data Packages.	GLIFWC does not agree with the co-lead disposition. Provide a link to the hydrology section in the appendix.
GLIFWC 149	GLIFWC	5.2.2.3.2 Partridge River Watershed	Pit seepage is a long term untreated discharge. The section should clearly state this.	The following edit has been made to the text: These untreated pit discharges to groundwater in the West Pit Surficial Flow Path and the East Pit Category 2/3 Surficial Flowpath would occur in perpetuity. Groundwater in these flowpaths would flow down gradient and eventually discharge to the Partridge River.	ok
GLIFWC 150	GLIFWC	5.2.2.3.2 Partridge River Watershed	The discussion in the fourth bullet states that sulfate exceedances would be "exclusively limited to the low flow winter months" This explanation is only relevant if the applicant is seeking a seasonal application of the sulfate standard. Other sections of the PSDEIS have stated that they are not. This conflict should be resolved.	PolyMet Is not seeking seasonal application for the Proposed Project. Any future request for a seasonal application would require MPCA approval.	GLIFWC does not agree with the co-lead disposition. Provide a link to the wild rice section in the appendix.
GLIFWC 151	GLIFWC	5.2.2.3.2 Partridge River Watershed	The entire discussion of sulfate being exceeded during low flows is colored by the fact that there is very little understanding of hydrology in the upper Partridge River. The XP-SWMM model used to interpolate flow data is fatally flawed and does not produce reliable data. The net effect is that the PSDEIS cannot reliably state wether the sulfate standard will be met or not.	We believe the XP-SWMM modeling is acceptable for use in the SDEIS. The 20 year old data is acceptable as there haven't been any significant changes within the watershed. We believe the assumptions used were reasonably conservative. Additional detail is provided in the water sections of the SDEIS, and further rationale is provided in the Water Data Packages.	GLIFWC does not agree with the co-lead disposition. Provide a link to the hydrology section in the appendix.

Chapter 5.2

Comment_No.	Agency	Section	Comment	Co-Lead Disposition	GLIFWC Response
GLIFWC 152	GLIFWC	5.2.2.3.2 Partridge River Watershed	The last bullet states that the no action alternative is assumed to be the same as existing conditions. This is not correct as it ignores the intermittent dewatering of the Northshore pits. A realistic no action alternative needs to be modeled.	The description of the No Action Alternative and Continuation of Existing Conditions will be further clarified in the SDEIS.	GLIFWC does not agree with the co-lead disposition. Provide a link to the hydrology section in the appendix.
GLIFWC 153	GLIFWC	5.2.2.3.2 Partridge River Watershed	The conclusion that sulfate concentrations at 200 years would be less than 10 mg/l may not be supportable by modeling. It assumes that the no action alternative is the same as existing conditions and that is not the case.	The GoldSim model results do suggest that sulfate concentrations in the Partridge River at SW-005 would be less than 10 mg/L.	GLIFWC does not agree with the co-lead disposition. Provide a link to the hydrology section in the appendix.
GLIFWC 154	GLIFWC	5.2.2.3.2 Partridge River Watershed	The discussion relies on dilution to meet the sulfate standard. Because hydrology at the mine site is not understood, there is no basis to make this claim.	We believe the XP-SWMM modeling is acceptable for use in the SDEIS. The 20 year old data is acceptable as there haven't been any significant changes within the watershed. We believe the assumptions used were reasonably conservative. Additional detail is provided in the water sections of the SDEIS, and further rationale is provided in the Water Data Packages.	GLIFWC does not agree with the co-lead disposition. Provide a link to the hydrology section in the appendix.
GLIFWC 155	GLIFWC	5.2.2.3.2 Partridge River Watershed	The first paragraph describes a situation where the wild rice sulfate standard "would be exceeded anyway". This is an acknowledgement that the standard is, at least at some times, being exceeded through cumulative impacts of other operations. If this is the case, the Clean Water Act does not allow Polymet to contribute any load to that exceedance regardless of dilution.	The Co-leads recognize this is a major difference of opinion.	Provide a link to the hydrology section in the appendix.
GLIFWC 156	GLIFWC	5.2.2.3.2 Partridge River Watershed	GLIFWC staff disagree that effective mitigation for sulfate exceedences are identified. There is conjecture about the dilutive effects of treated waste water but no modeling or analysis to demonstrate that effect.	The text has been edited to include possible contingency measures that could be implemented. Given that the identified contingency measures are based on engineered facilities that can be pilot tested, there is reasonable likelihood that contingency measures could be implemented (if needed) to prevent exceedance of the 10 mg/L sulfate standard in Partridge River surface water.	GLIFWC does not agree with the co-lead disposition. The purpose of the analysis was to demonstrate that the project would not exceed standards. The disposition is an assumption and not a demonstration.
GLIFWC 157	GLIFWC	5.2.2.3.2 Partridge River Watershed	GLIFWC staff disagree with the characterization of dust from the rail corridor as minor. See GLIFWC rail car attachment.	This section acknowledges the dust issue and refers the reader to section 5.2.3.2.2. There is no other discussion or characterization of dust in this section. Discussion of fine material being segregated in the center of rail cars has been removed.	GLIFWC does not agree with the co-lead disposition. Provide a link to the rail car section in the appendix.

Chapter 5.2

Comment_No.	Agency	Section	Comment	Co-Lead Disposition	GLIFWC Response
GLIFWC 158	GLIFWC	5.2.2.3.2 Partridge River Watershed	As previously stated, XP_SWMM is fatally flawed and therefore flow information cannot be used to show that standards are met through dilution. Therefore, the conclusions on arsenic in Colby lake cannot be supported.	We believe the XP-SWMM modeling is acceptable for use in the SDEIS. The 20 year old data is acceptable as there haven't been any significant changes within the watershed. We believe the assumptions used were reasonably conservative. Additional detail is provided in the water sections of the SDEIS, and further rationale is provided in the Water Data Packages.	GLIFWC does not agree with the co-lead disposition. Provide a link to the hydrology section in the appendix.
GLIFWC 159	GLIFWC	5.2.2.3.2 Partridge River Watershed	perpetual water treatment would be needed in to avoid violating standards in Colby Lake.	No change to SDEIS text.	GLIFWC does not agree with the co-lead disposition. Provide a link to the perpetual maintenance section in the appendix.
GLIFWC 160	GLIFWC	5.2.2.3.2 Partridge River Watershed	The last paragraph correctly discusses perpetual treatment needs. The improvements in water quality in the west pit are speculative and do not change the fact that perpetual treatment is necessary. Therefore the paragraph should indicate that while non-mechanical treatment options may be possible at some point in time, that non-mechanical treatment would also have to be perpetual for standards to be met.	Water quality changes in the pits are not speculative, but are predicted based on flow/chemical modeling with reasonable assumptions. Text clarified.	ok
GLIFWC 161	GLIFWC	5.2.2.3.2 Partridge River Watershed - Figures 5.2.2-37 through 5.2.2-39	Need to indicate the appropriate water quality standard	The West Pit is not considered an evaluation location so a water quality standard does not apply. Water quality standards would apply to the WWTF (which treats the West Pit overflow) discharge.	ok. We understand that there will be a polluted pit lake and water quality standards will not apply until water leaves the lake.
GLIFWC 162	GLIFWC	5.2.2.3.2 Partridge River Watershed	States that water quality in the permanent mine features left behind is expected to improve over time. This is misleading because the model was not run long enough to predict when that would be. It is clear that, using sulfate as an example, the west pit would be a perpetual source with the potential of contaminating downstream beds in perpetuity.	The flow/chemical modeling does predict that water quality will improve over the modeled time frame of 200 years. Text has been modified.	ok
GLIFWC 163	GLIFWC	5.2.2.3.2 Partridge River Watershed	Why was water quality modeling terminated after 200 years?	Before 200 years, the maximum chemical loading in affected groundwater is predicted to reach the Partridge River.	But the plume in bedrock is not.

Chapter 5.2

Comment_No.	Agency	Section	Comment	Co-Lead Disposition	GLIFWC Response
GLIFWC 201	GLIFWC	5.2.2.3.2 Partridge River Watershed	There is no consideration of the likely mercury pulse to the Partridge River resulting from placement of the stripped peat and unsaturated overburden into the unlined Overburden Storage and Laydown Area. See the supplemental document "Great Lakes Indian Fish and Wildlife Commission (GLIFWC) Comments Related to Mercury" [Comment 7] for details.	Surface runoff from the Overburden Storage and Laydown Area is considered "Process Water," and would be captured in an unlined pond (Pond PW-OSLA) and monitored for quality. If the Overburden Storage and Laydown Area water was of sufficient quality, it would be pumped to the CPS and discharged to the East Pit or the Tailings Basin. If water in Pond PW-OSLA required treatment, it would be pumped to the WWTF for treatment prior to delivery to the CPS.	ok
GLIFWC 164	GLIFWC	5.2.2.3.3 Embarrass River Watershed	States that the seepage capture system is not expected to have an effect on groundwater downgradient of wetlands because ponded water at the surface is expected to infiltrate and replace groundwater. This is a circular argument. The ponded water downgradient of the tailings basin is mostly tailings basin water that has been seeping over decades saturating the aquifer and flooding wetlands. The seepage capture system would reduce that water source and that capture system is likely perpetual. It is not reasonable to assume that the ponded water will be able to replace groundwater captured by the containment system in perpetuity because the tailings basin is the water source for both the ponds and the groundwater. What are the impacts to groundwater levels and wetlands outside the containment system once the pond water at the surface runs out?	The text has been changed to reflect the decrease in groundwater seepage would not be expected to have a significant effect on groundwater down gradient of the groundwater containment system because there would be sufficient natural recharge to maintain saturation in the surficial (unconsolidated) unit.	ok
GLIFWC 165	GLIFWC	5.2.2.3.3 Embarrass River Watershed	How long would the groundwater capture system need to operate? How long would the WWTP need to operate?	Modeling predicts that groundwater capture and mechanical (WWTP) or non-mechanical water treatment would need to occur for a minimum of 500 years. Capture and treatment would continue after that time until water quality monitoring at groundwater and surface water evaluation locations indicate that these measures are no longer needed.	GLIFWC does not agree with the co-lead disposition. Provide a link to the perpetual maintenance section in the appendix.
GLIFWC 166	GLIFWC	5.2.2.3.3 Embarrass River Watershed - Figure 5.2.2-40	Figure is misleading. Edit the figure to indicate that the long term does not end at year 45 but rather extends into perpetuity.	The figure will be edited.	There is not enough information for us to remove our comment.

Chapter 5.2

Comment_No.	Agency	Section	Comment	Co-Lead Disposition	GLIFWC Response
GLIFWC 167	GLIFWC	5.2.2.3.3 Embarrass River Watershed	The no action alternative is not the same as existing conditions. This assumption ignores ongoing VIC work and the Cliffs Erie consent decree that would improve water quality over time. It also ignores the fact that rain will fall on the tailings basin, percolate through the tailings and flush constituents. Over time this effect will reduce the source term of the facility. An accurate no action alternative needs to be modeled in order to compare impacts under NEPA. See GLIFWC attachment.	Description of the No Action Alternative will be clarified.	There is not enough information for us to remove our comment. Please add a link to the hydrology section in the appendix
GLIFWC 168	GLIFWC	5.2.2.3.3 Embarrass River Watershed	The discussion on TDS is not correct. The no action alternative is not the same as existing conditions. It does not matter that the exceedances from the tailings basin were caused by historic operations. PolyMet assumes responsibility for those exceedances if the project goes forward.	Description of the No Action Alternative will be clarified.	There is not enough information for us to remove our comment. Please add a link to the hydrology section in the appendix
GLIFWC 169	GLIFWC	5.2.2.3.3 Embarrass River Watershed	With respect to the TDS exceedances. How long before the model shows that groundwater criteria are met? And how does that differ from information in the consent decree?	The NorthMet Proposed Project water quality model indicates that the 90th percentile value for TDS in the Plant Site groundwater would drop below the 500-mg/l groundwater evaluation criteria at ~55 years after start of mining, as illustrated in Figure 5.2.2-44. Because the No Action condition for the LTVSMC Tailings Basin is represented in the GoldSim model without implementation of any mitigation measures, model predictions do not show a reduction in Plant Site groundwater TDS under the No Action conditions, also illustrated in Figure 5.2.2-44.	GLIFWC does not agree with the co-lead disposition. Provide a link to the hydrology section in the appendix.
GLIFWC 170	GLIFWC	5.2.2.3.3 Embarrass River Watershed	Flow in the tributary streams will change as effluent from the tailings basin changes over time under a no action scenario. The assumption that existing conditions is the same as the no action scenario is not supported. A no action alternative should be modeled.	The description of the No Action Alternative and Continuation of Existing Conditions will be further clarified in the SDEIS.	There is not enough information for us to remove our comment. Please add a link to the hydrology section in the appendix

Chapter 5.2

Comment_No.	Agency	Section	Comment	Co-Lead Disposition	GLIFWC Response
GLIFWC 171	GLIFWC	5.2.2.3.3 Embarrass River Watershed	The section should indicate that the assumption of meeting evaluation criteria depends on perpetual water capture, water treatment, and tailings facility maintenance. We disagree that water quality standards would be met. The PSDEIS states that standards would be exceeded for several constituents.	Text edited. As described in the SDEIS, the evaluation criteria do use the standards, but interpret the standards from a probabilistic perspective. The P90 approach is a reasonable method for applying the results of probabilistic modeling for EIS impact assessment. In this context, it is not appropriate to say that "a constituent will exceed a water quality standard". It is more accurate to say that "there is at least a 90 percent probability that a constituent will not exceed a standard (or up to a 10 percent probability that it will)". These quoted statements are very different.	GLIFWC does not agree with the co-lead disposition. Provide a link to the perpetual maintenance section in the appendix.
GLIFWC 172	GLIFWC	5.2.2.3.3 Embarrass River Watershed	As previously commented, the no action alternative is not the same as existing conditions.	The description of the No Action Alternative and Continuation of Existing Conditions will be further clarified in the SDEIS.	There is not enough information for us to remove our comment. Please add a link to the hydrology section in the appendix
5.2.3 Wetlands					
GLIFWC 182	GLIFWC	5.2.3.1.2 Potential Indirect Wetland Effects Methodology And Evaluation Criteria	The indirect impact analysis is fatally flawed. The analog approach is not scientifically defensible and further, it uses cherry picked data to reach conclusions. See GLIFWC wetland analysis attachment.	Per the Final Wetlands IAP Summary Memo, the Co-lead Agency position was that the assessment of potential indirect wetland impacts at the mine site should be conducted based upon an interpretation of the general analog guidelines regarding groundwater drawdown analog information provided by the Water Resources IAP Workgroup in accordance with the guidance provided in the attachment to this summary memo. The Co-lead Agencies believe that even with additional groundwater data collection and additional groundwater modeling, there would still be a high level of uncertainty regarding groundwater model outputs. Therefore, the Co-lead Agencies believe that the analog guideline method of estimating glacial aquifer groundwater drawdown near the proposed mine is reasonable and appropriate for this site and do not recommend that additional field data collection and groundwater modeling be conducted for the purpose of estimating glacial aquifer groundwater drawdown.	GLIFWC does not agree with the co-lead disposition. Provide a link to the wetland section in the appendix.

Chapter 5.2

Comment_No.	Agency	Section	Comment	Co-Lead Disposition	GLIFWC Response
				Some Wetland IAP Workgroup members disagree with the Co-lead Agency position. They believe that additional field data collection and additional groundwater modeling are necessary to provide groundwater drawdown cone of depression information near the open pit mine. That position was an earlier recommendation of the Wetland IAP Workgroup and was supported by Workgroup members from the Fond du Lac Band, Grand Portage Band, Great Lakes Indian Fish and Wildlife Service, U.S. Fish and Wildlife Service, 1854 Treaty Authority, Minnesota Pollution Control Agency and the U.S. Environmental Protection Agency. However; it was not supported by Workgroup members from the Co-lead Agencies, Environmental Resources Management, or Barr Engineering. In addition, some Workgroup members believe that the Co-lead Agency position is contrary to standard analysis that mining companies have to conduct as part of sulfide mine EIS processes across the country. In addition, the Grand Portage Band believes that the geology of the analog sites appear to be non-analogous with the geology of the proposed mine site.	We continue to believe that use of the <u>all</u> existing data is most appropriate.
GLIFWC 185	GLIFWC	5.2.3.1.2 Potential Indirect Wetland Effects Methodology And Evaluation Criteria	As commented previously, the modeling done to assess changes in Partridge River flow is fatally flawed and does not yield usable results.	The Co-lead Agencies have concluded that the use of lateral effect equations for ditches is not suitable for use in determining glacial aquifer drawdown near open pit mines, and that method should not be used to estimate groundwater drawdown near the NorthMet project open pits. There was no disagreement among any of the Workgroup members.	We agree with the statement regarding the lateral effects model. In fact we were convinced that it would not work when the Corps suggested using the model in the NorthMet SDEIS. However, The comment refers to the XP-SWMM modeling so the lead agency disposition is appropos of nothing. Add a link to the hydrology section in the appendix.
GLIFWC 188	GLIFWC	5.2.3.2.2 Mine Site And Transportation And Utility Corridor Indirect Wetland Effects	The section on changes in hydrology due to drawdown is scientifically indefensible and fatally flawed. See GLIFWC wetland attachment.	See GLIFWC 182	GLIFWC does not agree with the co-lead disposition. Provide a link to the wetland section in the appendix.
GLIFWC 189	GLIFWC	5.2.3.2.2 Mine Site And Transportation And Utility Corridor Indirect Wetland Effects	The XP-SWMM model used for assessing impacts t Partridge River flow is fatally flawed and should not be used in the PSDEIS. See GLIFWC hydrology attachment	We believe the XP-SWMM modeling is acceptable for use in the SDEIS. The 20 year old data is acceptable as there haven't been any significant changes within the watershed. We believe the assumptions used were reasonably conservative. Additional detail is provided in the water sections of the SDEIS, and further rationale is provided in the Water Data Packages.	GLIFWC does not agree with the co-lead disposition. Provide a link to the hydrology section in the appendix.

Chapter 5.2

Comment_No.	Agency	Section	Comment	Co-Lead Disposition	GLIFWC Response
GLIFWC 190	GLIFWC	5.2.3.2.2 Mine Site And Transportation And Utility Corridor Indirect Wetland Effects	Presents an incorrect characterization of the impacts of dust emissions along the rail line. The section states that the air IAP did not identify any air quality effects. This issue was raised in the water quality IAP and the lead agencies moved it to air quality. We maintain that this is a water quality issue. The lead agencies have refused to fully address the issue and have chosed to simply monitor the waters near the rail line in order to detect impacts after they have already occurred.	The Co-leads position on the potential for contamination along the rail line is discussed in 5.2.2 and 5.2.3.	GLIFWC does not agree with the co-lead disposition. Provide a link to the rail car section in the appendix.
GLIFWC 191	GLIFWC	5.2.3.2.2 Mine Site And Transportation And Utility Corridor Indirect Wetland Effects	Same comment a page 5.2.3-51. In addition the statement that deposition along the rail line would be minimal because of the coarse nature of the ore. This is incorrect. Relatively small ammounts of fine ore dust can create large water quality impacts as evidenced by the clean water act violations at the Flambeau mine in Wisconsin.	The Co-leads position on the potential for contamination along the rail line is discussed in 5.2.2 and 5.2.3.	GLIFWC does not agree with the co-lead disposition. Provide a link to the rail car section in the appendix.
GLIFWC 181	GLIFWC	5.2.3 Wetlands	Some wetlands in the indirect impact category are severely affected by drawdown, fragmentation, watershed destruction and dust deposition. These effects are well understood and so the Corps should require up front mitigation for these wetland impacts. See GLIFWC wetland attachment for additional analysis and information.	A wetland monitoring plan would be developed and implemented if the NorthMet project is permitted. The plan would require wetland hydrology monitoring, vegetation monitoring, and wetland water quality monitoring to identify if indirect wetland impacts occur during implementation of the project. If indirect wetland impacts resulting from the project are determined by the monitoring program, compensatory wetland mitigation would be required for those indirect wetland impacts. Text revised throughout the mitigation/monitoring discussions to address comment.	GLIFWC does not agree with the co-lead disposition. Provide a link to the wetland section in the appendix.
GLIFWC 193	GLIFWC	5.2.3.3.4 Monitoring	The section on monitoring for indirect effects, specifically the 4 goals, are exactly the type of analysis that is required for a federal EIS. This information should have been an integral part of the effects analysis for this project and GLIFWC staff have been advocating for this approach for years. This information, collected after the fact, cannot be used in impact assessment and thus cannot help mitigate the effects of the proposed project.	A wetland monitoring plan would be developed and implemented if the NorthMet project is permitted. The plan would require wetland hydrology monitoring, vegetation monitoring, and wetland water quality monitoring to identify if indirect wetland impacts occur during implementation of the project. If indirect wetland impacts resulting from the project are determined by the monitoring program, compensatory wetland mitigation would be required for those indirect wetland impacts.	GLIFWC does not agree with the co-lead disposition. Provide a link to the wetland section in the appendix.

Chapter 5.2

Comment_No.	Agency	Section	Comment	Co-Lead Disposition	GLIFWC Response
GLIFWC 216	GLIFWC	5.2.3.3.2 Wetland Mitigation and Contingency Mitigation	In discussing Financial Assurances there is no mention of the perpetual pump and treatment costs or liabilities for the mine. In reviewing various sections discussing Financial Assurances in no portion of the PSDEIS did authors identify: 1) annual projected operating costs for pollution control once the mine is closed including operation of the reverse osmosis system; 2) capital replacement costs and life cycle for pollution control infrastructure including piping, pumps, etc (i.e. What would have to be replaced every 10, 25, 50, 75 years and what would be the costs?); 3) and Net Present Value of the Financial Assurances (i.e. comparing the value of a dollar today to the value of that same dollar in the future). See GLIFWC socioeconomic attachment for additional information.	This comment appears to be addressing financial assurance in general and not just wetlands. Section 3 has a discussion on the project financial assurance. The level of detail provided in the SDEIS has been agreed upon by Co-Leads and with EPA. The details of the assurance will be developed during permitting. Section 3.2.2.4 provides a discussion of the financial assurance for the NorthMet Project Proposed Action.	ok
GLIFWC 184	GLIFWC	5.2.3.1.2 Potential Indirect Wetland Effects Methodology And Evaluation Criteria	The wetland sensitivity tables developed for the Crandon project in Wisconsin relied on a detailed understanding of the relationship between the surficial aquifer and the bottom of the wetland. That basic hydrologic information was never collected for this project therefore the significance criteria table is not necessarily applicable to NorthMet wetlands and its use in this context is not appropriate. See GLIFWC wetland attachment for additional information.	The wetland sensitivity tables in the Crandon mine project were used, though the Crandon project has different soils and hydrology than NorthMet, since it was decided and agreed upon in the IAP workgroup meetings. There is a general understanding on the NorthMet Project Mine Site of the general lack of connectivity of the surficial and bedrock aquifers, the soils present, the hydraulic conductivities, and the bedrock types (Barr 2006c; Barr 2008h; Barr 2010d). No text edit.	GLIFWC does not agree with the co-lead disposition. Provide a link to the wetland section in the appendix.
GLIFWC 187	GLIFWC	5.2.3.2.2 Mine Site And Transportation And Utility Corridor Indirect Wetland Effects	Based on information in the wetlands data package, we disagree with the assumptions used in defining if a wetland is fragmented or not. The method used in the PSDEIS would allow wetlands that have over 50% of their area filled to be classified as unimpacted by assuming that all of their hydrology depends on rainfall. This is not acceptable because filling a large percentage of a wetland disrupts the internal hydrologic regime and fragments the vegetation community in the wetland.	Fragmented wetlands are classified as indirect impact; however, fragmented wetlands are included in upfront mitigation. Total upfront mitigation is for the 912.5 acres of direct effects and 26.4 acres of fragmented wetlands (indirect effect). Tables have been revised to reflect this.	GLIFWC does not agree with the co-lead disposition. Provide a link to the wetland section in the appendix.
GLIFWC 183	GLIFWC	5.2.3.1.2 Potential Indirect Wetland Effects Methodology And Evaluation Criteria	The heading "Potential Indirect Wetland Effects Resulting from Changes in Hydrology" appears in both pages. Edit the title to specify how the sections are different.	Edited as suggested.	ok

Chapter 5.2

Comment_No.	Agency	Section	Comment	Co-Lead Disposition	GLIFWC Response
GLIFWC 186	GLIFWC	5.2.3.2.1 Mine Site And Transportation And Utility Corridor Direct Wetland Effects	Backfill of category 3 and 4 waste rock does not minimize or avoid wetland fill. That waste rock will be on the site for over 10 years and the wetlands in the footprint of the stockpile would be destroyed. What backfill does accomplish is provide an opportunity to create new wetlands in those locations. However, the high quality character of the existing wetlands will likely not be replaced.	Sentence revised. PolyMet proposes to mitigate wetland effects by placing waste rock back into the East Pit and Central Pit after year 11, thereby reducing the need for additional surface stockpile areas that would otherwise affect wetlands.	ok
GLIFWC 204	GLIFWC	5.2.3.3.4 Monitoring	It appears that wetland monitoring following restoration is only vegetative and hydrologic in nature. Total and methyl mercury should be monitored pre-project through post-reclamation to collect information on mercury levels and methylation rates and identify any necessary remedial actions.	Wetland monitoring following restoration would be vegetative and hydrologic in nature. Reference to water monitoring discussed in Section 5.2.2.3.6 was added. Water quality will be monitored downstream and piezometers will be located in the wetlands.	ok
5.2.5 Wildlife					
GLIFWC 205	GLIFWC	5.2.5 Wildlife - Throughout the section	The Wildlife Section (5.2.5) does not discuss mercury contamination. Similarly the Aquatic Species Section (5.2.6) does not discuss direct health impacts to aquatic species due to mercury. These impacts must be considered. See the	The Open Water discussion in Section 5.2.5.2.3 has been expanded to include discussion of the potential for wildlife exposure to mercury.	There is not enough information for us to remove our comment. Please add a link to the mercury section in the appendix
GLIFWC 207	GLIFWC	5.2.5.2.3 Species Of Greatest Conservation Need	The PSDEIS dismisses the possibility of waterfowl and waterbirds utilizing the tailings basin despite the fact that common waterfowl and waterbirds have been observed at the LTVSMC tailings basin during migration. The wetlands to be constructed over the East Pit and at the perimeter of the tailings basin are also not considered as potential waterbird/fowl habitat. We believe that there is a significant potential pathway of mercury exposure to these species from utilizing these sites. See the supplemental document "Great Lakes Indian Fish and Wildlife Commission (GLIFWC) Comments Related to Mercury" [Comment 12] for further discussion.	The Open Water discussion in Section 5.2.5.2.3 has been expanded to more accurately describe the potential wildlife use of the Tailings basin, as well as the potential for exposure to mercury.	There is not enough information for us to remove our comment. Please add a link to the mercury section in the appendix
5.2.6 Aquatic Species					

Chapter 5.2

Comment_No.	Agency	Section	Comment	Co-Lead Disposition	GLIFWC Response
GLIFWC 206	GLIFWC	5.2.6 Aquatic Species - Throughout the section	The Wildlife Section (5.2.5) does not discuss mercury contamination. Similarly the Aquatic Species Section (5.2.6) does not discuss direct health impacts to aquatic species due to mercury. These impacts must be considered. See the supplemental document "Great Lakes Indian Fish and Wildlife Commission (GLIFWC) Comments Related to Mercury" [Comment 11] for further discussion.	Mercury effects are being considered by the Co-leads and the SDEIS will be revised.	There is not enough information for us to remove our comment. Please add a link to the mercury section in the appendix
GLIFWC 208	GLIFWC	5.2.6 Aquatic Species	PSDEIS states there will be effects on flow in the Partridge R. and Embarrass R. tributaries, but that they are not expected to influence habitat. We feel that the water level fluctuations may be sufficient to impact habitat which could lead to changes in species composition or relative abundance which could in turn impact mercury foodweb dynamics. See the supplemental document "Great Lakes Indian Fish and Wildlife Commission (GLIFWC) Comments Related to Mercury" [Comment 13] for further discussion.	The text of Paragraph 2 on page 5.2.6-1 has been revised to clarify why the proposed projects flow reductions are not expected to lead to community alterations citing a 2013 USGS document that indicates that streamflow modifications below 25% are used as a baseline study and that affects on algae, fisheries, and macroinvertebrates would not be measurable at this flow reduction rate.	There is not enough information for us to remove our comment. Please add a link to the mercury section in the appendix
GLIFWC 209	GLIFWC	5.2.6.2.2 Embarrass River Watershed	Many lakes and rivers in the area are classified as "impaired waters" by the MPCA due to elevated fish mercury. All additional increases in mercury contributions to the environment therefore constitute a risk to human and ecosystem health. There are numerous aspects of the proposed action cited in the PSDEIS that will lead to increased mercury releases to the environment, increasing human and ecosystem risk. Further, the PSDEIS documents and increased risk (i.e., risk quotient) to human fish consumers as a direct result of the project. See the supplemental document "Great Lakes Indian Fish and Wildlife Commission (GLIFWC) Comments Related to Mercury" [Comment 14] for further discussion.	Mercury effects are being considered by the Co-leads and the SDEIS will be revised.	There is not enough information for us to remove our comment. Please add a link to the mercury section in the appendix
5.2.7 Air Quality					

Chapter 5.2

Comment_No.	Agency	Section	Comment	Co-Lead Disposition	GLIFWC Response
GLIFWC 203	GLIFWC	5.2.7.2.5 Mercury Deposition Impact Analysis	The estimate of air emissions of mercury as a result of the project (4.6 lbs/yr) does not take into account emissions from electricity generation for the site or from the burning of fuel by mining vehicles or other equipment. This should be quantified and included in the analysis.	Mercury emissions were calculated for mining vehicles and included in the emission inventory. In addition, emissions from electric generation have been incorporated within the TMDL development, by reference. Thus, these emissions have been taken into account for MPCA's evaluation and determination that the Project mercury emissions will not impede the reduction goals.	There is not enough information for us to remove our comment. Please add a link to the mercury section in the appendix
GLIFWC 210	GLIFWC	5.2.7.2.5 Mercury Deposition Impact Analysis	According to the PSDEIS, "the MPCA has conducted a review of the NorthMet Project Proposed Action mercury emissions and has determined that it will not impede the reduction goals." The mercury TMDL for the St. Louis River has not yet been established due to insufficient understanding of mercury dynamics in the watershed. It is known that the statewide TMDL is insufficient for reducing mercury to acceptable levels in fish of the SLR. Since there is no SLR mercury TMDL available, the impact of the project's mercury emissions on reduction goals in the area cannot be adequately assessed.	It is agreed that there is no specific TMDL for the St. Louis River system, however, until a specific TMDL is developed for this body of water, the Statewide TMDL is the driving regulation for all other water bodies within the state, including the St. Louis River.	Comment stands.
5.2.8 Noise and Vibration					

Chapter 5.2

Comment_No.	Agency	Section	Comment	Co-Lead Disposition	GLIFWC Response
GLIFWC 214	GLIFWC	5.2.8 Noise And Vibration	There is no cumulative analysis for noise vibration and airblast in the PSDEIS. Activities at existing facilities (Mesabi Nugget, Northshore) should be looked at in conjunction with the proposed NorthMet project. See GLIFWC noise and vibration attachment for more information.	In the absence of measured ambient sound data for receptors in the immediate vicinity of the Mine Site and Plant Site (except BWCAW), literature values from the USEPA Levels guideline document (USEPA 1974) were used to represent baseline levels in the areas (measured data have been provided for the BWCAW). Since the Northshore Mine is an existing facility, the ambient Leq assumed for receptors outside the Mine Site area (Figure 4.2.8-1 and Table 4.2.8-3) account for existing noise from the Northshore Mine located approximately 2 miles north of the Mine Site (see Section 4.2.8-2). The vibration associated with blasting at the Northshore mine is also already accounted for under baseline conditions. Similarly, the baseline noise and vibration conditions of all identified receptors near the Plant Site already capture or account for noise and vibration from the Mesabi Phase I Plant, which is an existing facility. Noise and vibration diminish with distance i.e., the impacts are reduced as the receptor distance to the source increase. The Mesabi Nugget Plant is approximately 1 mile and 8 miles away from the Plant Site and Mine Site respectively. Similarly, the Northshore Mine is approximately 2 miles and 11 miles away from the Mine Site and Plant Site, respectively. Project related noise plus baseline levels (which accounts for noise from other nearby existing sources/facilities) are provided in Table 5.2.8-7.	GLIFWC does not agree with the co-lead disposition. Lack of site specific data has not stopped the lead agencies from developing and using analog information for other resource areas (e.g. wetlands) While the appropriateness of analog data can be debated, the excuse of doing nothing because of a lack of data is not credible. Provide a link to the cumulative impact section in the appendix.
GLIFWC 212	GLIFWC	5.2.8.1.1 Noise	The methods used in the PSDEIS limit the analysis to selected locations defined as sensitive to noise. While these locations may in fact be sensitive, concentrating on those few places for the analysis inappropriately eliminates an impact assessment of other areas. See GLIFWC noise attachment for more information.	A discussion of noise impacts to all publicly accessible areas in the Superior National Forest has been included. The USFS has provided shapefiles for all recreational sites within the project vicinity (family camp grounds, camp sites, boating, fishing, swimming, and family picnic areas). In addition to the residential areas, BWCAW, and wildlife corridors already discussed in the SDEIS, we have also included recreational sites, trails, and closest State wildlife waters (used by tribal members for harvesting purposes) in all the noise and vibration contour maps. A discussion of noise impacts to all publicly accessible areas in the SNF (i.e., recreational sites) has been included in the text in Section 4.2.8.2. Though not depicted on the noise and vibration figures due to sensitivity regarding cultural resources and locations, a discussion of the nearest archaeological sites (e.g., Spring Lake Sugarbush and Mesabe Widju (Laurentian Divide)) within the Project vicinity has been included in the text.	ok

Chapter 5.2

Comment_No.	Agency	Section	Comment	Co-Lead Disposition	GLIFWC Response
GLIFWC 213	GLIFWC	5.2.8.2 Northmet Project Proposed Action	A discussion of applicable standards is appropriate. However, significant impacts from a project can occur without violating standards if the change from baseline condition is large enough. A discussion of this type of impact is needed.	A discussion of impacts based on change from baseline condition is discussed in Section 5.2.8.2.3, Total Noise Effects from NorthMet Project Proposed Action Operations. See sub sections titled "Daytime Operations (7 p.m. to 10 p.m.)" and "Nighttime Operations (10 p.m. to 7 a.m.). Text regarding noise change from baseline conditions in Section 5.2.8.2.3 have been revised to accommodate the new noise modeling results that accounts for reduced baseline noise levels at BWCAW and audibility limits for the BWCAW.	ok
5.2.9 Cultural Resources					
GLIFWC 211	GLIFWC	5.2.9 Cultural Resources - Throughout the section	Increased mercury, especially in fish, could negatively impact cultural resources, especially for local Native American tribes who rely on fish as a major source of subsistence food and who view fishing and fish consumption as vitally important cultural and spiritual activities. This is not acknowledge in the PSDEIS. Further, fish harvest is a treaty reserved right of these tribes. The presence of mercury in fish at levels that restrict consumption threaten the ability of the tribes to exercise this treaty right.	The Co-lead Agencies recognize that mercury accumulation in fish is an important issue to the Bands. The effects of mercury in fish are acknowledged in the SDEIS; please refer to the discussions in Sections 4.2.6, 4.2.10, 5.2.6, and 5.2.10. Additional text has been added to section 5.2.9.	There is not enough information available to remove the comment.
GLIFWC 220	GLIFWC	5.2.9.2.2 Treaty Resources - "There is little specific information concerning the use of natural resources by the Bands in the NorthMet Project area. This likely reflects limited subsistence gathering in the NorthMet Project area due to general inaccessibility. T"his lack of data also...	The authors make assumptions that because there is no written record of tribal use that no use takes place. To access potential socioeconomic impacts, all treaty resources [i.e. animals, fish and plants identified in LAC COURTE OREILLES CHIPPEWA IND. v. STATE OF WIS. NO. 74-C-313. 653 F.Supp. 1420 (1987)] need to be assessed on lands being transferred to the Forest Service and Forest Service lands being sold including: 1) presence and absence, 2) distribution, and 3) population density. See GLIFWC socioeconomics attachment for additional information.	The Co-lead Agencies disagree with the assertion that there was a focus only on the written record. Oral interviews, field surveys, consultation, and other sources were used when determining contemporary tribal use of the proposed NorthMet Project area.	Comment stands.
5.2.10 Socioeconomics					

Chapter 5.2

Comment_No.	Agency	Section	Comment	Co-Lead Disposition	GLIFWC Response
GLIFWC 215	GLIFWC	5.2 - Entire section	**It is essential that throughout the SDEIS authors need to repeatedly state that Indirect and Induced Effect employment numbers are calculated by IMPLAN and may be temporary, part-time, full-time, long-term or short term jobs. It is also critical to acknowledge estimates for full-time employment were provided by NorthMet. See GLIFWC socioeconomics attachment for additional information.	Section 5.2.10.1.3 contains this statement about type of jobs. Added a statement regarding the source of direct employment.	ok
GLIFWC 217	GLIFWC	5.2 Northmet Project Proposed Action	The Draft Environmental Impact Statement (DEIS) prepared in 2009 stated, "Due to the estimated 20-year operating life of the facility, it is estimated that approximately 55% of labor for the operations would be non-local and would be relocated to the east range; 20% would commute daily or weekly from centers such as Duluth; and the remaining labor would be local" DEIS (page 4.10-15). These two statements related to the same project give readers entirely different perspectives on this project. This confusion is caused by including 3 counties in the "study area". Since the most recent IMPLAN modeling done in April 2012 was restricted to a single county (Lake), this section should be re-written to reflect the estimated labor that would be relocated to the east range and the estimated labor that would commute from Duluth as done in the earlier DEIS for the estimated 360 direct operations-phase positions. Again authors need to state that Indirect and Induced Effect employment numbers are calculated by IMPLAN may be temporary, part-time, full-time, long-term or short term jobs. See GLIFWC socioeconomics attachment for additional information.	The DEIS definition of "local" appears to be limited to the East Range, essentially the nearby towns and cities in St. Louis County alone. By comparison, the PSDEIS clearly states that "local" workers--those who would commute daily or weekly--would come from a very wide commute shed, given the willingness of workers in this region to commute relatively long distances. The definitions of "local" are very different; therefore, no change is needed.	ok

Chapter 5.2

Comment_No.	Agency	Section	Comment	Co-Lead Disposition	GLIFWC Response
GLIFWC 218	GLIFWC	5.2.10.2.1 Population And Population Trends - "For purposes of this analysis, the SDEIS assumes that approximately 75 percent of direct and indirect operations phase employees would be local residents who would not need to relocate as a result of employment."	IMPLAN Modeling estimated that 112 of the 330 indirect jobs (i.e. temporary, part-time, full-time, long-term or short-term) would be in custom computer programming services (i.e. page 13, April 2012 IMPLAN report). Is it realistic to project 75 percent of the direct and indirect operations phase employees would be local residents given 33.9% of indirect jobs are in custom computer programming services? The basis for these estimates need to be explained and references used to base these estimates cited. See GLIFWC socioeconomic attachment for additional information.	Recall that "local" in this case is the commute-shed for the Project, which covers a wide area and several cities (Duluth, Hibbing, Virginia, etc.). As a high-level estimate, this is not unreasonable. No text edit.	ok
GLIFWC 219	GLIFWC	5.2.10.2.1 Population And Population Trends - Operations	The PSDEIS fails to provide a table entitled Anticipated Steady State Operation Employment Levels as provided in the 2009 Draft Environmental Impact Statement (DEIS) - see pages 4.10-17 and 4.10-18 Table 4.10-13. This table was provided for the 448 direct jobs originally projected and categorized employment by: 1) Management, 2) Mine Operations - Contract supervision, operators, maintenance, 3) Mine Technical - Geology, grade control, planning, 4) Railroad Operations, 5) Plant Operations, 6) Sample Preparation and analytical laboratory, and 7) Finance, purchasing, marketing, environmental, HR. A similar table is needed that would detail PolyMet's projected 360 full time direct jobs in the categories above. Without this data, it is impossible to evaluate the accuracy of the PSDEIS projections on employment and local hiring. See GLIFWC socioeconomic attachment for additional information.	The referenced table was produced by BBER as part of the IMPLAN model exercise. While useful to help explain the assumptions of the IMPLAN model, the table detailing the distribution of jobs by type is not a key finding of the SDEIS itself. Indeed, inclusion of the referenced table in the body of the SDEIS is not appropriate because it would distract the reader from the document's key findings about overall employment and other socioeconomic impacts of the NorthMet Proposed Project. This information is included in the IMPLAN report. Reference to IMPLAN report included.	ok

Chapter 6

Comment_No.	Agency	Section	Comment	Co-Lead Disposition	GLIFWC Response
GLIFWC 224	GLIFWC	6.2.1 Cumulative Effects Analysis Approach	The post-closure period is not correctly described. Closure in other sections of the document occurs from year 20 to year 40. Post closure is an open ended period after year 40. Because water treatment and facility maintenance needs at this project are perpetual, post-closure should be clearly defined here as year 40 to perpetuity.	For all resources, future temporal boundaries are the expected service life of the mining activities, including closure (years 20 to 40) and post-closure restoration (year 40 and beyond.)	ok
GLIFWC 225	GLIFWC	6.2.2.1.18 United Taconite	United Taconite facility is undergoing additional permit review due to their plans to fill over 1000 acres of wetland to expand the tailings basin. This would also contribute high sulfate water to the St. Louis river. The Corps and MPCA are currently involved in this work. Therefore, all appropriate information on this facility should be included in the cumulative effect analysis.	The Co-lead agencies believe that the cumulative wetland impact assessment area as defined in the wetlands work plan is sufficient to meet the requirements of NEPA and is appropriate for the NorthMet project EIS because it includes the watersheds in which the proposed direct and indirect wetland impacts would occur. For the NorthMet project, that would be the Embarrass River watershed and the Partridge River watershed. In addition, the Co-lead agencies included direction in the Final Wetland Resources IAP Summary Memo on how to identify the amount of wetland acreage below the OHWM within this part of the St. Louis River and to evaluate the potential for cumulative indirect wetland impacts in those wetlands from changes in flow in the St. Louis River based on the qualitative water flow evaluation to be conducted. No other direct or indirect NorthMet project impacts would occur in the St. Louis River watershed, and the Co-Lead Agencies do not believe that a cumulative wetland impact assessment needs to be conducted for the entire St. Louis River watershed for the environmental review of the Proposed PolyMet NorthMet project. The Co-lead agencies believe that a qualitative evaluation of cumulative wetland impacts on water quality in the Partridge River watershed and the Embarrass River watershed, including impaired waterbodies, should be included in the cumulative water quality impacts section of the SDEIS.	GLIFWC disagrees with the co-lead disposition. Provide a link to the cumulative impact section of the appendix.
GLIFWC 226	GLIFWC	6.2.2.1.21 Speculative Actions	Provide a map of the speculative projects and indicate in the text the potentially affected watershed for each project.	The speculative projects are provided for disclosure purposes only, and the locations of several of these projects are not known. No text edit.	GLIFWC disagrees with the co-lead disposition. Provide a link to the cumulative impact section of the appendix.
GLIFWC 227	GLIFWC	6.2.3.3 Water Resources	Impacts to dewatered wetlands should be mentioned in this section.	Section 6.2.3.3.3 discusses cumulative effects on hydrology. Section 6.2.3.4 discussed cumulative effects on wetlands.	GLIFWC disagrees with the co-lead disposition. Provide a link to the cumulative impact section of the appendix.

Chapter 6

Comment_No.	Agency	Section	Comment	Co-Lead Disposition	GLIFWC Response
GLIFWC 228	GLIFWC	6.2.3.3.1 Cumulative Effects Assessment Areas	The section should state that water quality standards are met only with perpetual water treatment and maintenance.	The following paragraph has been added to Section 5.2.2 - Summary: The Closure objective is to provide mechanical and non-mechanical treatment for as long as necessary to meet regulatory standards at evaluation locations in groundwater and surface water. Both mechanical and non-mechanical treatment will require periodic maintenance and monitoring activities. Modeling predicts that treatment activities will be a minimum 200 years at the Mine Site and a minimum of 500 years at the Plant Site. While long-term, these time frames for water treatment are not necessarily perpetual.	GLIFWC disagrees with the co-lead disposition. Provide a link to the perpetual maintenance section of the appendix.
GLIFWC 229	GLIFWC	6.2.3.3.1 Cumulative Effects Assessment Areas	The limited water quantity and quality data has been an issue for 7 years since the beginning of the project. The lead agencies and the applicant have been resistant to fill these data gaps. See GLIFWC hydrology attachment for further detail.	The 20 year old flow data is acceptable as there haven't been any significant changes within the watershed. Additional water quality sampling has been conducted and the results included in this PSDEIS (Section 4.2.2). No text edit.	GLIFWC disagrees with the co-lead disposition. Provide a link to the hydrology section of the appendix.
GLIFWC 230	GLIFWC	6.2.3.3.2 Cumulative Actions	Add United Taconite to the list.	Disagree. The analysis in Section 6.2.3.3 includes existing and potential future actions that have the potential, in combination with the NorthMet Project Proposed Action, to cumulatively affect surface water hydrology and quality within the Partridge River and Embarrass River watersheds. The United Taconite mine is outside the analysis area as the six permitted mine pit dewatering discharges all discharge to the St. Louis River Basin. No text edit.	GLIFWC disagrees with the co-lead disposition. Provide a link to the cumulative impact section of the appendix.
GLIFWC 231	GLIFWC	6.2.3.3.3 Cumulative Effects On Hydrology - Embarrass River	Should not assume that the passive treatment will prove effective. Change language to "...if passive treatment proves effective..."	No text change needed. The NorthMet Project Proposed Action would rely upon mechanical treatment to achieve water resource objectives as long as needed; however, the goal would be to transition to non-mechanical treatment to ensure attainment of water resources objectives, including compliance with applicable groundwater and surface water standards, during the closure phase.	GLIFWC disagrees with the co-lead disposition. Provide a link to the perpetual maintenance section of the appendix.
GLIFWC 232	GLIFWC	6.2.3.3.4 Cumulative Effects On Surface Water Quality - Partridge River Section	The section states that all water quality evaluation criteria would be met. The section should clearly state that that assumption is based on the successful operation of water capture and water treatment systems in perpetuity. In addition, evaluation criteria are not the same as water quality standards. Water quality standards would be exceeded for several constituents. The same comment applies to the assumptions in the sulfate and mercury sections.	The SDEIS is comparing water quality predictions against water quality evaluation criteria. We acknowledge that the evaluation criteria could differ from water quality standards.	ok
GLIFWC 233	GLIFWC	6.2.3.3.4 Cumulative Effects On Surface Water Quality - Embarrass River	The river is on the draft 2012 303d list for sulfate. Correct the text.	Text revised to clarify the current status of 303(d) listings.	ok

Chapter 6

Comment_No.	Agency	Section	Comment	Co-Lead Disposition	GLIFWC Response
GLIFWC 234	GLIFWC	6.2.3.3.4 Cumulative Effects On Surface Water Quality	Reduction in sulfate loads depend on perpetual capture and treatment of water. Include this caveat.	The following paragraph has been added to Section 5.2.2 - Summary: The Closure objective is to provide mechanical and non-mechanical treatment for as long as necessary to meet regulatory standards at evaluation locations in groundwater and surface water. Both mechanical and non-mechanical treatment will require periodic maintenance and monitoring activities. Modeling predicts that treatment activities will be a minimum 200 years at the Mine Site and a minimum of 500 years at the Plant Site. While long-term, these time frames for water treatment are not necessarily perpetual.	GLIFWC disagrees with the co-lead disposition. Provide a link to the perpetual maintenance section of the appendix.
GLIFWC 235	GLIFWC	6.2.3.4.4 Cumulative Effects Assessment - Partridge River watershed section	The section states that lake acreage has increased by 19% compared to pre settlement times. Are these lakes natural, impoundments/flowages, or flooded mine pits? Should specify in the text. If these new waters are mine pits, we disagree with their characterization as "resources" because of their contaminated nature. In addition, many of the impacted wetlands are part of the 100 mile swamp system A detailed discussion of the ecological significance of this wetland complex is needed as well as the overall effect of fragmenting the complex.	Pre-settlement conditions were identified using NWI and GLO survey maps, while existing conditions were determined using delineations, NWI maps, NHD shapefiles, and MDNR Mining features (2009 shapefile). The 19% increase in lakes between pre-settlement and existing conditions stems from the increase in size of White Water Reservoir (increase of 314 acres) and areas classified as lake in the NHD shapefile. When calculating pre-settlement, existing, and future lakes, no deepwater habitats/mine pits were included; these would fall under the deepwater category. The potential effects to the wetlands within the 100 mile swamp are discussed in Chapter 5.	ok
GLIFWC 236	GLIFWC	6.2.3.3.4 Cumulative Effects On Surface Water Quality - Embarrass river watershed section	Same comments an above for the Partridge River section. In addition, this section should provide a description of the wetlands impacted by seepage from the LTV tailings basin.	Section 6.2.3.3.3 discusses cumulative effects on hydrology. Section 6.2.3.4 discussed cumulative effects on wetlands.	The co-lead disposition does not answer the comment.
GLIFWC 237	GLIFWC	6.2.3.4.3 Cumulative Actions	The XP-SWMM model uses antiquated data collected from far downstream of the site. The model is fatally flawed and yields unreliable results. The conclusion that no effects would occur on riparian wetlands is not supportable. See GLIFWC hydrology attachment for more detail.	We believe the XP-SWMM modeling is acceptable for use in the SDEIS. The 20 year old data is acceptable as there haven't been any significant changes within the watershed. We believe the assumptions used were reasonably conservative. Additional detail is provided in the water sections of the SDEIS, and further rationale is provided in the Water Data Packages.	GLIFWC disagrees with the co-lead disposition. Provide a link to the hydrology section of the appendix.

Chapter 6

Comment_No.	Agency	Section	Comment	Co-Lead Disposition	GLIFWC Response
GLIFWC 238	GLIFWC	6.2.3.6.4 Cumulative Effects Assessment - Wildlife travel corridors	The corridor southeast of the plant site is characterized as poor. Therefore the discussion in the section is misleading because this is not in fact a viable wildlife corridor. It should then be removed from the corridor list and removed from the map. In addition, cumulative effects from noise and vibration are not analyzed and would have a significant impact on wildlife corridors (See GLIFWC noise attachment for more detail) Finally, the conclusions should be revisited in light of fewer corridors along the range than originally identified.	The Emmons and Oliver report characterizes this corridor as small but important. The Barr Report on wildlife corridors states that the current LTVSMC Tailings Basin is located within the moderate quality habitat corridor. Neither of these studies classifies the corridor as poor quality, though Section 6.2.3.6.4 describes the Tailings Basin, which is within (but not occupying the entire width of) the corridor, as being of poor quality for wildlife travel. The text will be edited for additional clarity.	ok
GLIFWC 239	GLIFWC	6.2.3.7.4 Cumulative Effects Assessment - Cumulative water quality effects	The conclusion of no cumulative effect depends on perpetual water capture and treatment as well as perpetual maintenance of the facilities that would remain after the end of mining. We believe that this is not a realistic assumption and that it short-circuits the evaluation of cumulative effects. In addition, evaluation criteria are not the same as water quality standards. Water quality standards would be exceeded for several constituents.	The Closure objective is to provide mechanical and non-mechanical treatment for as long as necessary to meet regulatory standards at evaluation locations in groundwater and surface water. Both mechanical and non-mechanical treatment will require periodic maintenance and monitoring activities. Modeling predicts that treatment activities will be a minimum 200 years at the Mine Site and a minimum of 500 years at the Plant Site. While long-term, these time frames for water treatment are not necessarily perpetual. Co-leads agree that evaluation criteria are not the same as water quality standards (for some constituents). The SDEIS is comparing water quality predictions against water quality evaluation criteria. We acknowledge that the evaluation criteria could differ from water quality standards.	GLIFWC disagrees with the co-lead disposition. Provide a link to the perpetual maintenance section of the appendix.
GLIFWC 240	GLIFWC	6.2.3.7.4 Cumulative Effects Assessment - Physical habitat effects	As previously stated, the conclusion of no changes to flows in the Partridge River is based on fatally flawed XP-SWMM modeling. This conclusion is not supported.	We believe the XP-SWMM modeling is acceptable for use in the SDEIS. The 20 year old data is acceptable as there haven't been any significant changes within the watershed. We believe the assumptions used were reasonably conservative. Additional detail is provided in the water sections of the SDEIS, and further rationale is provided in the Water Data Packages.	GLIFWC disagrees with the co-lead disposition. Provide a link to the hydrology section of the appendix.
GLIFWC 241	GLIFWC	6.2.3.8.10 Climate Change	A discussion of the effects of wetland destruction is needed in this section. The discussion should include the release of carbon to the atmosphere from wetland and peat excavation as well as the loss of carbon sequestration capacity of the existing high quality wetlands.	Agreed. The direct GHG estimated emissions will be revised in the text and in Table 6.2-20 as discussed in Comment # FDL 77.	ok

Chapter 6

Comment_No.	Agency	Section	Comment	Co-Lead Disposition	GLIFWC Response
GLIFWC 242	GLIFWC	6.2.3.8.11 Noise And Vibration	This section does not provide a cumulative assessment of noise impacts. For example the section should identify areas of national forest and forest service roads that would be subjected to noise plus airblast effects. Another example, what acreage of publicly accessible lands would be withing the noise and vibration / airblast zone. Reliance on an few receptors is not a proper way to conduct an analysis of noise impacts. See GLIFWC noise attachment for more detail.	The only reasonably foreseeable actions that could interact in such a way as to have a cumulative effect on the receptors identified in Sections 4.2.8 and 5.2.8 is the Mesabi Nugget Phase II Mine Project located approximately 2 miles west of the Plant Site and 10 miles west of the Mine Site. Other reasonable foreseeable projects in the region are 25 to 55 miles away from the NorthMet Project and as such, would have no cumulative effect on nearest receptors (see Figure 6.2.2-1 and Table 6.2-1). Noise from existing industries (logging, mining, etc.) have been accounted for in the baseline noise levels discussed in Section 4.2.8 and 5.2.8. Section 6.2.3.8.11 has been revised to assess the cumulative impact of the Mesabi Phase II Mine Project. The maximum impact area for noise (11,456 acres), ground vibration (11,469 acres), and airblast (11,334 acres) are discussed in Section 5.2.8.	GLIFWC disagrees with the co-lead disposition. Provide a link to the cumulative impact section of the appendix.
GLIFWC 243	GLIFWC	6.2.3.11.4 Cumulative Effects Assessment - Visual Resources	A calculation of the viewshed for the water vapor plumes and night visibility of tower lights should be developed and included. Are these features visible from public access points?	This comment belongs in Section 5.2.11, not here, since it is a primary impact of the operations themselves, and not cumulative with other resources. Please see response in Recreation/Visual spreadsheet. Response in this section to be developed based on language to be added to Section 5.2.11.	ok
GLIFWC 244	GLIFWC	6.2.3.3.4 Cumulative Effects On Surface Water Quality	There is a general lack of understanding of mercury dynamics in the St. Louis River Watershed. See the supplemental document "Great Lakes Indian Fish and Wildlife Commission (GLIFWC) Comments Related to Mercury" [Comment 1] for details.	The Co-leads agree that the mercury dynamics are complex; however, the analysis as presented indicated that there was minimal potential for a downstream increase in mercury loading	GLIFWC disagrees with the co-lead disposition. Provide a link to the mercury section of the appendix.

Chapter 7

Comment_No.	Agency	Section	Comment	Co-Lead Disposition	GLIFWC Response
GLIFWC 245	GLIFWC	7.2.4 Comparison Of Effects	As previously commented, the PSDEIS does not provide an adequate comparison of effects for water quality and water quantity. The assumption that the no action alternative is equivalent to a continuation of existing conditions leads to errors in water quality modeling. In addition, a lack of usable water quantity and flow data lead to conclusions that cannot be supported.	Refer to the water section and response to comments with respect to the suitability of the water quantity and flow data, and a discussion on the purpose and intent of the water modeling scenarios. Further clarity on these modeling scenarios is provided in Chapter 5.2.2	GLIFWC disagrees with the co-lead disposition. Provide a link to the hydrology section of the appendix.
GLIFWC 246	GLIFWC	7.2.4 Comparison Of Effects - water resources section	99.9% capture is not realistic and is not supported by text in other sections of the SDEIS.	Greater than 90% of water would be captured and treated to meet effluent limits set to meet water quality standards	ok
GLIFWC 247	GLIFWC	7.2.4 Comparison Of Effects - water resources section	GLIFWC staff disagree with second and third bullets of combined proposed action. Standard is exceeded for sulfate and there is not enough information in the document to reach a conclusion on mercury.	The GoldSim results do not indicate an exceedance of the waters supporting the production of wild rice sulfate standard pursuant to the MPCA staff recommendation. Mercury is addressed in the air and water sections (Section 5.2.2 and 5.2.7) as well as in aquatic resources (5.2.6)	Data collected at SW005 indicates that the standard is exceeded for some measurements. GOLDSIM is not properly calibrated and therefore is not able to reproduce existing conditions. Provide a link to the hydrology section in the appendix.
GLIFWC 248	GLIFWC	7.2.4 Comparison Of Effects - aquatic species section	The claim of a decrease in mercury loading is not supportable. See GLIFWC mercury attachment	The aquatic species summary points in the SDEIS table have been revised and does no longer include the mercury loading conclusion commented on.	ok
GLIFWC 249	GLIFWC	7.2.4 Comparison Of Effects - air quality and climate change	Combined proposed action would create a pulse of carbon through the exposure of peat. There would also be a loss of carbon sequestration potential due to the destruction of wetlands.	Acknowledge partial loss of carbon sink and release of stored carbon from wetlands destruction. The text has been updated to address carbon release in the wetland summary section of the table	ok pending review of the new language.
GLIFWC 250	GLIFWC	7.2.4 Comparison Of Effects - noise	Use of receptors to limit analysis is not appropriate. In addition no cumulative assessment is available. See GLIFWC noise attachment for more information.	A discussion of noise impacts to all publicly accessible areas in the Superior National Forest has been included in the noise section of Chapter 5 (Section 5.2.8).	ok
GLIFWC 251	GLIFWC	7.2.4 Comparison Of Effects - socioeconomics	biased information. There is no discussion of expected adverse effects.	See discussion in Section 5.2.10.14.	Information presented in the Freudenberg paper should be described here. The comment stands.

Chapter 7

Comment_No.	Agency	Section	Comment	Co-Lead Disposition	GLIFWC Response
GLIFWC 252	GLIFWC	7.3.1 Irreversible Or Irretrievable Commitment Of Resources	GLIFWC disagrees with the statement indicating no exceedance of water quality standards. The document indicates that standards would be exceeded.	As described in the SDEIS, the evaluation criteria do use the standards, but interpret the standards from a probabilistic perspective. The P90 approach for assessing compliance is a reasonable method for applying the results of probabilistic modeling to regulatory decision making. In this context, it is not appropriate to say that "a constituent will exceed a water quality standard". It is more accurate to say that "there is at least a 90 percent probability that a constituent will not exceed a standard (or up to a 10 percent probability that it will)". These quoted statements are very different.	GLIFWC disagrees with the co-lead disposition. Provide a link to the perpetual maintenance section of the appendix.
GLIFWC 253	GLIFWC	7.3.1 Irreversible Or Irretrievable Commitment Of Resources	Section should state that the NorthMet project would require maintenance and water treatment in perpetuity which constitutes and irreversible and irretrievable commitment of resources.	The Closure objective is to provide mechanical and non-mechanical treatment for as long as necessary to meet regulatory standards at evaluation locations in groundwater and surface water. Both mechanical and non-mechanical treatment will require periodic maintenance and monitoring activities. Modeling predicts that treatment activities will be a minimum 200 years at the Mine Site and a minimum of 500 years at the Plant Site. While long-term, these time frames for water treatment are not necessarily perpetual.	GLIFWC disagrees with the co-lead disposition. Provide a link to the perpetual maintenance section of the appendix.
GLIFWC 254	GLIFWC	7.3.2 Short-term Uses Versus Long-term Productivity Of The Environment	section does not appear to have been updated from information presented in the 2009 DEIS. It still talks about category 3 and 4 permanent stockpiles. Correct the text.	The section has been updated and does not talk about permanent category 3 and 4 stockpiles. Extra detail has been added to the section to help make it clear that the Category 2/3 and 4 Stockpiles will be removed and backfilled into the East Pit/	ok
GLIFWC 255	GLIFWC	7.3.2 Short-term Uses Versus Long-term Productivity Of The Environment	wetland impacts would not be short term. Restoration of wetlands is not likely to replace the high quality wetlands found at the site. In addition water quality impacts are long term because treatment would be needed in perpetuity.	The sentence commented on has been clarified. The Co-leads consider that the potential wetland impacts as described in the section would be short-term because impacts would be mitigated and monitored. Additional information on impacts, mitigation and monitoring of wetlands is provided in chapter 5.2.3.	GLIFWC disagrees with the disposition of the comment. It is not likely that mitigation will be able to replace the functions of the high quality wetlands that would be destroyed at the mine site.
GLIFWC 256	GLIFWC	7.3.3 Unavoidable Adverse Effects	GLIFWC staff disagree with the claim that new exceedances of relevant standards would not occur. Water quality standards will be exceeded. Perpetual water treatment and perpetual maintenance needs are residual practical effects of the proposed project.	As described in the SDEIS, the evaluation criteria do use the standards, but interpret the standards from a probabilistic perspective. The P90 approach for assessing compliance is a reasonable method for applying the results of probabilistic modeling to regulatory decision making. In this context, it is not appropriate to say that "a constituent will exceed a water quality standard". It is more accurate to say that "there is at least a 90 percent probability that a constituent will not exceed a standard (or up to a 10 percent probability that it will)". These quoted statements are very different.	The response does not address the fact that if standards are met, it will require perpetual treatment. Provide a link to the perpetual maintenance section in the appendix.

Executive Summary

Poly Met Mining Inc. (PolyMet) proposes to construct an open pit mine in northern Minnesota to extract low- to medium-quality copper-nickel-PGE minerals with low sulfide content. . This project, called the NorthMet Project (Project), is located in St. Louis County on the eastern end of the Mesabi Iron Range, about 60 miles north of the City of Duluth, and 6 miles south of the City of Babbitt, Minnesota. The Project areas include the Mine Site (3,015 acres), Plant Site (4,515 acres), and Transportation and Utility Corridors (120 acres) that connects the Mine Site to the Plant Site.¹

PolyMet plans to mine and process polymetallic ore from the northwestern portion of the Duluth Complex, a rock formation that forms much of the bedrock of northeastern Minnesota. The ore contains copper, nickel, gold, platinum, palladium, and cobalt. The Project would mine ore for approximately 20 years, using open pit mining methods similar to those currently in use at ferrous metallic mining operations on the Iron Range. The Plant Site was previously used as a taconite processing facility by the LTV Steel Mining Company (LTVSMC). PolyMet would upgrade existing facilities and construct new facilities to produce copper concentrates, nickel concentrates, and base and precious metal precipitates for off-site shipment and treatment. Tailings from ore processing would be placed in a tailings basin built atop the existing LTVSMC taconite tailings basin.

The Mine Site is used by wildlife, including Canada lynx (lynx), gray wolf (wolf), northern long-eared bat, and other species of concern to federal and state agencies. A 2014 Forest Service study also confirmed that northern long-eared bats utilize the Plant Site and Utility Corridor (USDA Forest Service 2014a). About 1,719 acres of the Mine Site would be directly disturbed by mining activities. Of these, 1,667 acres are administered by the Forest Service and 52 acres are privately owned. Habitats that would potentially be affected by the Project include coniferous forest (comprised primarily of black spruce², jack pine, tamarack, and balsam fir), deciduous forest (comprised primarily of trembling aspen and paper birch), mixed coniferous/deciduous forest, riparian (dominated by speckled alder, red-osier dogwood, and willow), and wetland (dominated by sedges, cattail, bog Labrador-tea, leatherleaf, and sphagnum moss).

Of the approximately 3,015 acres on the Mine Site, approximately 2,719 acres are owned by the United States (U.S.) Government (Government) and administered by the U.S. Department of Agriculture (USDA) Forest Service (Forest Service). In addition, about 3,776 acres adjacent to the Mine Site are owned by the Government and administered by the Forest Service.

The Forest Service is considering transferring approximately 6,495 acres (federal lands) to PolyMet in exchange for lands (non-federal lands) of similar value that have been offered for consideration by PolyMet. All lands potentially involved in the land exchange would be independently appraised according to the Uniform Appraisal Standards for Federal Land Acquisitions. The appraisals would determine the market value of the properties.

¹ Acreages given in this report are based on Geographic Information System (GIS) analysis. Acreages associated with the legal descriptions of the lands are based on original surveys performed by the Bureau of Land Management, Government Land Office (GLO) surveyors between 1858 and 1907. As such, GLO acreages are used as part of the project description for the Final Environmental Impact Statement (FEIS being prepared for the Project and would also be used to define the real estate transaction if the Land Exchange Proposed Action was approved. The analysis of effects presented in this Biological Assessment (BA) is based upon GIS data. GIS values indicate the actual size of the lands discussed in this BA, which may be different than the GLO legal acreage.

² Common and scientific names of plants and animals given in this report are provided in **Appendix A**.

EXECUTIVE SUMMARY

Information collected during wildlife and wetland functions and values studies would be used by the Forest Service in the land exchange appraisal, and would be used to evaluate impacts to wetlands, and wildlife and their habitats, for a Final Environmental Impact Statement (FEIS) for the Project and land exchange.

Assuming a land exchange occurs, the portions of the Mine Site, Dunka Road and Utility Corridor, and lands adjacent to the Mine Site that are administered by the Forest Service would no longer be part of the National Forest and therefore would not be subject to Forest Service management plans and policies. A land exchange for land adjustment is consistent with the 2004 *Land and Resource Management Plan for the Superior National Forest*.

To fulfill land exchange requirements, PolyMet is proposing to purchase and transfer all or a portion of 7,075 acres of non-federal lands to the Forest Service. The non-federal lands consist of Hay Lake Lands (4,926 acres), Hunting Club Lands (160 acres), Lake County Lands (382 acres), McFarland Lake Lands (31 acres), and Wolf Lands (1,576 acres). All lands are dominated by second-growth deciduous and coniferous forest habitats and a variety of wildlife, including lynx, wolf, and other species of concern, have been observed on or near the non-federal lands.

Assuming a land exchange occurs, the non-federal lands would be administered by the Forest Service. The non-federal lands are associated with four Forest Plan Management Areas, as designated by the Forest Service, which include General Forest, General Forest – Longer Rotation, Riparian Emphasis Area, and Candidate Research Natural Areas. If all or portions of the non-federal lands are acquired by the Forest Service, they would be administered by the Forest Service to meet the goals of these management areas.

The Project would directly impact an estimated 913 acres of wetlands, including about 758 acres at the Mine Site, 147 acres at the Plant Site, and 7.5 acres within the transportation corridors. PolyMet is proposing to purchase 2,169 acres (Wetland Mitigation Sites) as mitigation for wetland impacts from the Project. On the Wetland Mitigation Sites, 1,603 acres would be restored or converted to wetlands and 197 acres would be used as upland buffer.

Section 7 of the federal Endangered Species Act (ESA) requires that federal agencies “insure that any action authorized, funded, or carried out by such agency is not likely to jeopardize the continued existence of any listed species or result in the destruction or adverse modification of critical habitat of such species.” The U.S. Army Corps of Engineers (USACE), Minnesota Department of Natural Resources (MDNR) and Forest Service are co-lead agencies for an FEIS that is evaluating the impacts of the Project on federally listed species and other natural, cultural, and social resources. This Biological Assessment (BA) is prepared in accordance with the ESA and analyzes potential effects to federally listed threatened and endangered species, and species proposed for listing, and their designated critical habitats, as a result of the Project.

The lynx is a federally listed threatened species that has been sighted on and near the Project area. In the Great Lakes region, the lynx is found primarily in mixed forest habitats where snowshoe hare are common. On March 24, 2000, the lynx was federally listed as a threatened species in several states in the Northeast, Great Lakes Region (including Minnesota), and Southern Rockies. On November 9, 2006, the U.S. Department of the Interior (USDOI), U.S. Fish and Wildlife Service (USFWS), designated 319 square miles (mi²) as critical habitat in Voyageurs National Park. On February 25, 2009, the USFWS re-designated lynx critical habitat to include portions of Cook, Koochiching, Lake, and St. Louis Counties, including most of the federal lands and all of the non-federal lands. A total of 8,065 mi² were designated as critical habitat in Minnesota in 2009. The Wetland

Mitigation Sites are not included within designated critical habitat. The federal and non-federal lands and Wetland Mitigation Sites are located near the western edge of the lynx's range in the Great Lakes region. Lynx and/or their sign have been observed on or near the federal and non-federal lands.

The northern long-eared bat is a federally listed threatened species. The listing of the northern long-eared bat as a threatened species was determined by the USFWS on April 2, 2015 (USFWS 2015). The USFWS also announced interim 4(d) rules concurrent with the listing determination. However, the USFWS has deferred designation of critical habitat for northern long-eared bat to a later date.

The wolf was federally listed as an endangered species under the ESA in 1974, and was reclassified as threatened in 1977. On December 28, 2011, the wolf was delisted by the USFWS. However, on December 19, 2014, a federal court reversed the USFWS decision to delist the gray wolf, restoring federal threatened status and critical habitat designation in Minnesota. Approximately 9,800 mi² were identified as critical habitat for wolves in Minnesota. The federal and non-federal lands are within, but the Wetland Mitigation Sites are outside, the designated critical habitat zone.

The USACE and Forest Service have initiated consultation with the USFWS seeking concurrence with the determination of effects in this BA. Based on the analysis in this BA, the Project would affect lynx, and those effects would not be insignificant or discountable. Thus, the Project **is likely to adversely affect** Canada lynx. The Project would also directly affect about 1,719 acres of lynx critical habitat within the Mine Site. While project lands are rarely used by lynx, the Project would affect only about 0.03% of lynx designated critical habitat in Minnesota, including Primary Constituent Elements (PCEs) of lynx critical habitat. Suitable lynx habitat could be restored on about 397 acres that would be reclaimed after mining, but due to the time inherent in the successional process, it could be 10 or more years after mining before revegetation results in much suitable habitat for lynx. Thus, the Project **is likely to adversely affect** Canada lynx critical habitat.

Based on analysis in this BA, the Project **is likely to adversely affect the northern long-eared bat**. This is because of the potential loss of available summer roost habitat. There is no effect determination on northern long-eared bat critical habitat, because the USFWS has not designated critical habitat for the species.

Based on the analysis in this BA, the Project would affect gray wolves, and those effects would not be insignificant or discountable. Thus the Project **is likely to adversely affect gray wolves**. The Project would directly affect approximately 1,719 acres of gray wolf critical habitat. The 1,719 acres directly affected by the Project are about 0.03% of the over 6.3 million acres of wolf critical habitat in Minnesota, but include PCEs for wolf critical habitat. Approximately 397 acres of disturbed lands would be reclaimed after mining and could provide suitable gray wolf habitat 10 to 20 years after mining. Thus, the Project **is likely to adversely affect** gray wolf critical habitat.

1.0 Introduction

1.1 Overview

Poly Met Mining Inc. (PolyMet) proposes to construct an open pit mine in northern Minnesota to extract low-to medium-quality copper-nickel-PGE minerals with low sulfide content. . This project, called the NorthMet Project (Project), is located in St. Louis County on the eastern end of the Mesabi Iron Range, about 60 miles north of the City of Duluth, and 6 miles south of the City of Babbitt, Minnesota. The Project areas include the Mine Site (3,015 acres), Plant Site (4,515 acres), and Transportation and Utility Corridors (120 acres) that connect the Mine Site to the Plant Site³ (**Figure 1**).

PolyMet plans to mine and process polymetallic ore from the northwestern portion of the Duluth Complex. The Duluth Complex is an ore complex that forms much of the bedrock of northeastern Minnesota. The ore contains copper, nickel, gold, platinum, palladium, and cobalt. The Plant Site was previously used as a taconite processing facility by the LTV Steel Mining Company (LTVSMC). PolyMet would upgrade existing facilities and construct new facilities to produce copper concentrates, nickel concentrates, and base and precious metal precipitates for off-site shipment and treatment.

The Mine Site is used by wildlife, including Canada lynx (lynx), gray wolf (wolf), the northern long-eared bat, and other species of concern to federal and state agencies. About 1,719 acres of the Mine Site would be directly disturbed by mining activities. Of these, 1,667 acres are administered by the Forest Service and 52 acres are privately owned. Habitats that would potentially be affected by the Project include coniferous forest (comprised primarily of black spruce⁴, jack pine, tamarack, and balsam fir), deciduous forest (comprised primarily of trembling aspen and paper birch), mixed deciduous/coniferous forest, riparian (dominated by speckled alder, red-osier dogwood, and willow), and wetland (dominated by sedges, cattail, bog Labrador-tea, leatherleaf, and sphagnum moss). The Transportation and Utility Corridors are mostly disturbed lands and is little used by wildlife. The Plant Site has been operated as an industrial facility for decades, and also has little value to wildlife.

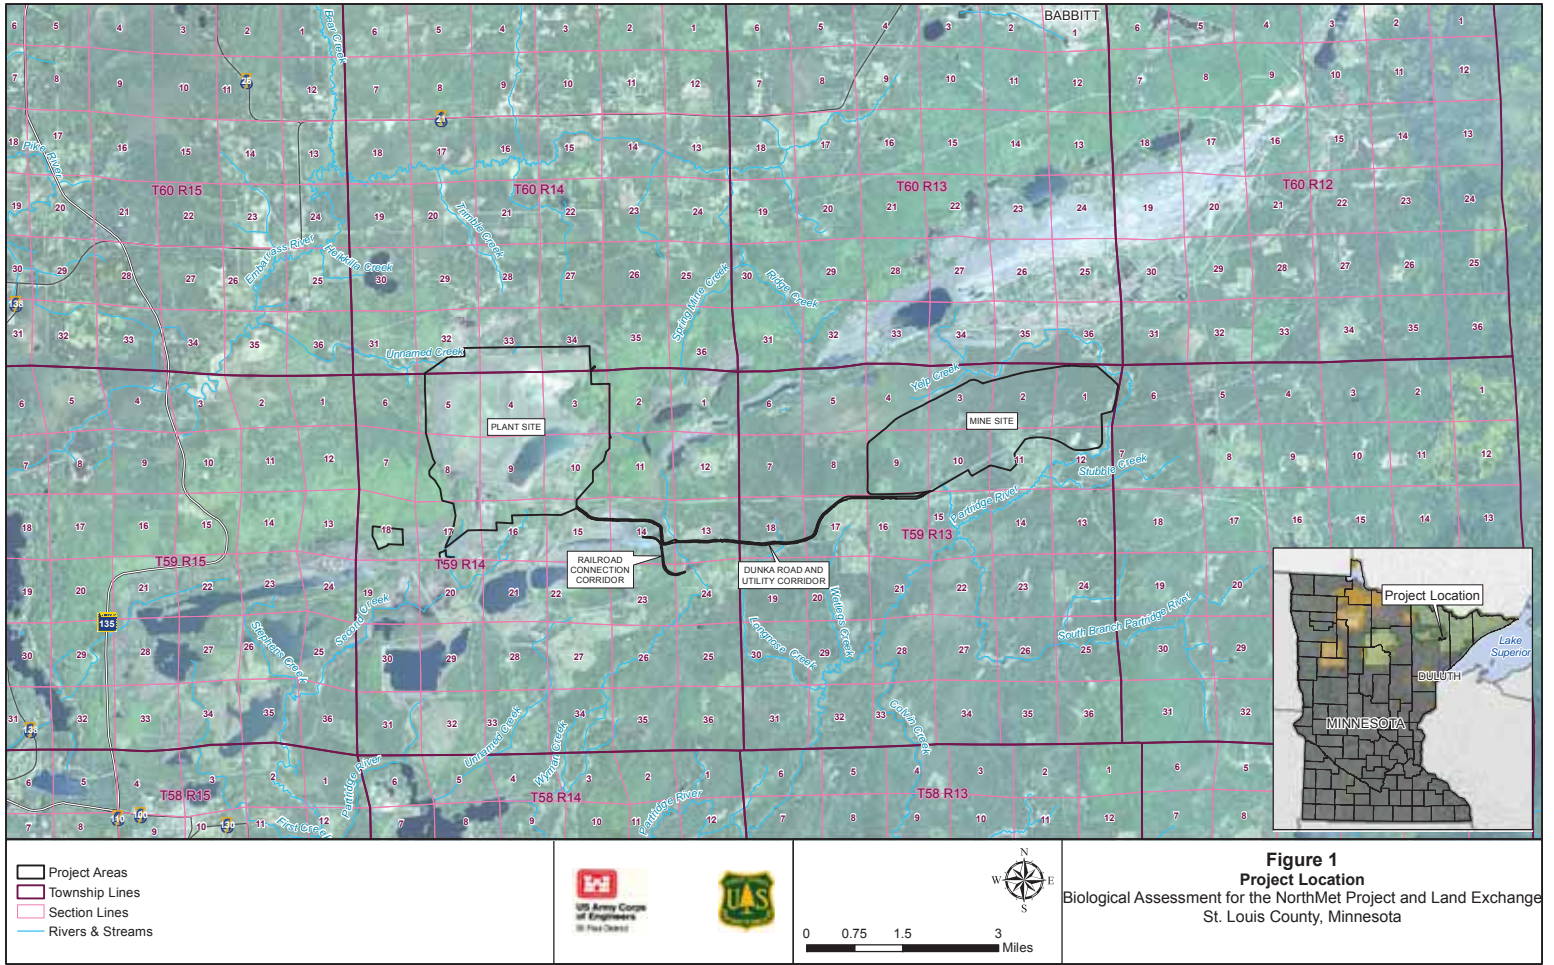

Of the approximately 3,015 acres on the Mine Site, approximately 2,719 acres are owned by the United States (U.S.) Government (Government) and administered by the U.S. Department of Agriculture (USDA) Forest Service (Forest Service). In addition, about 3,776 acres adjacent to the Mine Site are owned by the Government and administered by the Forest Service.

³ Acreages given in this report are based on Geographic Information System (GIS) analysis. Acreages associated with the legal descriptions of the lands are based on original surveys performed by the Bureau of Land Management, Government Land Office (GLO) surveyors between 1858 and 1907. As such, GLO acreages are used as part of the project description for the Final Environmental Impact Statement (FEIS) being prepared for the Project and would also be used to define the real estate transaction if the land exchange was approved. The analysis of effects presented in this Biological Assessment (BA) is based upon GIS data. The GIS values indicate the actual size of the lands discussed in this BA, which may be different than the GLO legal acreage.

⁴ Common and scientific names of plants and animals given in this report are provided in **Appendix A**.

INTRODUCTION

The Forest Service is considering transferring approximately 6,495 acres (federal lands) to PolyMet in exchange for lands (non-federal lands) of similar value that have been offered for consideration by PolyMet. Assuming a land exchange occurs, the portions of the Mine Site, Dunka Road and Utility Corridor, and

lands adjacent to the Mine Site that are administered by the Forest Service would no longer be part of the National Forest and therefore would not be subject to Forest Service management plans and policies. A land exchange for land adjustment is consistent with the 2004 *Land and Resource Management Plan for the Superior National Forest* (2004 Forest Plan; USDA Forest Service 2004a).

To fulfill exchange requirements, PolyMet is proposing to purchase and transfer 7,075 acres of non-federal lands to the Forest Service. The non-federal lands consist of Hay Lake Lands (4,926 acres), McFarland Lake Lands (31 acres), Lake County Lands (382 acres), Hunting Club Lands (160 acres), and Wolf Lands (1,576 acres; **Figure 2**). All non-federal lands are dominated by second-growth deciduous and coniferous forest habitats and a variety of wildlife, including lynx, wolf, and other species of concern, have been observed on or near the non-federal lands.

Assuming a land exchange occurs, the non-federal lands would be administered by the Forest Service. The non-federal lands are associated with four Forest Plan Management Areas, as designated by the Forest Service, which include General Forest, General Forest – Longer Rotation, Riparian Emphasis Area, and Candidate Research Natural Areas. If all or a portion of the non-federal lands are acquired by the Forest Service, they would be administered by the Forest Service to meet the goals of these management areas.

The Regional Forester or other authorized officer must decide if the proposed land exchange complies with the Forest Plan, is a fair value exchange, and is in the public interest. All lands potentially involved in the land exchange would be independently appraised according to the Uniform Appraisal Standards for Federal Land Acquisitions. The appraisals would determine the market value of the properties. Information collected during wildlife and wetland functions and values studies would be used by the Forest Service in the land exchange appraisal, and would be used to evaluate impacts to wetlands, and wildlife and their habitats for a *NorthMet Mining Project and Land Exchange Supplemental Environmental Impact Statement* (SEIS) for the Project and land exchange (Minnesota Department of Natural Resources [MDNR] et al. 2015).

The Project would directly impact an estimated 914 acres of wetlands, mostly within the Mine Site. A U.S. Army Corps of Engineers (USACE) permit would be required under Section 404 of the Clean Water Act for impacts to wetlands and other waters of the U.S., PolyMet is proposing to purchase 2,169 acres (Wetland Mitigation Sites) as mitigation for wetland impacts from the Project. On the Wetland Mitigation Sites, 1,620 acres would be restored or converted to wetlands and 197 acres would be used for upland buffer.

The Project and land exchange constitute the proposed actions of the two federal agencies, USFS and USACE. For convenience in this BA, the Project is referenced as the proposed action. The proposed action is further defined in Section 3.0.

1.2 Purpose for the Biological Assessment

In accordance with Section 7 of the federal Endangered Species Act (ESA) of 1973, as amended (19 United States Code [U.S.C.] §1536 [c], 50 Code of Federal Regulations (C.F.R.) § 402.14[c]), federal agencies must “insure that any action authorized, funded, or carried out by such agency is not likely to jeopardize the continued existence of any listed species or result in the destruction or adverse modification of critical habitat of such species.” The purpose of the ESA is to provide a means for conserving the ecosystems upon which endangered species and threatened species depend, and to provide a program for protecting these species.

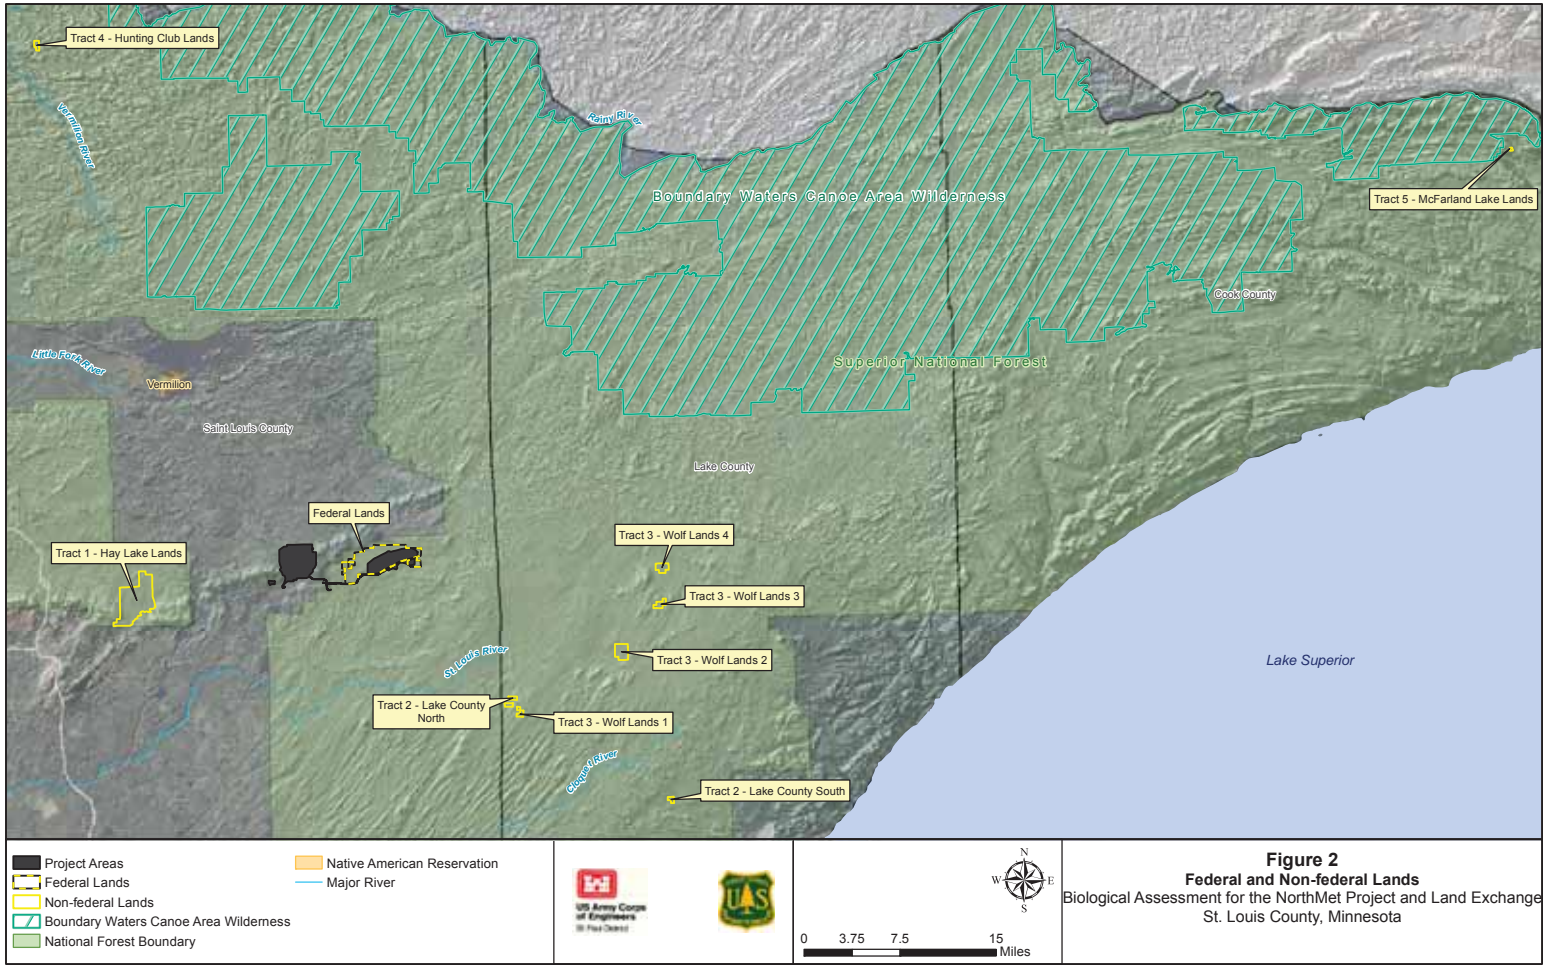

Figure 2
Federal and Non-federal Lands
 Biological Assessment for the NorthMet Project and Land Exchange
 St. Louis County, Minnesota

INTRODUCTION

Under Section 7 of the ESA, federal agencies are required to consult with the U.S. Department of the Interior (USDOI) U.S. Fish and Wildlife Service (USFWS), and/or National Oceanic and Atmospheric Administration National Marine Fisheries Service (NMFS; collectively the Services), to: 1) determine what species and critical habitats could be affected by the action; 2) determine what effect the action may have on these species or critical habitats; 3) explore ways to modify the action to reduce or remove adverse effects to the species or critical habitats; 4) determine the need to enter into formal consultation for listed species or designated critical habitats, or conference for species proposed for listing or proposed critical habitats; and 5) explore the design or modification of an action to benefit the species.

The USACE, MDNR, and Forest Service are co-lead agencies for the FEIS that is being prepared to evaluate the adverse and beneficial impacts from the Project, including the land exchange. As federal agencies that would authorize actions under the FEIS Record of Decision for the Project, the USACE and Forest Service must consult with the Services on their respective actions related to the Project and the land exchange.

The purpose of this Biological Assessment (BA) is to evaluate the effects of the Project and the land exchange on federally listed threatened and endangered species, species proposed for listing, and their critical habitats, as a result of the Project. The ESA defines an endangered species as a species that is in danger of extinction throughout all or a major portion of its range. A threatened species is defined as any species that is likely to become an endangered species within the foreseeable future throughout all or a major portion of its range. A species proposed for listing is a species for which the Services have sufficient information on its biological status and threats to propose it as endangered or threatened. Critical habitat is defined as “specific area within the geographical area occupied by the species...on which are found those physical and biological features (a) essential to the conservation of the species and (b) which may require special management considerations or protection” (USDOI USFWS and NMFS 1998).

The lynx is a federally listed threatened species that may use the Project area. The lynx is under the jurisdiction of the USFWS. In the Great Lakes region, the lynx is found primarily in mixed coniferous/deciduous forest habitat where snowshoe hare are common. The Project is located near the western edge of the lynx’s range in the region. Lynx have been sighted on and near the Project area. In addition, most of the federal and all of the non-federal lands are part of designated critical habitat for the lynx in Minnesota. The Wetland Mitigation Sites are not included within designated critical habitat.

Because the Project has the potential to modify the physical environment, this BA was prepared to analyze the potential effects of Project activities on the lynx and its designated critical habitat. This BA will be used by the USFWS to facilitate compliance with the requirements of Section 7(c) of the ESA. In addition, the BA will outline conservation measures to minimize or eliminate effects to lynx associated with the proposed action.

The northern long-eared bat is found across much of the eastern and north central United States and all Canadian provinces from the Atlantic coast west to the southern Northwest Territories and eastern British Columbia (USDOI USFWS 2013a). White-nose syndrome, a fungal disease known to affect bats, is currently the predominant threat to the northern long-eared bat, especially throughout the Northeast where the species has declined by up to 99% from pre-white-nose syndrome levels at many hibernation sites. White-nose syndrome has spread rapidly throughout the East and is currently spreading through the Midwest. Although the disease has not yet spread throughout the northern long-eared bat’s entire range (white-nose syndrome is currently found in at least 22 of 39 states where the northern long-eared bat occurs), it continues to spread. Other threats to the species include wind energy development, habitat destruction or disturbance (e.g.,

vandalism to hibernacula, roost tree removal), climate change, and contaminants. Although no significant population declines have been observed due to these threats, they may now be important factors affecting this bat's ability to persist while experiencing dramatic declines caused by white-nose syndrome.

The northern long-eared bat was listed as a federally threatened species on April 2, 2015. The listing determination included announcement of interim 4(d) rules, which will allow certain activities to be excepted from the ESA prohibition of take of northern long-eared bats, provided USFWS-proscribed conservation measures are followed. The April 2, 2015 listing decision deferred designation of critical habitat for northern long-eared bat to a later date.

The wolf is the largest wild member of the dog family (Canidae) and is common on and near the Project area. The wolf was determined to be endangered in 1967 under the Endangered Species Preservation Act of 1966, in response to their vastly declining numbers range-wide at that time. In 1974, the species was formally listed as endangered through the authority of the ESA, and the Minnesota population was reclassified to threatened in 1977. In April 2003, wolf populations in the United States were separated into three Distinct Population Segments (DPS) to more effectively manage the species. The Minnesota population was a designated portion of the Eastern DPS. In 1978, wolf critical habitat was designated for the Eastern DPS. That rule identified critical habitat in Isle Royale National Park, Michigan, and Minnesota wolf management zones 1, 2, and 3. In northeastern and northcentral Minnesota, wolf management zones 1, 2, and 3 comprised approximately 9,800 square miles (mi²) and included all of the Superior National Forest and portions of the Chippewa National Forest. Hunting Club and McFarland Lake lands were in Zone 1, while the federal lands and other non-federal lands were in Zone 2. The Wetland Mitigation Sites were outside the critical habitat zones.

On December 28, 2011, the USFWS revised the 1978 listing of the Minnesota population of wolf to conform to statutory and policy requirements. The USFWS renamed what was previously listed as the Minnesota population of gray wolf in the Eastern DPS as the Western Great Lakes DPS, and delineated the boundaries of the expanded Minnesota population segment to include all of Minnesota, Wisconsin, and Michigan and portions of the adjacent states. The USFWS December 2011 decision removed the Western Great Lakes DPS from the list of endangered and threatened wildlife. This final rule also removed the designated critical habitat for the gray wolf in Minnesota and Michigan and the special regulations under Section 4(d) of the ESA for wolves in Minnesota.

However, on December 19, 2014, a federal court reversed the USFWS decision to delist the gray wolf, restoring federal threatened status and critical habitat designation in Minnesota. Approximately 9,800 mi² were identified as critical habitat for wolves in Minnesota. The federal and non-federal lands are within, but the Wetland Mitigation Sites are outside, the formerly designated critical habitat zone.

2.0 Consultation

The consultation process is designed to assist federal agencies in complying with the ESA. The USACE, Forest Service, and USFWS initiated informal consultation on February 26, 2010, when the agencies met on the Project area to discuss the Project. The USACE met with the USFWS on May 3, 2011. The agencies held a conference call to discuss the project on September 1, 2011. The USACE also met with the USFWS on February 28, 2013. The USACE, USFWS, and Forest Service met in summer 2014 to identify tasks to be accomplished in the development of the BA.

Consultation can either be informal or formal, depending on the determination of effects in the BA. In making the determinations in this BA the following conclusions were considered, based on guidance in the *Endangered Species Consultation Handbook* (USDOJ USFWS and NMFS 1998).

No affect – the appropriate conclusion when the action agency determines its proposed action will not affect a listed species or its designated critical habitat.

May affect - the appropriate conclusion when a proposed action may pose any effects on listed species or designated critical habitat. When the Federal agency proposing the action determines that a “may affect” situation exists, then they must either initiate formal consultation or seek written concurrence from the USFWS that the action “is not likely to adversely affect” (see definition below) listed species.

Is not likely to adversely affect – the appropriate conclusion when effects on listed species, or their critical habitat, are expected to be discountable, insignificant, or completely beneficial. Beneficial effects are contemporaneous positive effects without any adverse effects to the species. Insignificant effects relate to the size of the impact and should never reach the scale where take occurs. Discountable effects are those extremely unlikely to occur. Based on best professional judgment, a person would not: 1) be able to meaningfully measure, detect, or evaluate insignificant effects; or 2) expect discountable effects to occur.

Is not likely to jeopardize proposed species – the appropriate conclusion when the action agency or the USFWS determines that the proposed action is not likely to jeopardize the proposed species or adversely modify the proposed critical habitat.

Is likely to adversely affect – the appropriate finding in a BA (or conclusion during informal consultation) if any adverse effect to listed species, or their critical habitat, may occur as a direct or indirect result of the proposed action or its interrelated or independent actions, and the effect is not discountable, insignificant, or interdependent actions, or beneficial. In the event the overall effect of the proposed action is beneficial to the listed species, but is also likely to cause some adverse effects, then the proposed action “is likely to adversely affect” the listed species. If incidental take is anticipated to occur as a result of the proposed action, then an “is likely to adversely affect” determination should be made.

Is likely to jeopardize proposed species – the appropriate conclusion when the action agency or the USFWS determines that the proposed action is likely to jeopardize the proposed species or adversely modify the proposed critical habitat.

If the BA concludes that the project “is not likely to adversely affect” listed species or critical habitat, the lead federal agencies (USACE and Forest Service) have the discretion to choose either informal or formal consultation. If informal consultation is chosen, the agency asks for written concurrence by the USFWS for the

CONSULTATION

BA's conclusion. Informal consultation is complete if a concurrence letter is obtained from the USFWS. If the BA concludes that the project is "likely to adversely affect" listed species or critical habitat, the agency must request formal consultation. When formal consultation is requested by the agency, the USFWS prepares and issues a Biological Opinion (BO), which completes the consultation. For proposed species, if the BA determines that the project is "likely to jeopardize a proposed species," the agency must request a conference with the USFWS.

Using information obtained in the BA, the USFWS will provide an opinion in the BO on whether the Project is: 1) "likely to jeopardize the continued existence of a listed species or result in the destruction or adverse modification of critical habitat" (a "jeopardy" biological opinion), or 2) "not likely to jeopardize the continued existence of a listed species or result in the destruction or adverse modification of critical habitat" (a "no jeopardy" biological opinion). If the USFWS issues a "jeopardy" opinion, it must include any "reasonable and prudent alternatives" to the project that would avoid jeopardy. If the USFWS issues a "no jeopardy" opinion, it may include discretionary "conservation recommendations," which are steps the USFWS believes could be taken to further minimize potential effects on listed species or critical habitat.

3.0 Description of the Proposed Action

3.1 Overview

The USACE and the USFS have separate proposed actions on which consultation is occurring. The USACE has an application under the Clean Water Act to impact wetlands and other waters of the U.S. associated with the construction and operation of the NorthMet mine. The USFS is evaluating a land exchange of federal and non-federal lands. For convenience, the impacts are described in terms of the Project and its associated activities.

PolyMet proposes to construct an open pit mine in northern Minnesota to extract low- to medium-quality copper-nickel-PGE minerals with low sulfide content. This Project is located in Sections 5, 6, 8, 9, 13, 14, 15, 16, 17, 23, and 24, Township 58 North, Range 14 West; Sections 1, 2, 3, 4, 9, 10, 11, 12, 15, 16, 17, and 18, Township 59 North, Range 13 West; Sections 3, 4, 5, 8, 9, 10, 11, 13, 14, 15, 16, 17, 20, 23, 24, 29, and 32, Township 59 North, Range 14 West; and Sections 32, 33, and 34, Township 60 North, Range 14 West, in St. Louis County on the eastern end of the Mesabi Iron Range, about 60 miles north of the City of Duluth, and 6 miles south of the City of Babbitt, Minnesota (**Figure 3**).

This section describes specific Project features that could have effects on lynx, wolf, northern long-eared bat, and lynx and wolf critical habitat. Additional Project features that are not relevant to potential effects on lynx or wolf and their critical habitats are listed in this section, but are not described in detail. Full Project details are available in the FEIS (MDNR et al. 2013).

Ore would be excavated at the Mine Site and hauled by railroad approximately 8 miles west to the Plant Site for processing. Corridors for roads, railroad, utilities, and water pipelines would connect the Mine Site and the Plant Site. The four Project areas are shown on **Figure 3** and include:

- Mine Site
- Plant Site
- Dunka Road and Utility Corridor
- Railroad Connection Corridor

3.2 Mine Site

The Mine Site, approximately 3,015 acres, would be developed at a greenfield site that has previous disturbance from logging and mining exploration activities. The Project would develop open mine pits (up to 528 acres), stockpiles (up to 794 acres), and supporting infrastructure (up to 397 acres). The location and dimensions of Mine Site features are shown on **Figure 4**. The Project features at the Mine Site would include:

- mine pits;
- ore storage and handling facilities, including an Ore Surge Pile and a Rail Transfer Hopper;

DESCRIPTION OF THE PROPOSED ACTION

- stockpiles for overburden and waste rock with engineered systems to manage potential water resource impacts (such as liners, covers, and the Category 1 Waste Rock Stockpile Groundwater Containment System);
- a Waste Water Treatment Facility and process water collection systems to collect and treat water from the mine pits, waste rock stockpiles, ore handling facilities, and haul roads,

- Mine Site
- Year 1 Mine Pits
- Year 11 Mine Pits
- Year 1 Stockpiles
- Year 11 Stockpiles
- Haul Roads
- Treated Water Pipeline
- Dunka Road
- Existing Private Railroad
- Proposed Railroad Track

Biological Assessment for the NorthMet Project and Land Exchange
St. Louis County, Minnesota

- a Central Pumping Station and Treated Water Pipeline to transport water from the Mine Site to the Plant Site; and
- supporting infrastructure (such as roads, electrical supply, rail connections, and fueling and maintenance facilities).

3.2.1 Pre-production Mine Development

Mine Site infrastructure would be constructed during the estimated 12 to 18 months of pre-production mine development. Pre-production mine development would be followed by a gradual ramp-up of ore output over 6 to 12 months. The following Project features would be constructed during pre-production mine development:

- Roads - site access roads, haul roads, and Dunka Road upgrades.
- Railroad infrastructure - the Rail Transfer Hopper, the rail spur connecting the Rail Transfer Hopper with Cliffs Erie railroad track, and the rail spur between the Cliffs Erie railroad track and PolyMet railroad track that serves the Coarse Crusher Building.
- Surface water management features – dikes, ditches, water collection ponds, and sumps.
- Overburden Storage and Laydown Area.
- Stockpile liners and containment systems.
- Waste Water Treatment Facility, Treated Water Pipeline, and Central Pumping Station.
- Substation drop from the 138 kilovolt (kV) Minnesota Power transmission line and a 13.8 kV Mine Site power distribution system.
- Mine Site Fueling and Maintenance Facility.

3.2.2 Mining Activities

PolyMet expects to mine a total of 533 million tons of waste rock and ore over 20 years, which would include 225 million tons of ore and 308 million tons of waste rock. Mining activities include overburden removal, open pit mining, drilling and blasting, excavation and haulage, ore storage and loading for transport to the Process Plant, waste rock stockpiling, and mine site water management.

3.2.2.1 Overburden Removal

The marketable timber would be cleared and the overburden removed from the footprints of the mine pits, the Ore Surge Pile, and the waste rock stockpiles, as necessary. PolyMet would follow the USFWS northern long-eared bat interim guidance for tree removal (USFWS 2014).

Overburden, which has been defined for this Project as the material that lies on top of bedrock, would be stripped incrementally as needed for mine development in order to minimize the amount of bedrock exposed at any one time. After removal of overburden from the initial mining area, additional overburden stripping could take place concurrently with the mining of ore and waste rock. Approximately 32% of the required overburden

DESCRIPTION OF THE PROPOSED ACTION

stripping for the pit development would be done in the first 2 years of mine operation. All of the overburden that needs to be stripped from the pits would be removed by the end of Mine Year 11.

3.2.2.2 Open Pit Mining

The Project would use open pit mining methods similar to those used at ferrous metallic mining operations on the Iron Range. The mine would consist of three separate open pits known as the East, Central, and West pits. For approximately the first 10 years of operations, mining would take place in the East and West pits simultaneously, with the East Pit mining ending in Mine Year 11. The Central Pit mining would occur between Mine Years 11 and 16. During Central Pit mining, the East and Central pits would converge into one pit which would then be referred to as the East Pit.

At its maximum size, each pit is projected to have the approximate maximum area and depth shown in **Table 1**.

Table 1
Maximum Pit Dimensions

Mine Pit	Area (acres)	Maximum Depth (feet below ground surface)
East	155	696
Central	52	356
West	321	630

Drilling and blasting would be conducted to remove waste rock and extract ore. Two conventional electric or diesel powered rotary drilling rigs would be used. Blasting of ore and waste rock is anticipated to take place approximately every 2 to 3 days.

After being drilled and blasted, the ore would be loaded by excavators into haul trucks that would haul the ore to the Rail Transfer Hopper or to the Ore Surge Pile for temporary storage and haul the waste rock to the stockpiles or the East Pit. Up to nine haul trucks would be in service with a maximum speed of 34 miles per hour loaded, however their speed would typically be lower.

Mining operations would be supported by mine auxiliary vehicles (for example [e.g.], water trucks, dozers, graders) traveling on access and haul roads within the Mine Site.

3.2.2.3 Ore Storage and Loading

Ore would be loaded for transport to the Plant Site at the Rail Transfer Hopper. The Rail Transfer Hopper would consist of a raised platform from which haul trucks dump into a hopper over a pan feeder into rail cars. The Rail Transfer Hopper would be located to the south of the mine pits and would be connected to the existing Cliffs Erie main line track by a new spur line (**Figure 4**).

An Ore Surge Pile would be constructed adjacent to the Rail Transfer Hopper to allow for temporary storage of ore until it could fit into the processing schedule or as required by operational delays. Drainage from the Ore Surge Pile would be collected on a liner and routed to a sump for pumping to the Waste Water Treatment Facility.

3.2.2.4 Stockpiling

Waste rock and overburden would be managed according to its geochemical properties as determined using a sampling and analysis program approved by the MDNR. PolyMet has categorized waste rock into four categories defined according to its sulfur content, in ascending order of reactivity. These waste rock categories are summarized in **Table 2**.

The Category 1 Waste Rock Stockpile would be the only permanent stockpile for the Project. During Mine Years 1 through 11, Category 2, 3 and 4 waste rock would be placed on the temporary Category 2/3 or Category 4 Waste Rock Stockpiles (**Figure 4**). When at its maximum size, each stockpile is projected to have the approximate area, height, and elevation shown in **Table 3**.

Table 2
Waste Rock Properties

Waste Rock Categorization	Sulfur Content (percent) ¹	Approximate Percent of Total Waste Rock Produced during Mining (percent)
Category 1	≤ 0.12	70
Category 2	> 0.12 to ≤ 0.31	24
Category 3	> 0.31 to ≤ 0.60	3
Category 4	> 0.6	3

¹In general, the higher the rock's sulfur content, the higher it's potential for generating acid rock drainage or leaching heavy metals.

Table 3
Maximum Stockpile Dimensions - Approximate

Stockpile	Mine Year of Maximum Footprint	Maximum Footprint (acres)	Maximum Height (feet)	Maximum Elevation (feet above sea level)
Category 1 waste rock	6/21 ¹	508/526 ¹	280	1,880
Category 2/3 waste rock	6	180	200	1,770
Category 4 waste rock	3	57	180	1,790
Ore Surge Pile	NA ²	31	120	1,690

¹The Category 1 Waste Rock Stockpile has a maximum footprint of 508 acres while active. It would reach this size by Mine Year 6. The stockpile would be re-graded as part of reclamation with a final footprint of 526 acres.

²The Ore Surge Pile would have ore moving in and out as needed to meet mine and plant operations.

All waste rock stockpiles would be engineered to manage water resource impacts. The temporary Category 2/3 and Category 4 Waste Rock Stockpiles, which have the potential to generate acid rock drainage, would have liner systems to capture water passing through the stockpile. The permanent Category 1 Waste Rock Stockpile, which does not have the potential to generate acid rock drainage, would be constructed with a groundwater containment system to collect stockpile drainage from around the entire stockpile.

3.2.2.5 Progressive Reclamation

Reclamation of the East Pit and the temporary waste rock stockpiles would begin during operations. The temporary Category 2/3 and Category 4 Waste Rock Stockpiles would be relocated to the East Pit starting in

DESCRIPTION OF THE PROPOSED ACTION

Mine Year 11. The infrastructure associated with the temporary stockpiles (pipes, pumps, liners, et cetera [etc.]) would be removed and the footprint of each area would be reclaimed.

After the temporary stockpiles are reclaimed, all future Category 2, 3, and 4 waste rock would be placed in the East Pit. Most of the Category 1 waste rock mined after Mine Year 12 would also be placed in the East Pit. Ultimately, approximately 45% of the total waste rock mined would be backfilled to the East Pit.

The East Pit would be flooded to keep the waste rock in a subaqueous environment to reduce the environmental impact associated with further oxidation and dissolution of sulfide minerals. If natural inflow of water into the East Pit is insufficient to keep the waste rock submerged, water could be pumped from the Waste Water Treatment Facility. During periods of high precipitation or during spring snowmelt, dewatering (to the Waste Water Treatment Facility and ultimately to the Flotation Tailings Basin) may be required to allow safe placement of the waste rock.

Reclamation of the Category 1 Waste Rock Stockpile would also begin during operations. A cover system would be added incrementally after Mine Year 13 to limit infiltration through the stockpile. The stockpile would be sloped and graded, an engineered geomembrane system would be installed, soil would be placed on top of the cover, and vegetation would be planted to meet the requirements of Minnesota Rules, part 6132.2200, subpart 2, item B. The cover system would be designed to promote runoff with minimal erosion.

3.2.2.6 Mine Site Water Management

This section summarizes information from the Water Management Plan - Mine, which would become part of the MDNR Permit to Mine and Water Appropriations permits and Minnesota Pollution Control Agency (MPCA) National Pollutant Discharge Elimination System/State Disposal System permit. These plans include water management system designs, operating and maintenance plans, water quality monitoring plans, reporting requirements, and adaptive management approach.

In addition to the stockpile liners, the stockpile cover, and the groundwater containment system, water management at the Mine Site would include pit dewatering, stormwater dikes and ditches, and the Waste Water Treatment Facility that would treat water that comes in contact with mining features. During operations, there would be no direct discharge of treated waste water to public waters.

It would be necessary to dewater the pits during mining to remove groundwater flow and precipitation runoff. These waters would be directed to low areas in the pits where it would be collected in sumps and pumped to the Waste Water Treatment Facility.

Non-contact stormwater, the result of precipitation that falls on natural or reclaimed vegetated surfaces, would be routed through sedimentation ponds prior to discharge to a small watercourse that flows to the Partridge River. A system of dikes and ditches constructed at the Mine Site perimeter would minimize the amount of surface water flowing onto the site and into the mine pits, manage the amount of water that comes into contact with mining features, and control non-contact stormwater flowing off the site.

During operations, the Waste Water Treatment Facility would treat water that comes into contact with the waste rock stockpiles, haul roads, Ore Surge Pile, and mine pits. For the first approximately 10 years, all Waste Water Treatment Facility effluent would be pumped to the Plant Site Flotation Tailings Basin Pond for reuse in the beneficiation process. Reuse of the Mine Site process water at the Plant Site would eliminate the

need to discharge any process water to surface waters during operations. Starting in Mine Year 11, some Waste Water Treatment Facility effluent would be sent to the East Pit to augment flooding as the pit is backfilled, with the remainder of the effluent continuing to go to the Flotation Tailings Basin. The purpose of the Waste Water Treatment Facility is to maintain water quality in the Flotation Tailings Basin pond at concentrations that do not have an adverse impact on Beneficiation Plant operations or future reclamation of the Flotation Tailings Basin.

Mine Site water would be managed in accordance with a future MPCA National Pollutant Discharge Elimination System/State Disposal System permit, which would include a Stormwater Pollution Prevention Plan (SWPPP). The SWPPP would identify and describe Best Management Practices for the Mine Site to minimize the discharge of potential pollutants in stormwater runoff.

3.2.3 Fueling and Maintenance Facilities

The Mine Site Fueling and Maintenance Facility would consist of two buildings, one for fueling mobile equipment, and one for minor service and repair of mobile equipment. Major scheduled maintenance and repair work lasting several days on most mobile equipment would be done in the refurbished and reactivated former LTVSMC Area 1 Shop. Stationary or slow-moving equipment such as excavators, dozers, drill rigs, and light plants would be fueled in the field using mobile fuel tankers.

The former LTVSMC Area 2 Shop, about 1 mile east of the Process Plant, would be reactivated to provide office space for mining and railroad operations supervision and management, as well as clothes changing facilities, toilets, lunch rooms, first aid facility, emergency response center, and training and meeting rooms for mining and railroad crews. The Area 2 Shop facilities would include a Locomotive Fueling Station, Locomotive Service Building, and Mine Reporting Building.

3.3 Plant Site

The Plant Site was previously used as a taconite processing facility by the LTVSMC. The location and dimensions of Plant Site features are shown on **Figure 5**.

At the Plant Site, the Project would upgrade existing facilities (Beneficiation Plant, Tailings Basin, Area 1 Shop, sewage collection system, rail connections, access roads) and construct new facilities (Hydrometallurgical Plant, Hydrometallurgical Residue Facility, Concentrate Dewatering/Storage Building, Sewage Treatment System Ponds, and Waste Water Treatment Plant) within a brownfield facility. The Flotation Tailings would be stored atop the existing LTVSMC Tailings Basin by staged construction of new dams. The Plant Site also includes supporting infrastructure (e.g., roads, electrical supply, rail connections, Area 1 Shop, and Area 2 Shop).

Plant Site environmental controls would include cover systems to limit infiltration of oxygen and water through the Flotation Tailings Basin dams, beaches, and pond bottom and seepage capture systems to collect seepage from the Flotation Tailings Basin. Most water used in processing would be recycled for use. A Waste Water Treatment Plant would be constructed, including reverse osmosis or similar membrane separation technology, to treat any water that could not be recycled prior to discharge to the environment. If makeup water is needed for processing, it may be provided via the Colby Lake Water Pipeline. No new construction is required for the Colby Lake Water Pipeline.

<ul style="list-style-type: none"> Existing NPDES Discharge Stations Treated Water Discharge Pipe Seepage Water Pipe Flotation Tailings Pipeline 	<ul style="list-style-type: none"> Hydrometallurgical Residue Pipeline Electric Transmission Lines Existing Private Railroad Proposed Railroad Track Project Areas 			<p>Figure 5 Plant Site Layout Biological Assessment for the NorthMet Project and Land Exchange St. Louis County, Minnesota</p>
--	--	--	--	---

3.3.1 Ore Processing

A Beneficiation Plant and Hydrometallurgical Plant would process the ore at the Plant Site to recover base metals, gold, and platinum group metals. The purpose of the beneficiation process would be to produce final separate concentrates. One of the separate concentrates would be a copper concentrate. The other separate concentrates would be differing grades of nickel concentrate. The concentrates could be shipped to customers, used as a feedstock to the hydrometallurgical process, or divided for both uses. PolyMet expects that the Beneficiation Plant would be operational several years before the Hydrometallurgical Plant and during that period all concentrates would be shipped to customers. Once the Hydrometallurgical Plant becomes operational, some or all of the nickel concentrates would be feedstock to the hydrometallurgical process. The decision to ship or process concentrates would be based on equipment maintenance schedules, customer requirements, and overall Project economics.

3.3.1.1 Beneficiation Plant

The Beneficiation Plant processes would include ore crushing, grinding, flotation, dewatering, storage, and shipping. Crushing and grinding would occur in the existing Coarse Crusher Building, Fine Crusher Building, and Concentrator Building. Flotation would occur in a new Flotation Building located on previously disturbed ground immediately to the west of the Concentrator Building. Dewatering, storage, and shipping would occur in a new Concentrate Dewatering/Storage Building located on previously disturbed ground.

3.3.1.2 Hydrometallurgical Plant

Hydrometallurgical processing technology would be used for the treatment of nickel concentrates. This process would involve high pressure and temperature autoclave leaching followed by solution purification steps to extract and isolate platinum group metals, precious metals, and base metals. All equipment used in the hydrometallurgical process would be located in a new Hydrometallurgical Plant Building. Should spillage of process fluids occur, it would remain within the Hydrometallurgical Plant Building and be returned to the appropriate process streams.

3.3.1.3 Plant Site Infrastructure

Plant Site infrastructure that exists at this site includes:

- County Road 666 ends at the Main Gate for the industrial area that includes the Process Plant, Area 1 Shop, and Area 2 Shop.
- The Canadian National Railroad serves the industrial area that would include the Process Plant. The PolyMet railroad would connect to the Area 1 Shop and the Area 2 Shop.
- Three Minnesota Power Company 138 kV transmission lines serve the Project substation.
- The existing mechanical Sewage Treatment Plant would be replaced with new Sewage Treatment System Ponds, and the existing sewage collection system would be upgraded to meet current construction and performance standards and sized as appropriate.

DESCRIPTION OF THE PROPOSED ACTION

- The Process Plant potable water treatment plant located near the Plant Reservoir would be refurbished and reactivated. The potable water distribution system extends to the Area 1 Shop and Area 2 Shop. This water would be used for showers and sinks and would be treated (chlorinated) to be drinkable. However, bottled water would be brought in for drinking as well.
- Area 1 Shop and Area 2 Shop.

3.3.2 Flotation Tailings Basin

Flotation Tailings from the flotation process at the Beneficiation Plant would be pumped to the Flotation Tailings Basin, which would be constructed on top of cells 1E and 2E of the existing LTVSMC Tailings Basin. Treated water from the Waste Water Treatment Facility would also be pumped to the Flotation Tailings Basin, enabling it to serve as the primary collection and distribution point for water used in the beneficiation process.

The existing LTVSMC Tailings Basin is unlined and was constructed in stages beginning in the 1950s. It has been inactive since January 2001, except for reclamation activities consistent with a MDNR-approved Closure Plan currently managed by Cliffs Erie.

The future Flotation Tailings Basin perimeter dams would be raised using upstream construction methods. The dams would be constructed using compacted LTVSMC tailings borrowed from the existing Tailings Basin. Once the LTVSMC tailings supply has been completely used for dam construction, offsite borrow from MDNR-approved sources would be utilized. Material from LTVSMC Area 5 would be a likely source, but other sources could also be considered.

Emergency overflow channels would be provided to protect the dams in the unlikely event that freeboard within the Flotation Tailings Basin is not sufficient to contain all water from an extreme storm event. Even though there is a low likelihood of overflow, it is standard practice in dam design to accommodate overflows in a manner that protects the integrity of the dams.

Seepage from the Flotation Tailings Basin would be collected by the Flotation Tailings Basin Containment System located around the northern, western, and portions of the eastern sides of the Tailings Basin and the Flotation Tailings Basin South Surface Seepage Management System located south of Tailings Basin Cell 1E. These two systems are collectively referred to as the Flotation Tailings Basin seepage capture systems. The Flotation Tailings Basin Containment System would include a low permeability cutoff wall so that it can collect seepage (from up-gradient), but avoid drawing in water from down-gradient wetlands.

3.3.3 Hydrometallurgical Residue Facility

The Hydrometallurgical Residue Facility would be constructed to manage residues generated by the hydrometallurgical process. The Hydrometallurgical Residue Facility would consist of one-lined cell located adjacent to the southwest corner of Tailings Basin, on previously disturbed ground (**Figure 5**).

The Hydrometallurgical Residue Facility liner system would be a double liner system consisting of two barrier layers separated by a leakage collection layer. This system would substantially remove all hydraulic head from the lower liner, virtually eliminating leakage from the Hydrometallurgical Residue Facility.

Residue from the Hydrometallurgical Plant would be pumped to the Hydrometallurgical Residue Facility as slurry. A pond would be maintained within the Hydrometallurgical Residue Facility so that the solids in the slurry would settle out. Most of the liquid would be recovered by a pump system and returned to the plant for reuse.

3.3.4 Plant Site Water Management

This section summarizes information from the Water Management Plan - Plant, which is a support document for the MDNR Permit to Mine and Water Appropriations permits and MPCA National Pollutant Discharge Elimination System/State Disposal System permit. These plans include water management system designs, operating and maintenance plans, preliminary water quality monitoring plans, preliminary reporting requirements, and adaptive management approach. Final water quality monitoring and reporting requirements would be determined in the permits.

Water management features at the Plant Site would include the Flotation Tailings Basin and seepage capture systems, Hydrometallurgical Residue Facility, stormwater dikes and ditches, drainage swale, Waste Water Treatment Plant, and stream augmentation. With the exception of the Flotation Tailings Basin seepage containment system, all Plant Site water management features would be located on previously disturbed areas.

3.3.4.1 Waste Water Treatment Plant

The Waste Water Treatment Plant would treat any water collected by the Flotation Tailings Basin seepage capture systems that cannot be reused as process water. It would include a reverse osmosis unit, or similar membrane separation technology, designed to achieve an effluent sulfate concentration that meets the sulfate standard for waters used for the production of wild rice (10 milligrams per liter (mg/l)). Water would be treated to meet appropriate discharge limits, then discharged along the west, northwest, and north perimeter of the Flotation Tailings Basin, beyond the Flotation Tailings Basin Containment System, and to Second Creek at the south end of the Flotation Tailings Basin to replenish the flow to the surrounding wetlands and streams. This discharge strategy would limit the potential for indirect wetland impacts due to reduced seepage from the Tailings Basin to the wetlands.

3.3.4.2 Stream Augmentation

Construction of the Flotation Tailings Basin Containment System would reduce the amount of seepage that is currently leaving the existing Tailings Basin. Consequently, the stream flow in the four tributaries around the Tailings Basin (Unnamed Creek, Second Creek, Trimble Creek, and Mud Lake Creek) would be reduced from current levels. Flow to Unnamed Creek, Second Creek, and Trimble Creek would be augmented by treated water from the Waste Water Treatment Plant. Flow to Mud Lake Creek would be augmented by construction of a drainage swale east of the Flotation Tailings Basin.

3.4 Transportation and Utility Corridors

The remaining Project components are linear corridor features, including the following (**Figure 6**):

- Dunka Road and Utility Corridor
- Railroad Connection Corridor

Figure 6
Transportation and Utility Corridor
 Biological Assessment for the NorthMet Project and Land Exchange
 St. Louis County, Minnesota

This section describes Project features in the Transportation and Utility Corridors and presents information on the types of traffic that would result from the Project.

3.4.1 Dunka Road and Utility Corridor

Dunka Road is an existing, compacted-gravel, private road that extends from near the LTVSMC Plant Site to the Mine Site, then continues roughly northeast toward Babbitt, Minnesota. The portion of Dunka Road that connects the Plant Site to the Mine Site would be widened. The Treated Water Pipeline would be constructed parallel and adjacent to the Dunka Road in the Utility Corridor to transport treated water from the Mine Site to the Plant Site. The distance along Dunka Road from the Plant Site gate to the Mine Site gate is approximately 6.4 miles. Including the road segments located within the Plant Site and the Mine Site, the total distance from the ore processing area at the Plant Site to the ore loading area at the Mine Site is approximately 8.5 miles.

Traffic on Dunka Road would include light trucks and automobiles, sport utility vehicles (SUVs), fuel trucks, supply and waste trucks, and haul trucks needing maintenance.

- Automobiles, light trucks, or SUVs transporting employees would travel between the Area 2 Shops and the Mine Site each day, at speeds of 30 to 45 miles per hour.
- Trucks carrying fuel and blasting agents would travel to the Mine Site every day, at speeds of 25 to 40 miles per hour. These trucks would travel from County Highway 666 to Dunka Road.
- Trucks transporting supplies and waste to and from the Waste Water Treatment Plant and the Waste Water Treatment facility would travel between the Plant Site and the Mine Site each day, at speeds of 25 to 40 miles per hour.
- Haul trucks would travel from the Mine Site to the Area 1 Shop for maintenance occasionally, at a maximum speed of 35 miles per hour.

3.4.2 Railroad Connection Corridor

The railroad route from the Mine Site to the Plant Site would be from a new spur at the Rail Transfer Hopper, to the existing track on the Cliffs Erie private railroad, to a new approximately 1.1 mile connecting railroad track between the Cliffs Erie railroad track and existing PolyMet track railroad that serves the Coarse Crusher Building at the Process Plant (**Figure 6**).

Each ore train would consist of 16 to 20 100-ton side dumping ore cars and one diesel-electric “Gen-Set” or “Multi-Engine” locomotive. Ore trains would make approximately 22 roundtrips per day delivering ore from the Mine Site to the Plant Site, traveling between 15 to 25 miles per hour.

To minimize the amount of ore that escapes from rail cars, ore would be loaded into the center of the car so that fines would be located at the center of the car and the larger ore pieces would be at the edge. The result would be that fines would be kept from reaching the edge of the car where they would be subject to spillage through the hinge gaps. Large pieces that extend over the edge of the rail car would be pushed into the center of the car using a rubber-tired dozer or a front-end loader. In the event that a large ore piece would fall over the top edge of the cars during transit, it would be recovered during routine track maintenance.

In order to guard against possible adverse impacts from spilled ore, monitoring and mitigation activities can be developed. It is expected that the surface water quality sampling in the two streams traversed by the rail line would be included in permit monitoring. Mitigation measures could include alterations to the stream crossings (bridges or culverts) to collect any spilled material or the physical collection of spilled ore from the top of the rail ballast.

3.5 Traffic

Transportation of Project consumables and products would result in traffic on public roads and commercial railroads. Public roads would also have additional traffic from employees and service providers.

3.5.1 Transport of Consumables and Products

Process consumables and products would be transported to and from the Plant Site by truck and rail. This section describes the traffic on public roads and commercial railroad lines that would result from the Project.

Trucks transporting raw materials needed for the beneficiation process and the hydrometallurgical process would make approximately 80 round trips per month, entering the Plant Site from Highway 135. Trucks transporting copper and nickel concentrates would make up to approximately four round trips per day, also entering the Plant Site from Highway 135.

A locomotive, similar to the locomotives that would be hauling ore from the Mine Site to the Plant Site, would transfer loaded and empty cars carrying process consumables and concentrates to and from the interchange location with the Canadian National Railroad. Cars carrying process consumables and concentrate would meet railroad common carrier requirements.

Product shipment would require an approximately 100-car train once per month and a 30-car train 4 times per month, year-round. Process consumables would require an approximately 100-car train once per week, April through October. It is expected that outgoing PolyMet products would go by rail from the Plant Site to Virginia, Minnesota, with about half going south to Duluth, Minnesota, and the other half going north to International Falls, Minnesota. Product transport beyond Virginia is likely to be a part of the existing commercial rail traffic, with limited potential to generate additional commercial train trips. Process consumables would arrive at the Plant Site from the south from Duluth through Virginia. This movement is likely to be a part of the existing commercial rail traffic, with limited potential to generate additional commercial train trips.

3.5.2 Traffic from Employees and Service Providers

The Project would employ as many as 500 full-time workers over an 18-month period during peak construction period, and about 360 full-time workers during operation. There would be approximately 38 employee vehicles per day and 4 service vehicles per day entering the Main Gate (from County Road 666). In addition, there would be approximately 113 employee vehicles per day and 36 service vehicles per day entering the North Gate (from Highway 135).

3.6 Project Reclamation

Mining is expected to be completed approximately 20 years after operations begin. This section summarizes information from the Reclamation Plan, which is a support document for the MDNR Permit to Mine, and focuses on those aspects of Project Reclamation that have potential effects on lynx, northern long-eared bat, and wolf. Additional information on Project reclamation is available in the FEIS (MDNR et al. 2015).

In general, Project facilities have been designed and would be operated to allow for progressive reclamation, or “mining in a manner that creates areas that can be reclaimed as soon after initiation of the operation as practical and as continuously as practical throughout the life of operation” (Minnesota Rules, part 6132.0100). This would leave a smaller portion of the Project area needing to be reclaimed after closure. Project features that would be progressively reclaimed include the Waste Rock Stockpiles, the East Pit, the exterior slopes of the Flotation Tailings Basin, and the Hydrometallurgical Residue Facility. The Waste Water Treatment Facility and the Waste Water Treatment Plant would remain operative during reclamation and long-term closure⁵.

3.6.1 Building and Structure Demolition and Equipment Removal

The buildings and structures would be removed and foundations razed. All mining, dewatering, and electrical equipment would be removed from the mine pit and scrapped, decommissioned, or sold. Debris and equipment would be removed from the Mine Site and Plant Site. Most roads, parking areas, or storage pads built to access these facilities would be demolished. Utility tunnels would be sealed and reclaimed in place. After demolition, these areas would be reclaimed and vegetated according to Minnesota Rules, part 6132.2700. All areas would be stabilized as required for stormwater management.

Demolition waste from structure removal would be disposed of in the existing on-site demolition landfill located northwest of the Area 1 Shop. Most concrete from demolition would be crushed and used for structural fill, placed in the basements of the Plant Site buildings, or placed in the existing on-site industrial landfill. Asphalt from paved surfaces would be removed and recycled or properly disposed of. Railroad track and ties that were not used by common carriers would be removed and recycled. All disturbed areas would be reclaimed and vegetated.

Any roads, including Mine Site access roads that may develop into unofficial off-road vehicle trails, would require a variance from MDNR reclamation rules to allow a 15-foot-wide unpaved, unvegetated track down the centerline of the road. Such approvals would also be coordinated with the St. Louis County Mine Inspector’s Office.

Special materials would be disposed of appropriately during reclamation:

- Any ore remaining in the Rail Transfer Hopper, the Ore Surge Pile, or anywhere else in the vicinity of the Rail Transfer Hopper, as well as sediment removed from ditches and process

⁵ “Long-term closure” is defined as being the time period when the West Pit has filled with water and the Waste Water Treatment Facility is discharging water to the outlet channel to the Upper Partridge River. This will likely occur during the post-closure maintenance period of reclamation.

water ponds, would be placed in the East Pit.

- Asbestos-containing materials would be removed intact, properly packaged, and disposed of in the on-site demolition landfill. The locations of asbestos-containing materials in the landfill would be noted on the property deed. Any asbestos-containing materials found in utility tunnels would be sealed before the utility tunnel is sealed.
- Fluorescent and sodium halide bulbs, nuclear sources, oil-stained concrete, and partially used paint, chemical, and petroleum products would be removed and recycled or properly disposed of.
- Any materials remaining in storage tanks would be sent to appropriate recycling or waste disposal facility. All storage tanks would be cleaned, disassembled, and recycled or disposed of appropriately. Tank foundations would be removed and all disturbed areas would be vegetated.
- Material remaining in the equipment and process piping would be properly disposed of in the Hydrometallurgical Residue Facility or other MPCA-approved locations.
- On-site sewer and water systems, powerlines, pipelines, and culverts would be closed according to regulatory requirements.

3.6.2 Reclamation of Mine Site

Mine Site reclamation would include building and structure demolition and equipment removal, mine pit reclamation, stockpile reclamation and watershed restoration. Mine Site reclamation would begin as soon as practical throughout mining operations, with reclamation of the East Pit and Waste Rock Stockpiles commencing before mining activities cease.

3.6.2.1 Mine Pit Reclamation

Mine pit reclamation would include pit flooding, construction of overflows and outlet control structures, sloping and vegetation of pit walls, and fencing to control access to the pits. East Pit reclamation would begin during operations, while West Pit reclamation would commence when mining activity ceases.

Mine pit dewatering systems would be removed from the pits and the pits would be allowed to flood with water. All areas disturbed during pipe removal would be graded and revegetated. Some temporary pumps may remain in the pits for dewatering that would be performed during pit flooding.

East Pit flooding would start in Mine Year 11 and be completed by Mine Year 20. Overflow from the East Pit would flow to the West Pit through a new ditch. An East Pit outlet structure would be built, which would establish the steady-state water level in the East Pit. The East Pit would be revegetated with wetland vegetation, resulting in approximately 207 acres of wetland (**Figure 7**).

Upon completion of mining operations, the West Pit would begin to flood naturally with groundwater, precipitation, and surface runoff from the tributary watershed. West Pit flooding would be accelerated with treated water from the Plant Site. With the addition of water pumped from the Plant Site to the West Pit,

West Pit flooding is projected to be completed between Mine Years 40 and 45. The West Pit would remain an open pit lake (MDNR et al. 2013).

- Mine Site
- Covered Stockpile
- West Pit
- East Pit Wetland
- Haul Roads
- Groundwater Containment System
- Process Water Pipe
- Stormwater Collection Ditch
- Perimeter Dike
- Discharge Pipe
- Culverts
- Fence

Figure 7
Mine Site Plan Long-term Closure
 Biological Assessment for the NorthMet Project and Land Exchange
 St. Louis County, Minnesota

When the West Pit is full, discharge would be prevented by pumping West Pit water to the Waste Water Treatment Facility for treatment. The Waste Water Treatment Facility would be upgraded to include reverse osmosis or similar membrane separation technology to achieve an effluent concentration that meets the sulfate standard for waters used for the production of wild rice (10 mg/l). After the upgrade, effluent would be discharged through Dunka Road into an existing wetland, and eventually into the Partridge River through an existing tributary channel.

The overburden portions of the pit walls would be sloped, graded, and vegetated in accordance with Minnesota Rules, part 6132.2300. Lift heights would be selected based on the need to protect public safety, the location of the pit wall in relation to the surrounding land uses, the soil types and their erosion characteristics, the variability of overburden thickness, and the potential use of the pit following mining.

A pit perimeter fencing system would be installed consisting of fences, rock barricades, ditches, stockpiles, and berms. The barrier system plan would be submitted to the St. Louis County mine inspector for review and approval before installation. Safe access would be provided to the bottom of each mine pit via selected haul roads built during pit development. The access road would be selected such that, as pit water level rises, there would always be a clear path to the water surface. A gated entrance would be placed at each pit access location.

3.6.2.2 Stockpile Reclamation

Stockpile reclamation would begin during operations. Upon full reclamation of the Category 1 Waste Rock Stockpile, runoff from the top and sides of the stockpile would be classified as non-contact stormwater and discharged into the natural drainage system. The Category 1 Waste Rock Stockpile Groundwater Containment System would continue to collect drainage from the stockpile during reclamation, with drainage treated at the Waste Water Treatment Facility. The Category 1 Waste Rock Stockpile would be reclaimed as a grass/forb community and shrubs and trees would be removed to prevent damaging the liner system. The other stockpiles (Category 2/3 and Lean Ore) would be removed, the areas would be initially planted with grasses, with a successional trajectory towards forest.

3.6.2.3 Watershed Restoration

During mining operations, stormwater runoff from reclaimed stockpile areas and natural (undisturbed) areas would be routed via dikes and ditches to stormwater sedimentation ponds. During reclamation, dikes and ditches that were no longer needed would be removed or filled and ponds would be filled. The reclaimed surfaces would then be scarified, topsoil placed on the surface, and the area revegetated with native species.

Surface runoff inflows would be routed to the mine pits using a combination of existing and new ditches. Some portions of the pit rim dikes may be left in place, if needed, to prevent an uncontrolled flow to or from the pits and potential erosion (head cutting) of the pits walls.

All stormwater ponds, the Overburden Storage and Laydown Area process water pond, haul road process water ponds, and all stockpile sumps and overflow ponds would be filled with overburden and peat (that was removed from the site during construction and stored in the Overburden Storage Area), and covered with topsoil and revegetated, or converted into wetlands. If the process water ponds were converted into wetlands, any sedimentation that occurred within the pond would be evaluated to determine if removal of sediment or

covering of the pond would be necessary prior to restoration. Stormwater pond outlet control structures would remain in place as necessary to manage water flows.

3.6.3 Reclamation of Plant Site

Plant Site reclamation would include building and structure demolition and equipment removal, Flotation Tailings Basin reclamation, and Hydrometallurgical Residue Facility reclamation. Similar to the Mine Site,

Plant Site facilities have been designed and would be operated to allow for progressive reclamation. Features that would remain at the Plant Site are shown on **Figure 8**.

The Waste Water Treatment Plant, Flotation Tailings Basin Seepage Management Systems, and Hydrometallurgical Residue Facility Leakage Collection System would continue to operate during reclamation, although seepage and leakage rates would be progressively reduced. Seepage and leakage would be recycled back into the Flotation Tailings Basin Pond or treated at the Waste Water Treatment Plant and pumped to the Mine Site to aid in West Pit flooding, or discharged.

3.6.3.1 Flotation Tailings Basin Reclamation

Permanent vegetation would be established on the Flotation Tailings Basin to control fugitive dust. Flotation Tailings Basin exterior dam surfaces would be reclaimed progressively, while interior areas would be seeded and mulched after closure.

Infiltration would be reduced through the dam faces, beaches, and pond bottom of the Flotation Tailings Basin by bentonite amendment. The exterior face of the dams would be reclaimed progressively, with a bentonite layer added as they are constructed to limit oxygen diffusion. The exposed beaches and dam tops would be amended with a bentonite layer to limit oxygen diffusion. The pond bottom would be covered with a bentonite layer to maintain a permanent pond that would limit oxygen diffusion.

During reclamation, several sources of water from the Flotation Tailings Basin would require management. The sources and a summary of the type of management needed are described as follows:

- Ponded water within the Flotation Tailings Basin – a pond and wetland would remain in the Flotation Tailings Basin. The pond and wetland would receive surface water runoff from the crest and beaches of the basin and natural terrain adjacent to the Flotation Tailings Basin. The pond and wetland would continue to lose water via seepage, but at a reduced rate as compared to during operations as a result of the bentonite augmentation of the Flotation Tailings Basin pond bottom. Excess water would be pumped from the Flotation Tailings Basin pond to the Waste Water Treatment Plant for treatment prior to discharge.
- Stormwater management would include grading to provide a gently sloping surface that effectively routes surface water runoff to the interior of the Flotation Tailings Basin, and to accommodate future differential settlement of the underlying Flotation Tailings.
- An emergency overflow channel would be constructed to carry stormwater from the pond to the adjacent wetland in case of an extreme storm or snowmelt event after reclamation. The conceptual location of the emergency overflow channel is from the combined Cell 1/2E to the adjoining land.

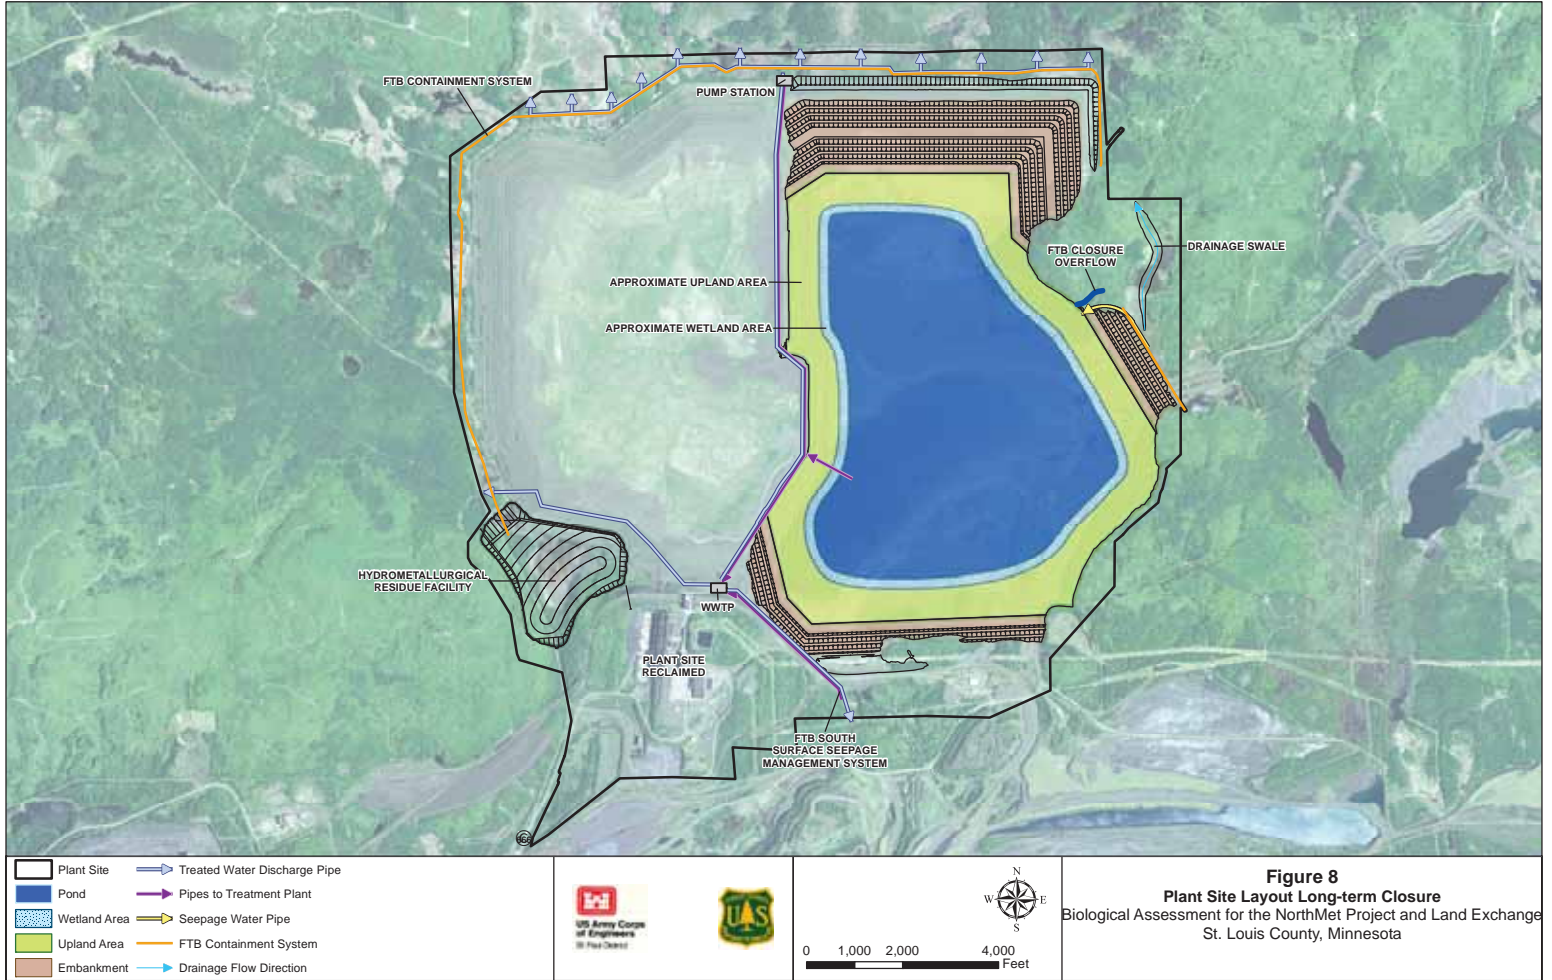

Figure 8
Plant Site Layout Long-term Closure
 Biological Assessment for the NorthMet Project and Land Exchange
 St. Louis County, Minnesota

3.6.3.2 Hydrometallurgical Residue Facility Reclamation

Reclamation of the Hydrometallurgical Residue Facility cell would include removal of ponded water from the cell surface, removal of pore water from the residue, construction of the cell cover system, establishment of vegetation, and surface water runoff control.

Ponded water remaining in the cell would be removed and treated at the Waste Water Treatment Plant. Drainage would be collected from the base of the cell at the geocomposite drainage system and managed as described for ponded water. The rate of drainage would decrease over time as the pore water within the Hydrometallurgical Residue Facility was collected and removed.

The Hydrometallurgical Residue Facility cell area would be graded into a gently sloping surface, and an engineered cover system would be installed to limit infiltration. Permanent vegetation would be established over the cover system. The turf and final cover would be inspected, mowed once per year or as needed, fertilized if vegetation growth is poor, and repaired as needed.

The cover would slope gently toward the site perimeter to accommodate natural drainage of the runoff. Final cover slopes on the cell interior would be relatively shallow to minimize surface water runoff flow velocity and the associated erosion. Runoff channeled along the cell perimeter would be routed downslope via rip-rapped drainage swales or plug-resistant inlet structures and piping systems. Once runoff was conveyed down the cell exterior dam slope, it would be routed to the surrounding natural drainage system. All runoff would be from reclaimed cover or dam exterior slopes, which would be constructed of MDNR-approved material.

3.6.4 Long-Term Closure Activities

Mechanical water treatment systems (the Waste Water Treatment Facility and the Waste Water Treatment Plant) would continue to operate during long-term closure. The water collected by the Category 1 Waste Rock Stockpile Groundwater Containment System and the West Pit water would be treated using the Waste Water Treatment Facility (upgraded to reverse osmosis or similar membrane separation technology) to ensure that the discharge meets applicable water quality discharge limits. The Waste Water Treatment Plant would treat water collected by the Flotation Tailings Basin seepage capture systems, Hydrometallurgical Residue Facility Leakage Collection System, and excess Flotation Tailings Basin pond water, to meet applicable water quality discharge limits. Inspection, water treatment maintenance, and reporting activities would continue while the mechanical treatment systems operated during long-term closure.

Surface water and groundwater quality would be monitored. These long-term closure activities would be expected to be ongoing until such time as the various facility features are deemed environmentally acceptable, in a self-sustaining and stable condition.

Other long-term closure activities would include repair of stockpile and Flotation Tailings Basin dam slope erosion, up-keep of constructed wetlands and outflow structures, removal of shrubs and trees from the Hydrometallurgical Residue Facility and Category 1 Waste Rock Stockpile cover systems, and on-going operation/maintenance and inspection of the seepage capture systems at the Category 1 Waste Rock Stockpile and Flotation Tailings Basin.

When PolyMet has completed all reclamation and long-term closure activities required under the Permit to Mine, a Request for Release per Minnesota Rules, part 6132.1400 would be submitted to the MDNR. This

request would provide the Commissioner of the MDNR with detailed information on the final closure status of the Project.

3.7 Federal and Non-federal Lands

3.7.1 Land Exchange Process

The federal lands are in St. Louis County, approximately 70 miles north of the City of Duluth, 20 miles south of the Boundary Waters Canoe Area Wilderness (BWCAW), and 6 miles south of the City of Babbitt. The federal lands are bounded on the north by the Northshore taconite mine and on the south by the Dunka Road and Utility Corridor. The federal lands include a portion of the Mine Site and Dunka Road and Utility Corridor.

The proposed land exchange between the Government, acting through the Forest Service, and PolyMet is an assembled land exchange. The exchange is proposed under the authority of the Weeks Act of March 1, 1911 as amended; General Exchange Act of March 20, 1922; Federal Land Exchange Facilitation Act of 1988; and the Federal Land, Policy and Management Act of October 21, 1976.

The federal lands are located within the General Forest and General Forest - Longer Rotation Management Area. The theme of the General Forest – Longer Rotation Management Area emphasizes land and resource conditions that provide a wide variety of goods, uses, and services. The characteristics and use of the General Forest Management Area are similar to the General Forest – Longer Rotation Management Area, except that harvests are more frequent, more uniform in age, and more extensive. The General Forest Management Area has the highest amount of young forest and the largest-sized timber harvest units.

Land ownership adjustment direction for these Management Areas allows the exchange of federal lands, with the desired condition described as “Land ownership patterns (federal, state, county, corporation and private) are consolidated, promote efficient administration and reduce the costs of managing resources.” A detailed discussion of the Land Exchange Process is provided in Chapter 3.3 of the SDEIS.

3.7.2 Federal Lands

The federal lands include approximately 2,719 acres of the 3,015-acre Mine Site and 3,776 acres of lands surrounding the Mine Site that are owned by the Government and administered by the Forest Service. The federal lands are located in Sections 6 and 7, Township 59 North, Range 12 West; Sections 1 to 12 and 16 to 18, Township 59 North, Range 13 West; Sections 1, 12, and 13, Township 59 North, Range 14 West; Section 31, Township 60 North, Range 12 West; and Sections 32 to 36, Township 60 North, Range 13 West. Most of the federal lands are part of the General Forest – Longer Rotation Management Area, while the remainder is within the General Forest Management Area.

The federal lands include a portion of One Hundred Mile Swamp, a large black spruce, tamarack, and northern white cedar wetland, and Mud Lake. Most of One Hundred Mile Swamp will not be affected by the Project. Refer to Figure 4 to see the limits of active mining at the Mine Site. Federal lands, including most of One Hundred Mile Swamp, outside of the active mining areas will not be affected by the Project. Yelp Creek and the Partridge River flow through the federal lands on the north, east, and southeast. Management of the 3,776 acres surrounding the Mine Site may include some upland timber management that could enhance wildlife habitat.

3.7.3 Non-federal Lands

PolyMet has acquired non-federal lands for transfer to the Government that encourage efficient land ownership patterns, with the desired condition of consolidating federal, state, county, corporate and private ownership to promote efficient administration and reduce the cost of managing resources to the Forest Service. The non-federal lands would be incorporated with adjacent federal ownership and managed in accordance with Forest Service's Forest Plan direction for that particular area. Lands with obvious recreational values would be managed to enhance those public recreation opportunities. The non-federal lands are assembled in five different tracts totaling approximately 7,075 acres that consist primarily of forest and wetland habitat (**Figure 2**).

3.7.3.1 Hay Lake Lands

Hay Lake Lands are in central St. Louis County, Minnesota, and are approximately 3 miles west of Biwabik, Minnesota. The lands, located at the eastern end of the Mesabi Iron Range, include approximately 4,926 acres in all or portions of Sections 9, 16, 19, 20, 21, 27, 28, 29, 30, 31, and 32 in Township 59 North, Range 16 West. The lands are moderately hilly and consist predominantly of second- or third-growth deciduous and coniferous forest uplands and emergent, shrub swamp, and forested wetlands. Approximately 59% (2,931 acres) of Hay Lake Lands consists of wetlands. The lands include Hay Lake, identified as a Wild Rice Water by the MDNR, and Little Rice Lake, and are bordered on the east by the Pike River. Forest Service lands border the lands to the north, east, and west. Forest Service lands adjacent to the lands are managed as General Forest and Candidate Research Natural Areas. Research Natural Areas are areas that the Forest Service has designated to be permanently protected and maintained in natural condition. These protected natural areas include unique ecosystems or ecological features; rare or sensitive species of plants and animals and their habitat; and/or high-quality examples of widespread ecosystems. Candidate Research Natural Areas are those areas which are in various stages of review for possible establishment as a Research Natural Area.

3.7.3.2 Hunting Club Lands

Hunting Club Lands are in northern St. Louis County, Minnesota, and includes approximately 160 acres in Section 17, Township 66 North, Range 17 West. The lands are nearly level and consist predominantly of second- or third-growth deciduous and mixed deciduous and coniferous forest uplands and emergent, shrub swamp, and forested wetlands. Approximately 40% (64 acres) of Hunting Club Lands consists of wetlands. The lands are bordered by Forest Service and county lands. Nearby Forest Service lands are managed as General Forest – Longer Rotation.

3.7.3.3 Lake County Lands

Lake County Lands consist of approximately 382 acres, with 265 acres in Sections 5 and 6, Township 57 North, Range 11 West (Lake County Lands North), and 117 acres in Section 17, Township 56 North, Range 9 West (Lake County Lands South) in Lake County, Minnesota. The lands are administered by Lake County. The lands are nearly level and consist predominantly of second- or third-growth mixed coniferous/deciduous forest uplands and bog, emergent, shrub swamp, and forested wetlands. Much of Lake County Lands South was recently logged. Approximately 74% (283 acres) of Lake County Lands consists of wetlands. The lands are bordered by the Superior National Forest. Forest Service lands near Lake County Lands North are managed as Riparian Emphasis Area and General Forest – Longer Rotation. Forest Service lands near Lake County Lands South are managed as General Forest – Longer Rotation. In Riparian Emphasis Areas, riparian

ecological functions are actively restored, protected, and enhanced in areas where ecosystem processes are sensitive to degradation. This includes maintaining and restoring native vegetation communities; maintaining and restoring riparian/hydrologic functions such as shoreline stability, wildlife habitat, coarse woody debris recruitment to aquatic and riparian ecosystems, and temperature regulation; and controlling non-native invasive species. Restoration focuses on components of the ecosystem that are not functioning at or within the range of desired conditions. Those components that are functioning properly are protected. These areas are also managed for recreational opportunities and visual quality adjacent to bodies of water.

3.7.3.4 McFarland Lake Lands

McFarland Lake Lands are approximately 31 acres in Section 9, Township 64 North, Range 3 East, in Cook County, Minnesota. These lands are approximately 3 miles west of the U.S. - Canada border and 10 miles north of Hovland, Minnesota. The lands are mostly on a hillslope and consist of second- or third-growth deciduous and coniferous upland forest. McFarland Lake is an entry point to the BWCAW. There are no wetlands on the lands. The lands are bordered by Forest Service land. Forest Service lands near McFarland Lake Lands are managed as General Forest – Longer Rotation.

3.7.3.5 Wolf Lands

Wolf Lands total 1,576 acres and are comprised of 126 acres in Section 8, Township 57 North, Range 11 West (Wolf Lands 1); 769 acres in Sections 15 and 22, Township 58 North, Range 10 West (Wolf Lands 2); 277 acres in Sections 30 and 31, Township 59 North, Range 9 West (Wolf Lands 3); and 405 acres in Sections 7, 8, 15, 17, and 18, Township 59 North, Range 9 West (Wolf Lands 4) in Lake County, Minnesota. The lands are nearly level and consist predominantly of second- or third-growth mixed deciduous and coniferous forest uplands and bog, emergent, shrub swamp, and forested wetlands. Much of Wolf Lands 3 has been recently logged. Approximately 88% (1,392 acres) of Wolf Lands consists of wetlands. Forest Service lands border portions of all of Wolf Lands and are managed as General Forest (Wolf Lands 2, 3, and 4) and General Forest – Longer Rotation (Wolf Lands 1). These lands would supplement National Forest ownership by reducing federal exterior boundaries and would eliminate several private in-holdings.

3.8 Wetland Mitigation Sites

The Project would directly impact an estimated 914 acres of wetlands, mostly within the Mine Site. A USACE permit would be required under Section 404 of the Clean Water Act for impacts to wetlands and other waters of the U.S. The majority of the direct wetland impacts would occur at the Mine Site (about 758 acres) and the Flotation Tailings Basin (141 Acres), with an additional 7 acres associated with Dunka Road and Railroad construction and 7.5 acres at the proposed Hydrometallurgical Facility.

PolyMet is proposing to purchase 2,169 acres (Wetland Mitigation Sites) as mitigation for wetland impacts from the Project. On the Wetland Mitigation Sites, 1,603 acres would be restored or converted to wetlands and 197 acres would be used for upland buffer. Wetland monitoring would be conducted to identify potential indirect impacts to wetlands caused by mining activities. PolyMet would work with USACE and MDNR to mitigate indirect impacts as appropriate.

Compensation for wetland impacts is required under Section 404 of the federal Clean Water Act and the Minnesota Wetland Conservation Act (Minnesota Rules part 8420.0100). The wetland mitigation planning process for the Project relied on the Wetland Conservation Act wetland replacement siting rules (Minnesota

Rules part 8420.0522), state compensatory mitigation requirements under state water quality standards (Minnesota Rules part 7050.0186), and the USACE St. Paul District Policy for Wetland Compensatory Mitigation in Minnesota (USACE 2009), which prioritizes the location of project-specific compensation to first replace lost wetlands on-site, then within the same watershed or county, and finally within adjacent watersheds.

3.8.1 On-site Restoration

In accordance with the USACE St. Paul District Policy for Wetland Compensatory Mitigation in Minnesota and state guidelines, the potential for creating wetlands on-site was considered first. Approximately 102 acres of onsite wetland creation opportunities were identified, which may occur at Project closure (Barr Engineering [Barr] 2012).

3.8.2 Off-site Mitigation

It was not possible to identify sufficient acreage on-site to mitigate for wetland impacts from the Project. Thus, potential wetland mitigation sites were identified and evaluated to determine their relative potential for mitigation, the level of risk and uncertainty, and the likely costs.

Sites were initially eliminated from further consideration due to issues that included unwilling landowners, significant private properties that would be hydrologically impacted by wetland restoration, insufficient agricultural history, insufficient wetland drainage to qualify for restoration credit, considerable existing upstream drainage through the site, or active pursuit of the properties by others. Three sites were identified that had the potential to accomplish compensatory wetland mitigation for the Project. These are the 1,070 acre Aitkin Site, 530 acre Hinckley Site, and the 569 acre Zim Site, which includes Zim North (481 acres) and Zim South (88 acres) (Figure 2; Barr 2007, 2014a, 2014b, 2014c, 2014d). Of these 2,169 acres, about 1,603 acres would be restored to wetland habitat.

3.8.2.1 Aitkin Site

The Aitkin Site is 1,070 acres in Section 6, Township 47 North, Range 26 West, and Section 1, Township 47 North, Range 27 West in Aitkin County, near Aitkin, Minnesota, and within the Mississippi River-Brainerd watershed. The site is a sod farm. PolyMet proposes to restore 808 acres of wetland and preserve 83 acres of upland buffer at the site (Barr 2007, 2014a, 2014d).

Initially, the internal drainage system at the site would be removed and outlets would be constructed to maintain desired hydrological conditions (Barr 2012, 2014a). Once desired hydrological conditions have been achieved, wetland vegetation would be promoted on the site by allowing native species that are present in the seed bank or that may be transported to the area from adjacent wetlands to develop on the site. Diverse, native wetland vegetation is expected to develop in the wetland. Wetland habitats likely to develop on the site include shallow marsh, shrub-carr, hardwood swamp, and coniferous swamp. Non-native and other invasive vegetation on the site would be removed through mechanical means or herbicide application. If vegetation development is not adequate to meet the success criteria, seed may be installed after the first or second growing season.

Hardwood and coniferous swamp would require herbaceous and woody species seedings and plantings.

Vegetation in the upland areas would be managed to promote natural succession of the existing plant communities. The primary maintenance activity would be control of non-native and other invasive species.

At completion of the monitoring period required to establish the wetland credits, the land would be conveyed to the third party that performs the construction to create the wetland mitigation credits. That ownership would also be subject to conservation easements (Pylka 2013a).

3.8.2.2 Hinckley Site

The Hinckley Site is 530 acres in Section 5, Township 39 North, Range 22 West, in Pine County, near Hinckley, Minnesota, and within the Snake River watershed. PolyMet proposes to restore 286 acres of wetlands and preserve 91 acres of upland buffer. The overall objective of the Hinckley restoration plan is to restore the hydrologic connection between upstream watersheds and the restoration site and to disable the internal drainage system on the site (Barr 2007a, 2014b, 2014d).

Initial activities would be focused on developing desired hydrological conditions (Barr 2014b). Restoration of wetlands would follow a similar process as that described for the Aitkin Site and would include the use of native seedbank and seed dispersal mechanisms to establish wetland vegetation on the site. Wetland habitats likely to develop on the site include sedge/wet meadow, shrub-carr, alder thicket, and hardwood swamp. Site management would include control of non-native and other invasive vegetation, and seeding and plantings of coniferous trees.

PolyMet would continue to own the land after the credits are created. At the time the credits were accepted it could be determined that PolyMet keeps the lands or transfers the lands to another third party subject to the conservation easement placed upon the lands for the creation of the credits (Pylka 2013a).

3.8.2.3 Zim North

The Zim North Site is 481 acres in Sections 2, 3, 10, 11, 14, and 15, Township 55 North, Range 18 West, in St. Louis County, approximately 12 miles southwest of Eveleth, and within the St. Louis River watershed. PolyMet proposes to restore the site to coniferous bog and shallow, open water wetland. Approximately 352 acres of coniferous bog and 7 acres of shallow, open water would be created on the Zim North site. In addition, 18 acres of ditches would be filled, 44 acres of partially drained wooded areas would be restored, and 12 acres of forested woodland and 12 acres upland buffer would be preserved. Approximately 36 acres of roads and other lands would not be restored. The overall objectives of the Zim North restoration plan would be to restore the native coniferous bog wetland community, restore the hydrologic connection between upstream watersheds and the restoration site, and disable the internal drainage system on site. Developing a bog community is highly dependent on soil and groundwater parameters that may be difficult to control. Therefore, a coniferous swamp community would be the contingent community if the soil and groundwater conditions are not adequate for bog regeneration. Coniferous bog or swamp is the target for the whole site, however, where trees do not successfully establish, the target community would be a shallow, open water wetland.

3.8.2.4 Zim South

The Zim South Site is 88 acres in Sections 26, 27, 34, and 35, Township 55 North, Range 18 West, in St. Louis County, approximately 16 miles southwest of Eveleth, and within the St. Louis River watershed. PolyMet proposes to restore the site to coniferous bog and shallow, open water wetland. Approximately 50

DESCRIPTION OF THE PROPOSED ACTION

acres of coniferous bog and 1 acre of shallow, open water would be created on the Zim South site. In addition, 3 acres of ditches would be filled, 5 acres of partially drained wooded areas would be restored, and 17 acres of forested woodland and 10 acres upland buffer would be preserved. Approximately 2 acres of roads and open ditches would not be restored. The overall objectives of the Zim North restoration plan would be to restore the native coniferous bog wetland community, restore the hydrologic connection between upstream watersheds and the restoration site, and disable the internal drainage system on site. As mentioned above, developing a bog community is highly dependent on soil and groundwater parameters that may be difficult to control. Therefore, a coniferous swamp community would be the contingent community if the soil and groundwater conditions are not adequate for bog regeneration. Coniferous bog or swamp is the target for the whole site, however, where trees do not successfully establish, the target community would be a shallow, open water wetland.

Initial activities at both sites would be focused on developing desired hydrological conditions through site grading to fill ditches and break drain tiles (Barr 2014c, 2014d). Restoration of wetlands include finding suitable donor bog materials, transporting materials to the site, spreading bog materials over areas to be restored, spreading fresh straw mulch over bog plant fragments, and applying slow-release fertilizer. Trees and shrubs would be planted 1 to 3 years after spreading of bog materials. In addition, several ponds would be excavated to a depth no greater than 6 feet to allow for development of shallow, open water wetland communities. Site management would include control of non-native and other invasive vegetation.

PolyMet would convey the land to the third party that performs the construction to create the wetland credits upon acceptance of the credits. This ownership is also subject to conservation easements that would be placed upon it during the mitigation period (Pylka 2013a).

4.0 Description of the Lands Affected by the Project

4.1 Federal Lands

The federal lands include approximately 2,719 acres at the 3,015-acre Mine Site and 3,776 acres bordering the Mine Site that are owned by the Government and administered by the Forest Service.

4.1.1 Mine Site

The Mine Site encompasses 3,015 acres; 2,719 acres are Government owned while 296 acres are privately owned. The Mine Site has little topographic relief. It consists of a mosaic of slightly elevated upland areas surrounded by wetlands, and slopes toward the east-northeast, in the direction of the Partridge River. About 57% of the Mine Site is upland habitat, and 43% is wetland habitat. Most upland habitat is associated with the central portion of the Mine Site. One Hundred Mile Swamp, northwest of the Mine Site, is the dominant feature on the landscape. The Partridge River drains this swamp and flows along and outside the northeastern and eastern boundary of the Mine Site (ENSR 2000, 2005).

Habitat observed on the Mine Site is typical of habitats associated with much of the Iron Range. Forest vegetation dominates the Mine Site (**Figure 9**; **Table 4**). Most forest stands contain trees that are 12 inches diameter-at-breast-height (dbh) or less.

The site can be divided into three general areas. The northwest area is dominated by lowland black spruce, with scattered stands of trembling aspen and balsam fir/trembling aspen; tamarack is also scattered throughout these stands. Most trees are estimated to be 60 years or older (USDA Forest Service 2000). Interspersed within forest stands are brush/young tree stands that were recently logged and provide habitat for white-tailed deer and moose. Young trees are generally up to 4 inches dbh and 10 years of age.

The northeastern area is dominated by nearly equal amounts of jack pine and black spruce, with scattered trembling aspen stands and speckled alder swamps (ENSR 2000, 2005). Although there are scattered black spruce stands containing trees greater than 60 years in age, most trees, especially jack pine, are 30 to 70 years in age (USDA Forest Service 2000a). There are a few recently logged areas within this area. Several large wetlands are found in this area. Most shrub/young tree habitat is associated with these wetlands and drainages.

The southern area contains a nearly equal mix of lowland and upland black spruce, jack pine, and trembling aspen, with some balsam fir and paper birch (ENSR 2000, 2005). Most tree stands are from 40 to 80+ years of age, although jack pine tree stands along Dunka Road are from 20 to 40 years of age.

Vegetation in the recently logged areas consists of grasses and ferns with trembling aspen saplings and speckled alder (ENSR 2000, 2005). The areas of more mature upland forests consist of jack pine, balsam fir, and trembling aspen, with lesser amounts of paper birch, red pine, and white pine. The mature lowland areas consist mainly of black spruce and tamarack growing on a bed of sphagnum moss and club moss with speckled alder, bog Labrador-tea, and leatherleaf. The open wetland areas consist of grasses, sedges, cattails, speckled alder, and pussywillow.

Approximately 1,719 acres of the Mine Site would be affected by the Project. **Table 4** shows the cover types that would be affected by the Project, using the MDNR Gap Analysis Program (GAP) land cover types

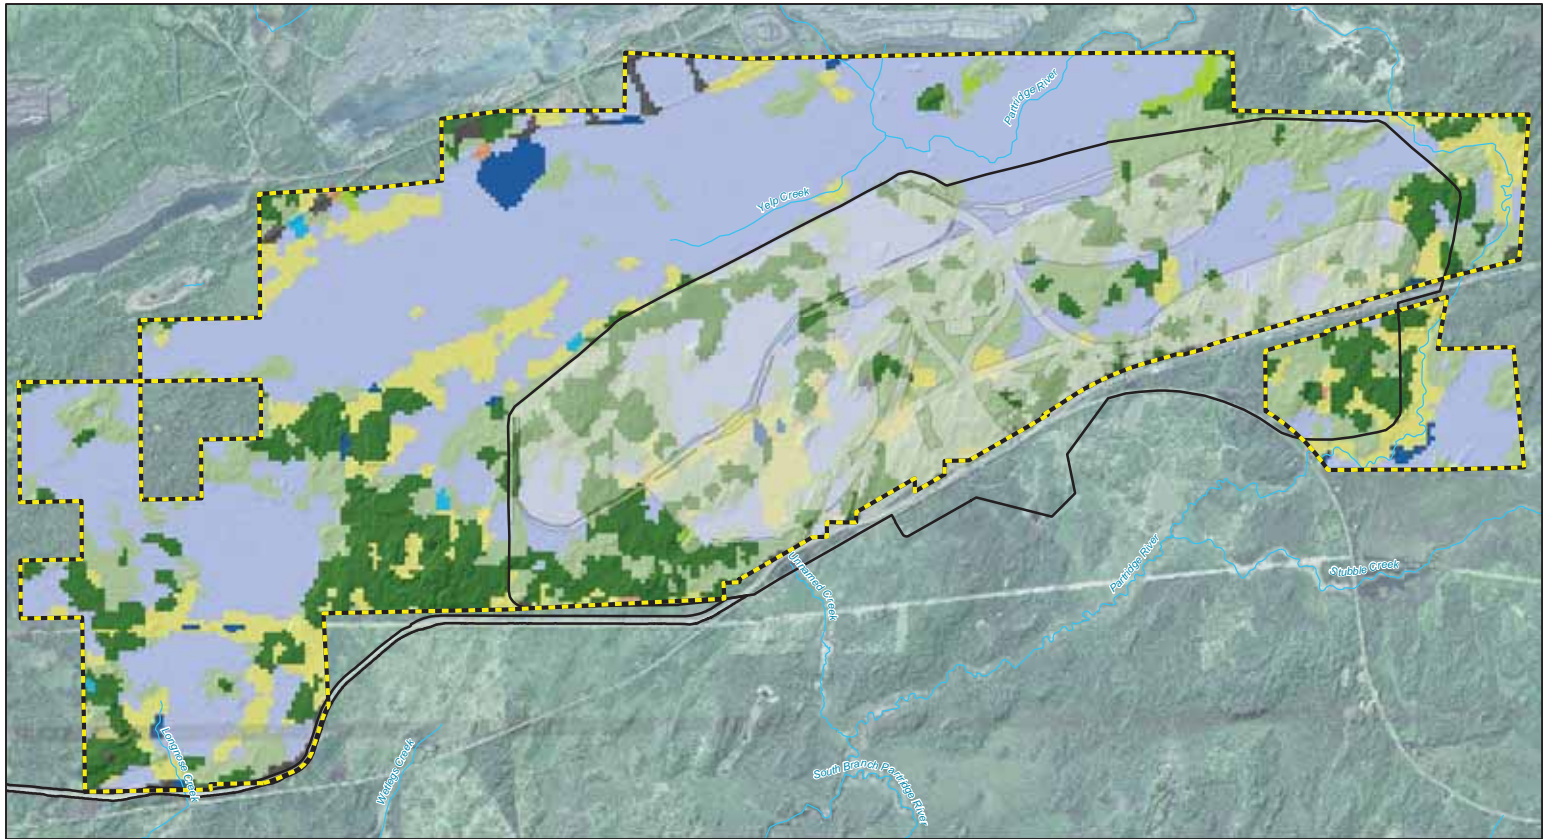

Figure 9
GAP Land Cover/Habitat Types - Federal Lands
 Biological Assessment for the NorthMet Project and Land Exchange
 St. Louis County, Minnesota

(MDNR et al. 2013). The GAP land cover system is a hierarchical land classification system that organizes vegetation communities into 1-acre blocks and was developed by the MDNR.

4.1.2 Federal Lands Surrounding the Mine Site

Federal lands surrounding the Mine Site encompass about 3,776 acres and border the Mine Site to the west, north, and east. This area has little topographic relief. The lands consist of a mosaic of slightly elevated upland areas surrounded by wetlands, and slope toward the east-northeast in the direction of the Partridge River. Most (76%) of the area is wetland habitat, including a portion of One Hundred Mile Swamp, although upland habitat (24%) is an important component in the western portions of the area (**Figure 9**). Yelp Creek flows from One Hundred Mile Swamp to the Partridge River, which flows around the northern, eastern, and southeastern edges of the federal lands, outside of the Mine Site (AECOM 2011a). Under the Proposed Action, the areas not disturbed by the Project on the lands adjacent to the Mine Site would be managed for wildlife habitat, including timber management.

Forest vegetation dominates the federal lands. Most forest stands contain trees that are 12 inches dbh or less. The area can be divided into three general parts (AECOM 2011a). The eastern portion is dominated by the Partridge River. Large stands of lowland black spruce with scattered northern white cedar and tamarack are found in low areas associated with the river. Emergent and shrub swamp speckled alder wetland is adjacent to most of the river. Stands of immature (trees from 5 to 11 inches dbh, and from about 10 to 80 years of age) and mature (trees greater than 11 inches dbh and over 80 years of age) mixed coniferous/deciduous forest, coniferous forest dominated by jack pine, and smaller patches of immature deciduous forest, are found at higher elevations (USDA Forest Service 2000a).

Table 4
GAP Cover Types Affected by the Project at the Mine Site

Cover Type	Affected Acres	Non-affected Acres	Total Cover Type Acres	Percent of Cover Type Affected
Upland coniferous forest	742	454	1,196	62
Lowland coniferous forest	437	344	781	56
Upland deciduous forest	355	293	648	55
Shrubland	133	109	242	55
Disturbed	44	84	128	34
Aquatic environments	6	7	13	47
Upland coniferous-deciduous forest	2	1	2	63
Cropland/grassland	<1	5	5	4
Lowland deciduous forest	0	<1	<1	0
Total	1,719	1,296	3,015	57

Source: MDNR et al. (2013).

The northern portion of the federal lands surrounding the Mine Site includes a portion of One Hundred Mile Swamp. The swamp is comprised of some young (trees less than 5 inches dbh and 10 years of age), but mostly immature and mature black spruce, northern white cedar, and tamarack forests. Northern white cedar is prevalent in the northcentral portion of the northern area, while black spruce and tamarack are more common

in the remaining areas. Scattered stands of speckled alder are associated with the swamp, as are bog and emergent wetlands, especially along the Partridge River.

There are scattered “islands” of mature deciduous and mixed coniferous/deciduous forest. Most of the forest stands are 90 years or older, with many of the remaining stands 70 to 90 years of age (USDA Forest Service 2000a).

The western portion of the federal lands surrounding the Mine Site is dominated by lowland immature black spruce forest in its center, bordered by bog wetlands and wetlands dominated by speckled alder and red-osier dogwood. A large area dominated by cattail is associated with the transmission line rights-of-way (ROW). Upland immature and mature deciduous and mixed coniferous/deciduous forest, with scattered stands of coniferous forest, surround the centrally located black spruce forest. Clearings comprised of grasses, forbs, and shrubs are associated with the transmission line ROW, while scattered low areas, dominated by emergent and shrub swamp wetland vegetation, are interspersed within upland forest habitats.

4.2 Plant Site and Transportation and Utility Corridors

The Plant Site encompasses about 4,515 acres, which includes the former LTVSMC processing plant, existing LTVSMC Tailings Basin, Area 1 Shop, Hydrometallurgical Residue Facility, and administration buildings.

The southwestern corner of the Plant Site, the former LTVSMC processing plant, has almost entirely been disturbed by past mining activities. No wetlands are present within this portion of the Plant Site, although there is a plant reservoir located east of the concentrator that is not regulated as a wetland (Poly Met 2014a). The regulated wetlands within the Plant Site include a total of 52 wetlands covering approximately 245 acres. About 147 acres would be directly impacted by filling or excavation. Approximately 61% (2,756 acres) of the Plant Site is disturbed and supports little vegetation. The remaining areas consist of trembling aspen and trembling aspen-paper birch forest (14%), aquatic habitat (14%), grass/shrubland (7%), upland coniferous forest (2%), and lowland coniferous forest (1%; **Figure 10**; MDNR et al. 2013).

The Dunka Road and Utility Corridor is approximately 108 acres and the Railroad Connection Corridor is approximately 12 acres. Because of prior use during the former LTVSMC taconite mining operation, the Dunka Road and Utility Corridor is now defined as having a “disturbed” cover type. The remaining MDNR GAP land cover types that are not disturbed include cropland/grassland (8%), shrubland (6%), and smaller acreages of the remaining types. A total of 25 wetlands, encompassing approximately 7 acres, have been identified within the Dunka Road and Utility Corridor (MDNR et al. 2013). Approximately 7 acres of wetlands would be directly affected.

4.3 Non-federal Lands

4.3.1 Hay Lake Lands

Hay Lake Lands are approximately 4,926 acres and have moderate topographic relief. The lands consists of a mosaic of slightly elevated upland areas surrounded by wetlands, and slope toward the east-northeast, in the direction of the Pike River (AECOM 2011b).

Most (59%) of Hay Lake Lands is wetland habitat, although upland habitat (41%) is an important component in the central and western portions of the lands (**Figure 11**). The Pike River, Hay Lake, and Little Rice Lake are dominant features of the landscape. The Pike River flows along the eastern boundary of the lands.

Figure 11
GAP Land Cover/Habitat Types -
Hay Lake Lands, Lake County Lands, and Wolf Lands 1 and 2
 Biological Assessment for the NorthMet Project and Land Exchange
 St. Louis County, Minnesota

Forest vegetation dominates Hay Lake Lands. Nearly all forest stands contain trees that are 12 inches dbh or less, and most of the upland trees are 8 inches dbh or less. The lands can be divided into four general habitats. The eastern portion is dominated by the Pike River. Floodplain associated with river is dominated by emergent wetland with sedge and grass habitat, and shrub swamp wetland with speckled alder habitat. Wetland areas to the west of the river are dominated by lowland black spruce forest, with scattered northern white cedar and tamarack, and shrub swamp wetlands, especially in areas with evidence of past disturbance by logging activities.

Higher elevations in the northern, central, and western portions of the lands are dominated by upland deciduous and mixed coniferous/deciduous forest. Upland forest stands in the northern, central, and southwestern portions of the lands are immature to mature in size and age, while stands in the western portion of the lands are young to immature in size and age, having been harvested in recent years. Most trees are estimated to be 60 years or younger. Two transmission line ROWs are found on the lands. Emergent wetland and upland grassland/shrubland vegetation dominates the ROWs. Abandoned logging roads are also found on the lands. Low areas along roads are dominated by emergent wetland vegetation consisting of sedges and grasses, while upland portions of roads are dominated by grasses and forbs.

4.3.2 Hunting Club Lands

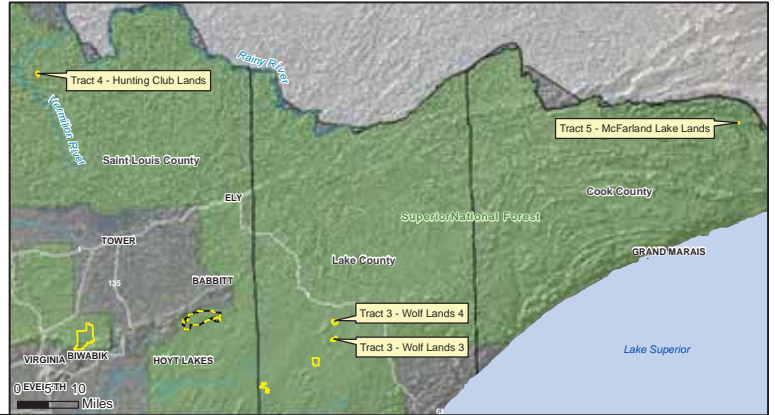

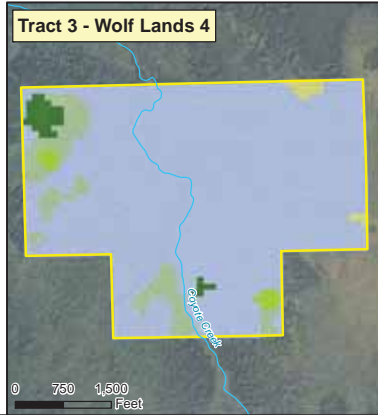

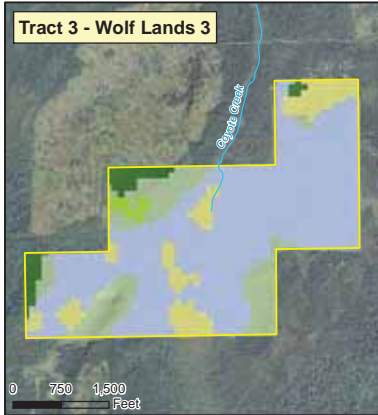

Hunting Club Lands are approximately 160 acres, of which about 64 acres are wetland (**Figure 12**). The lands drain to the north and then northeast via an unnamed creek. Several beaver dams are found along the creek. From this low area, the lands slope upward to the east and west. The lands consist primarily of shrub swamp wetland, with lesser amounts of emergent wetland, and upland immature and mature deciduous forests (AECOM 2011c).

Beaver ponds and dams are the dominant wetland features on the lands. Open water habitat is typical near the dams. Emergent vegetation, consisting of Canada bluejoint, narrow-leaved cattail, and sedges, is found in water from 12 to 24 inches deep, while speckled alder shrub swamp wetlands are found near ponds at water depths from 6 to 18 inches. Speckled alder makes up to 80% of the cover in the shrub swamp wetlands. A large immature black spruce forest is found in the middle of Hunting Club Lands. The midstory consists of speckled alder, while leatherleaf, bog Labrador-tea, and sphagnum moss are found below the speckled alder. Immature black ash is found in a drainage leading to wetlands on the lands.

Habitat in the northwestern and northeastern portions and near the southern boundary of the lands are comprised of upland mature mixed coniferous/deciduous forest, dominated by eastern white pine to 24 inches dbh, and paper birch and trembling aspen to 12 inches dbh. The midstory consists primarily of balsam fir, while beaked hazel is found in the shrub layer.

The eastern and southern portions of the lands consist of patches of upland young and immature trembling aspen. The midstory consists of beaked hazel, with scattered black spruce and balsam fir. There is little ground cover.

An “island” of trembling aspen-eastern white pine forest is found within the young/immature trembling aspen forest. It is mature forest comprised of trembling aspen and eastern white pine to 16 inches dbh and black spruce to 12 inches dbh. There are many downed trees and much woody debris on the ground.

Non-federal Lands	Lowland Deciduous Forest
Federal Lands	Non-vegetated
Shrubland	Upland Conifer Forest
Aquatic Environments	Upland Conifer-Deciduous mix
Crop/Grass	Upland Deciduous Forest
Lowland Conifer Forest	

Figure 12
GAP Land Cover/Habitat Types - Hunting Club Lands, McFarland Lake Lands, and Wolf Lands 3 and 4
 Biological Assessment for the NorthMet Project and Land Exchange
 St. Louis County, Minnesota

4.3.3 Lake County Lands

Lake County Lands consist of Lake County Lands North and Lake County Lands South.

4.3.3.1 Lake County Lands North

Lake County Lands North is approximately 265 acres, of which about 209 acres are wetland (**Figure 11**). The lands have moderate topography, with the terrain generally sloping toward the southwest and Pine Lake. Lake County Lands North consists of two small areas to the north, and a single, small area to the south that is adjacent to Wolf Lands 1. The lands are comprised of mostly wetland habitat, except for areas of upland habitat on the northern portion of the northern area and on portions of the southern area. Portions of the lands have recently been logged. Wetland habitat consists mostly of immature coniferous forest, with lesser amounts of mature mixed coniferous/deciduous forest and shrubland. Upland habitat is dominated by mature deciduous and immature deciduous forests (AECOM 2011c).

Wetlands are comprised primarily of immature northern white cedar and black spruce with lesser amounts of tamarack, although several drainages also contain black ash. The midstory consists of balsam fir and black spruce, while speckled alder, leatherleaf, and bog Labrador-tea are found in the shrub layer. Club moss and sphagnum moss cover most of the ground.

Shrub swamp and emergent wetland habitats are also found on the lands. Shrub swamp habitat is associated with several drainages, a beaver pond, a bog area, and recently logged areas, while emergent wetland habitat was found near the beaver pond and on recently logged areas. Shrub swamp wetlands are dominated by speckled alder. Vegetation in the emergent wetlands consists of sedges and Canada bluejoint, with scattered black spruce, northern white cedar, tamarack, and speckled alder.

Upland habitats are comprised of immature and mature paper birch and black spruce, while recently logged areas supported young paper birch stands or shrub habitat. The midstory cover is comprised of balsam fir, black spruce, and beaked hazel. Young paper birch with scattered young trembling aspen and scattered immature paper birch are in areas that had been recently logged.

Older forests contain large amounts of downed woody material; this material is mostly absent in logged areas. Tree wind-throw is common in forest stands adjacent to the clearcuts, and walking in these forests is difficult due to downed trees and woody debris, and the dense stand of balsam fir, black spruce, and northern white cedar in the midstory.

4.3.3.2 Lake County Lands South

Lake County Lands South is approximately 117 acres, of which about 74 acres are wetland (**Figure 11**). The lands are relatively flat in the northwestern section, rise in elevation to the northeast, and fall in elevation to the southeast. Water flows from west to east. A series of beaver dams and ponds dominate the landscape. Several areas have been recently logged and shrubland is the dominant upland habitat (AECOM 2011c).

Forested wetlands dominate the western and southeastern portions of the lands and are comprised of immature and mature black spruce and northern white cedar, although immature tamarack is found in some forest stands and immature black ash is an important component of several drainages. The midstory consists of balsam fir and black spruce. Speckled alder, leatherleaf, bog Labrador-tea, and red-osier dogwood are common shrubs,

while sphagnum moss covers most of the ground. Forests in the northwestern section contain a dense mix of northern white cedar and black spruce with scattered black ash in the drainages. The northwestern portion of this section is dominated by mature northern white cedar.

Five beaver ponds were found on the lands. These ponds are comprised of open water with scattered dead spruce surrounded by emergent wetland dominated by sedges, narrow-leaved cattail, woolgrass, and Canada bluejoint, or by dense stands of speckled alder in more shallow areas. Shallower drainages, especially in areas that have been logged, are covered by speckled alder, sedges, and narrow-leaved cattail.

Most upland areas have been recently clearcut, with the exception of the southwestern portion of the lands. This area has been partially thinned, leaving areas where mature paper birch, black spruce, jack pine, eastern white pine, and northern white cedar trees remain, ranging from 12 to 24 inches dbh. Balsam fir and beaked hazel are found in the midstory, while forbs and grasses cover the ground layer. Because of recent logging activity, woody debris and large downed trees are abundant.

4.3.4 McFarland Lake Lands

McFarland Lake Lands are about 31 acres on a hillslope that rises from 1,483 feet above mean seal level at McFarland Lake to 1,778 feet above mean seal level on the western boundary of the lands. Rocky cliffs, about 150 feet in height, are found at the top of the hillslope and large boulders are found on the hillslope (AECOM 2011b).

McFarland Lake Lands are dominated by deciduous and mixed coniferous/deciduous forest habitats (**Figure 12**). Tree sizes and ages range from immature to mature. Some logging has occurred at the top of the hillslope along the western boundary of the lands.

4.3.5 Wolf Lands

Wolf Lands total 1,576 acres and consist of four parcels, Wolf Lands 1, 2, 3, and 4.

4.3.5.1 Wolf Lands 1

Wolf Lands 1 is approximately 126 acres, of which about 90 acres are wetland (**Figure 11**). Most upland habitat consists of mature coniferous and deciduous forest, while most wetland habitat consists of immature coniferous forest. The lands are relatively flat but slope gently downward toward the southwest. The lands are adjacent to Lake County Lands North (AECOM 2011c).

Wetland communities are comprised primarily of young and immature forests in nearly equal amounts. Young forests are comprised of black spruce, with scattered northern white cedar and tamarack. Young forests have characteristics of more open bogs, as tree cover is sparse, trees are short, and most of the ground is covered by bog Labrador-tea and leatherleaf, and sphagnum moss. In immature forests, the canopy is dominated by 6 to 10 inches dbh black spruce, with tamarack and northern white cedar also present. The midstory consists of balsam fir and black spruce, while speckled alder, leatherleaf, bog Labrador-tea, and red-osier dogwood dominate the shrub layer. Club moss and sphagnum moss cover most of the ground (AECOM 2011c).

Upland mixed coniferous/deciduous immature and mature forest is found in the southwestern portion of the lands. Paper birch and trembling aspen cover about half of the area, and the midstory consists of mostly balsam fir; beaked hazel, and red-osier dogwood.

4.3.5.2 Wolf Lands 2

Wolf Lands 2 is approximately 769 acres, of which about 706 acres are wetland (**Figure 11**). The lands consist of gently undulating terrain and slope toward the southwest. Water generally flows to the southwest and to Mary Ann Creek, Wenho Creek, and Greenwood Lake. The lands consist primarily of wetlands comprised of immature black spruce and northern white cedar forest, while shrub swamp comprised of speckled alder also is common. Black spruce is the dominant tree in wetlands in the northern and eastern portions of the lands, while northern white cedar is more prevalent in other portions of the lands (AECOM 2011c). Several drainages are dominated by speckled alder or have a black ash component, while emergent wetland habitat is associated with beaver ponds. Most upland habitat consists of immature mixed coniferous/deciduous forest.

Wetland immature forests are of three types: black spruce dominant, a mix of black spruce and northern white cedar, or northern white cedar dominant. Canopy trees range from 4 to 8 inches dbh. The midstory consists of young black spruce, northern white cedar, and balsam fir. Bog Labrador-tea comprises 10 to 30% of the low shrub cover, while sphagnum moss often covers more than 80% of the ground.

Several drainages are dominated by shrub swamp vegetation. These drainages generally have a sparse overstory of black spruce, northern white cedar, and tamarack. Speckled alder and young trees are in the midstory while low shrub cover consists of bog Labrador-tea.

Beaver dams and ponds are found in the southeastern portion of the lands. Typically, open water is adjacent to the dams, with emergent wetland surrounding the open water and shrub swamp wetland upstream of the dams.

Upland habitat in the northern portion of the lands consists of an overstory of young and immature mixed coniferous/deciduous forest over a shrub layer of beaked hazel. Some of the upland area on the northern portion of the lands has been logged. Upland habitat is also found in the southern portion of the lands and is comprised of paper birch, trembling aspen, and black spruce, over a midstory of balsam fir and shrub layer of beaked hazel.

4.3.5.3 Wolf Lands 3

Wolf Lands 3 is approximately 277 acres, of which about 233 acres are wetland (**Figure 12**). The lands are relatively flat and Coyote Creek begins its northward flow within the lands. Wetlands are dominated by shrub swamp and immature coniferous forest habitat, while uplands consist of mostly shrubland and immature deciduous forest (AECOM 2011c).

About half of the lands have been recently logged. Logged wetlands are dominated by grasses, forbs, and low growing shrubs, including red-osier dogwood and speckled alder. In shrub swamp wetlands, speckled alder dominates. Bog Labrador-tea is often thick in areas where there is a dense cover of speckled alder. Vegetation on logged uplands includes grasses, forbs, and beaked hazel.

In the unlogged areas, wetland forests are comprised of immature black spruce. In the northern portion of the lands, black spruce is co-dominant with tamarack; in the rest of the lands, tamarack is present in the canopy

but in much lower amounts. The midstory consists of balsam fir and black spruce, while the shrub layer is dominated by bog Labrador-tea, over a ground layer of nearly continuous sphagnum moss with scattered grasses and forbs. There are numerous downed trees and much woody debris associated with tree wind-throw in areas adjacent to the clearings.

Coyote Creek is bordered by emergent sedge meadow wetland comprised of sedges, narrow-leaved cattail, and Canada bluejoint. There are also scattered young tamarack and northern white cedar, as well as scattered patches of speckled alder and bog Labrador-tea. The emergent wetland is bordered by dense speckled alder. Water depth in the emergent and shrub swamp wetlands is about 18 to 24 inches.

Upland areas within the lands have been logged recently. Most of these areas have few trees remaining, though some areas still support paper birch up to 16 inches dbh and scattered balsam fir. The upland habitat along the boundary of the lands consists of both young and mature paper birch with scattered black spruce and northern white cedar, over an understory comprised of balsam fir.

4.3.5.4 Wolf Lands 4

Wolf Lands 4 is approximately 405 acres, of which about 363 acres are wetland (**Figure 12**). Coyote Creek bisects the lands, while the Stony River is found about 2,000 feet northwest of the lands. Timber harvests have recently occurred along the western border of the lands. Wetland habitats are dominated by immature coniferous forest and shrub swamp, while upland habitat consists primarily of mature deciduous forest (AECOM 2011c).

Coniferous forest dominates the wetland habitat. Black spruce forest dominates in the northern half of the lands, while northern white cedar is more prevalent in the southern half of the lands. Immature-size trees prevail over most of the lands, but patches of young black spruce are more common in the northeastern portion of the lands, and young northern white cedar and black spruce are more common in the southwestern portion of the lands. Emergent communities comprised of sedges and Canada bluejoint, and shrub swamp communities comprised primarily of speckled alder, are found in floodplains that border Coyote Creek.

Immature black spruce and black spruce/northern white cedar wetlands are dominated by trees ranging from 4 to 8 inches dbh. Scattered young and immature tamarack is also found in these wetlands. The low shrub layer is nearly continuous, and is comprised of leatherleaf, bog Labrador-tea, and other vegetation. Sphagnum and club mosses cover most of the ground.

Shrub swamp is dominated by speckled alder, with scattered black spruce, tamarack, and northern white cedar in the overstory. Leatherleaf and bog Labrador-tea cover comprise about 40 to 50% of the shrub layer.

Upland habitat consists of immature and mature paper birch and some black spruce. Trees are up to 18 inches dbh, although a 30 inches dbh jack pine and several large red pines to 24 inches dbh are found on the lands. Balsam fir is common in the midstory, while beaked hazel and raspberry are dominant in the shrub layer. In areas that have been logged recently, young paper birch is common over a shrub layer of beaked hazel, raspberry, and bog Labrador-tea.

4.4 Wetland Mitigation Lands

4.4.1 On-site Restoration

In accordance with the USACE *St. Paul District Policy for Wetland Compensatory Mitigation in Minnesota* and state guidelines, the potential for creating wetlands on-site was considered first. Approximately 102 acres of onsite wetland creation opportunities were identified that may occur at Project closure (Barr 2012, 2014d).

4.4.2 Off-site Mitigation

Three sites were identified to develop compensatory wetland mitigation for the Project. These are the 1,070-acre Aitkin Site, the 530-acre Hinckley Site, and the 569-acre Zim Site, which includes 481-acre Zim North (481 acres) and Zim South (88 acres) (**Figure 2**; Barr 2014a, 2014b, 2014c, 2014d). Of these 2,169 acres, about 1,603 acres would be restored to wetland habitat.

4.4.2.1 Aitkin Site

The Aitkin Site is a 1,070-acre planned mitigation area with about 876 acres of agricultural production, 46 acres of roads, buildings, and ditches, 48 acres are grassland, and 13 acres of forest (**Figure 13**). The types of habitats that would be restored on the site are discussed in Section 3.8.2.

4.4.2.2 Hinckley Site

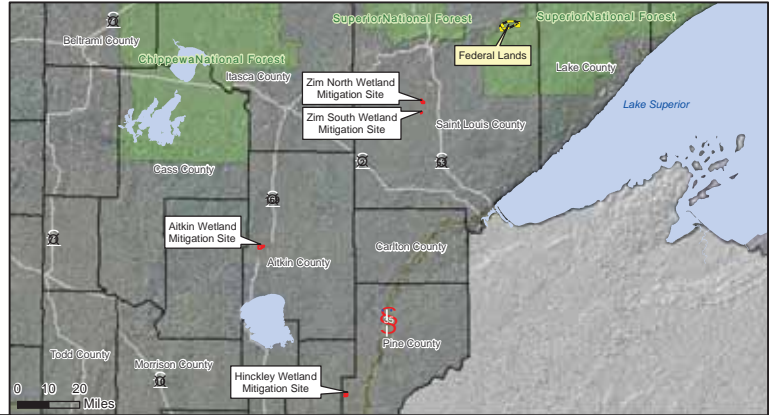

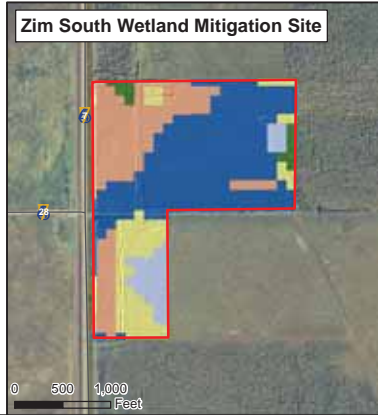

The Hinckley Site is a 530-acre planned mitigation area. About 357 acres are in agricultural (sod) production; 95 acres are forestland, shrubland, and wet meadow/sedge wetland; 42 acres are upland forestland; 28 acres are comprised of roads, railroad tracks, buildings, and ditches; and 8 acres are grassland (**Figure 13**). The types of habitats that would be restored on the site are discussed in Section 3.8.2.

4.4.2.3 Zim North

The Zim North Site is approximately 481 acres, including about 393 acres of fields and open areas, 79 acres of woodlands, and 8 acres of buildings, roads, and borrow areas (**Figure 13**). This site primarily is used for sod production (Barr 2014c, 2014d). The types of habitats that would be restored on the site are discussed in Section 3.8.2.

4.4.2.4 Zim South

The Zim South Site is approximately 88 acres, including about 79 acres of fields and open areas, 8 acres of woodlands, and 2 acres of buildings, roads, and borrow areas (**Figure 13**). This site primarily is used for sod production (Barr 2014c, 2014d). The types of habitats that would be restored on the site are discussed in Section 3.8.2.

5.0 Biological Assessment Methodology

5.1 Literature Review

5.1.1 Biological Assessments and Biological Opinions

Several recent BAs and BOs have been prepared for proposed actions on or near the federal and non-federal lands and provided information that is used in this BA. These are:

- *Federally Listed Threatened and Endangered Species Programmatic Biological Assessment for the Revised Forest Plan Chippewa and Superior National Forests* (2004 Forest Plan BA; USDA Forest Service 2004b) – evaluated potential impacts to lynx and wolf and their critical habitats from proposed vegetation management activities in the Chippewa and Superior National Forests, including federal lands.
- *Biological Opinion for the Revised Land and Resource Management Plans (Forest Plans) for the Chippewa and Superior National Forests* (USDOI USFWS 2004) – provided the USFWS evaluation of the potential effects to lynx and wolf and their critical habitats from proposed vegetation management activities in the Chippewa and Superior National Forests, including Project lands.
- *Whyte Project Biological Assessment* (USDA Forest Service 2006) – evaluated potential impacts to lynx and wolf and their critical habitats from proposed vegetation management activities in areas that include Wolf Lands 2, 3, and 4.
- *Final Biological Assessment for the Proposed Mesaba Energy Project* (AECOM 2009a) – evaluated potential impacts to lynx and wolf and their critical habitats for a proposed electric generating facility about 3 miles southwest of the Plant Site.
- *Tracks Forest Management Project Laurentian Ranger District, Superior National Forest, Biological Assessment* (Tracks Project BA; USDA Forest Service 2010) – evaluated potential effects to special status plants and animals from proposed forest management activities on the Tracks Forest Management Project (Tracks Project) area east of Hoyt Lakes and north of Brimson, Minnesota, in Lake and St. Louis Counties. The Track Project area encompasses about 152,000 acres of land of which approximately 78,000 acres are in the Superior National Forest.
- *Draft Biological Assessment for the Federal Hardrock Mineral Prospecting Permits Draft EIS* (2011 Hardrock Mining BA; USDA Forest Service 2011a) – evaluated potential impacts to lynx and wolf and their critical habitats from proposed hardrock mineral prospecting activities in the Superior National Forest, including the federal land.
- *Programmatic Biological Assessment for Federally-listed Species: Gray Wolf, Canada Lynx, and Their Critical Habitats for the Superior National Forest* (USDA Forest Service 2011b) – evaluated potential impacts to lynx and wolf and their critical habitats from proposed implementation of management direction for the Superior National Forest Plan, including the federal land.

- *Biological Opinion Mesabi Nugget Prevention of Significant Deterioration Permit* (USDOJ USFWS 2009a) – evaluated potential impacts to lynx and wolf and their critical habitats from actions at the Mesabi Nugget facility immediately west of the Plant Site.
- *Biological Opinion Northshore Mine Eastern Progressions and CSAH 70 Relocation St. Louis County, Minnesota* (USDOJ USFWS 2011a) – evaluated potential impacts to lynx and wolf and their critical habitats from actions east of the Northshore Mine and about 5 miles northeast of the Mine Site.

5.1.2 Other Sources of Information

This section is based on information (and references cited therein) in the following documents:

5.1.2.1 General

- *Consultation Handbook: Procedures for Conducting Consultation and Conference Activities under Section 7 of the Endangered Species Act* (USDOJ USFWS and NMFS 1998).

- *Endangered and Threatened Wildlife and Plants; Final Rule To Identify the Western Great Lakes Populations of Gray Wolves as a Distinct Population Segment and To Revise the List of Endangered and Threatened Wildlife* (USDOJ USFWS 2009b).
- *Endangered and Threatened Wildlife and Plants; Reinstatement of Protections for the Gray Wolf in the Western Great Lakes in Compliance With Settlement Agreement and Court Order* (USDOJ USFWS 2009c).
- *Endangered and Threatened Wildlife and Plants; Proposed Rule To Revise the List of Endangered and Threatened Wildlife for the Gray Wolf (*Canis lupus*) in the Eastern United States, Initiation of Status Reviews for the Gray Wolf and for the Eastern Wolf (*Canis lycaon*;* USDOJ USFWS 2011b).

5.2 Database Inquiries

The MDNR Natural Heritage Information System Rare Features Database was queried for federally protected species documented within 1 mile of the federal and non-federal lands and Wetland Mitigation Sites (MDNR 2014a). The MDNR lynx database was also reviewed for lynx sightings that have occurred in the vicinity of these areas between 2000 and 2006 (MDNR 2007). The Natural Resources Research Institute (NRRI) lynx website was reviewed for records of radiomarked lynx within the study area (NRRI 2012). The Superior National Forest's lynx genetic reference database was also reviewed for records of lynx occurrence on or near the federal and non-federal lands and Wetland Mitigation sites.

5.3 Consultation with Biologists with Local Knowledge of the Species

Telephone and in-person interviews were conducted with agency and other personnel with knowledge of lynx in the region, including staff with the MDNR, Forest Service, USFWS, and University of Minnesota. The

information received from these contacts was used to gain information on lynx and wolf likely to be found in the areas of interest.

5.4 Field Studies

Canada lynx winter tracking surveys have been conducted in the vicinity of the Mine Site, including a 2006 survey at the Mine Site (ENSR 2006) and at sites about 6 miles east of the Mine Site (Barr 2011).

5.4.1 Project Lynx Survey

A survey was conducted for lynx within a radius of 6 miles of the Project during January through March of 2006. This area was identified by the USFWS as the minimum area that needed to be assessed to identify lynx that could be impacted by the Project (Burke 2006). The USFWS felt that lynx having territories further than 6 miles from the mine project would likely not be directly affected by the Project.

Six hundred sixteen miles of transect were surveyed in seven townships in and around the Project. Tracks and scat of four female lynx were identified during the survey, concentrated in areas approximately 5 miles south and east of the Mine Site. Lynx sign was most common in dense coniferous forests of balsam fir and jack pine. ENSR (2006) concluded that at least three lynx resided near the Mine Site.

5.4.2 Other Lynx Surveys near Project Area

A lynx survey was conducted for the Birch Lake Project and Maturi Project for Franconia Minerals Corporation, which is about 12 miles northeast of the Mine Site. Several lynx were found during the study, based on DNA analysis of scat samples and track locations. Open bog and stunted black spruce forest and jack pine and eastern white cedar cover provided habitat for snowshoe hare and lynx (Barr 2011).

5.4.3 Other Field Surveys

The Forest Service and other biologists with an interest in lynx and wolf have conducted informal track and scat surveys on or near the federal and non-federal lands and Wetland Mitigation Sites, and their data are included in this BA. These included radiotelemetry surveys of lynx conducted by the NRRI (2012) and surveys of wolf conducted by the International Wolf Center (2012).

General wildlife surveys were conducted for the federal lands in 2000, 2004 2008, and 2009 (ENSR 2000, 2005; AECOM 2009, 2011a); and for the non-federal lands in 2009 and 2010 (AECOM 2011b, c). These surveys included track surveys for Canada lynx and the results of these surveys are included in the BA.

Wildlife habitat features on the federal and non-federal lands, including plant species composition and structure and special features (snags, downed woody debris, rock outcrops, wetlands, and deer snow-intercept thermal cover) were recorded during field surveys. In particular, species composition, density, and size (dbh) of trees and shrubs near survey areas were noted, and the use of snags and other special habitat features by wildlife. The location of special features was recorded using Global Positioning System units. This information was recorded on aerial photographs, and, in conjunction with information on shrubs and herbaceous vegetation collected during surveys, was used to prepare habitat maps of the project lands.

The USFS Superior National Forest staff conducted surveys for the northern long-eared bat at three general locations in the Project area in July and August 2014 (USDA Forest Service 2014a). The three Project areas included the Mine Site, the Plant Site, and the Dunka Road and Utility Corridor. Survey methods utilized passive sonic (Anabat) detectors on the Mine Site and Dunka Road and Utility Corridor. At the Plant Site, the methods were primarily direct observation of bat species, supplemented by passive sonic detectors when feasible. The surveys found northern long-eared bats present at the Mine Site, Plant Site, and the Dunka Road and Utility Corridor.

Survey data confirmed that northern long-eared bats utilize the Mine Site and the Dunka Road and Utility Corridor for foraging and travel to and from foraging and roost sites. The Mine Site may also contain roost sites; however, the 2014 Forest Service surveys found no conclusive evidence of roost sites. The direct observations and passive sonic survey data suggested that northern long-eared bats used the Plant Site buildings for foraging, and that the Coarse Crusher and Concentrator Buildings “have potential for limited roost sites” (USDA Forest Service 2014a). No conclusive evidence of roost sites was found in the Plant Site buildings.

In addition, the 2014 USFS surveys and examination of the Mine Site, Plant Site buildings, and the Dunka Road and Utility Corridor found no evidence of northern long-eared bat hibernacula, or conditions suitable for hibernacula (USDA Forest Service 2014a).

In the spring of 2014, the Forest Service Superior National Forest staff and MDNR staff, with additional funding from USFWS, conducted a pilot project to describe summer habitat use by northern long-eared bats in Minnesota. Surveys were conducted at 12 sites, five of which were on the Superior National Forest. The survey captured six of the seven species of bats known to occur in Minnesota; tri-colored bat was the only species not captured. The most frequently captured bats were little brown bats (45%), and northern long-eared bats (22%) (Forest Service 2014b).

Acoustic surveys for bats were conducted as part of wildlife surveys for the federal and non-federal lands (AECOM 2011a, b, c). No effort was made to determine the species of bat making the echolocation. Seven bat species could occur in the Project area—northern long-eared bat, little brown myotis, big brown bat, tri-colored bat, silver-haired bat, eastern red bat, and hoary bat. Echolocations recorded during the surveys could have come from any of these seven bat species.

Echolocation surveys were conducted at five stations on the federal lands, although only four stations gave usable information due to rainfall during the survey at one station. Recordings indicated the presence of bats at all sites, with the greatest number of echolocations occurring at open water sites associated with the Partridge River and an unnamed creek, and the fewest echolocations at emergent wetlands covered with water and some aquatic vegetation.

Recordings on Hay Lake Lands showed that most echolocations occurred at an emergent wetland with open water (814 echolocations, mostly feeding activity). Moderate numbers of echolocations were recorded at the two sites along the Pike River (164 echolocations at the north Pike River site, 230 echolocations at the middle Pike River site; feeding activity was moderate), and at two small emergent wetland ponds with limited open water (64 and 181 echolocations; AECOM 2011b). An echolocation site to the south of Hay Lake Lands was located at a small patch of open water associated with an old beaver pond; 72 echolocations were recorded at this site. No echolocation surveys were made on Hunting Club Lands, Lake County Lands, and Wolf Lands as

surveys were conducted in November and bats would have already migrated from the area. Surveys were also not conducted at McFarland Lake Lands, although bats likely forage over McFarland Lake.

Acoustic surveys for bats have also recently been conducted on the federal lands by the Superior National Forest and the NRRI, but analysis has not been completed to determine the species making the calls.

Project effects on lynx, northern long-eared bat, and wolf habitat use were based on habitat classification systems developed by the MDNR and Forest Service. The primary GAP land cover types on the federal lands are lowland coniferous forest (46%), upland coniferous forest (25%), and upland deciduous forest (17%). On the non-federal lands, GAP land cover types include lowland coniferous forest (41%), shrubland (26%), and upland deciduous forest (17%).

The Forest Service designates and maintains data about Management Indicator Habitat (MIH) types on federal lands. The MIHs are based on forest type, including dominant species, stand age class, and stand condition. There are 14 MIHs, of which 13 MIHs pertain to forest habitats and 1 MIH pertains to aquatic habitats. A subset of these MIH types was used for the analysis of effects in the BE, including upland forest types (MIH 1; jack pine, red pine, white pine, balsam fir/trembling aspen-paper birch, black spruce-balsam fir, black spruce-jack pine, northern hardwoods, including oak and maple, trembling aspen, paper birch, and trembling aspen-black spruce-balsam fir); upland coniferous forest (MIH 5; all upland conifer and conifer-dominated mixed forest types); lowland black spruce-tamarack forest (MIH 9; all lowland conifer and lowland mixed conifer types dominated by black spruce or tamarack); and aquatic habitats (MIH 14; lakes, rivers, streams, pond, marshes or pools [permanent, intermittent, or seasonal]). A smaller subset of all MIH types were used for this analysis of effects to lynx, northern long-eared bat, and wolf, including upland forest (MIH 1), upland coniferous forest (MIH 5), lowland black spruce-tamarack forest (MIH 9), and aquatic habitats (MIH 14).

6.0 Baseline Analysis and Assessment of Effects

Section 6 includes background information and an analysis of the effects of the Project on lynx, northern long-eared bat, and wolf. The first part of each section provides background information on lynx and wolf abundance and distribution, habitat requirements, reproductive biology and life history, and current status and presence/absence of designated critical habitat. This is followed by a discussion of potential beneficial, direct, indirect, interdependent, and interrelated threats to lynx, northern long-eared bat, and wolf. Effects that are unrelated to the Project and that may result in cumulative effect as a result of the Project, are presented in Sections 6.1.4, 6.2.4, and 6.3.4, Analysis of Cumulative Effects. These effects are defined as follows:

- Beneficial – Effects of an action that are wholly positive, without any adverse effects, on a listed species or designated critical habitat. Determination that an action will have beneficial effects is a “may effect” situation.
- Direct – The direct or immediate effects of the project on the species or its habitat. Direct effects result from the proposed action including the effects of interrelated actions and interdependent actions.
- Indirect – Effects caused by or resulting from the proposed action that are later in time, and are reasonably certain to occur. Indirect effects may occur outside of the area directly affected by the action.
- Interdependent – Effects that result from an activity that has no independent utility apart from the action under consideration.
- Interrelated – Effects that result from an activity that is part of the proposed action and depends on the proposed action for its justification.
- Cumulative – Include the effects of future state, tribal, local, or private actions that are reasonably certain to occur in the action area considered in this BA. Future federal actions that are unrelated to the proposed action are not considered in this section because they require separate consultation pursuant to Section 7 of the ESA. Cumulative effects are discussed in Sections 6.1.4, 6.2.4, and 6.3.4.

For a more detailed discussion of types of effects, see USDOJ USFWS and NMFS (1998).

The effects assessment is based on the following factors:

- dependency of the species on specific habitat components,
- habitat abundance,
- population levels of the species,
- degree of habitat impact, and
- potential to mitigate for an adverse effect.

For the purposes of this assessment, the action area for direct and indirect effects includes those areas within 6 miles of Project, or approximately 250 mi². This area was identified by the USFWS as the minimum area that

needed to be assessed to identify lynx that could be impacted by the Project (Burke 2006). In addition, we have provided information on lynx and wolf found within about 6 miles of the federal lands, non-federal lands, and Wetland Mitigation Sites.

6.1 Canada Lynx

6.1.1 Environmental Baseline

6.1.1.1 Species Description and Status and Critical Habitat Status

The lynx is a medium-sized cat with long legs. Adult males average 22 pounds in weight and 33.5 inches in length (head to tail), and females average 19 pounds and 32 inches (Quinn and Parker 1987). The lynx's long legs and large feet make it highly adapted for hunting in deep snow.

The bobcat is a North American relative of the lynx. Compared to the lynx, the bobcat has smaller paws, shorter ear tufts, and a more spotted pelage (coat), and only the top of the tip of the tail is black. The paws of the lynx have twice the surface area as those of the bobcat. The lynx also differs from the bobcat in its body proportions; lynx have longer legs, with hind legs that are longer than the front legs, giving the lynx a "stooped" appearance (Quinn and Parker 1987). Bobcats are largely restricted to habitats where deep snows do not accumulate (Koehler and Hornocker 1991). Hybridization (breeding) between lynx and bobcat was first documented in 2002 in Minnesota (Schwartz et al. 2004).

Classification of the lynx has been subject to revision. In accordance with Wilson and Reeder (1993), the USFWS currently recognizes the lynx in North America as *Lynx canadensis*. The USFWS previously used the scientific name *L. lynx canadensis* for the lynx (Jones et al. 1992). Other scientific names still in use include *Felis lynx* or *F. lynx canadensis* (Jones et al. 1986, Tumlison 1987).

On March 24, 2000, the lynx was federally listed as a threatened species in several states in the Northeast, Great Lakes Region (including Minnesota), and Southern Rockies (USDOJ USFWS 2000a). On November 9, 2006, the USFWS designated 317 mi² as critical habitat in Voyageurs National Park (USDOJ USFWS 2006a). On February 25, 2009, the USFWS re-designated lynx critical habitat to include portions of Cook, Koochiching, Lake, and St. Louis Counties, including portions of the federal lands, and all of the non-federal lands. A total of 8,065 mi² were designated as critical habitat in 2009 (USDOJ USFWS 2009a). However, the designated critical habitat does not include lands immediately north of the Project which are part of the Iron Range and have been disturbed by past and ongoing mining activities (**Figure 14**). The Wetland Mitigation Sites also are not included within designated critical habitat. Lynx and/or their sign (scat, tracks) have been observed on or near the federal and non-federal lands, but not near the Wetland Mitigation Sites.

6.1.1.2 Distribution

The historical and present range of the lynx, north of the contiguous U.S., includes Alaska and the portion of Canada extending from the Yukon and Northwest Territories south to the U.S. border and east to New Brunswick and Nova Scotia. In the contiguous U.S., lynx historically occurred in the Cascades Range of Washington and Oregon; the Rocky Mountain Range in Montana, Wyoming, Idaho, eastern Washington,

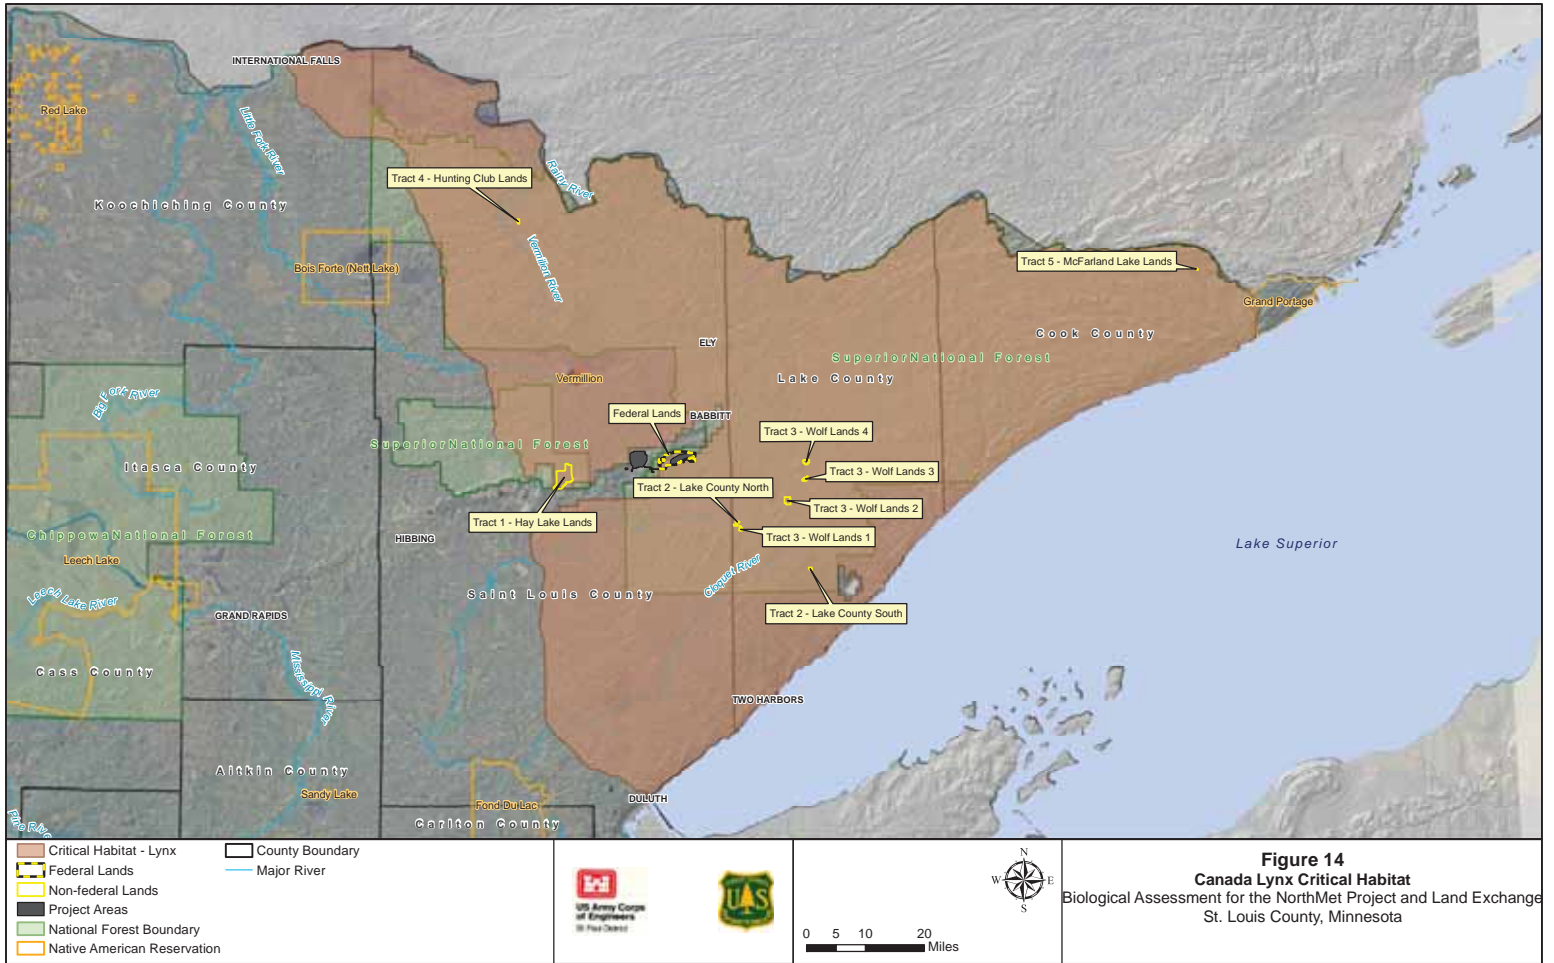

Figure 14
Canada Lynx Critical Habitat
 Biological Assessment for the NorthMet Project and Land Exchange
 St. Louis County, Minnesota

eastern Oregon, northern Utah, and Colorado; the western Great Lakes Region; and the northeastern U.S. region from Maine southwest to New York (**Figure 15**; McCord and Cardoza 1982, Quinn and Parker 1987).

In the contiguous U.S., the distribution of the lynx is associated with the southern boreal forest, comprised primarily of subalpine coniferous forest in the West and mixed coniferous/deciduous forest in the East (Aubry et al. 2000). In Canada and Alaska, lynx inhabit the classic boreal forest ecosystem known as the taiga (McCord and Cardoza 1982, Quinn and Parker 1987, Agee 2000, McKelvey et al. 2000a). Within these general forest types, lynx are most likely to persist in areas that receive deep snow, for which the lynx is highly adapted (Ruggiero et al. 2000).

Lynx in the contiguous U.S. are part of a larger metapopulation whose core is located in the northern boreal forest of central Canada; lynx populations emanate from this area (Buskirk et al. 2000a, McKelvey et al. 2000a, b). The boreal forest extends south into the contiguous U.S. along the Cascade and Rocky Mountain Ranges in the West, the western Great Lakes Region, and the Appalachian Mountain Range of the northeastern U.S. At its southern margins, the boreal forest becomes naturally fragmented into patches of varying size as it transitions into other vegetation types. These southern boreal forest habitat patches are small relative to the extensive northern boreal forest of Canada and Alaska, which constitutes the majority of the lynx range. Lynx are considered “not at risk” in Canada (Committee on the Status of Endangered Wildlife in Canada 2006).

Many of these southern boreal forest habitat patches within the contiguous U.S. are able to support resident populations of lynx and their primary prey species. It is likely that some of the habitat patches act as sources of lynx (recruitment is greater than mortality) that are able to disperse and potentially colonize other patches (McKelvey et al. 2000b). Other habitat patches act as “sinks” in which lynx mortality is greater than recruitment and lynx are lost from the overall population. The ability of naturally dynamic habitat to support lynx populations may change as the habitat undergoes natural succession following natural or man-made disturbances (i.e., fire, clearcutting). In addition, fluctuations in the prey populations may cause some habitat patches to change from being sinks to sources and vice versa. The term “resident population” refers to a group of lynx that has exhibited long-term persistence in an area based on a variety of factors, such as evidence of reproduction, successful recruitment into the breeding cohort, and maintenance of home ranges. The word “transient” refers to a lynx moving from one place to another within suitable habitat. The word “dispersing” refers to lynx that have left suitable habitat for various reasons, such as competition or lack of food. When dispersing lynx leave suitable habitat and enter habitats that are unlikely to sustain them, these individuals are considered lost from the metapopulations unless they return to boreal forest.

6.1.1.3 Population Dynamics

Lynx numbers and snowshoe hare densities in the contiguous U.S. generally do not get as high as those in the center of their range in Canada, and there is no evidence they ever did so in the past (Hodges 2000a, b, McKelvey et al. 2000a). It appears that northern and southern snowshoe hare populations have similar cyclic dynamics, but that in southern areas both peak and low densities are lower than in the north (Hodges 2000b). However, it is unclear whether hare populations cycle everywhere in the contiguous U.S. Relatively low snowshoe hare densities at southern latitudes are likely a result of the naturally patchy, transitional boreal habitat at southern latitudes that prevents hare populations from achieving densities similar to those of the expansive northern boreal forest (Wolff 1980, Buehler and Keith 1982, Koehler 1990, Koehler and Aubry 1994). Additionally, the presence of more predators and competitors of hares at southern latitudes may inhibit the potential for high-density snowshoe hare populations with extreme cyclic fluctuations (Wolff 1980). As a result

- Resident Population
- Dispensers
- Resident/Dispensers

 Biological Assessment for the NorthMet Project and Land Exchange
 St. Louis County, Minnesota

of naturally lower snowshoe hare densities, lynx densities at the southern part of the range rarely achieve the high densities that occur in the northern boreal forest (Aubry et al. 2000).

The density of lynx near the Project area was estimated to range from one lynx per 72 to 86 mi² based on lynx surveys conducted on or near the Project (ENSR 2006, Barr 2011). However, Moen (2009) noted that given the low densities of Canada lynx in Minnesota, it may be impossible to provide an accurate population estimate.

6.1.1.4 Lynx and Snowshoe Hare Relationships

The association between lynx and snowshoe hare is considered a classic predator-prey relationship (Saunders 1963, van Zyll de Jong 1966, Quinn and Parker 1987). In northern Canada and Alaska, lynx populations fluctuate on approximately 10-year cycles that follow the cycles of snowshoe hare populations (Elton and Nicholson 1942, Hodges 2000a, b, McKelvey et al. 2000a). Generally, researchers believe that when snowshoe hare populations are at their cyclic high, the interaction of predation and food supply causes the populations to decline drastically (Buehler and Keith 1982, Krebs et al. 1995, O'Donoghue et al. 1997). There is little evidence of regular snowshoe hare cycles in the Northeast, southern Quebec, and Minnesota (Hoving 2001, McCann 2006), but snowshoe hare populations can fluctuate widely in this region. Snowshoe hare fluctuations in this region may be more influenced by forest practices, weather, and other ecological factors.

Snowshoe hare provide the quality prey necessary to support high-density lynx populations (Brand and Keith 1979). Lynx also prey opportunistically on other small mammals and birds, particularly when hare populations decline (Nellis et al. 1972, Brand et al. 1976, McCord and Cardoza 1982, O'Donoghue et al. 1997, 1998a). Red squirrels are an important alternate prey (O'Donoghue et al. 1997, 1998a, Apps 2000, Aubry et al. 2000). However, a shift to alternate food sources may not sufficiently compensate for the decrease in snowshoe hares consumed to be adequate for lynx reproduction and kitten survival (Brand and Keith 1979, Koehler 1990, Koehler and Aubry 1994). When snowshoe hare densities decline, the lower quality diet causes sudden decreases in the productivity of adult female lynx and decreased survival of kittens, if any are born during this time. As a result, recruitment of young into the population nearly ceases during cyclic lows of snowshoe hare populations (Nellis et al. 1972, Brand et al. 1976, Brand and Keith 1979, Poole 1994, Slough and Mowat 1996, O'Donoghue et al. 1997, Mowat et al. 2000).

6.1.1.5 Home Range and Dispersal

Lynx require very large areas containing boreal forest habitat. The size of lynx home ranges varies by the animal's gender and age, abundance of prey, season, and the density of lynx populations (Hatler 1988, Koehler 1990, Poole 1994, Slough and Mowat 1996, Aubry et al. 2000, Mowat et al. 2000). Based on a limited number of studies in northeastern Minnesota, the average home range varied between 11 and 201 mi² for males, and 2 and 37 mi² for females (Burdett 2007). Male home ranges expanded during the breeding season, perhaps due to males searching for females, while female home ranges contracted (Moen et al. 2008).

Lynx are highly mobile and have a propensity to disperse. Long-distance movements (greater than 60 miles) are characteristic, and are more common among males (Mowat et al. 2000, Burdett 2007). Lynx disperse primarily when snowshoe hare populations decline (Ward and Krebs 1985, Koehler and Aubry 1994, O'Donoghue et al. 1997, Poole 1997). Subadult lynx also disperse even when prey is abundant (Poole 1997), presumably as an innate response to establish home ranges. Lynx also make exploratory movements outside their home ranges. Lynx are capable of moving extremely long distances (greater than 300 miles; Brainerd 1985, Washington Department of Wildlife 1993, Poole 1997, Mowat et al. 2000). While it is assumed lynx would prefer to travel

where there is forested cover, the literature contains many examples of lynx crossing large, unforested openings. The ability of both male and female lynx to disperse long distances, crossing unsuitable habitats, indicates they are capable of colonizing suitable habitats and finding potential mates in areas that are isolated from source lynx populations.

Moen et al. (2010) found that lynx in Minnesota disperse outside their home range and travel between Ontario, Canada, and Minnesota. About 40% of radiocollared male and female lynx made long-distance movements outside of their home range. Of those making long distance movements, females tended to move 62 to 124 miles and not return to their original home range, while males moved 31 to 49 miles and went back and forth between Ontario and Minnesota. Travel was generally linear, water was not avoided, and lynx walked around lakes while on long-distance movements. Movements were made across roaded areas, and also across the BWCAW, which has few linear features such as roads, trails, and logging roads that could guide movement by lynx. Observations suggested that geographically or topographically definable movement corridors do not exist for lynx in northeastern Minnesota, or between Minnesota and Ontario (Moen et al.2010).

6.1.1.6 Mortality

Common causes of mortality for lynx include starvation of kittens (Quinn and Parker 1987, Koehler 1990), and trapping (Ward and Krebs 1985, Bailey et al. 1986). Lynx mortality due to starvation has been shown in cyclic populations of the northern taiga, during the first 2 years of snowshoe hare scarcity (Pool 1994, Slough and Mowat 1996). During periods of low snowshoe hare numbers, starvation can account for up to two-thirds of all natural lynx deaths. Trapping mortality may be additive rather than compensatory during the low period of the snowshoe hare cycle (Brand and Keith 1979). Hunger-related stress, which induces dispersal, may increase exposure of lynx to other forms of mortality such as trapping and vehicle collisions (Brand and Keith 1979, Carbyn and Patriquin 1983, Ward and Krebs 1985, Bailey et al. 1986).

Predation on lynx by mountain lion, coyote, wolverine, wolf, and other lynx has been observed (Berrie 1974, Koehler et al. 1979, Poole 1994, Slough and Mowat 1996, O'Donoghue et al. 1997, Apps 2000, Squires and Laurion 2000). Squires and Laurion (2000) reported two of six mortalities of radiocollared lynx in Montana were due to mountain lion predation.

An indirect effect of long-distance movements can be that some lynx are legally harvested in Ontario (USDA Forest Service 2011b). Although this harvest has little effect on the population of lynx in Ontario, it can affect the relatively small Minnesota population of lynx (Moen 2009, Moen et al. 2010).

There are few records of lynx being killed on highways, but direct mortality from vehicular collisions may be detrimental to small lynx populations in the lower 48 states. The MDNR lynx sighting records indicate that six lynx were killed by vehicle collisions in Minnesota between 2000 and 2006, and one lynx was killed by a train (MDNR 2007). Of those killed by vehicles, two occurred on Interstate 35, two on Highway 61, one on a county road, and one on the Gunflint Trail. No lynx-vehicle collisions have been reported on roads associated with mining projects, even though lynx have been observed using mine roads at the Northshore Mine and former Cliffs Erie mine site near the Project (ENSR 2006).

The USFWS Twin Cities Field Office has maintained an incidental take database since 2000. From 2000 to 2012, of 43 animals killed, 15 were from unknown causes, 13 were from trapping (4 due to legal trapping in Ontario, Canada), 7 were killed by vehicles, 6 were shot, and 2 were killed by trains (Rowse 2012). Between

2003 and 2009, the NRRI found that 15 of 19 radiocollared lynx deaths were directly or indirectly associated with human activities (Moen 2009, USDA Forest Service 2011b).

Many resident lynx that make movements into Ontario are harvested, particularly those that go long distances. Three radiocollared animals made 300 to 400 road mile movements to the same area in Ontario (USDA Forest Service 2011b). Lynx that conduct long-distance movements from Minnesota to Ontario are vulnerable to legal harvest in Canada whereas trapping mortality in Minnesota is incidental to trapping for other species because there is no legal trapping of lynx in the U.S. (Moen 2009). Moen et al. (2010) suggested that linear features such as roads benefit lynx from an energetic perspective, but may also be negative if they increase the chance of incidental mortality because of exposure to humans.

6.1.1.7 Recruitment

Lynx reproduction occurs in Minnesota. Based on 6 years of telemetry studies, an estimated 40 to 50 kittens were born to 33 radiocollared females. Only a few kittens survived past 2 years of age. Human factors have led to nearly all deaths, while starvation has been less important. These data suggest that lynx populations in Minnesota are influenced by lynx population dynamics in Ontario, Canada (Moen 2009).

6.1.1.8 Interspecific Relationships with other Carnivores

Buskirk et al. (2000b) described the two major competition impacts to lynx as exploitation (competition for food) and interference (avoidance). Of several predators examined (birds of prey, coyote, gray wolf, mountain lion, bobcat, and wolverine), it was deemed that coyotes were the most likely to pose local or regionally important exploitation impacts to lynx, and coyotes and bobcats were deemed to possibly impart important interference competition effects on lynx. Mountain lions were described as interference competitors, possibly impacting lynx during summer and in areas lacking deep snow in winter, or when high elevation snow packs develop crust in the spring.

In southern portions of snowshoe hare range, predators may limit snowshoe hare populations to lower densities than in the taiga (Dolbeer and Clark 1975, Wolff 1980, Koehler and Aubry 1994). Exploitation competition may contribute to lynx starvation and reduced recruitment. During periods of low snowshoe hare numbers, starvation accounted for up to two-thirds of all natural lynx deaths in the Northwest Territories of Canada (Poole 1994).

Parker et al. (1983) discussed anecdotal evidence of competition between bobcats and lynx. On Cape Breton Island, Nova Scotia, lynx were found to be common over much of the island prior to bobcat colonization. Concurrent with the colonization of the island by bobcats, lynx densities declined and their presence on the island became restricted to the highlands, the one area where bobcats did not become established.

Predation on adult lynx has rarely been observed and recorded in the literature. Predators of lynx include mountain lion, coyote, wolverine, wolf, and other lynx. The magnitude or importance of predation on lynx is unknown.

6.1.1.9 Behavioral Response to Humans

Staples (1995) described lynx as being generally tolerant of humans. Other anecdotal reports also suggest that lynx are not displaced by human presence, including moderate levels of snowmobile traffic (Mowat et al. 2000) and ski area activities (Roe et al. 1999).

In a lightly roaded study area in northcentral Washington, logging roads did not appear to affect habitat use by lynx (McKelvey et al. 2000c). In contrast, six lynx in the southern Canadian Rocky Mountains crossed highways within their home ranges less than would be expected (Apps 2000). The latter study area contained industrial road networks, twin-tracked railway, and 2 to 4-lane highways with average daily traffic volumes of about 1,000 to 8,000 vehicles per day.

6.1.1.10 Habitat Requirements

To understand habitat relationships of lynx one must first understand the habitat relationships of snowshoe hares. Generally, lynx hunt within habitats where snowshoe hare are common or abundant. An essential aspect of habitat is dense coniferous or mixed coniferous/deciduous forest cover that provides security for snowshoe hares. Snowshoe hares have evolved to survive in areas that have deep snow and use black spruce and balsam fir forests with dense understory vegetation that provide forage, cover to escape from predators, and protection during extreme weather (Wolfe et al. 1982, Monthey 1986, Hodges 2000a, b). Generally, earlier succession (younger) forest stages have greater understory structure than do mature forests and, therefore, support higher snowshoe hare densities (Fuller 1999, Hodges 2000a, b). The branches of trees in mature forests also capture more snow than younger forests, resulting in shallower snow in mature and younger forests (ENSR 2005).

Most lynx snowshoe hare kills occur in habitat where young or immature timber is prevalent and where a significant acreage of this habitat type is available. Lynx also hunt snowshoe hares in high stem density deciduous cover, such as speckled alder in riparian areas, and Canada bluejoint, willow, and bog birch in creek bottoms.

Communities used most often by lynx are young jack pine/balsam fir forests. Balsam fir often occurs as inclusions or “pockets” of regenerating trees within other cover types (e.g., in mature jack pine stands or in maturing black spruce/trembling aspen stands), and along forest edges. Lynx also use coniferous or mixed coniferous/deciduous forest patches in regenerating logged areas, including 10- to 25-year-old stands of jack pine or balsam fir/trembling aspen mixed coniferous/deciduous forest. Other important habitat types include black spruce/balsam fir and black spruce/tamarack forests.

Communities used by lynx often originate as a result of natural or “facilitated” regeneration after logging. However, fire and spruce budworm outbreaks also play a role in influencing forest stand composition and age in sites used by lynx. It generally takes 12 to 30 years after a forest thinning or fire before conditions become suitable for snowshoe hare, as forests mature from the young to the immature stage.

Lynx use coniferous forest plantations, especially where large stands of plantation forest occur in proximity to each other. Lynx use white spruce, jack pine, eastern white pine, red pine, and mixed coniferous/deciduous plantations, especially forests ranging from 10 to 30 years in age. Recent studies of snowshoe hare and red squirrel pellet density suggest that snowshoe hare and squirrel numbers are greatest in jack pine, red pine, black spruce, and mixed immature/mature and mature coniferous/deciduous forests; presumably, lynx would be more common in these habitats (Moen et al. 2004). Lynx in Minnesota have been observed hunting snowshoe hare in dense stands of young and mid-sized immature forest, especially balsam fir, black spruce, and jack pine forests. They have been reported avoiding lowland coniferous habitats, while favoring forest edges (Burdett 2007).

6.1.1.11 Diet

Snowshoe hares are the primary prey to lynx, comprising 35 to 97% of the diet throughout the range of the lynx (Koehler and Aubry 1994). Other prey species include red squirrel, several species of grouse, northern flying squirrel, ground squirrel, porcupine, beaver, mice, voles, shrews, fish, and ungulates as carrion or occasionally as prey (Saunders 1963, van Zyll de Jong 1966, Nellis et al. 1972, Brand et al. 1976, Brand and Keith 1979, Koehler 1990, Staples 1995, O'Donoghue et al. 1998b).

Several studies have shown that the importance of other prey species, especially red squirrel, increases in the diet during periods when snowshoe hares become scarce (Brand et al. 1976, O'Donoghue et al. 1998b, Apps 2000, Mowat et al. 2000). Recent research in northeastern Minnesota and northwestern Montana (Burdett 2007, Hanson and Moen 2008, Squires and Ruggerio 2007), however, concluded that red squirrel contributed little to the lynx diet and that lynx made little use of alternative prey species.

Hanson and Moen (2008) investigated the winter diet of lynx in northern Minnesota based on prey remains in lynx scat. Snowshoe hare remains were present in 76% of scats. Hair of white-tailed deer was found in scat, but white-tailed deer remains were used as bait to lure lynx to traps for a radiotelemetry study, and the authors felt that if scat with white-tailed deer hair were eliminated, snowshoe hare remains were found in 97% of scats. The study indicated that alternative prey are an insignificant component of Minnesota lynx diets in winter. No red squirrel remains were found in the analysis.

Most research has focused on the winter diet. Summer diets are poorly understood throughout the range of lynx. Mowat et al. (2000) reported that summer diets consist of less snowshoe hare and more alternate prey species than winter diets.

6.1.1.12 Den Site Selection

Lynx den sites are found where coarse woody debris, such as downed logs and wind-throw, provides denning sites with security and thermal cover for lynx kittens (McCord and Cardoza 1982, Koehler 1990, Koehler and Britnell 1990, Slough 1999, Squires and Laurion 2000). The integral component for all lynx den sites appears to be the amount of downed woody debris present rather than the age of the forest stand (Mowat et al. 2000, Moen and Burdett 2009). In Washington, lynx denned in immature lodgepole pine, black spruce, and subalpine fir forests older than 200 years with an abundance of downed woody debris (Koehler 1990). A den site in Wyoming was located in a mature subalpine fir/immature lodgepole pine forest with abundant downed logs and dense understory (Squires and Laurion 2000).

Based on radiotelemetry studies in Minnesota, most lynx dens are found in tree wind-throw areas with dense vertical and horizontal cover. Dens were often located in an area with foraging habitat and denning cover, and often in small patches of upland within a larger wetland. These are often areas where wind-throw occurs (Moen and Burdett 2009).

Female lynx appear to use a habitat mosaic that includes both foraging habitat and cover for denning. Den sites were often associated with wetland areas where dens were on small patches of upland surrounded by wetter low-lying areas (Moen et al. 2008). Moen and Burdett (2009) speculated that shallow soils in the low-lying areas may increase the chance that wind-throw would occur and provide suitable denning cover. Lynx appear to be adaptable in the selection of habitats to den in, but select specific types of areas based on the prevalence of wind-throw.

Moen et al. (2008) found that all den sites were associated with a downed tree, with disturbance area varying from about 50 square feet to greater than 2.5 acres. They also found that lynx den sites consistently had lower tree stem density than the surrounding area, with greater than 80% of tree stems being coniferous species. Lowland and upland coniferous forest cover types made up greater than 70% of the area within 330 feet of den sites and the percentage of those cover types decreased with greater distance from the den sites. These findings suggest that suitable denning habitat includes both upland and lowland forest 60 to 80 years old or greater depending on forest type (USDA Forest Service 2011b).

Moen et al. (2008), using denning habitat data, developed a model to estimate the spatial distribution of suitable denning habitat in northeastern Minnesota. This model has estimated that about 25% of the landscape in northeastern Minnesota consists of suitable lynx denning habitat. This suggests that lynx denning habitat is abundant and well-distributed in northeastern Minnesota and on the Superior National Forest.

6.1.1.13 Range of Lynx within the Contiguous United States

Within the contiguous U.S., the lynx's range coincides with that of the southern margins of the boreal forest along the Appalachian Mountains in the Northeast, the western Great Lakes, and the Rocky Mountains and Cascade Mountains in the West (**Figure 15**). In these areas, the boreal forest is at its southern limits, becoming naturally fragmented into patches of varying size as it transitions into subalpine forest in the West and deciduous temperate forest in the East (Agee 2000). Because the boreal forest transitions into other forest types to the south, scientists have difficulty mapping its exact boundaries (Elliot-Fisk 1988). Precisely identifying and describing the distribution of lynx habitat also is difficult because there are several vegetation and landform classifications and descriptions that have been published for various parts of North America (USDA Forest Service and Bureau of Land Management 1999). However, the term "boreal forest" broadly encompasses most of the vegetative descriptions of this transitional forest type that makes up lynx habitat in the contiguous U.S. (Agee 2000).

In addition to appropriate vegetation type, delineation of the range of the lynx within the contiguous U.S. must consider snow conditions. Lynx are at a competitive advantage over other carnivores (e.g., bobcats or coyote) in areas that have cold winters with deep snow because of their morphological adaptations for hunting and surviving in such environments. Therefore, lynx populations may not be able to successfully compete and persist in areas with insufficient snow even if suitable forest conditions otherwise appear to be present (Ruediger et al. 2000, Ruggiero et al. 2000b, Hoving 2001). A consistent winter presence of bobcats indicates an area that is not of high quality for lynx.

Lynx in the contiguous U.S. are part of a larger metapopulation whose center is located in the northern boreal forest of central Canada; lynx populations emanate from this area (Buskirk et al. 2000, McKelvey 2000a, b). When there is a high in the lynx population in central Canada, it acts like a wave radiating out to the margins of the lynx range. The magnitude of the lynx population high emanating from the central Canadian boreal forest varies for each cycle. This wave can be produced by local populations reacting to environmental conditions, dispersers, or a combination of these (McKelvey et al. 2000a, b).

An example of the cyclic population "wave" occurred in the 1960s and 1970s, when numerous lynx were reported in the contiguous U.S. far from source populations. These records of dispersing lynx correlate to unprecedented cyclic lynx highs in Canada (Adams 1963, Mech 1973, Gunderson 1978, Thiel 1987, McKelvey et al. 2000a, Mowat et al. 2000). These dispersers frequently were documented in areas, such as Wisconsin, that

are close to source populations of lynx in Canada or possibly northeastern Minnesota and that contain some boreal forest. But there also have been a number of occurrences of dispersers in unsuitable habitats far from source populations, such as the North Dakota prairie (Adams 1963, Gunderson 1978, Thiel 1987, McKelvey et al. 2000a).

Lynx populations in the northeastern U.S. and southeastern Canada are separated from those in northcentral Canada by the St. Lawrence River. There is little evidence of regular snowshoe hare or lynx population cycles in this area (Hoving 2001), but wide fluctuations in lynx and snowshoe hare populations do occur. On a smaller scale, fluctuating populations in the core of this area (Quebec's Gaspé Peninsula, western New Brunswick, and northern Maine) can potentially influence lynx distribution up to several hundred miles distant.

Lynx dispersing during periods of population highs will occupy many patches of boreal habitat at the periphery of their range. Some patches will be suitable to maintain a long-term population and some will not. Where the boreal forest habitat patches within the contiguous U.S. are large, with suitable habitat, prey, and snow conditions, resident populations of lynx are able to survive throughout the low period of the approximately 10-year cycle. Most likely the influx of lynx from populations in Canada at the high point of the cycle augments these resident populations. It is likely that some of these habitat patches within the contiguous U.S. are able to act as sources of lynx (where recruitment is greater than mortality) that are able to disperse and potentially colonize other patches (McKelvey et al. 2000b).

In other areas, few lynx may remain after a cyclic population high, or the habitat may be naturally marginal, so they are not able to persist or establish local populations, although some reproduction may occur. Such areas naturally act as population sinks (McKelvey et al. 2000b). Sink habitats are most likely those places on the periphery of the southern boreal forest where habitat naturally becomes patchier and more distant from larger lynx populations. Lynx found in these sink habitats are considered dispersers, but are usually included within the species range. Changes in the habitat conditions or cyclic fluctuations in the prey populations may cause some habitat patches to change from being sinks to sources and vice versa. Through this natural process, local lynx populations in the contiguous U.S. may "blink" in and out as the metapopulation goes through the 10-year cycle. Where habitat is of high enough quality and quantity, resident lynx populations are able to become established or existing populations are augmented, aiding in their long-term persistence.

Some maps (e.g., Hall and Kelson 1959) incorrectly portray the range of the lynx by encompassing peripheral records from areas that are not within boreal forest or do not have cold winters with deep snow, such as prairie or deciduous forest. Such maps have led to a misperception that the historic range of the lynx in the contiguous U.S. was once much more extensive than ecologically possible. Records of lynx outside of the southern boreal forest in peripheral habitats that are unable to support lynx represent long-distance dispersers that are lost from the metapopulation unless they return to the boreal forest and contribute to the persistence of a population. These unpredictable and temporary occurrences are not included within either the historic or current range of lynx because they are well outside of lynx habitat. This includes records from Connecticut, Indiana, Iowa, Massachusetts, Nebraska, Nevada, North Dakota, Ohio, Pennsylvania, South Dakota, and Virginia (Hall and Kelson 1959, Burt 1954 as cited in Brocke 1982, Gunderson 1978, McKelvey et al. 2000a). States that support some boreal forest and have frequent records of lynx are assumed to be the historic and current species range; these states include Colorado, Idaho, Maine, Michigan, Minnesota, Montana, New Hampshire, New York, Oregon, Utah, Vermont, Washington, Wisconsin, and Wyoming.

6.1.1.14 Range of Lynx within Great Lakes Geographic Region

Lynx are found within several geographic areas within the U.S.—the Cascade Mountains Geographic Area, Northern Rocky Mountains Geographic Area, Southern Rocky Mountains Geographic Area, Great Lakes Geographic Area, and Northeast Geographic Area. These geographic areas are separated from each other by expanses of unsuitable habitats that limit or preclude lynx movement, except the Northern Rockies and Cascades (USDOI USFWS 2000a).

Canada lynx in northern Minnesota are found within the Great Lakes Geographic Area. The Great Lakes Geographic Area encompasses northeastern and northcentral Minnesota, northern Wisconsin, Michigan's Upper Peninsula, and northern portions of Michigan. The majority of lynx occurrence records in the Great Lakes Geographic Area are associated with the mixed coniferous/deciduous habitat type (McKelvey et al. 2000a). Within this general forest type, the highest frequency of lynx occurrences have been in white spruce, balsam fir, jack pine, white pine, red pine, black spruce, and mixed black spruce/tamarack forest types. These forest types are found primarily in northern Minnesota, northern Wisconsin, and Michigan's Upper Peninsula.

About 4.5 million of the 6 million acres of Forest Service-administered lands in the Great Lakes Geographic Area are mapped as primary lynx habitat. These lands comprise about 19% of all lynx habitat within the Great Lakes Geographic Area. About 2 million acres are included within non-developmental land allocations where natural processes are expected to predominate. Private lands account for about 81% of the lynx habitat within the Great Lakes Geographic Area.

Although the mixed coniferous/deciduous forest covers an extensive area in the Great Lakes Region, much of this area may be marginal habitat for lynx because it is a transitional forest type at the edge of the snowshoe hare range. Habitat at the edge of hare range supports lower hare densities that may not be sufficient to support lynx reproduction (Buehler and Keith 1982). Furthermore, appropriate habitat with snow depths that allow lynx a competitive advantage over other carnivores (e.g., coyotes) occur only in limited areas in northeastern Minnesota, extreme northern Wisconsin, and Michigan's Upper Peninsula.

The historic status of lynx in the Great Lakes Region is uncertain. Minnesota has a substantial number of lynx reports (McKelvey et al. 2000a), which is expected because of the connectivity of the boreal forest with that of Ontario, Canada, where lynx occur. As noted earlier, lynx regularly travel between Minnesota and Ontario, Canada (Moen 2009, Moen et al. 2010). Wisconsin and Michigan have substantially fewer records of lynx. Researchers have debated whether lynx in this region are simply dispersing individuals emigrating from Canada, are members of a resident population, or are a combination of a resident population and dispersing individuals. Recent research efforts in Minnesota have confirmed a reproducing population of lynx. Reproduction has been documented in all years since 2001. However, there are a few records of lynx occurrence in Michigan and Wisconsin during this same period.

6.1.1.15 Range of Lynx in Minnesota

The majority of lynx occurrence records are from the northeastern portion of Minnesota; however, dispersing lynx have been found throughout Minnesota outside of typical lynx habitat (Gunderson 1978, Mech 1980, McKelvey et al. 2000a). In northeastern Minnesota, where deep snow accumulates, suitable lynx and snowshoe hare habitat is present. Much of this area is protected as designated wilderness, including the BWCAW. Furthermore, these habitats are contiguous with the boreal forest in southern Ontario. Until 1965, lynx had a bounty placed on them in Minnesota. In 1976, the lynx was classified as a game species, and harvest seasons

were established (DonCarlos 1994). Harvest and bounty records for Minnesota are available for 1930 to 1984. Approximate 10-year cycles are apparent in the data, with highs in the lynx cycle in 1940, 1952, 1962, and 1973 (Henderson 1978, McKelvey et al. 2000a). During a 47-year period (1930–1976), the Minnesota lynx harvest was substantial, up to 400 lynx in a year (Henderson 1978). These harvest returns for Minnesota are believed to be influenced by influxes of lynx from Canada, particularly in the 1960s and 1970s (Henderson 1978, Mech 1980, DonCarlos 1994, McKelvey et al. 2000a). When an anticipated lynx cyclic high for the early 1980s did not occur, the harvest season was closed in 1984 (DonCarlos 1994) and remains closed today.

Reproduction and maintenance of home ranges by lynx in Minnesota were documented in the early 1970s (Mech 1973, 1980), which may be evidence of a resident population (but see Section 6.1.1.7; Recruitment). The early 1970s were a period when the second highest lynx harvest returns in the 20th century occurred throughout Canada. The high numbers of lynx trapped in Minnesota during this period likely included immigrants from Canada (McKelvey et al. 2000b). Lynx were consistently trapped over 40 years during cyclic lows, which may indicate that a small resident population occurred historically.

Lynx Analysis Units

The Superior National Forest first established Lynx Analysis Units (LAUs) in 2000 to map lynx habitats in the Superior National Forest using the criteria and procedures developed by the Lynx Science Team and Steering Committee (USDA Forest Service 2000b). Lynx Analysis Units are described in the Lynx Conservation Strategy and Assessment (Ruediger et al. 2000) as the smallest landscape-scale analysis units used to determine direct, indirect, and cumulative effects for lynx. Lynx Analysis Units may contain habitat that may or may not provide habitat or environmental conditions necessary to support lynx reproduction and survival. Lynx habitat outside LAUs exists because those areas did not contain sufficient habitat conditions to be viable LAUs (USDA Forest Service 2000b, 2004b).

In 2004, the LAUs were revised (USDA Forest Service 2004b, c, d) to add new LAUs, refine boundaries of some LAUs, and designate the BWCAW as a refugium for lynx.

The federal lands are in LAU Superior National Forest (SNF) 12. This LAU is 70,980 acres, of which 49,409 acres are on Forest Service-administered lands (Ryan 2013a). Under the proposed land exchange, there would be a loss of 6,495 acres under Forest Service administration within this LAU after transfer of the federal lands from the Forest Service to PolyMet, a 13% reduction in acreage administered by the Forest Service within LAU SNF 12. Under the land exchange, the non-federal lands, except Hay Lake Lands, would be incorporated into LAUs SNF 4, 16, 21, and 42, increasing the acreage of these LAUs administered by the Forest Service by approximately 2,149 acres (**Figure 16**). There is no LAU associated with Hay Lake Lands.

Table 5 shows the total acres of suitable and unsuitable lynx habitat in each LAU. After the land exchange, there would be a net decrease of about 1,719 acres of suitable lynx habitat within LAU SNF 12 due to the effects of the Project, or about a 2% decrease of suitable lynx habitat within the LAU. After reclamation, about 397 acres could provide suitable habitat for lynx in the future; however, due to the successional process, it could be 10 or more years after mining before revegetation results in much suitable habitat for lynx. Under the land exchange, there would be a loss of about 6,495 acres of suitable lynx habitat under Forest Service administration within LAU SNF 12, but a gain of 2,134 acres on other LAUs, for an overall loss of 4,361 acres under Forest Service administration within LAUs (MDNR et al. 2013, Ryan 2013a). However, the Forest Service would gain about 4,675 acres of suitable lynx habitat on Hay Lake Lands, although this acreage is not associated with an

LAU, resulting in an overall gain of 314 acres of suitable lynx habitat under Forest Service Administration after the land exchange.

Boundary Water Canoe Area Wilderness

The BWCAW serves as an important habitat refugium in northeastern Minnesota that connects with lynx habitat in Ontario, Canada. Moen et al. (2010) found that many lynx in the Superior National Forest portion of northern Minnesota travel through the BWCAW to and from Ontario, Canada. The quality, quantity, and distribution of lynx habitat in the BWCAW is primarily influenced by natural disturbance events and natural succession, although some prescribed fire management activities have occurred within the BWCAW (USDA Forest Service 2004b).

The BWCAW provides large amounts of lynx habitat, including about 755,000 acres of suitable lynx habitat, 667,000 acres of snowshoe hare habitat, and 481,000 acres of lynx denning habitat (USDA Forest Service 2011b:Table 15). The BWCAW is not managed using the LAU approach, and LAU management direction does not apply to the BWCAW. The 2004 Forest Plan BA concluded that the BWCAW refugium met the direction for minimum habitat conditions established for LAUs (USDA Forest Service 200b).

6.1.1.16 Observations of Lynx in the Vicinity of the Project

Minnesota Department of Natural Resources Lynx Database

Of 426 reports from March 2000 to November 2006 in the MDNR lynx sightings database, 323 (76%) of lynx sightings occurred in St. Louis (113 sightings), Cook (109 sightings), and Lake (101 sightings) Counties (**Figure 17**; MDNR 2007). Most sightings are incidental encounters, and as such, tend to be clustered along roads and other places frequented by observant and interested people. Thus, while these reports tell us something about where lynx are, they provide no information about where lynx do not occur. Similarly, we cannot know the relationship between the number of reports and the number of lynx in Minnesota at the time of the reports.

A review of the database revealed that a probable lynx sighting was made by a trained biologist in Section 13 of Township 59 North, Range 16 West, east of Hay Lake Lands, in October 2003. Another lynx sighting was made 1 mile to the west of Hay Lake Lands the same year. Unverified lynx sightings were made in December 2002 and January 2003 in Sections 22 and 27 of Township 64 North, Range 3 West, south of McFarland Lake Lands. There were no records of lynx within 6 miles of the other federal and non-federal lands or Wetland Mitigation Sites.

The relatively high proportion of lynx detected in northeastern Minnesota reflects, in part, the disproportionate survey effort that has occurred within this region as compared to other regions of the state that likely harbor lynx, and the number of lynx sightings may not be representative of the availability of suitable habitat or relative numbers of lynx.

Superior National Forest Genetic Reference Collection

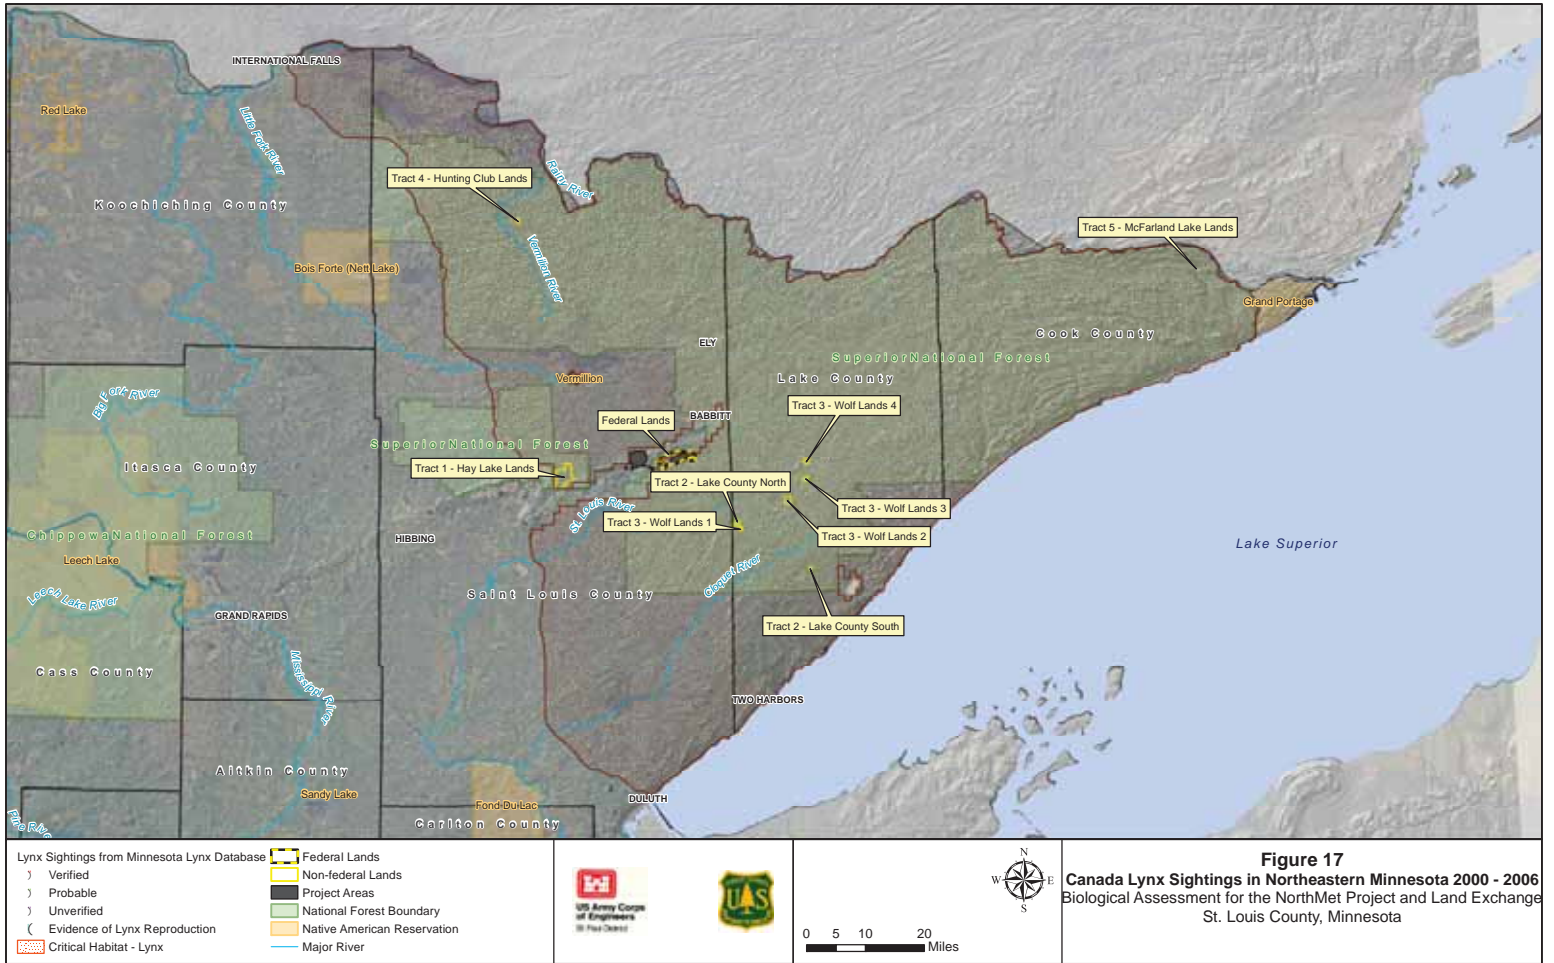

The Superior National Forest's genetic reference collection has 128 DNA sample collection points that have occurred within 6 miles of the Project since February 2004 (**Table 6**; Ryan 2013b). Lynx DNA have also been collected within 6 miles of the federal lands and all of the non-federal lands, except Hunting Club and McFarland Lake Lands; lynx DNA has been found within 10 miles of Hunting Club Lands and McFarland Lake Lands. Lynx DNA has been collected within 10 miles of the Hinckley Wetland Mitigation Site, but not within 10 miles of the other Wetland Mitigation Sites.

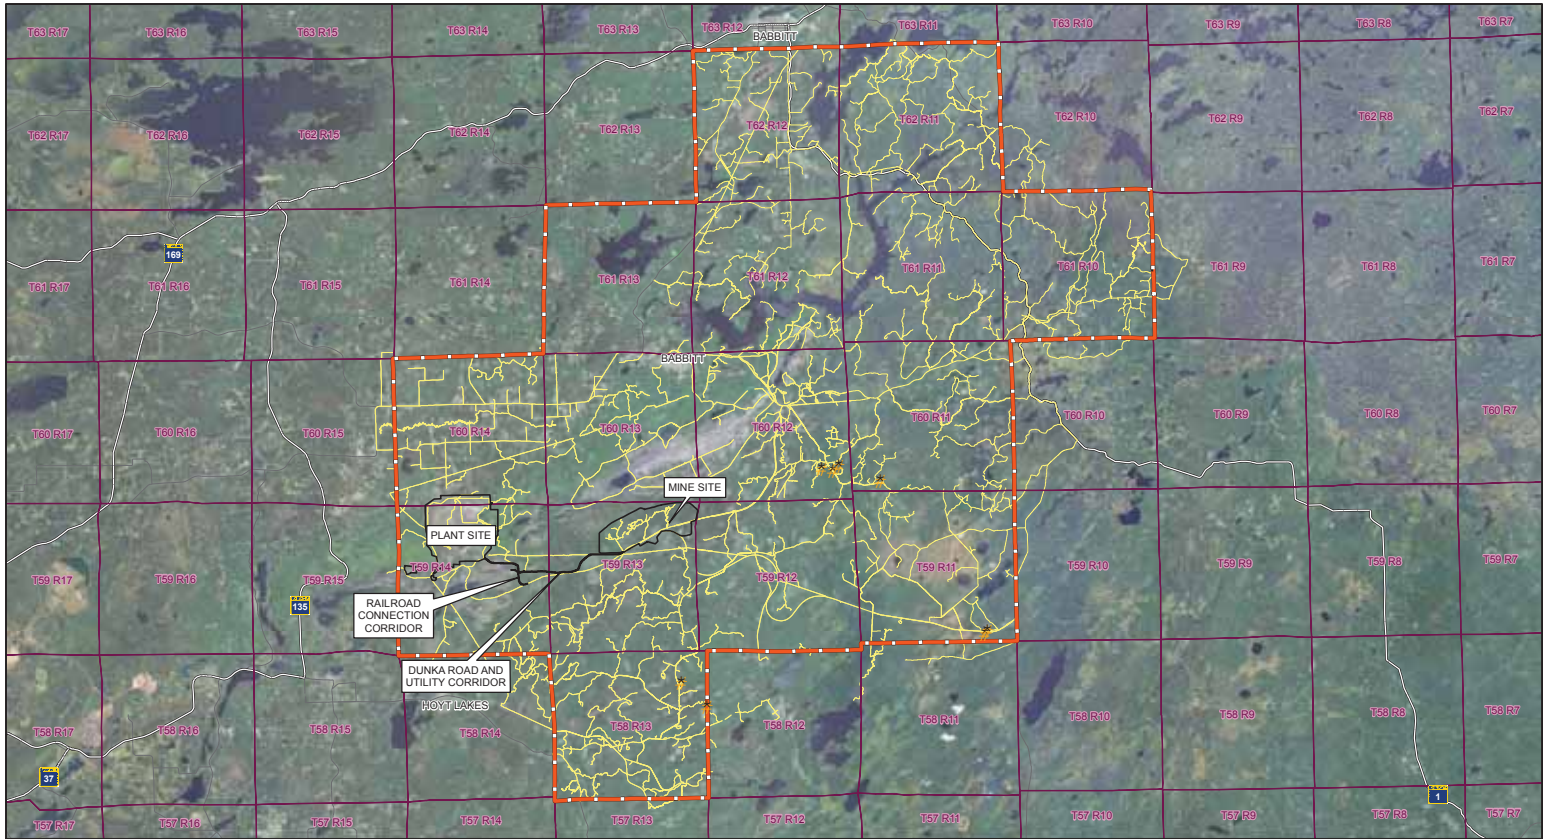

Natural Resources Research Institute Radio Telemetry Studies

Since 2003, the NRRI (2012) has captured and radiocollared and tracked 36 lynx in northeastern Minnesota. Four NRRI radiocollared study animals that were not identified in Superior National Forest's reference collection have been recorded within 6 miles of the Project.

Field Surveys

Several surveys have been conducted on and near the Project to determine lynx use based on tracks and scat. The Project lynx survey was conducted during January through March 2006 (ENSR 2006). Tracks and scat of three female lynx were identified during the survey within the study area, concentrated in areas approximately 5 miles east and south of the Mine Site; a fourth female was found adjacent to the study area (**Figure 18**). Lynx sign was most common in dense coniferous forests of balsam fir and jack pine. No evidence of lynx was found on the federal lands or Project areas.

 Biological Assessment for the NorthMet Project and Land Exchange
 St. Louis County, Minnesota

No lynx or their sign were seen on the federal and non-federal lands during wildlife surveys in 2000, 2004, 2008, 2009, and 2010 (ENSR 2000, 2005, AECOM 2009b, 2011a, b, c). However, Forest Service biologists did observe lynx tracks at the proposed Mine Site during a site visit in February 2010 (Ryan 2013c).

¹Some of the Project areas are within the federal lands.
Source: Ryan (2013b).

Tracking surveys for lynx were also conducted east of the federal lands. Several lynx were found during the study, based on DNA analysis of scat samples and track locations (Barr 2011). Open bog and stunted black spruce forest and jack pine and eastern white cedar cover provided habitat for snowshoe hare and lynx.

Habitat suitability for lynx and snowshoe hare was determined by the Forest Service for Superior National Forest lands within LAUs. This information is used in this BA to evaluate habitat suitability and impacts to lynx and snowshoe hare habitats from activities on the federal lands.

6.1.2 Analysis of Direct and Indirect Effects to Lynx and Its Critical Habitat

6.1.2.1 Effects to Canada Lynx within the Action Area

The USFWS concluded in the *Endangered and Threatened Wildlife and Plants: Determination of Threatened Status for the Contiguous U.S. Distinct Population Segment of the Canada Lynx and Related Rule; Final Rule* (USDOI USFWS 2000a) that the single biggest factor threatening the lynx in the contiguous U.S. is the inadequacy of existing regulatory mechanisms, specifically the lack of guidance for conservation of the lynx in National Forest and other resource management plans. In addition, the USFWS noted that timber harvest and fire suppression impact lynx in the Great Lakes Geographic Area.

Lands under federal management are necessary to lynx conservation regionally and nationally, as federal lands often provide large amounts of forested habitat needed by lynx and snowshoe hare. Large tracts of National Forest lands are found to the east of the Project. Most of the lands not associated with Mesabi Iron Range mining and related activities are forests. These forestlands could provide important habitat for lynx that use the Project area, and for movement of lynx between the Project area and areas with higher densities of lynx to the northeast.

The Project is within the Superior National Forest and the lynx critical habitat includes the Project area. These forestlands, as well as nearby private forestlands, provide important habitat for lynx that use the Project area, and for movement of lynx between the Project area and areas with higher lynx densities to the northeast of the Project area.

Other Lynx Risk Factors

The *Lynx Conservation Assessment and Strategy* (Ruediger et al. 2000) identified several other risk factors for lynx in the contiguous U.S., which could also apply to lynx in or near the Project area. These factors are considered in the following section on the effects of the Project, and the cumulative effects of the Project and other projects within or near the study area, on lynx. These include (**bolded items** considered important in the Project area).

1. Factors Affecting Lynx Productivity
 - a. **Timber management**
 - b. **Wildland fire management**
 - c. **Recreation**
 - d. **Forest/backcountry roads and trails**
 - e. Livestock grazing
 - f. **Other human developments (mining, power generation, etc.)**
2. Factors Affecting Lynx Mortality
 - a. **Trapping**
 - b. Predator control
 - c. **Incidental or illegal shooting**
 - d. **Competition and predation as influenced by human activities**
 - e. **Highways (vehicular collisions)**
3. Factors Affecting Lynx Movements
 - a. **Highways, roads, and rights-of-ways**
 - b. **Land ownership patterns**
 - c. Ski areas and large resorts
4. Other Large-scale Risk Factors
 - a. **Fragmentation and degradation of lynx refugia**
 - b. Lynx movement and dispersal across shrub-steppe habitats
 - c. Habitat degradation by non-native invasive plant species

The Project would result in both beneficial and adverse direct and indirect impacts to factors of importance to lynx. This section summarizes effects associated with the lynx risk factors 1 to 3 affected by the Project. The effects of past, present, and future activities on risks to lynx, and issues associated with lynx risk factor 4, are discussed in Section 6.1.4.

Factors Affecting Lynx Productivity

Timber, Wildland Fire, and other Habitat Management

Direct and Indirect Effects

Direct and indirect effects to lynx from timber and other habitat management, and wildland fire, were assessed based on information collected during lynx tracking and radiocollar studies and wildlife habitat surveys on and near the federal and non-federal lands, and from lynx and snowshoe hare habitat assessments conducted on LAUs.

Timber and other Habitat Management

Mine Site

The Forest Service manages the federal lands as a General Forest and General Forest – Longer Rotation Management Area. The General Forest - Longer Rotation Management Area emphasizes land and resource conditions that provide a wide variety of goods, uses, and services. These include wood products, other commercial products, scenic quality, developed and dispersed recreation opportunities, and habitat for a diversity of terrestrial and aquatic wildlife and fish species (USDA Forest Service 2004a). The characteristics and use of the General Forest Management Area are similar to the General Forest – Longer Rotation Management Area, except that harvests are more frequent, more uniform in age, and more extensive. The General Forest Management Area has the highest amount of young forest and the largest sized timber harvest units.

The Forest Service identified vegetative cover, denning habitat, and prey habitat as important habitat elements for lynx (USDA Forest Service 2004b). Open water, highly disturbed, and forested areas less than 4 years (upland) or 9 years (lowland) old were considered unsuitable habitat for lynx. These are general guidelines, as lynx have been seen crossing frozen lakes and highly disturbed areas. For example, a lynx tracked about 5 miles northeast of the Mine Site used mine disturbance areas where shrubs, jack pine, trembling aspen, and paper birch had partially revegetated the landscape, providing habitat for snowshoe hare and ruffed grouse, especially where waste rock talus provided escape cover for snowshoe hares.

Based on Forest Service criteria and wildlife assessments done at the Mine Site, all of the Mine Site could provide suitable habitat for lynx. Most forests consisted of immature/mature-size trees, with tree cover near 80% in younger forests, and 40 to 50% in immature and mature forests. These stands would be favored by lynx for foraging, bedding, and traveling. Small patches of mature forest are found in the central and western portions of the Mine Site that could provide foraging, bedding, traveling, and denning habitat.

Habitat of lesser suitability is primarily limited to roads, railways, clearings, and recent clearcuts near the Dunka Road, and at other scattered locations on the Mine Site. Shrublands and young forests are associated with areas that had been recently logged. Scattered trees (trembling aspen, paper birch, jack pine, and black spruce) are

occasionally found in these areas, but shrubs, including speckled alder, beaked hazel, blueberry, and raspberry may cover up to 80% or more of the landscape; percent vegetative cover is much less in more recently logged areas.

Denning habitat typically occurs in more mature forest stands, especially in areas with tree wind-throw, although lynx have been seen denning in immature forests (Moen et al. 2004, 2008, Moen et al. 2008)). There are about 5,393 acres of denning habitat on the federal lands; approximately 1,333 acres of denning habitat are found within the area that would be impacted by mining (MDNR et al. 2013). Most mature forest habitat was in the central and western portions of the Mine Site. The largest trees are up to about 16 inches dbh for both coniferous and deciduous trees. There is little wind-throw in these forests, but large snags (up to 16 inches dbh), stumps, and woody debris are common in mature forest stands and could provide denning habitat for lynx (ENSR 2000, 2005, AECOM 2011a).

About 397 acres of habitat lost to mining would be reclaimed after mine closure, but due to the successional process, it could be 10 or more years after mining before revegetation results in much suitable habitat for lynx. Based on the mine closure plan, most of the 397 acres of the habitat lost to mining that would be reclaimed would be reclaimed as grassland/herbaceous (54%), wetland and/or grassland/herbaceous (27%), and wetland (18%). The West Pit would not be reclaimed, but would remain as a 320-acre open pit lake (MDNR et al. 2013).

Studies of snowshoe hare and red squirrel pellet density suggest that snowshoe hare and red squirrel numbers are greatest in jack pine, red pine, black spruce, and mixed immature/mature forests; presumably, lynx would be more common in these habitats (Moen et al. 2004). Snowshoe hare were seen throughout the Mine Site, but were most common in young and immature coniferous forest dominated by jack pine. Although upland coniferous forests are dominated by jack pine, jack pine is especially abundant in the eastern portion of the Mine Site, as were snowshoe hare.

Three lynx were found within 6 miles of the Mine Site during lynx tracking surveys (ENSR 2006). Important habitat features used by lynx were identified during snow tracking. One lynx hunted snowshoe hares in mature jack pine where balsam fir inclusions in the understory were prevalent and provided dense cover, and in immature jack pine forest, often near lowland edges where balsam fir and other young and immature conifers provided relatively dense cover. This lynx also used lowland coniferous habitats. This lynx stalked three locations where white-tailed deer had bedded and investigated one site where grouse activity had occurred. It used an area where white-tailed deer activity was high, and also followed white-tailed deer trails and hunted snowshoe hare at this location. Two resting beds used by this lynx were found, one in mature jack pine and the other in a recent clearcut near a timbered edge.

A second lynx used mature black spruce swamp and hunted primarily in young and immature jack pine forest regenerating on sites that had been clearcut within 25 years. Snowshoe hare densities were abundant in a small stand of jack pine/balsam fir where the lynx hunted. Two resting beds, within 325 feet of each other, were found in this stand. The lynx pursued a white-tailed deer for a short distance and visited a site where humans had deposited venison trimmings. The lynx also investigated the empty snow roost of a grouse.

Federal Lands Surrounding the Mine Site

The federal lands surrounding the Mine Site would also be transferred to PolyMet under the Proposed Action. PolyMet could include some upland timber management that could enhance wildlife habitat.

Based on Forest Service criteria and wildlife assessments done for the federal lands, nearly all of this area could provide habitat for lynx and snowshoe hare. Forest vegetation dominates the federal lands (88%; **Figure 9; Table 7**). Most forest stands contain trees that are 12 inches dbh or less. Large stands of lowland black spruce with scattered northern white cedar and tamarack are found in low areas, while stands of immature and mature forest dominated by jack pine, and smaller patches of immature deciduous forest are found in upland areas.

The northern area of the federal lands includes a portion of One Hundred Mile Swamp. The swamp is comprised of some young, but mostly immature and mature black spruce, northern white cedar, and tamarack forests. Northern white cedar is prevalent in the northcentral portions of the northern area of the swamp, while black spruce and tamarack are more common in the remaining areas. Most of the forest stands are 90 years or older, with much of the remaining stands 70 to 90 years of age (USDA Forest Service 2000a). Because this area is very wet, it would probably provide little habitat for lynx and snowshoe hare, except perhaps during winter.

Approximately 3,161 acres of immature and mature forest habitat are found on the federal lands surrounding the Mine Site. Large downed woody material was seen in these areas that could provide denning habitat for lynx, but there was little tree wind-throw observed on these lands, except along old logging roads in mature white cedar forests.

Transportation and Utility Corridors

Because of prior use during the former LTVSMC taconite mining operation, the Transportation and Utility Corridors are now defined as having a “disturbed” cover type. The remaining MDNR GAP land cover types that are not disturbed include cropland/grassland (8%), shrubland (6%), and smaller acreages of the remaining types. The corridors could be used by lynx for travel between more suitable habitat types.

Plant Site

Of the 2,189 acres that would be disturbed at the Plant Site, approximately 50% (1,103 acres) of the Plant Site is disturbed and supports little vegetation. The remaining areas consist of aquatic environments (26%), upland deciduous forest (13%), shrubland (7%), upland coniferous forest (2%), and lowland coniferous forest (1%; **Figure 10**; MDNR et al. 2013). Development of the Plant Site would have little impact on lynx habitat, as about 75% of the site has been disturbed by LTVSMC taconite mining operations or is aquatic habitat. The remaining habitat may be used by snowshoe hare and provide foraging habitat for lynx. Lynx could also use portions of the site for travel and bedding. Given the amount of existing land disturbance, and noise and other human disturbance that would be associated with Plant Site activities, it is unlikely that the Plant Site would be used by lynx during Plant operations, although the Plant Site could be used by lynx after reclamation.

Non-federal Lands

Under the Proposed Action, approximately 7,075 acres of non-federal lands would be transferred to the Forest Service. The Forest Service and MDNR cover type mapping and field and wildlife habitat surveys were conducted for these lands and give an indication of the suitability of these lands for lynx. Portions of the non-federal lands have been harvested during the past 20 years, with much of the harvest occurring on Lake County Lands North, Lake County Lands South, and Wolf Lands 2 and 3, as indicated by acres of grassland and shrubland habitats shown in **Table 7**. Snowshoe hare and lynx could use these areas, especially if these areas are in proximity to coniferous stands. About 267 acres consists of aquatic habitat, which would not be used by snowshoe hare, red squirrel, or lynx, except perhaps during winter.

Mature	3,854	460	60	145	48	30	38	615	75	354	(2,029)

¹Acreages may differ slightly from acreages given in FEIS due to rounding.

The majority of habitat on the non-federal lands consists of immature and mature (age class) upland and lowland coniferous and deciduous forest totaling 5,365 acres (76%) that could be used by lynx and snowshoe hare (**Table 7**; MDNR et al. 2013). Mixed coniferous/deciduous forest and lowland shrub swamp and upland shrubland are also important habitat components that could be used by both snowshoe hare and lynx.

Wetland Mitigation Sites

Under the Proposed Action, approximately 2,169 acres of Wetland Mitigation Site lands would be purchased by PolyMet as compensatory mitigation for impacts to wetlands and other waters of the U.S. These lands are used for sod production, but under the Proposed Action would be restored to native wetland and upland vegetation. According to the Wetland Management Plan (Barr 2014d), approximately 1,603 acres (this includes the preservation of 29 acres of coniferous bog) of wetland and 197 acres of upland would be restored/created at the off-site Wetland Mitigation Sites. These sites could provide habitat for lynx and snowshoe hare, but there have been no recent records of lynx in the immediate vicinity of these lands.

Wildland Fire Management

Fire, wind, insects, and disease historically played an important role in maintaining the mosaic of forest successional stages that provide habitat for both snowshoe hare and lynx (Bailey et al. 1986, Quinn and Thompson 1987, Koehler and Brittell 1990, Slough and Mowat 1996, Ruediger et al. 2000). For the first few years after a burn, there appears to be a negative correlation between lynx use and the amount of area burned. This short-term effect is likely due to the reduction of snowshoe hare populations, removal of cover, and possibly also to increased competition from coyotes in open habitats (Koehler and Brittell 1990). The lag time until the peak of snowshoe hare population increase is generally about 15 to 30 years (this varies depending on tree species, habitat type, and severity of disturbance). Re-sprouting of deciduous trees occurs more quickly, in 3 to 12 years. Snowshoe hare populations again decrease as the forest canopy develops and shades out the understory. Forest gaps processes, such as large wind-throws, insect infestations, and outbreaks of disease, produce similar effects (Agee 2000).

The Superior National Forest lies within a boreal forest system where natural fire occurrence is common. The Forest also provides for a variety of recreational and management activities which sometimes result in unwanted human-caused fires.

Fire management is an integral part of land and resource management on the Superior National Forest. Fire plays a natural role in achieving long-term goals of ecosystem health. Wildland fire management decisions and resource management decisions go hand-in-hand and are based on approved Fire Management and Land and Resource Management Plans. Wildland fire, as a critical natural process, may be re-introduced into the ecosystem where human life, property, or resource values are not at risk.

In all cases, protection of human life is the first priority in wildland fire management. Property and resource values are the second priority, with management decisions based on values to be protected. Structural fire protection in the wildland/urban interface is the responsibility of tribal, state, and local governments.

Lynx and snowshoe hare favor early successional habitats that occur in the boreal forest about 10 or more years after disturbance. Thus, wildland fire can initiate plant succession to the benefit of lynx and snowshoe hare. Lynx denning habitat would not be available until at least 60 or more years after a wildland fire event (see Sections 6.1.1.10 and 6.1.1.12).

Under the Proposed Action, fire prevention would be a high priority at the Plant Site and on federal lands to protect human life and mine and plant infrastructure. After mine closure, wildland fire may again become part of the natural ecosystem on the federal lands, but would likely not be allowed at the Plant Site due to its close proximity to other mine infrastructure and other private properties.

Wildland fire could occur on the non-federal lands, but would likely be actively controlled to minimize loss of timber on the lands and to minimize the risk to nearby properties. Most habitat management on these lands would primarily be associated with timber management and harvests, and for Wetland Mitigation Sites, wetland and upland restoration under the Proposed Action.

Summary of Impacts to Lynx Habitat

Numerous habitat and human-disturbance factors influence lynx use of an area. Factors most important in the study area include timber management, mining activity, and habitat fragmentation. The mine project would remove forestlands, reduce the amount of available habitat for lynx, and increase habitat fragmentation; much of this habitat would be reclaimed after mine closure. However, large tracts of land associated with the Superior National Forest and adjacent to the Mine Site would be managed for lynx and other wildlife habitat. These lands have the potential to reduce the amount of habitat fragmentation within the region and help to maintain travel corridors between areas of suitable habitat.

Despite the presence of suitable habitat over most of the federal lands, sightings of lynx on the federal lands have been few. Based on tracking surveys on and near the federal lands, lynx density appears to be relatively low near the federal lands (approximately one lynx per 83 square miles) compared to other portions of northeastern Minnesota (ENSR 2006). Lynx sightings were more common a few miles east of the federal lands (Barr 2011). Thus, the loss of habitat due to the mining may have little impact on lynx.

None of the federal lands surrounding the Mine Site would be directly impacted by the Proposed Action. However, noise, light, and other disturbances at the mine site could limit use of the area by lynx, and perhaps to a lesser extent by snowshoe hare.

Lynx have not been recorded on the federal lands associated with the Mine Site, based on tracking surveys, NRRI field studies, Forest Service DNA data (collected from lynx scat), and MDNR lynx records databases. However, lynx tracks were seen on the Mine Site by a Forest Service biologist during February 2010 (Ryan 2013c). Although the lands contain much potential habitat for lynx, they also consist of much wetland habitat that is little used by snowshoe hare and could make lynx travel difficult outside of winter. Thus, the Project may have little direct impact on lynx use of these lands.

Lynx were not observed on the non-federal lands during wildlife studies, but lynx scat has been collected within 6 miles of all of the non-federal lands, except Hunting Club Lands and McFarland Lake Lands; lynx DNA has been found within 10 miles of Hunting Club Lands. The MDNR lynx database showed that lynx have been recorded within a mile of Hay Lake Lands and McFarland Lake Lands, but there were no records of lynx within 6 miles of the other non-federal lands.

The Forest Service would gain additional lands that would provide habitat for lynx and snowshoe hare under the Proposed Action. However, given that these lands would not be directly or indirectly impacted by the Project, would likely not be developed in the near future, and would remain mostly in timber production with

limited recreational use, there would likely be little or no adverse or beneficial effects to lynx using the non-federal lands with or without the proposed land exchange.

Although the Forest Service would administer additional habitat for lynx under the land exchange, there would still be a net loss of habitat to lynx and snowshoe hare due to habitat loss at the Mine Site. If the land exchange does not take place, and non-federal lands are not acquired by PolyMet and remain privately owned, non-federal lands would likely be managed primarily for timber production and some recreational use (hunting, fishing, and cabins). Most of the non-federal lands are wetland and lowland coniferous forest and not suitable for most types of recreational development. At this time, there also appears to be little interest in mining these lands or conducting other large scale surface disturbance. Thus, these lands would continue to provide similar acres of habitat for lynx and snowshoe hare with or without the land exchange.

No lynx tracking surveys have been conducted on or near the Wetland Mitigation Sites. Only one lynx scat has been collected within 10 miles of the Wetland Mitigation Sites, and there are no records in the MDNR lynx database of lynx within 6 miles of the Wetland Mitigation Sites. These sites are sod farms that would be restored to wetland and upland habitat. They could provide habitat for lynx in the future, but the beneficial effects to lynx from acquisition of these lands would be minor, if any, as there appears to be little or no use of these sites by lynx.

Recreation

Recreational activities are becoming increasingly widespread across the landscape, but their effects on lynx are little known. Very few studies have investigated the complex interactions between humans and wildlife. Some anecdotal information suggests that lynx are quite tolerant of humans (USDOI USFWS 1992, Staples 1995, Roe et al. 1999, Mowat et al. 2000).

Non-consumptive recreational activities are growing in popularity over the more traditional consumptive recreation uses of hunting and fishing (Duffus and Dearden 1990). Trends indicate that land-based activities occurring within developed recreation sites or near roads involve the greatest number of people.

Roads and trails used for recreation may present several risks to lynx, depending on their distribution over the landscape, their accessibility, the season of use, and the intensity and frequency of use. Management concerns include the potential for increased human use associated with roads and trails, which could increase disturbance at den sites, shooting or trapping of lynx, lynx-vehicle collisions, and compaction of snow that may increase inter-species competition. Dispersed recreation activities seldom result in a direct loss of habitat, but are more likely to impart indirect effects, such as increased competition resulting from snow compaction.

Recreational snowmobile use has expanded dramatically over the past 25 years, and is a common recreational activity in northern Minnesota. The growth of snowmobile use and an expanded trail system over the past 2 to 3 decades has increased human presence in lynx habitat in northern Minnesota and elsewhere in the U.S.

Direct and Indirect Effects

Federal Lands and Plant Site

Access to the Project and federal lands is controlled by a security gate near the Plant Site, and a locked gate prevents vehicle access to the Dunka Road at the Northshore Mine. The Dunka Road is a private road,

however, recreationalists could access the Mine Site by using all-terrain vehicles or snowmobiles, or on foot, from the east by traveling along the Dunka Road, and from the south on Forest Service Road 113. The Northshore Mine is north of the federal lands and recreationalists are not allowed to access the Northshore Mine property.

Recreational hunting and all-terrain vehicle/snowmobile use have been observed on or near the federal lands, but use of the site by recreationalists is limited as there is not easy access to the site. During mine operations, access to the Project area would be strictly controlled and recreational activities would not be allowed on the Project area.

Natural population growth, along with an influx of workers to support the Project, would further increase the growth of recreational activity in the Project area and could possibly impact lynx activities. Causes of lynx mortality varies, but Moen (2009) found that most known deaths of lynx were directly or indirectly associated with human activities, both in Minnesota and Ontario, Canada. Dispersed recreation activities seldom result in a direct loss of habitat. However, the road and trail network that is used by dispersed recreation has resulted in a loss of lynx habitat by displacing native vegetation.

Risks to lynx from recreationalists from the Project could increase during mine operations from current levels, as lynx that use the federal lands would be forced into areas surrounding these sites where hunting and other recreational activities are allowed. However, studies have shown that lynx use of the federal lands is uncommon, and thus this risk to lynx would be low. After mine closure, the Project area would remain privately owned and access to the Project area by the public would be prohibited.

If public access to the Project areas and federal lands was no longer restricted, it is likely that recreational use of these lands would increase, to the potential detriment of lynx. However, there is little evidence of lynx use of the Mine Site and Plant Site, with most lynx observations occurring east of the Mine Site. Thus, there should be little impact to lynx if the land exchange does not occur.

Non-federal Lands and Wetland Mitigation Sites

The non-federal lands are privately owned, but some hunting and off-road vehicle use occurs on these lands, except McFarland Lake Lands. Under the Proposed Action, the non-federal lands would be administered by the Forest Service and would be open to public recreation, including hunting and off-road travel. The Wetland Mitigation Sites would be privately owned and hunting and off-road vehicle would not be allowed. It is unlikely that new roads would be constructed to improve access to the non-federal lands and Wetland Mitigation Sites. Thus, risks to lynx from recreational activity would likely not change substantially under the Proposed Action.

If the land exchange does not occur and if the Project is not permitted, non-federal lands and Wetland Mitigation Sites would remain privately owned. Non-federal lands would likely be managed primarily for timber production, and some recreational use (hunting, fishing, and cabins), while the Wetland Mitigation Sites would be managed for agriculture. The level of recreation use and risks to lynx on these areas would not change substantially from current levels.

Forest and Backcountry Roads and Trails

There is a well-established forest and backcountry road and trail system along the Mesabi Iron Range, associated with mining activity, accessing federal, state, county, and privately owned forestlands, and serving recreational areas, private residences, and pasturelands. Roads and trails may present several risks to lynx based on the potential for increased human use in lynx habitat.

Construction of roads may reduce lynx habitat by removing forest cover and increasing the threat of illegal hunting and trapping. On the other hand, in some instances, along less-traveled roads where vegetation provides good snowshoe hare and white-tailed deer habitat, lynx may use the roadbed for travel and foraging (Koehler and Brittell 1990).

Forest backcountry roads and trails may facilitate snowmobile, cross-country skiing, and other human uses in the winter. As described later, snow compaction on roads or trails may allow competing carnivores, such as coyotes and mountain lions, access into lynx habitat (Buskirk et al. 2000). In the absence of roads and trails, snow depths and snow conditions normally limit the mobility of these other predators during midwinter.

Squires et al (2010) found no evidence that lynx are sensitive to forest roads, including roads used by snowmobiles in the winter. This study concluded that seasonal resource-selection patterns of lynx were little affected by forest roads with low vehicular or snowmobile traffic. In densely forested areas, vehicle use was concentrated on roads and trails and lynx were disturbed less than in other more open areas. Lynx were often seen crossing roads near the Mine Site and Northshore Mine during winter lynx surveys in 2006 and 2008 (ENSR 2006, Barr 2011).

Moen et al. (2010) showed that lynx will take advantage of roads when present and that a road and trail network increases habitat connectivity for lynx. In northeastern Minnesota, lynx on long-distance movements traveled within an average distance of less than 656 feet to a road. Lynx use of roads and other linear features is probably based on the energetic efficiency of moving along a road compared to moving through a forest. The northeastern Minnesota landscape is characterized by dense forests, bogs, and lakes of various sizes. Lynx may find that it is more energetically efficient to walk on or alongside of a road, whether within the home range or while on a long-distance movement.

Snowshoe hare densities may be higher along roads and trails due to the juxtaposition of land cover types and ages along these linear routes. The forest edges along forest roads provide preferred habitat for snowshoe hare. Regenerating and young forest is the cover type that has the highest density of snowshoe hares in Minnesota. Therefore, road and trails appear to provide productive snowshoe hare edge habitat that lynx opportunistically utilize (Moen et al. 2008).

Moen et al. (2010) indicated that the road and trail network may increase the connectivity of different parts of the Superior National Forest, and may enable lynx to move further than they would in the absence of a road and trail network. It is also possible that the existing road and trail network would make it easier for immigrating Canada lynx to find parts of the Superior National Forest with adequate snowshoe hare densities.

While linear features such as roads may benefit lynx from an energetic perspective, they may also be negative if they increase the chance of incidental mortality because of exposure to humans. It is unlikely that lynx behavior could be modified to prevent lynx from using linear features such as roads and trails (Moen et

al. 2010). Managing the road and trail network can minimize the potential for conflicts. But whether roads and trails are closed to motorized vehicle use or not, it may be impossible to totally eliminate human-lynx conflicts because human use would continue on non-motorized routes. The benefit of reducing mortality risk by managing road networks and densities has to be balanced against the cost of not being able to use linear features on long-distance movements.

Direct and Indirect Effects

Federal Lands, Transportation and Utility Corridors, and Plant Site

Impacts to lynx in and surrounding the Project area may include mortality from collisions with vehicles and trains. Construction and operation of the project, and the influx of workers to the area, would mean an increase in vehicular and rail traffic. The FEIS estimates that the Project would generate up to 1,316 miles per day of vehicle traffic near the Project site, including trips between the Mine Site and the Plant Site, and trips between the Plant Site and the Area 1 Shop. Vehicle traffic would consist primarily of light trucks and maintenance vehicles traveling between 30 and 45 miles per hour (mph), and a few large fuel, waste/supply, and haul trucks traveling between 25 and 40 mph. The Project would also generate 418 total miles per day of rail traffic between the Mine and Plant sites during mine operations. Trains would operate at 15 to 25 miles per hour (MDNR et al. 2013).

Harm or loss of lynx from collisions with vehicles or trains traveling within the Project boundaries cannot be discounted, but the risk would be very small as there is currently little use of the Project area by lynx, and use of the area by lynx would decrease substantially during project operations due to loss of habitat and noise and disturbance associated with Project activities.

In previous BOs for federal actions that are ongoing in Minnesota, including the *Mesaba Nugget Prevention of Significant Deterioration Permit U.S. Environmental Protection Agency* (USDOI USFWS 2009d), and *Northshore Mine Eastern Progression and CSAH 70 Relocation St. Louis County, Minnesota* (USDOI USFWS 2011a), the USFWS anticipated various levels of take, or loss of lynx to collisions with vehicles or other factors. Based on these opinions, the USFWS estimated that several lynx could be killed annually by current ongoing project-related activities in northern Minnesota, although actual take has been substantially less.

A Wisconsin study (Kohn et al. 2000 *cited in* USDOI USFWS 2009d) of wolf deaths by vehicles was used to estimate the number of lynx and wolf that could be killed by collisions with vehicles along the Dunka Road and Utility Corridor. In that study, an estimated 0.01 wolf were killed per mile of road for a traffic volume of 4,700 vehicles per day and a wolf density of 0.006 wolf per square kilometer. For the previous BOs, and this BA, it was assumed that the likelihood of a collision is the same for lynx and wolves, that trains and vehicles are equally likely to hit a lynx or a wolf, and that the collision frequency is related to the density of the species in the Project area and the vehicle/rail miles traveled per year. The USFWS noted that even intensive studies, such as the wolf mortality study in Wisconsin, may not document all road-related mortality within the study area (USDOI USFWS 2009d). Thus, the USFWS assumed that lynx and wolf mortalities due to automobile collision were actually twice the levels reported from the Wisconsin study (0.02 wolf killed per mile of road).

Based on the assumption that there is about 0.0048 lynx/square kilometer (km²; 1 lynx per 80 mi²; 1 lynx per 207 km²; see Section 6.1.1.3); that there would be about 1,316 vehicle and 418 rail miles traveled each day; that vehicle/rail collisions with lynx could occur during the Project ; and that vehicles and trains are equally likely to collide with lynx, it was estimated that approximately 0.006 lynx would be killed annually by vehicle/rail

traffic on the road/rail line between the Mine Site and Plant Site, or less than one (0.12) lynx during the estimated 20-year life of the Project (assuming that mortalities due to collisions with vehicles and trains were twice the estimated level). Thus, although risk of loss of lynx due to a collision with a vehicle or train is very small, it could occur during the life of the Project.

After mine operations cease, temporary roads would be closed and reclaimed except for a short road from the Dunka Road to the Waste Water Treatment Facility. The Dunka Road would be retained and would provide access to the Mine Site area after mine closure, but would be a private road and closed to public use. Although roads would be constructed to support mine and plant operations, it is expected that the miles of roads on the Mine and Plant sites would decrease from current levels after Mine Site and Plant Site reclamation, thus benefiting lynx (Pylka 2013b).

Temporary roads have been constructed on the federal lands to support timber harvest activities and within a ROW to support powerline maintenance. Except for recently constructed gravel roads to access timber harvest areas, temporary roads are now overgrown in places with vegetation and are generally only suitable for foot, all-terrain vehicle, and snowmobile travel. Vegetation within the ROW is maintained at a low height for safety purposes, and the ROW is accessible to all-terrain vehicles and snowmobiles. Temporary roads may be constructed to support future management, but roads would be likely closed after their intended use and allowed to revegetate; it is unlikely that permanent roads would be constructed. The miles of temporary roads would likely remain at or below current levels, to the benefit of lynx, and roads would be closed to the public (Pylka 2013b).

Non-federal Lands and Wetland Mitigation Sites

Access onto most of the non-federal lands is by secondary roads that branch off of Forest Service or county roads. Most secondary roads were constructed to support timber harvest activities. There is no road access onto Hunting Club Lands and Wolf Lands 4. Access to McFarland Lake Lands is controlled by a locked gate. If acquired by the Forest Service, the non-federal lands would be managed for General Forest, General Forest-Longer Rotation, Riparian Areas, and Candidate Research Natural Areas (MDNR et al. 2013). If new roads are constructed on the non-federal lands, they would likely be temporary and used to support timber management. There would likely be little change in the number of miles of backcountry roads and trails on the non-federal lands, and the number of miles may decrease if existing roads are closed and revegetated or allowed to revegetate naturally, benefitting lynx.

The Aitkin Wetland Mitigation Site is bisected by County Road 1. The Hinckley Wetland Mitigation Site is bordered on the south by Township Road 56, while the Zim Wetland Mitigation Sites are bordered on the west by County Road 7. Secondary access roads are also associated with the sites, but the sites are in rural areas. It is unlikely that new roads would be constructed within the sites, and some roads may be reclaimed in the future, to the benefit of lynx.

Other Human Developments (mining, power generation, etc.)

Other human developments that may alter lynx habitat near the federal and non-federal lands and Wetland Mitigation Sites include rural development, forestry, agriculture, and mine exploration, development, and operation. These activities affect lynx habitat by changing or eliminating vegetation, and may also contribute to habitat fragmentation. There may be an increased potential for human-caused mortality associated with the developments (Ruediger et al. 2000).

Direct and Indirect Effects

Federal Lands and Plant Site

The Northshore Mine is immediately north of the Mine Site and the Mesaba Nugget Mine Project is immediately west of the Plant Site. Sources of noise at these sites include trucks, bulldozers, rock drills, jack hammers, graders, backhoes, air compressors, and cranes. Noise from these facilities could impact lynx residing in or traveling through the Project area. The impacts of noise on lynx and other wildlife are largely unknown and the assessment of impacts remains subjective. Wildlife are receptive to different sound frequency spectrums, many of which may be inaudible to humans. Wildlife are also known to habituate to noise, especially noises that are steady or continuous, such as noises that would occur near the Project. For example, lynx have been seen within about a quarter mile of loud noise sources and other human disturbance at Northshore Mine facilities, and have been seen by drillers within a few hundred feet of operating exploration drill rigs to the east of the Project.

Disturbance associated with these facilities and associated transportation infrastructure includes lights, glare, and noise. Lynx traveling through the Project area may avoid areas that are active and well lit.

Non-federal Lands and Wetland Mitigation Sites

There are no large developments near the non-federal lands or Wetland Mitigation Sites. The non-federal lands are currently managed primarily for timber and recreation, similar to how these lands would be managed by the Forest Service. The Wetland Mitigation Sites would be restored to wetland and upland wildlife habitat. Lynx observations are rare near the Wetland Mitigation Sites and lynx use of the sites after restoration would be infrequent.

Factors Affecting Lynx Mortality

Trapping and Incidental or Illegal Shooting

Lynx mortality has been monitored in northeastern Minnesota since 2000. From 2000 to 2012, 43 incidents of lynx mortality occurred (Rowse 2012). Nineteen of 28 mortalities in which the cause of death was determined were due to illegal trapping or shooting. The 2004 Forest Plan BA reiterated findings from Ruediger et al. (2000) that incidental or illegal mortality may occur from trapping and hunting/poaching activities. The 2004 Forest Plan BA assumed and reported that mortality from trapping and shooting could and has occurred on lands managed by the Forest Service. Lynx mortality could indirectly or cumulatively occur on National Forest lands based on incidental trapping for other species such as fox, fisher, and gray wolf. This cause and effect relationship has not changed since 2004 (USDA Forest Service 2004b).

Since 2004, two lynx within the Superior National Forest, and four lynx outside the Superior National Forest, were killed due to incidental trapping or shooting. Three lynx were killed due to legal trapping in Canada. Five trapped lynx were released alive from traps during that same period in Minnesota (USDA Forest Service 2011b).

Access to the Project area would be carefully controlled and use of the site by workers would be monitored by security personnel. Workers would also be given training in how to avoid harming or killing lynx while working on the site.

Direct and Indirect Effects

Federal Lands and Plant Site

Hunting and trapping of lynx is illegal in Minnesota and would not be allowed on all lands affected by the Project. The Project area would be closed to all types of hunting and trapping during construction and operations. Project personnel would be trained to not harass lynx in the Project area, and to report dead or injured lynx seen on the property. The Project area would be privately owned and closed to the public after mine closure (Pylka 2013b).

Non-federal Lands and Wetland Mitigation Sites

Hunting and trapping are allowed on the non-federal lands and on nearby Forest Service lands. It is assumed that hunting and trapping would be allowed on the non-federal lands if acquired by the Forest Service. As noted above, two lynx have been illegally trapped or shot within Superior National Forest boundaries since 2004, and lynx could be illegally shot or trapped on the non-federal lands after transfer to the Forest Service. However, the risk of loss of lynx from hunting and trapping would be similar to these risks that now occur on the non-federal lands under private ownership.

Competition and Predation as Influenced by Human Activities

New roads and trails associated with Project activities and the influx of workers may facilitate snowmobile, cross-country skiing, and other human uses in the winter. Snow compaction on roads or trails may allow competing carnivores, such as coyotes and mountain lions, access into lynx habitat. In the absence of roads and trails, snow depths and snow conditions normally limit the mobility of these other predators during mid-winter. It is likely that lynx near the Project area would compete with these competitors and predators for primary lynx prey (Buskirk et al. 2000b).

Lynx and carnivore biologists (Bider 1962, Ozoga and Harger 1966, Murray and Boutin 1991, Koehler and Aubry 1994, Murray et al. 1995, Lewis and Wenger 1998, Buskirk et al. 2000b) have suggested that packed trails created by snowmobiles, all-terrain vehicles, and cross-country skiers may serve as travel routes for potential competitors and predators of lynx, especially coyotes. Buskirk et al. (2000b) hypothesized that the usual spatial segregation of lynx and coyotes may break down where human modifications to the environment increase access by coyotes to deep snow areas. Such modifications include expanded forest openings throughout the range of the lynx.

Fuller and Kittredge (1996) noted that the distribution and numbers of coyotes have dramatically expanded in recent decades. Geir (1975) and Nowak (1979) suggested that coyotes are thought to have originated in areas where snow cover was minimal, and it is only within the last century that they have colonized the boreal forests.

Buskirk et al. (2000b) hypothesized that coyotes may be locally or regionally important competitors for lynx food resources, possibly exerting interference competition pressures on lynx as well. O'Donoghue et al. (1998b) also suggested coyotes exert potentially important exploitation competition pressures on lynx. Predation rates by coyotes on snowshoe hares exceeded those of lynx in the Yukon Territories during periods when snowshoe hare population levels are high. Coyotes then shifted their prey preference from snowshoe hares to carrion because of intolerance to deep snow conditions (Todd et al. 1981). Coyotes have been shown to increase their use of open habitats between November and March due to the increase in packed snow conditions and the load-bearing

strength of snow in openings. It is this strong prey- and habitat-switching ability of the coyote that may contribute to its success as a competitor with lynx (Buskirk et al. 2000b).

Murray and Boutin (1991) reported that both lynx and coyotes used travel routes with shallow snow, but that coyotes traveled on harder snow more frequently. They also reported that the use of trails in the snow not only reduced the depth to which an animal sinks into the snow, but aided coyotes and lynx in obtaining additional food. Keith et al. (1977) suggested that during population peaks of snowshoe hares, the density of trails in snow facilitates coyote movement. Murray and Boutin (1991) reported similar results with their study where hare densities were high.

Dispersed recreation activities seldom result in a direct loss of habitat. However, the road and trail network that is used by dispersed recreation has resulted in a loss of lynx habitat by displacing native vegetation on the landscape. Snow compaction can result in increased access by competitors, and increased access for bobcat, thereby increasing the potential for hybridization.

Direct and Indirect Effects

Federal Lands and Plant Site

New roads would be constructed on the Project area. However, these roads would be well traveled and there would be much noise and activity associated with Mine Site and Plant Site activities. In addition, most of the vegetation within the disturbed areas of the Mine Site would be removed, and it may be 10 or more years after mine closure before the Mine Site is reclaimed to wetland, grassland, and shrubland habitat. Coyotes have been seen near the Plant Site, but would be unlikely to use the Project area during operation until after mine reclamation. There could be competition between lynx and coyotes for food resources and other habitat components, but given the low numbers of lynx and coyotes found near the Project area, these effects should be negligible. After mine closure, most roads would be reclaimed; only the Dunka Road and a short road from the Dunka Road to the Waste Water Treatment Facility would remain. These roads would be privately owned and closed to the public (Pylka 2013b).

Non-federal Lands and Wetland Mitigation Sites

As discussed earlier, the non-federal lands and Wetland Mitigation Sites would likely be managed for fish and wildlife habitat, forestry, and recreation with or without the Project. Road densities would remain near current levels. Thus, competition between lynx and coyotes associated with road density should remain near current levels.

Highways (vehicular collisions)

Direct and Indirect Effects

Federal Lands and Plant Site

Direct mortality from vehicular collisions may be detrimental to lynx populations in the lower 48 states (Ruediger et al. 2000). In their 2004 Forest Plan BA, the Forest Service assumed that mortality between high and low standard roads could differ, with potential mortality likely being higher on high standard (high-speed)

paved roads that are typically federally, state or county managed highways and lower on low standard (low-speed) non-paved roads that are typically managed by the Forest Service (USDA Forest Service 2004b).

An estimated 42 worker/supply vehicle round trips would be made daily between the Plant Site and Hoyt Lakes, Minnesota, and 156 worker/supply vehicle round trips would be made daily between U.S. Highway 135 and the Plant Site (Barr 2013a). For purposes of analysis, it was assumed that the average distance between Hoyt Lakes and the Plant Site main security gate is 6 miles, and that traffic accessing the Plant from Highway 135 comes from Babbitt to the Plant Site north gate, or about 33 miles on average. Average speed would be about 50 mph between the Plant Site and Hoyt Lakes, and Plant Site and Highway 135. In addition, about seven trains per month would carry supplies and materials to and from the Plant Site and Virginia, Minnesota, a distance of about 30 miles. These trains would continue on to Duluth or International Falls, Minnesota, but would likely be included with other rail traffic and thus not add to the potential for risk of collision with lynx (Barr 2013b).

The USFWS did not assess risks to lynx from off-site vehicle and train collisions for worker and mine/plant supply delivery traffic associated with other projects in northern Minnesota as discussed in earlier BOs (USDOJ USFWS 2009d, 2011a); the USFWS requested that these risks be estimated for the Project.

Using the same assumptions and methodology used earlier to estimate lynx mortality on Project roads and railroads (see Forest and Backcountry Roads and Trails), approximately 0.037 lynx would be killed annually by vehicle/rail traffic on off-Project access roads/rail lines to the Plant Site, or about two (0.74) lynx during the estimated 20-year life of the Project (assuming that mortalities due to collisions with vehicles and trains were twice the estimated level).

Increased traffic to and from the Project area would increase the threat of lynx mortality from vehicle collisions in the vicinity of the Project. Harm or loss of lynx from collisions with vehicles within the vicinity of the Project cannot be discounted, but the risk would be very small as MDNR lynx observation records suggest there is little lynx use of areas associated with project access roads, and use of these road corridors would decrease substantially during project operations due to noise and disturbance associated with Project and other nearby mining activities, and activities in Hoyt Lakes. In addition, studies by the USFWS found that the estimated loss of lynx to vehicle traffic, based on the methodology used in this study, was substantially greater (3-fold) than the actual loss of lynx (USDOJ USFWS 2009d).

After mine closure, nearly all access roads would be closed. The Dunka Road would remain privately owned and closed to the public. There would be little, if any, rail traffic between the Plant Site and Virginia, Minnesota.

Non-federal Lands and Wetland Mitigation Sites

Lynx have been observed on or near most of the non-federal lands. There are no rail lines on or adjacent to these lands, and limited vehicle access. The lands are primarily used for timber and recreation, and except for Hay Lake Lands, where vehicles travel along the Pike River Road on the eastern boundary of the lands, access to the lands is on logging roads that are primarily used during the hunting season. Access to the lands by vehicles is expected to remain near current levels, with or without the land exchange. No lynx deaths from vehicular collision have been reported on or near the non-federal lands (MDNR 2007). Thus, risks to lynx from vehicular collisions should be negligible.

Some of the Wetland Mitigation Sites are used for sod production. Trucks and other vehicles access the sites for sod production and removal. Under the Proposed Action, these sites would be restored to wetland and upland habitat and except during restoration and monitoring activities, few vehicles would be expected to access the sites. Thus, risks to lynx from vehicular collisions on the Wetland Mitigation Sites may be less under the Proposed Action than under current conditions. Given that lynx have not been reported within 6 miles of these sites, risk to lynx under both use scenarios is negligible.

Other

Hazardous Materials

The Project would use, or generate as waste, the following hazardous materials:

- Fuels, equipment maintenance products, and solvents – diesel fuel, gasoline, oils, grease, lubricants, anti-freeze, solvents, and lead-acid batteries used for equipment operation and maintenance.
- Plant reagents – sodium hydrosulfide, sodium hydroxide, acids, flocculants, and antiscalants used in processing plant applications.
- Mine Site Waste Water Treatment Facility chemicals – calcium hydroxide (hydrated lime), sodium metasilicate, ferric chloride, sodium hydroxide, polymer flocculent, carbon dioxide liquid, citric acid, and sodium hypochlorite.
- Plant Site Waste Water Treatment Plant chemicals – potassium permanganate, antiscalant, carbon dioxide liquid, and calcium hydroxide (hydrated lime).
- Blasting agents – ammonium nitrate/fuel oil (ANFO), emulsions, emulsion blends (a blend of ANFO and emulsion), blasting caps, initiators and fuses, and other high explosives used in blasting.
- Other materials – assay chemicals, and other by-products characterized as hazardous waste.

Mishandling of these materials or wastes could result in spills, accidental release, or discharge into the environment, which could pose risks to lynx. Sections 5.2.13 and 5.3.13 of the FEIS discuss the risks posed to the public and the environment from the transport, handling, storage, and use of hazardous materials. Mitigation measures to prevent releases in transportation, storage, and handling or use of these materials are described in several hazardous material management plans necessary to comply with various regulatory requirements for the Project and in the FEIS. Based on the FEIS analysis, and scarcity of lynx on the areas where these materials would be used, risks to lynx would be negligible and should not result in harm or death to lynx (MDNR et al. 2013).

Factors Affecting Lynx Movements

Highways, Roads, and Rights-of-ways

Moen et al. (2010) observed that lynx movements were made across roaded areas, and also across the BWCAW, which has few linear features such as roads, trails, and logging roads that could guide movement by

lynx, in northeastern Minnesota. Observations suggested that geographically or topographically definable movement corridors do not exist for lynx in northeastern Minnesota, nor between Minnesota and Ontario. Moen et al. (2010) suggested that linear features such as roads benefit lynx from an energetic perspective, but may also be negative if they increase the chance of incidental mortality because of exposure to humans.

Direct and Indirect Effects

Federal Lands and Plant Site

As discussed earlier, traffic associated with the Project would be on access roads leading to and from the Project area, along the Dunka Road and Utility Corridor, and on access roads to the Mine Site. Most traffic would travel on existing roads; new roads would be primarily limited to the Mine Site. After mine closure, many of the access roads would be closed to traffic and reclaimed. Traffic on the Dunka Road between the Mine Site and Plant Site during mine construction and operation should discourage use by lynx. However, most traffic within the corridor would likely occur during shift changes. Because lynx rarely use the Mine Site, Plant Site, or Transportation and Utility Corridors, and noise and disturbance associated with the Mine Site and Plant Site would discourage use of these areas by lynx, it would be unlikely that lynx would use these areas during mine construction and operations and effects of traffic on lynx movements would be negligible.

Non-federal Lands and Wetland Mitigation Sites

If lands are exchanged to the Forest Service, it is unlikely that the Forest Service would build new access roads to the lands. It is also unlikely that state or federal agencies would construct new roads near the lands, as these lands are in remote locations and little used by the public. Thus, activities on highways, roads, and ROWs near the non-federal lands, and their effects on lynx movements, would be little changed with or without the land exchange.

Access onto most of the non-federal lands is by secondary roads that branch off Forest Service or county roads. Most secondary roads were constructed to support timber harvest activities. There is no road access onto Hunting Club Lands and Wolf Lands 4. Access to McFarland Lake Lands is controlled by a locked gate. These roads are little used and traffic levels should change little under the land exchange. There would likely be little change in the number of miles of backcountry roads and trails on the non-federal lands, and the number of miles may decrease if existing roads are closed and revegetated or allowed to revegetate naturally, benefitting lynx.

The Aitkin Wetland Mitigation Site bisected by County Road 1. The Hinckley Wetland Mitigation Site is bordered along the south by Township Road 56, while the Zim Wetland Mitigation Sites are bordered on the west by County Highway 7. Because lynx are rarely observed near the wetland mitigation sites, highway and local traffic should have little effect on lynx.

Land Ownership Patterns

Lynx exemplify the need for landscape-level ecosystem management. Land and population management must cross international, federal, state, county, and private land boundaries. Coordination within and between agencies and other landowners has often been difficult. In situations where habitat connectivity is needed to maintain adequate populations, private land development may preclude use by lynx, and may interrupt the

connectivity of habitat and populations. In these situations, it will be important to provide conservation easements, land exchanges, or purchases to maintain adequate lynx habitat and populations.

Habitat fragmentation also may impede lynx movements. This could have negative effects by isolating lynx and/or prey populations, or by retarding movements to other areas (Ruediger 2000).

Contiguous tracts of land in public ownership (national and state forests, wilderness areas) provide an opportunity for management that can maintain lynx habitat connectivity. Throughout most of the lynx range in the lower 48 states, connectivity with habitats and source populations in Canada is critical to conservation of populations in the U.S. The size, amount, and spatial distribution of federal land vary considerably from west to east across the U.S.

The ability to provide connectivity between the two northern Minnesota National Forests is complicated by the lack of contiguous National Forest ownership and varied land use patterns. However, the eastern two thirds of the Superior National Forest is largely federally owned, and the BWCAW refugium remains intact and contiguous with Canada.

Ownership adjustments have occurred on the Superior National Forest since 2004. The largest land exchange, the South Kawishiwi Cabin Group, occurred in 2010. In that land exchange approximately 1,213 acres were acquired by the Forest Service and approximately 425 acres were disposed of, resulting in a net acquisition of 788 acres. All other individual land purchases, donations, and exchanges were less than 100 acres (USDA Forest Service 2011b). The land ownership changes contribute towards Forest-wide lynx habitat but the amounts that have occurred since 2004 have been relatively insignificant compared to the large area of the Superior National Forest (2,125,931 acres).

Direct and Indirect Effects

Federal Lands and Plant Site

The Project would involve the transfer of approximately 6,495 acres of Forest Service-administered lands to PolyMet, in exchange for 7,075 acres of privately owned lands. This land exchange would be the largest land exchange conducted by the Forest Service, and would result in a net acquisition of 580 acres by the Forest Service. The land exchange would help the Forest Service to consolidate ownerships by obtaining non-federal lands that are adjacent to Forest Service lands. However, the exchange would also increase the amount of land converted to mining and unavailable to lynx, at least until the Mine Site is reclaimed. Land reclaimed after mining could provide suitable lynx habitat, but it could be 10 or more years before revegetation, due to the successional process, results in much suitable habitat for lynx.

Although there is little documented use of the Mine Site by lynx, loss of habitat and noise and disturbance from the Project, could influence lynx movements on or near the Mine Site. It is possible that lynx could travel between forestlands to the south of the Mine Site and the Northshore Mine by traveling through the federal lands surrounding the Mine Site, or through forestlands further east of the Mine Site. Given the loss of habitat and increase in disturbance that would be associated with the Mine Site, it seems more likely that lynx would primarily use forestlands to the south and east of the Mine Site and Northshore Mine, and avoid the Mine Site and lands between the Mine Site and Plant Site. That said, lynx, including adults with kittens, have been seen using portions of the Northshore Mine, and could use the federal lands, even during mine construction and operations.

Non-federal Lands and Wetland Mitigation Sites

The transfer of the non-federal lands to the Forest Service should have negligible, if any, effect on lynx movements. Management of these lands would remain relatively unchanged, and lands would primarily be used for timber production and recreation.

Wetland Mitigation Sites would be converted from agricultural uses to wildlife habitat. Although lynx have not been reported on or near these sites, their value to lynx would increase once taken out of agricultural production, and lynx may move onto these sites in the future.

6.1.2.2 Effects to Lynx Critical Habitat

Overview

Primary Constituent Elements of Lynx Critical Habitat

Critical habitat is defined as “specific area within the geographical area occupied by the species...on which are found those physical and biological features (a) essential to the conservation of the species and (b) which may require special management considerations or protection” (USDOJ USFWS and NMFS 1998).

On November 9, 2006, the USFWS designated 319 mi² as critical habitat in Voyageurs National Park, Minnesota. On February 25, 2009, the USFWS re-designated lynx critical habitat to include portions of Cook, Koochiching, Lake, and St. Louis Counties, Minnesota, including a portion of the federal lands, and all of the non-federal lands. A total of 8,065 mi² were designated as critical habitat in 2009 (USDOJ USFWS 2009a). The Wetland Mitigation Sites are not included in the designated critical habitat area.

In its 2009 designation of critical habitat for lynx in northeastern Minnesota, including the Project area, the USFWS identified physical and biological features that are essential to the conservation of the species and that may require special management considerations or protections. The physical and biological features are primary constituent elements (PCEs) laid out in a specific quantity and spatial arrangement to be essential to the conservation of the species. The PCEs of critical habitat for lynx are found in boreal forest landscapes supporting a mosaic of differing successional forest stages and containing:

- a. Presence of snowshoe hares and their preferred habitat conditions, which include dense understories of young trees, shrubs, or overhanging boughs that protrude above the snow, and mature multistoried stands with coniferous boughs touching the snow surface.
- b. Winter snow conditions that are generally deep and fluffy for extended periods of time.
- c. Sites for denning that have abundant coarse woody debris, such as downed trees and root wads.
- d. Matrix habitat (e.g., hardwood forest, dry forest, non-forest, or other habitat types that do not support snowshoe hares) that occurs between patches of boreal forest in close juxtaposition (at the scale of a lynx home range) such that lynx are likely to travel through such habitat while accessing patches of boreal forest within a home range.

The Forest Service identified quantitative indicators in the 2004 Forest Plan BA to analyze the impacts of those risk factors that have the most substantive impacts on lynx habitat (USDA Forest Service 2004b). These indicators have been used to assess impacts to lynx critical habitat in this BA. These analysis indicators also serve as appropriate indicators for analysis of effects to critical habitat and its constituent elements. This is because the indicators address relevant PCEs of lynx critical habitat—those physical and biological features that are essential to the conservation of the species.

Table 8 compares the lynx risk analysis indicators to the PCEs and identifies the risk analysis indicators evaluated in this BA. For this analysis, risk analysis indicators are grouped as follows—habitat management, human activity (recreation and roads and trails), and cumulative. The cumulative effects risk analysis indicators are addressed in Section 6.1.4.

The following discussion provides an overview of the direct and potential indirect impacts to PCEs from the Project. It is followed by an analysis of impacts to PCEs based on lynx analysis indicators developed by the Forest Service.

Effects of NorthMet Project on Primary Constituent Elements

Presence of snowshoe hares and their preferred habitat conditions, which include dense understories of young trees, shrubs, or overhanging boughs that protrude above the snow, and mature multistoried stands with conifer boughs touching the snow surface.

The Forest Service has determined that there are about 6,365 acres of foraging habitat for snowshoe hare on the federal lands, or about 98% of the federal lands. Although snowshoe hare were seen throughout the federal lands, the largest concentrations of snowshoe hares were seen in the eastern portion of the federal lands in areas dominated by jack pine (ENSR 2000). Based on an assessment of existing conditions and conditions at the closure of the mine, there would be a loss of approximately 1,669 acres of snowshoe foraging habitat due to mining, or about 26% of the federal lands. Approximately 4,696 acres of federal lands owned by PolyMet adjacent to the Mine Site would still provide habitat for snowshoe hare.

In addition, basic foraging habitat, including forbs, grasses and small shrubs could be available to snowshoe hare about 10 years after mine closure due to succession within the disturbed areas, although it is uncertain if snowshoe hare would move from areas outside of the Mine Site to suitable habitat on the Mine Site. More mature snowshoe hare habitat, including young trees and boughs overhanging snow, could be available about 25-30 years after mine closure. Therefore, while about 397 acres of habitat lost to mining would be reclaimed after mine closure, it could be a minimum of 10 years before revegetation results in much suitable habitat for lynx. This is because of the estimated minimum 10-year period for basic snowshoe hare forage habitat (forbs, shrubs) to develop. Based on the mine closure plan, most of the 397 acres of the habitat lost to mining that would be reclaimed would be reclaimed as grassland/herbaceous (54%), wetland and/or grassland/herbaceous (27%), and wetland (18%). Areas reclaimed as wetland would not be suitable habitat for lynx. Snowshoe hare and lynx tracks were seen at the base of waste rock piles with scattered stands of young forest near the Dunka Pit. These rock piles are about 5 miles from undisturbed habitat used by snowshoe hares. Thus, snowshoe hare have shown the ability to re-colonize areas associated with mine development. The West Pit would not be reclaimed to the surface for revegetation, but would remain as a 320-acre open pit lake (MDNR et al. 2013).

Winter snow conditions that are generally deep and fluffy for extended periods of time.

Northeastern Minnesota generally receives approximately 70 inches of snow per year. Snow cover at least 1 inch deep is present between 85 days per year and 140 days per year depending on the part of the state. In general, snow can be found on the federal lands between October and April. Studies of lynx and other wildlife on the federal lands found that the snow is relatively dry, fluffy, and several feet deep during much of the winter (ENSR 2000, 2006). As discussed in Section 6.1.1.10, snowshoe hare favor areas that have deep snow and use black spruce and balsam fir forests with dense understory vegetation that provide forage, cover to escape from predators, and protection during extreme weather (Wolfe et al. 1982, Monthey 1986, Hodges 2000a, b). Generally, earlier succession (younger) forest stages have greater understory structure than do mature forests and, therefore, support higher snowshoe hare densities (Fuller 1999, Hodges 2000a, b). Generally, open areas and areas with earlier succession forest stages have deeper snow depths than areas with more mature forest, as the branches of trees in mature forests capture more snow than younger forests, resulting in shallower snow in mature than younger forests (ENSR 2005).

There are approximately 271 acres of young and 1,539 acres of immature forest on the federal lands. Of these, approximately 1,333 acres (73.6%) would be directly impacted by the mine project and lost to snowshoe hare and lynx during mine operation and closure. As discussed above, approximately 397 acres would be reclaimed, and as these lands change from grassland to shrubland and young/immature forestland, their value to snowshoe hare and lynx would increase.

Sites for denning that have abundant coarse woody debris, such as downed trees and root wads.

Based on radiotelemetry studies in Minnesota, most lynx dens are found in tree wind-throw areas with dense vertical and horizontal cover. Dens were often located in an area with foraging habitat and denning cover, and often in small patches of upland within a larger wetland. These are often areas where wind-throw occurs (Moen and Burdett 2009). Tree age is generally greater than 60 years.

About 5,393 acres of lynx suitable denning habitat are found on the federal lands, or 83% of federal lands. Snags and large woody debris were uncommon in disturbed areas, shrublands, and young and immature forests. Large snags (up to 16 inches dbh), stumps, and woody debris were common in more mature forest stands (ENSR 2005). Little blowdown was observed on the federal lands and generally occurred adjacent to recent forest harvest areas and near roads and transmission lines. Based on an assessment of existing conditions and conditions at closure of the mine, there would be a loss of approximately 1,333 acres of denning habitat due to mining. Thus, there would be a 20% reduction of denning habitat on the federal lands.

Matrix habitat (e.g., hardwood forest, dry forest, non-forest, or other habitat types that do not support snowshoe hares) that occurs between patches of boreal forest in close juxtaposition (at the scale of a lynx home range) such that lynx are likely to travel through such habitat while accessing patches of boreal forest within a home range.

Communities used most often by lynx are young jack pine/balsam fir forests. Balsam fir often occurs as inclusions or “pockets” of regenerating trees within other cover types (e.g., in mature jack pine stands or in maturing black spruce/trembling aspen stands), and along forest edges. Lynx also use coniferous or mixed coniferous/deciduous forest patches in regenerating logged areas, including 10- to 25-year-old stands of jack pine or balsam fir/trembling aspen mixed coniferous/deciduous forest. Other important habitat types include black spruce/balsam fir and black spruce/tamarack forests.

Communities used by lynx often originate as a result of natural or “facilitated” regeneration after logging. However, fire and spruce budworm outbreaks also play a role in influencing forest stand composition and age in sites used by lynx. It generally takes 12 to 30 years after a forest thinning or fire before conditions become suitable for snowshoe hare, as forests mature from the young to the immature stage.

Upland forest greater than 4 years of age, and lowland stands with forest greater than 9 years of age, provide suitable lynx cover to support habitat connectivity (USDA Forest Service 2004b). As shown on **Figure 9** and **Table 9**, the Mine Site consists of a mix of lowland and upland conifer and deciduous forest of various ages. Conifer forest habitat dominates the mine site, but other habitat types, including open grasslands and wetlands, deciduous forest, frozen lakes, roads, and utility corridors are found in close proximity to conifer forests and have been used by lynx on or near the Mine Site.

There are about 6,372 acres (98% of federal lands) of lynx habitat with adequate canopy cover on the federal lands. Based on an assessment of existing conditions and conditions at closure of the mine, there would be a loss of approximately 1,669 acres of lynx habitat with adequate canopy cover due to mining, or about 26% of lynx habitat with adequate canopy cover within the federal lands (MDNR et al. 2013).

Risk Analysis Indicators

Habitat Management

Direct and Indirect Effects

The Forest Service has identified five risk analysis indicators to measure loss of habitat that would apply to the Project (Ryan 2011). Parameters used by the Forest Service to identify suitable lynx habitat, and foraging habitat for snowshoe hare, were given in the Forest Plan BA (USDA Forest Service 2004b). In general, snowshoe hare foraging habitat was found in upland forest stands that were 3 to 15 years of age, or older than 60 years of age, while lowland stands are generally 10 years or older. Lynx denning habitat is typically found in forest stands that are 80 years or older and have large down woody material or areas of tree wind-throw. The existing condition of habitat-related indicators and impacts to lynx habitat from actions at the Mine Site and Plant Site for LAUs are provided in **Table 9**. All non-federal lands, except Hay Lake Lands, are within LAUs. Although the land exchange would not increase or decrease the amount of lynx habitat within these LAUs, it would contribute to the amount of lynx habitat administered by the Forest Service. Habitat gains and losses by LAU for lands under Forest Service administration for risk analysis indicators are summarized in **Table 9**.

Indicator 1a – Snowshoe Hare Foraging Habitat

The Mine Site is in LAU SNF 12. The Forest Service determined that there are about 6,365 acres of foraging habitat for snowshoe hare on the federal lands (**Figure 19**). Based on an assessment of existing conditions and conditions at closure of the mine, there would be a loss of approximately 1,669 acres of snowshoe hare foraging habitat due to mining, or about 6% of the snowshoe hare foraging habitat within LAU SNF 12 that is administered by the Forest Service (the Forest Service has not identified snowshoe foraging habitat on those portions of the LAU that are not administered by the Forest Service (MDNR et al. 2013).

The lands adjacent to the Mine Site would still provide habitat for snowshoe hare even though lands would be owned by PolyMet. In addition, foraging habitat could be available to snowshoe hare about 20 years after mine

closure due to restoration of disturbed areas, although it is uncertain if snowshoe hare would move from areas outside of the Mine Site to suitable habitat on the Mine Site. Snowshoe hare and lynx tracks were seen at the

¹ Acreages may differ slightly from acreage given in FEIS due to rounding.

² Acres under all ownerships within the LAU/acres administered by the Forest Service within the LAU; acreage under all ownerships not available for indicators 1-3.

NA = Acreages do not include Hay Lake Lands, which is not within an LAU.

Total acreage within the LAU for all land ownerships —LAU SNF 4 = 55,071 acres, SNF 12 = 70,980 acres, SNF 16 = 76,108 acres, SNF 21 = 73,266 acres, SNF 22 = 58,154 acres, and SNF 42 = 32,305 acres; total acreage for lands administered by the Superior National Forest —LAU SNF 4 = 33,321 acres, SNF 12 = 49,409 acres, SNF 16 = 33,679 acres, SNF 21 = 36,082 acres, SNF 22 = 41,210 acres, and SNF 42 = 24,687 acres.

Sources: MDNR et al. (2013), Ryan (2013a).

base of waste rock piles with scattered stands of young forest near the Dunka Pit. These rock piles are about 5 miles from undisturbed habitat used by snowshoe hares. Thus, snowshoe hare have shown the ability to re-colonize areas associated with mine development.

Collectively, there about 6,777 acres (96% of available habitat) of snowshoe hare foraging habitat on the non-federal lands (**Figures 20 and 21**). This habitat, which is associated with several different LAUs, and Hay Lake Lands, would be administered by the Forest Service under the Proposed Action (**Table 9**). Based on habitat losses on the federal lands, and gains from the non-federal lands, there would be a net gain of 412 acres of snowshoe hare foraging habitat under Forest Service administration under the Proposed Action (MDNR et al. 2013).

Indicator 1b – Unsuitable Habitat

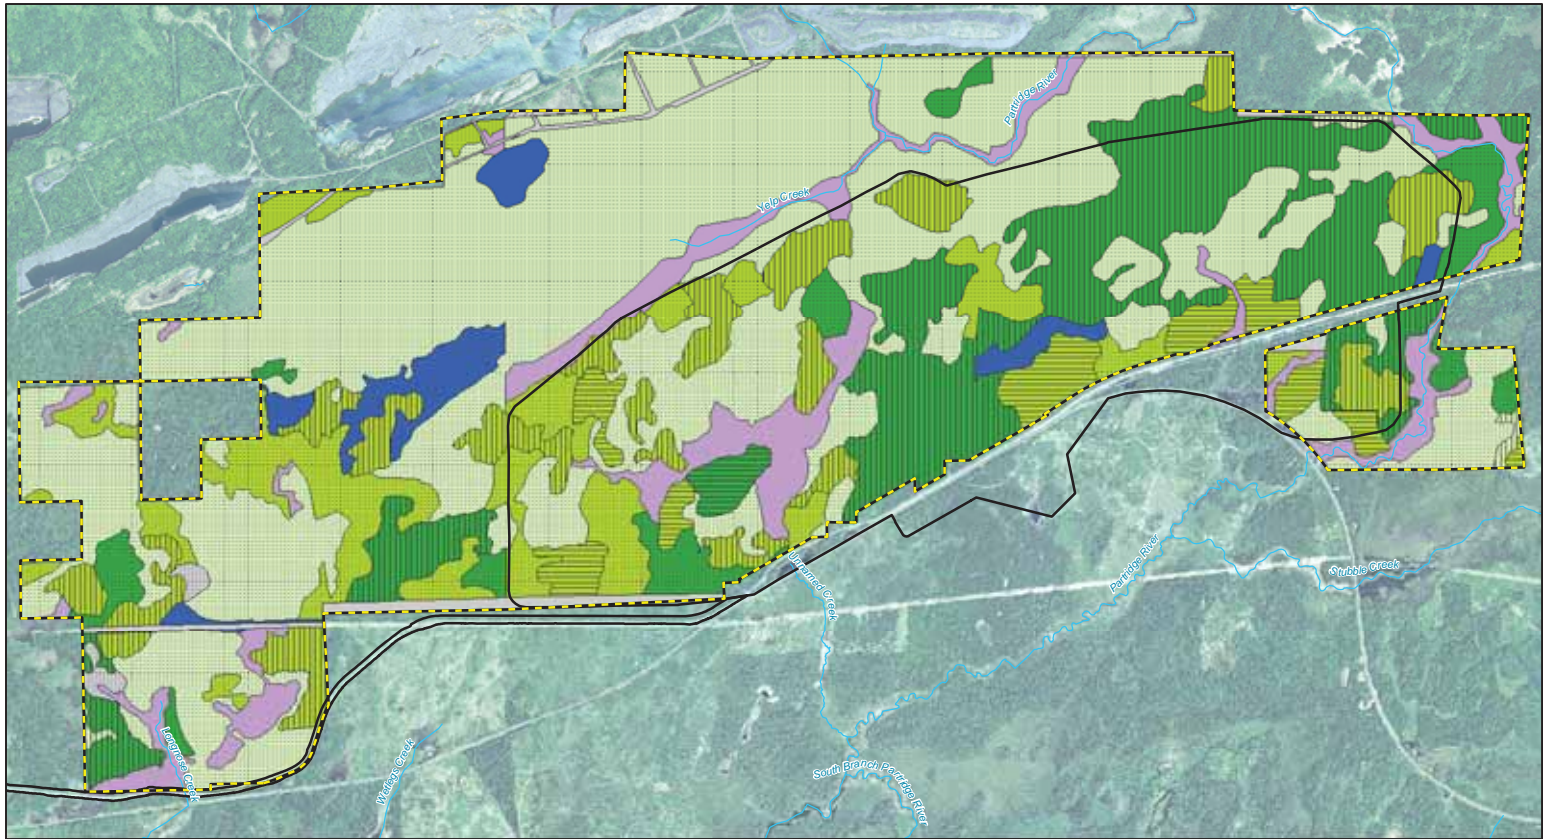

There are about 130 acres of unsuitable habitat for snowshoe hare on the federal lands (MDNR et al. 2013). Unsuitable habitat is defined as areas that are in the initial stages of forest growth where vegetation has not developed sufficiently to support snowshoe hare populations during all seasons (USDA Forest Service 2004b). For purposes of this BA, these are disturbed, cropland/grassland, and aquatic environments based on MDNR cover types (MDNR et al. 2013). Based on an assessment of existing conditions and conditions at mine closure, there would be a gain of approximately 1,669 acres of unsuitable habitat for snowshoe hare due to the Proposed Action, as about 50 acres of the disturbance area is already unsuitable for snowshoe hare. Some of this habitat may become suitable for snowshoe hare over time, as discussed above. There would be no change in the amount of unsuitable habitat on the federal lands surrounding the Mine Site due to the Project. However, because unsuitable habitat associated with the federal lands would be transferred from the Forest Service to PolyMet, there were be a reduction in unsuitable habitat for snowshoe hare administered by the Forest Service in LAU SNF 12 from current levels under the Proposed Action.

Collectively, there are about 267 acres of unsuitable habitat for snowshoe hare on the non-federal lands. This habitat, which is associated with several different LAUs and Hay Lake Lands, would be administered by the Forest Service under the Proposed Action (**Table 9**). There would be a gain of 137 acres of unsuitable habitat for snowshoe hare under Forest Service administration under the Proposed Action.

Indicator 3 – Denning Habitat

Based on an assessment of existing conditions and conditions at closure of the mine, there would be a loss of approximately 1,333 acres of denning habitat due to mining. There are about 5,393 acres of lynx suitable denning habitat on the federal lands. Thus, there would be a 7% reduction of denning habitat under in LAU SNF 12 from current levels (MDNR et al. 2013).

Collectively, the non-federal lands would provide about 5,363 acres of denning habitat (76% of all habitats within the non-federal lands). This habitat, which is associated with several LAUs and Hay Lake Lands, would be administered by the Forest Service under the Proposed Action (**Table 9**). Based on habitat losses on the federal lands, and gains from the non-federal lands, there would be a net loss of 30 acres of denning habitat under Forest Service administration under the Proposed Action.

Indicator 4 – Lynx Habitat with Adequate Canopy Cover

Upland forest greater than 4 years of age, and lowland stands with forest greater than 9 years of age, provide suitable lynx cover to support habitat connectivity (USDA Forest Service 2004b).

There are about 6,372 acres of lynx habitat with adequate canopy cover on the federal lands. Based on an assessment of existing conditions and conditions at closure of the mine, there would be a loss of approximately 1,669 acres of lynx habitat with adequate canopy cover due to mining, or about 2% of lynx habitat with adequate canopy cover within LAU SNF 12 (MDNR et al. 2013). Under the land exchange, the Forest Service would no longer administer 6,372 acres of lynx habitat with adequate canopy within LAU SNF 12 (13% loss of suitable habitat administered by the Forest Service in LAU SNF 12), but would gain 2,134 acres of suitable habitat in other LAUs. The Forest Service would also gain an additional 4,675 acres of suitable habitat on Hay Lake Lands, or 6,809 acres in total, for a net gain of 437 acres of lynx habitat with adequate canopy cover under Forest Service administration (MDNR et al. 2013).

Human Disturbance

Recreation

Risk Analysis Indicators

The Forest Service identified four risk analysis indicators to measure risks to lynx from recreational activities.

Indicator 5 – Miles of Designated All-terrain Vehicle Trails

Indicator 6 – Miles of Designated Snowmobile Trails

As discussed in the 2004 Forest Plan BA, one of the key concerns associated with all-terrain vehicles and snowmobile trails is the potential for increased and deeper access for humans into lynx habitat (USDA Forest Service 2004b). Snowmobile and all-terrain vehicle use (or, on some trails, other means of access such as walking or driving other types of vehicles) for trapping, hunting, or other recreational activities may increase the chance for lynx disturbance, harm, or mortality throughout wider areas of the Superior National Forest and on privately owned lands. Because of the lynx's vulnerability to trapping, this potential impact is difficult, if not impossible, to avoid. Because Forest Service plans foster recreation and encourage recreational uses of the Forest, there is an increased potential for negative impacts to lynx on lands administered by the Forest Service.

The 2004 Forest Plan (USDA Forest Service 2004a) provides overall direction for road and trail density in lynx habitat, recommending upper limits for road and trail density of 2 miles/mi² and guidance to seek opportunities to reduce density. Direction for designated snow-compacted trails, on the other hand, guides the Forest Service to generally allow for no net increase of winter trails unless they serve to consolidate use.

Another concern with new construction of designated all-terrain vehicle trails and snowmobile trails is the potential for increased snow compaction and access for competitors to lynx habitat. This is not a major issue on Forest Service-administered lands as the 2004 Forest Plan allows no net increase in designated snow-compacting trails unless they effectively consolidate use. However, there may be a concern with new all-terrain vehicle trails because in most locations it is likely that these routes could appear inviting to snowmobiling, and thus may have an unintended result of increasing snow compaction where trails coincide with lynx habitat.

These two indicators were not analyzed in this BA. There are no designated all-terrain vehicle or snowmobile trails on the federal and non-federal lands and Wetland Mitigation sites, except for 0.03 miles of designated trail on Wolf Lands 3. The Forest Service would promote recreational use of the lands it acquires in the land exchange, but is not expected to develop new all-terrain vehicle or snowmobile trails, or improve existing non-designated trails. Thus, all-terrain vehicle and snowmobile use of the non-federal lands is expected to remain near current levels, without or without the land exchange.

Under the Proposed Action, PolyMet would gain control of the federal lands and Wetland Mitigation Sites. Access to the Project area would be strictly controlled during mine operations and PolyMet has no plans to construct designated all-terrain vehicle or snowmobile trails on the federal lands or Wetland Mitigation Sites. Thus, there would be no change in designated trails on federal and non-federal lands with or without the proposed land exchange.

Indicator 8 – Policy of Cross-country Use of All-terrain Vehicles and Snowmobiles

This indicator applies to lands administered by the Forest Service. Cross-country use by all-terrain vehicles and snowmobiles is allowed now and would also be allowed in the future in most management areas on the Superior National Forest. It is difficult to estimate the consequences of this policy. Ruediger et al. (2000) suggested that recent advances in snowmobile technology may allow snowmobiles to travel in deeper snow and to areas that were not accessible with older machines. However, most snowmobiles used on the Superior National Forest are getting larger and are designed for use on maintained system trails, and machines are difficult to take off trails or open areas because of the density of the forest. Places that can currently be traversed cross-country frequently are already used from year to year. For example, rivers or open non-forest lands that provide a long enough travel way can become *de facto* trails, because they are used in most winters and during most of the winter.

Under the Proposed Action, Superior National Forest policies would not apply on the federal lands. As noted above, public access to these areas would be restricted during and after mine operations.

Forest Service policies would apply to the non-federal lands under the Proposed Action. Some cross-country use of these lands occurs now, and would be expected to continue if these lands are administered by the Forest Service. Because there would be few changes under the Proposed Action, and because snowmobilers typically prefer established trails to cross-country travel through forested habitat, there should be little change in impacts to lynx with or without the land exchange. This indicator is not analyzed in this BA.

Indicator 9 – Policy on Cross-country Use of All-terrain Vehicles and Snowmobiles on OML 1 and 2 Roads

The Forest Service generally allows all-terrain vehicles and snowmobile use on all existing Objective Maintenance Level (OML) 1 and 2 roads and on unclassified roads (generally these are former temporary or low standard roads).

Objective Maintenance Level 1 designation is assigned to intermittent service roads when they are closed to street legal motorized vehicular traffic. The closure period must exceed 1 year. Roads receiving OML 1 maintenance would generally be managed at OML 2 during the time they are open for traffic. Basic custodial maintenance is performed to keep damage to adjacent resources to an acceptable level and to perpetuate the road to facilitate future management activities. Emphasis is normally given to maintaining drainage facilities and runoff patterns.

Objective Maintenance Level 2 designation is assigned to roads operated for use by high clearance vehicles. Passenger car traffic is not a consideration. Traffic is normally minor, usually consisting of one or a combination of administrative, permitted (such as log haul), dispersed recreation, or other specialized uses. Log haul may occur at this level. Temporary and newly constructed OML 1 and 2 roads would be effectively closed following their intended management use.

County and temporary or low standard roads are found on the non-federal lands and were constructed to facilitate timber management and recreational access. The effects of the Proposed Action on all-terrain vehicle and snowmobile use of temporary or low standard roads associated with the federal and non-federal lands would be similar to those described for Indicator 8. Thus, this indicator is not analyzed in this BA.

Roads and Trails

Risk Analysis Indicators

The Forest Service has identified one risk analysis indicator to measure impacts from forest and backcountry roads and trails.

Indicator 7 – Miles of Temporary and OML 1 and 2 Roads

Temporary roads are authorized by contract, permit, lease, other written authorization, or emergency operation. They are not intended to be a part of the forest transportation system, and are not necessary for long-term resource management. These roads are not included on the National Forest System road inventory and are decommissioned after use (USDA Forest Service 2004b). Objective Maintenance Level 1 and 2 roads are discussed above under Indicator 9. This indicator is not analyzed in this BA because there would be little or no change in the miles of temporary and OML 1 and 2 roads on federal and non-federal lands under the Proposed Action (Ryan 2013a).

Under the Proposed Action, PolyMet would gain control of the federal lands. There are approximately 5.9 miles of temporary and OML 1 and 2 roads on the federal lands. Temporary roads built to support historic timber management and mine exploration on the proposed Mine Site would be lost to mine development. Access to the Project area would be strictly controlled during mine operations.

These roads would likely have little impact on lynx, as lynx would be discouraged from using the roads due to noise and other disturbances. After mine closure, most access roads would be closed and the property would remain privately owned and closed to public access. Temporary roads may be constructed on the federal lands associated with the Mine Site to support forest management activities, but the number of miles of temporary backcountry roads and trails on the Project area should be similar to, or less than, existing miles of backcountry roads and trails on the federal lands. Roads would be privately owned and closed to public access. (Pylka 2013b).

The Forest Service would primarily manage the non-federal lands for timber production and recreation. If new roads are constructed on the lands, they would likely be temporary and used to support timber management. There would likely be little or no change in the number of miles of backcountry roads and trails on the non-federal lands, and the number of miles may decrease if existing roads are closed and revegetated or allowed to revegetate naturally, benefitting lynx.

6.1.3 Interrelated and Interdependent Effects

No known activities are interrelated or interdependent to the Project that would have the potential to affect Canada lynx. It is possible that future specific programs or projects may have relevant interrelated and interdependent actions (e.g., expansion of the Mine Site due to discovery of new ore bodies) and they would be considered in the context of consultations for those actions.

6.1.4 Cumulative Effects

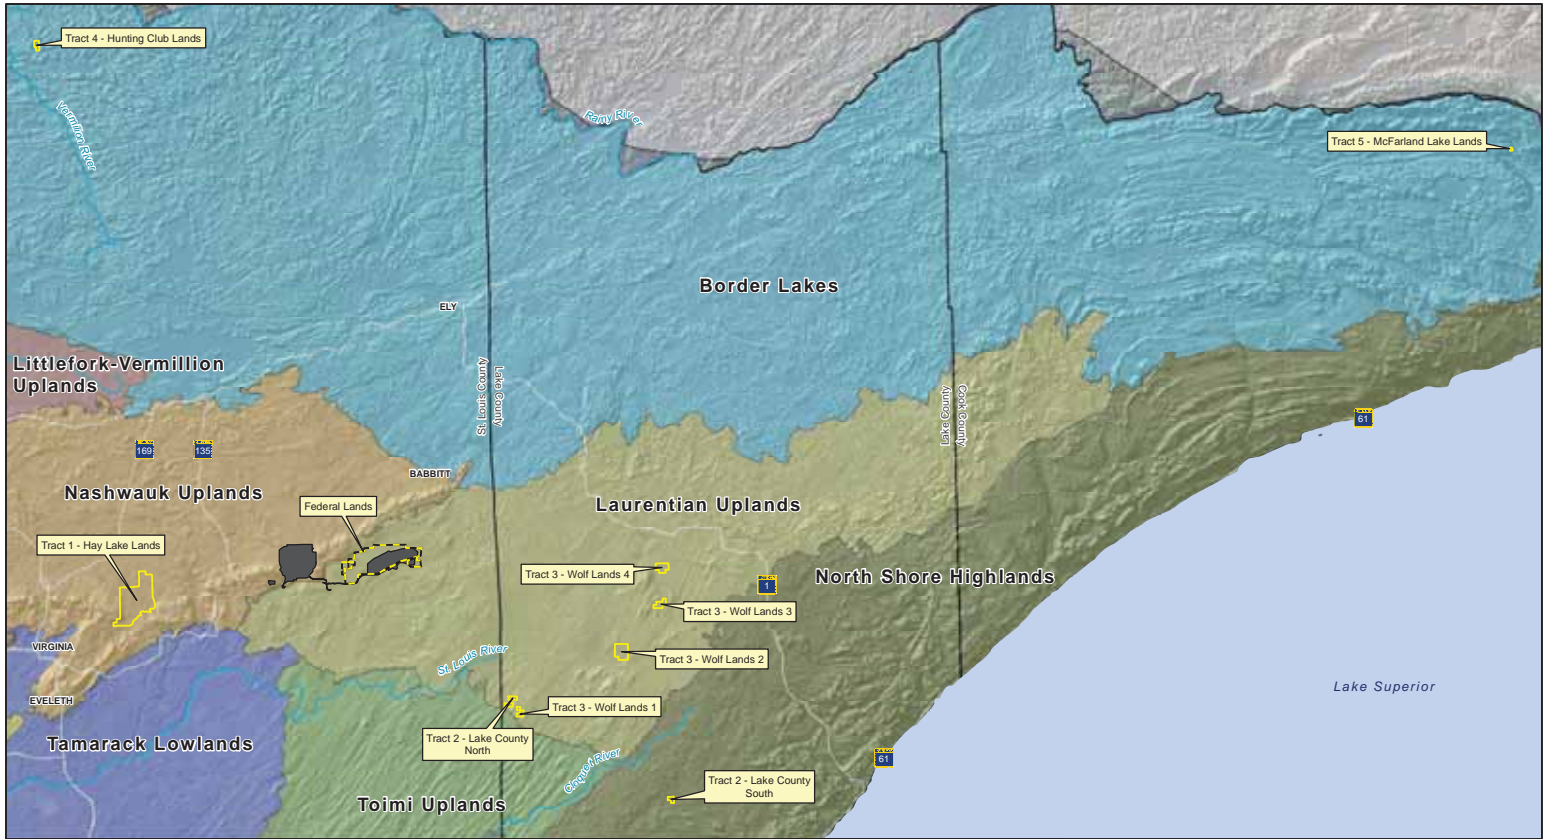

Cumulative effects include the effects of future state, tribal, local, or private actions that are reasonably certain to occur in the cumulative effects study area (CESA) considered in this BA. Future federal actions that are unrelated to the Proposed Action are not considered in this BA because they require separate consultation pursuant to Section 7 of the ESA.

The CESA includes the Nashwauk and Laurentian Uplands ecological subregions within the Arrowhead Region of Minnesota. This area totals approximately 1.38 million acres in the northeast corner of Minnesota (**Figure 22**; Emmons and Olivier Resources, Inc. 2006). The period for analysis of cumulative effects in this BA was from pre-settlement (approximately 1890) through closure and reclamation of Project facilities (approximately 40 years).

Cumulative effects to plants and animals are discussed in Chapter 6 of the FEIS (MDNR et al. 2013). The impacts discussed in that section were based on an analysis conducted for a 2006 MDNR report titled *Cumulative Effects Analysis on Wildlife Habitat and Travel Corridors in the Mesabi Iron Range and Arrowhead Regions of Minnesota* (Emmons and Olivier Resources, Inc. 2006), and a report titled *Cumulative Effects Analysis of Wildlife Habitat and Threatened and Endangered Wildlife Species* (Barr 2009).

In accordance with Council on Environmental Quality guidance on June 24, 2005 (Council on Environmental Quality 2005), past actions associated with the Project are addressed through their current aggregate effects and have not been provided as a list of individual projects in this BA. The FEIS identifies a number of projects that should be considered reasonably foreseeable future actions and that may contribute to cumulative effects to plants and animals. These include mining and other land development activities, and land management activities such as timber harvest, prescribed fire, and road construction that may be authorized or carried out on nearby federal, state, and private lands and that are likely to have both positive and negative effects to plants and animals.

Based on analysis conducted by Emmons and Olivier Resources, Inc. (2006), approximately 1,700 acres of wildlife habitat were lost from the Arrowhead Region between 1890 and the 1990s, with loss due to forestry and mining accounting for 88% of the loss. In much of the region, forest communities have transitioned from predominately pine- and tamarack-dominated forests to trembling aspen and other non-pine community-dominated forest species. Forest composition has changed, and the Minnesota Forest Resource Council (2003) concluded that forest fragmentation has increased, with decreased forest stand sizes and more miles of forest edge.

Ecological Subsections
 Biological Assessment for the NorthMet Project and Land Exchange
 St. Louis County, Minnesota

Barr (2009) estimated habitat loss due to mining at about 17,000 acres over the next 25 to 30 years. In the future, the rate of habitat losses due to mining would decrease as vegetation establishes on disturbed lands. Potential disturbances to habitat within the Laurentian Uplands ecological subsection would be primarily due to timber harvest and mining, and habitat types most likely to be affected include upland and lowland coniferous forest, upland deciduous forest, and upland shrub/woodland. Within the Nashwauk Uplands ecological subsection, mining activities and urban development would be more likely to affect habitat, with upland deciduous forests and upland shrub/woodland habitats most affected (Emmons and Olivier, Inc. 2006).

Although more land would be impacted by timber management than mining in the future, forestry management offers a greater range of options for lynx, northern long-eared bat, and wolf to co-exist with the practice, as it can mimic natural disturbances, whereas mining represents a complete land conversion that could affect long-term lynx habitat availability. Between 2005 and 2014 within the Laurentian Uplands ecological subregion, an average of approximately 1,034 forest acres were (or would be) harvested annually on state lands (0.2% of the subsection). Between 2010 and 2019 within the Nashwauk ecological subregion, an average of approximately 1,189 forest acres were (or would be) harvested annually on state lands (0.1% of the subsection). On average, 1% of timberland in the Superior National Forest is harvested annually (MDNR et al. 2013). Private timber harvest data are generally not available.

6.1.4.1 Factors Considered in the Cumulative Effects Analysis

The 2004 Forest Plan BA and 2011 Hardrock Mining BA identified several factors to consider when evaluating impacts to lynx in northeastern Minnesota at a landscape level of analysis. These are 1) habitat loss and fragmentation, including loss and fragmentation of lynx critical habitat, 2) human disturbance and access, and 3) habitat connectivity.

6.1.4.2 Cumulative Effects Assessment

Habitat Loss and Fragmentation, including Prey Habitat

The Project and other nearby proposed mine projects would increase the amount of habitat fragmentation in the area, changing wooded/forested and other vegetated habitats to disturbed/developed areas with limited habitat value. Development of iron mines along the Iron Range has made much of this area of limited value to lynx, especially areas with pits, tailings, and waste rock piles. Historic waste rock piles and tailings have begun to revegetate and provide some habitat for lynx and their prey, but their value is greatly reduced compared to habitat that existed in the area prior to mining.

Development of the Plant Site would have little impact on habitat fragmentation, as 61% of the site (2,756 of 4,515 acres) has been disturbed by LTVSMC taconite mining operations and the remaining habitat occurs in scattered tracts on the Plant Site. In addition, most of the land within several miles of the Plant Site have been disturbed by past and ongoing taconite operations, including lands within the Transportation and Utility Corridors.

Activities at the Plant Site would have little impact on lynx, as surveys suggest the Plant Site and nearby areas are avoided or rarely used by lynx, probably due to poor quality habitat and moderate level of human disturbance at or near the Plant Site. Development of the Mine Site would add to habitat fragmentation by converting much of the habitat on the Mine Site to an open water pit lake and waste rock stockpiles of limited value to lynx. Most lynx sightings on or near the Project area have been to the east of the Mine Site, but lynx

tracks have been seen on the Mine Site and it is likely that lynx move in an east-west direction between Forest Service and private forestlands in the vicinity of the Mine Site. Development of the Mine Site would force lynx to move further south to travel in an east-west direction to access these forests, and would also force lynx to travel south of the Mine Site, or north of the Mine Site through the federal lands surrounding the Mine Site. Use of the lands adjacent to the Mine Site by lynx may be limited during mine operations due to disturbance associated with the Mine Site and the Northshore Mine to the north. Impacts to lynx from habitat loss and fragmentation may not be great, however, as lynx studies in the area suggest that lynx primarily reside in an area east and southeast of the Mine Site on Superior National Forest lands and the BWCAW, and only occasionally use the Mine Site.

The Mine Site would account for about 1,719 acres, or 10% of the estimated 17,000 acres of habitat impacted by future mining activity within the next 25 to 30 years. It should be noted that while losses to forestry represent the bulk of habitat loss in the region, they are not as permanent or destructive as mining or economic development losses from the perspective of lynx and their prey. Forestry practices remove some or all trees from an area, reducing the value of that area as lynx habitat, but the natural process of succession ensures the regeneration of forest stands that can once again serve as high-quality habitat. Occasional timber harvest may actually promote the growth of dense coniferous stands that are favored by snowshoe hare, the primary prey species of the lynx.

Areas of mine disturbance would be reclaimed and available to lynx about 10 or more years after reclamation. Thus, habitat lost for use by lynx on the Mine Site would be only a small portion of the amount of habitat impacted by forestry and other mining activities. Although impacts to lynx would be expected at the individual level, they would not be expected at the population or species level.

Risk Analysis Indicators

The Forest Service has identified two risk analysis indicators to measure impacts to lynx from cumulative effects associated with habitat loss and fragmentation (**Table 10**).

Indicator 10 – Lynx Habitat Unsuitable on All Ownerships

Indicator 10 was developed by the Forest Service to identify the amount of habitat within a LAU that is unsuitable to lynx. If more than 30% of all lynx habitat within an LAU (all ownerships) is unsuitable,

**Table 10
Unsuitable Habitat and Road/Trail Density within the Lynx Analysis Units Affected by the Project**

Lynx Analysis Indicator	Lands	LAU	Existing Condition		Proposed Action ¹	
			Acres	Percent ²	Acres	Percent ²
10. Lynx Habitat Unsuitable on All Ownerships	Federal Lands	SNF 12	2,737	4.0	4,456	6.4
	Non-federal Lands					
	Hunting Club	SNF 4	2,470	4.9	2,470	4.9
	Lake County North and Wolf Lands 1	SNF 16	3,127	4.4	3,127	4.4
	Wolf Lands 2, 3, and 4	SNF 21	2,931	4.2	2,931	4.2
	Lake County South	SNF 22	913	1.6	913	1.6
	McFarland Lake	SNF 42	534	1.9	534	1.9

Lynx Analysis Indicator	Hay Lake	NA			NA	
	Lands/Parcels	LAU	Existing Condition		Proposed Action ³	
			Miles within LAU ⁴	Density within LAU ³	Miles within LAU	Density within LAU ⁵
11. Road and Snow-Compacted Trail Density	Federal Lands	SNF 12	99	0.9	93	0.8
	Non-federal Lands					
	Hunting Club	SNF 4	185	2.2	185	2.2
	Lake County North and Wolf Lands 1	SNF 16	98	0.9	98	0.9
	Wolf Lands 2, 3, and 4	SNF 21	93	0.8	93	0.8
	Lake County South	SNF 22	105	1.2	105	1.2
	McFarland Lake	SNF 42	70	1.7	70	1.7
	Hay Lake	NA			NA	

¹ After Project closure. Some unsuitable habitat on the Mine Site would become suitable for lynx 10 or more years after reclamation of the Mine Site.

² Acres and percent of unsuitable habitat provided by USDA Forest Service (Ryan 2013a). Acres of suitable habitat are: SNF 4 – 49,994; SNF 12 – 69,131; SNF 16 – 70,743; SNF 21 – 69,632; SNF 22 – 57,107; and SNF 42 – 27,775.

³ After Project closure and reclamation.

⁴ Miles of roads and snow-compacted trail density provided by USDA Forest Service (Ryan 2013a).

⁵ Density = Miles of road per square mile.

Total acreage within the LAU for all land ownerships —LAU SNF 4 = 55,071 acres, SNF 12 = 70,980 acres, SNF 16 = 76,108 acres, SNF 21 = 73,266 acres, SNF 22 = 58,154 acres, and SNF 42 = 32,305 acres; total acreage for lands administered by the Superior National Forest —LAU SNF 4 = 33,321 acres, SNF 12 = 49,409 acres, SNF 16 = 33,679 acres, SNF 21 = 36,082 acres, SNF 22 = 41,210 acres, and SNF 42 = 24,687 acres.

then no further reduction in suitable condition should occur as a result of vegetation management activities by the Forest Service. **Table 10** shows the amount of unsuitable habitat within LAUs that would be affected by the Project. The amount of unsuitable habitat would increase in LAU SNF 12 to 6.4% from 4.0% due to Mine Site development, but would not exceed 30%. Because habitat management would be little changed due to the proposed transfer of the non-federal lands, the amount of area with unsuitable habitat within the other LAUs should not change with or without the proposed land exchange.

Indicator 11 – Road and Snow-compacted Trail Density

Indicator 11 provides a measure of the Forest Service goal to maintain road and snow-compacting trail densities below 2 miles/mi² within LAUs to maintain the natural competitive advantage of lynx in deep snow (**Table 10**). Where total road and regularly-used snow-compacting trail densities are greater than 2 miles/mi² and coincide with lynx habitat, effort should be made to prioritize roads for seasonal restrictions or reclamation in those areas, where practical or feasible. “Roads” include all ownerships of classified and unclassified roads and “regularly-used trails” are those that are used most years for most of the snow season. The 2004 Forest Plan allows no net increase in designated snow-compacting trails unless they effectively consolidate use (USDA Forest Service 2004a). However, there may be a concern with new all-terrain vehicle trails because in most locations it is likely that these routes could appear inviting to snowmobiling, and thus may have an unintended result of increasing snow compaction where trails coincide with lynx habitat.

Approximately 5.9 miles of OML 1 roads are on the federal lands, or about 0.6 miles/mi². After mine closure, these roads would be reclaimed, except for a short access road from the Dunka Road to the Waste Water Treatment Facility. Public access to the Mine and Plant sites is currently prohibited, and access to the Plant Site

and lands adjacent to the Mine Site would be strictly controlled during mine operations. The Project area would remain privately owned after mine closure and public access would be restricted (Pylka 2013b).

There are no designated all-terrain vehicle or snowmobile trails on the federal lands. It is unlikely that new designated trails would be constructed on the federal lands after mine closure.

There are designated and undesignated roads and trails on or bordering the non-federal lands, and recreational use of these roads and trails was evident on these sites. Road density exceeds 2.2 miles/mi² in LAU SNF 4. There are historic logging roads on Hunting Club Lands, and it is possible that new logging roads could be constructed in the future, but these would not be regularly used roads. Thus, regular use road density should not increase in LAU SNF 4 due to the land exchange. Road densities are below 2 miles/ mi² for the other lands. As noted for Indicator 7, there would be no immediate change in miles of designated and undesignated roads and designated all-terrain vehicle or snowmobile trails within the LAUs with or without the land exchange.

Human Access and Disturbance

Human Access and Traffic

The Project and other nearby proposed projects would increase the amount of human access and disturbance in the area. Increased human populations in the Project area may also lead to increased risk to lynx from collisions with vehicles and trains, increased levels of recreation activities and use of backcountry roads and trails, and increased mortality from illegal hunting and trapping.

There is a well-established road system along the Mesabi Iron Range, associated with mining activity, and to serve nearby towns, recreational areas, private residences, pasturelands, and forestlands. It is expected that the number of miles of roads within the Project area would show little increase during the life of the Project, and some roads could be taken out of service or reclaimed during the life of the Project. The Forest Service estimated that up to 157 miles of temporary roads could be constructed annually within the Superior National Forest from hardrock mining activities and that up to 761 miles could exist at any one time during the period of hardrock mining within the Superior National Forest (USDA Forest Service 2011a). Still, this would be less than the mileage gain estimated to occur under the 2004 Forest Plan, which was based on mileage limits to protect lynx (USDA Forest Service 2004a). Given that the number of miles of roads associated with the Mine Site, Dunka Road and Utility Corridor, Plant Site, and non-federal lands after mining is expected to be similar to or less than current levels, impacts associated with road mileage are not expected to accumulate from the Project.

Human activity associated with the Project, and other ongoing and proposed projects near the Project area, would increase the amount of vehicle and rail traffic in the region and the potential for collisions between lynx and vehicles and trains. Vehicle and rail traffic within and to/from the Project area could result in the loss of a lynx during the 20-year mine operation period, and accumulate with losses of lynx from collisions with trains and vehicles elsewhere in the CESA.

Trapping and Incidental or Illegal Shooting

There is evidence that lynx may be accidentally trapped during furbearer, including bobcat, fisher, gray wolf, and pine marten trapping seasons. Of the 435 records in the MDNR (2007) lynx database for 2000 to 2006, ten records list that the animal was caught in a trap, and of these, three were killed, six were released unharmed, and the

status of one is unknown. Based on records kept by the USFWS since from 2000 to 2012, 13 lynx died from trapping incidents (4 were legally trapped in Canada), and another 10 were trapped and released alive (Rowse 2012). It is likely that other lynx have been trapped, but not reported. The magnitude of accidental lynx trapping in the project area and in northern Minnesota is unknown.

Lynx could be shot mistakenly or intentionally by hunters or by poachers. Lynx and wolves may be shot by hunters during deer and other hunting seasons for fun, or lynx may be mistakenly identified as bobcat and shot during the bobcat season. The actual magnitude of lynx shooting in northern Minnesota is unknown. Of the 435 records in the MDNR (2007) lynx database for 2000 through 2006, only 1 record lists that the animal was intentionally shot, while another lynx was accidentally shot; the USFWS database lists six lynx shot since 2000 (Rowse 2012). However, it is likely that lynx shootings are generally not reported. It is unlikely that many lynx would be shot within the Project area due to limited numbers of lynx in the general vicinity of the Project, and because hunting would not be allowed on the Project area during mining, and most likely after mine closure.

The number of people, and potential for trapping and incidental or illegal shooting, would increase in the region due to the Project. Education of the public as to the importance of protecting lynx and other wildlife, however, has helped to reduce the accidental or intentional loss of lynx in recent years. Trapping and illegal or accidental shooting of lynx would be unlikely on the federal lands during mine construction and operation if conservation measures given in Chapter 7 of this BA are followed. Although the Project would cause an increase in the number of people in the region, the cumulative effects of the Project on trapping and illegal or accidental shooting of lynx on the non-federal lands and Wetland Mitigation Sites would be negligible.

Competition and Predation as Influenced by Human Activities

Lynx interact with other carnivores throughout their range. Competition with or predation by coyotes, gray wolves, mountain lions, bobcats, and birds of prey have been inferred or documented throughout the range of the lynx. Some human activities, particularly those related to timber harvest and over-the-snow access routes, have the potential to alter natural relationships between lynx and other predators.

Certain timber harvest practices increase edges and openings within forest stands, which may improve foraging conditions for generalist predators such as coyotes, bobcats, and great horned owls. This in turn increases the potential for both exploitation and interference competition with lynx to occur.

Snow compaction due to resource management or recreation activities may facilitate movement of coyotes and other potential competitors and predators into lynx habitat, making it likely that lynx in the study area would compete with these competitors and predators for primary lynx prey (Buskirk et al. 2000b).

The Forest Service recommends that road and snow-compacting trail densities be kept below 2 miles/mi². Where road and snow-compacting trail densities exceed 2 miles/mi², the Forest Service would prioritize roads for season restrictions or reclaim some roads. Of the 47 LAUs in northeastern Minnesota, 15 have road and snow-compacting trail densities exceeding 2 miles/mi², including LAU SNF 4. Based on road building activities between 2004 and 2010, the Forest Service estimates that about 77 miles of OML 1 and 123 miles of OML 2 roads would be constructed in the Superior National Forest each year. Another 532 to 860 miles of temporary roads could be constructed to support hardrock mining activities (USDA Forest Service 2011a). As noted earlier, however, most, if not all new roads constructed on the Mine Site and Plant Site would be removed or reclaimed after mining ceases, and there would be little or no new road construction on the lands adjacent to the Mine Site and non-federal lands. Thus, competition between lynx

and its predators due to an increase in road and snow-compacting trail densities would not accumulate due to the Project long term.

Habitat Connectivity

Much of the habitat for lynx along the Iron Range has been eliminated by mining, other industrial activities, and residential development, and remaining habitat is heavily fragmented. However, large patches of suitable lynx habitat exist on either side of the range, primarily within the Superior National Forest, Chippewa National Forest, and various state forests. To travel between habitat patches on either side of the Iron Range, lynx must find suitable corridors of habitat that traverse the range and allow safe movement. Emmons and Olivier Inc. (2006) identified 13 wildlife travel corridors, while Barr (2009) identified 18 travel corridors, which facilitate movement of wildlife across the Iron Range. Three wildlife travel corridors exist in the vicinity of the Project that could be impacted by the project and other projects in the area (**Figure 23**).

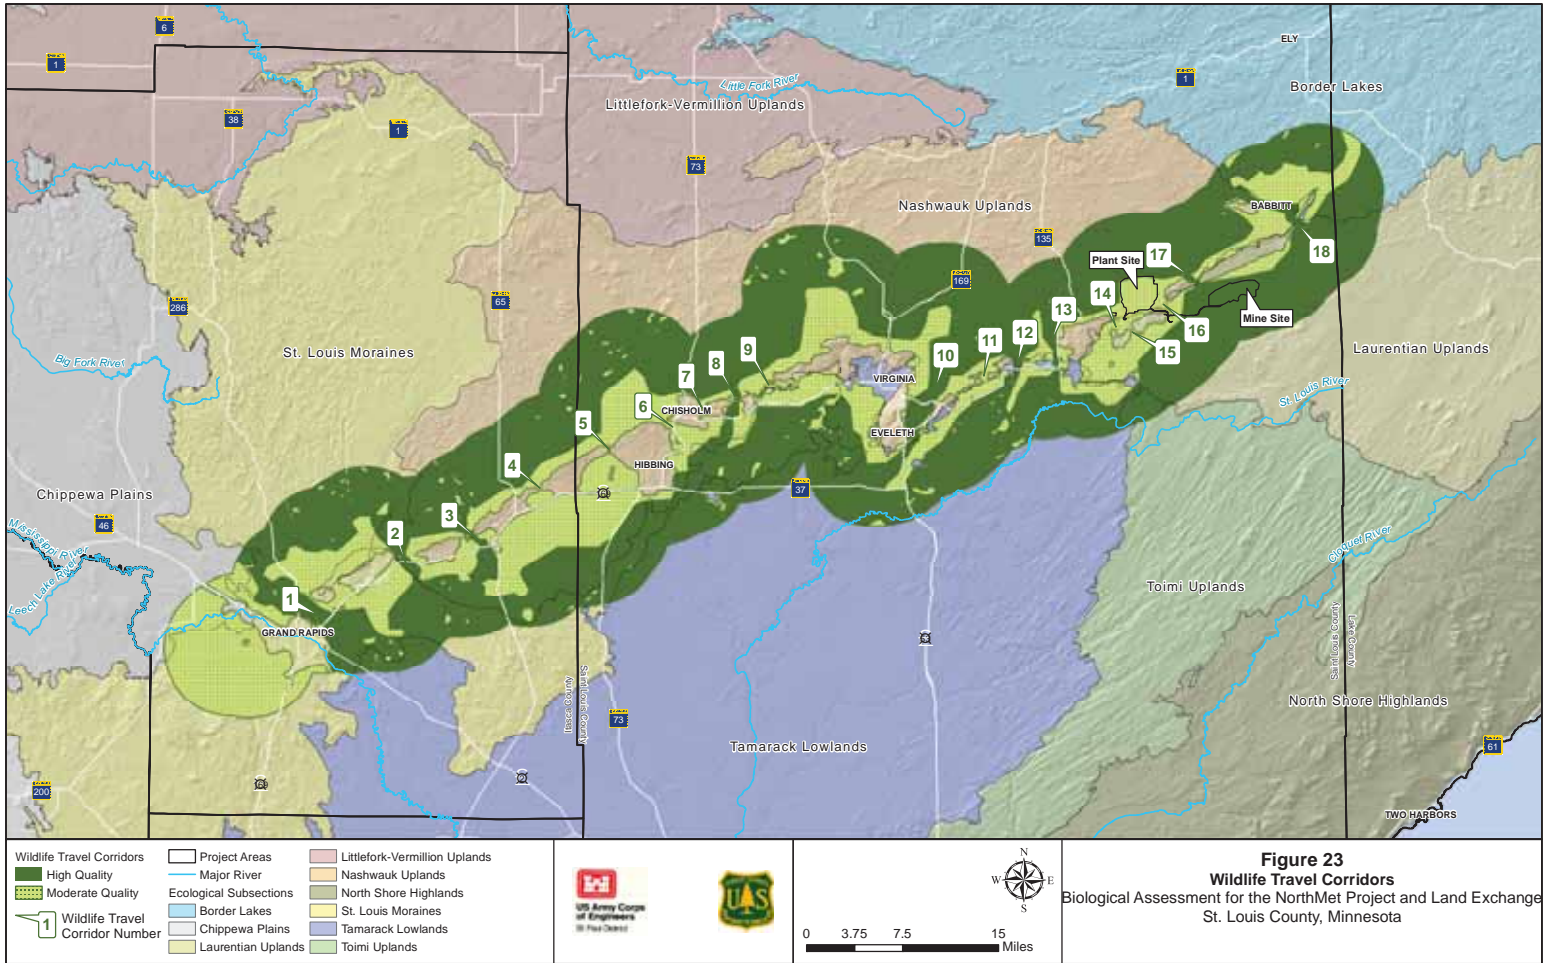

Corridor 16 is a small but important corridor, approximately 0.6 mile wide, which connects large habitat blocks to the east-southeast and north-northwest. The corridor is unlikely to be impacted by the Project because the Plant Site Tailings Basin area would be sited approximately 1 mile to the northwest on the existing LTVSMC Tailings Basin. The Emmons and Olivier, Inc. (2006) report also noted that an area to the southwest has high potential for future growth, which could impact the corridor, but estimated that the corridor would continue to serve as an important connection for wildlife in the future. Lynx have not been reported using this corridor.

Corridor 17 is a 1,200-foot wide strip that is between two open pits operated by the Northshore Mine and is approximately 0.5 mile northwest of the Mine Site. Operations at the Mine Site would indirectly impact the corridor by reducing the size of the large habitat block southeast of the corridor. Noise and mining activity could also discourage lynx use of this corridor. The corridor could be accessed from north of the Mine Site, and from the south and southwest of the corridor. Lynx have been observed using this corridor.

Corridor 18 is about 2,800 feet wide, located at the eastern boundary of the Northshore Mine, about 7 miles northwest of the Mine Site. The corridor follows a river, and several small roads cross this corridor. Recent expansion of the Northshore Mine easterly pit, and a relocation of County State Aid Highway 70 that is east of the pit, has reduced the width of the corridor to about 2,200 feet (USDOJ USFWS 2011a). Lynx have been observed using this corridor.

Research conducted by the NRRI indicates that lynx have varied home ranges, and disperse from them within the Superior National Forest, and to and from Canada (Burdett 2007, Moen et al. 2010). Movements were made across roaded areas, and also across the BWCAW, which has few or no linear features such as roads, trails, and logging roads that could guide movement by lynx. When lynx made long distance movements, they often crossed several LAU boundaries without changes in direction.

Moen et al. (2010) suggested that habitat connectivity does not appear to be a limiting factor for lynx in northeastern Minnesota. The combination of low topographic relief, the linear nature of movement paths, and the relative lack of differences in cover conditions indicate that geographically or topographically definable movement corridors do not exist for lynx either within in northeastern Minnesota, or between Minnesota and Ontario, Canada. Because northeastern Minnesota is the southern limit of boreal forest, no connectivity or linkage areas could be managed for lynx movement to the south and west because of unsuitable habitat in those directions.

Dense forests occur in northeastern Minnesota, and while forest management activities alter patterns of vegetation community composition and structure at landscape and smaller scales, Ravenscroft et al. (2010) considered northeastern Minnesota forest landscape as largely unfragmented. In addition, Galatowitsch et al. (2009) stated that the BWCWA and the North Shore portion of the Superior National Forest are high quality protection areas.

Therefore, large portions of northeastern Minnesota provide excellent connectivity habitat. There is no indication that lynx use defined linkage areas, and they appear to move freely across the landscape throughout the Superior National Forest, and north into Canada. Although actions associated with the Project could impact Corridors 16 and 17, and these impacts would accumulate with impacts to nearby corridors from other projects in the region, there is good habitat connectivity within designated critical habitat and the Project area.

6.2 Northern Long-eared Bat

6.2.1 Environmental Baseline

The following baseline information is from *Endangered and Threatened Wildlife and Plants; 12-Month Finding on a Petition To List the Eastern Small-Footed Bat and the Northern Long-Eared Bat as Endangered or Threatened Species; Listing the Northern Long-Eared Bat as an Endangered Species; Proposed Rule* (USDOJ USFWS 2013b) and references cited therein. A full description of references cited in this rule is available at URL: <http://www.regulations.gov/#!documentDetail;D=FWS-R5-ES-2011-0024-0002>. Any additional information that is not from one of these sources is cited in the text.

6.2.1.1 Species Description and Status and Critical Habitat Status

The northern long-eared bat belongs to the order Chiroptera, suborder Microchiroptera, family Vespertilionidae, subfamily Vespertilioninae, genus *Myotis*, subgenus *Myotis*. The northern long-eared bat was considered a subspecies of Keen's long-eared myotis (*Myotis keenii*), but was recognized as a distinct species by van Zyll de Jong (1979).

A medium-sized bat species, the northern long-eared bat adult body weight averages 0.2 to 0.3 ounces, with females tending to be slightly larger than males. Average body length ranges from 3.0 to 3.7 inches. Fur colors include medium to dark brown on its back, dark brown, but not black, ears and wing membranes, and tawny to pale-brown fur on the ventral side. The northern long-eared bat is distinguished from other *Myotis* species by its long ears (average 0.7 inches), that, when laid forward, extend beyond the nose. Within its range, the northern long-eared bat can be confused with the little brown myotis or the western long-eared myotis. The northern long-eared bat can be distinguished from the little brown myotis by its longer ears, tragus, slightly longer tail, and less glossy pelage. The northern long-eared bat can be distinguished from the western long-eared myotis by its darker pelage and paler membranes (Caceres and Barclay 2000:1).

White-nose syndrome, a fungal disease known to affect bats, is currently the predominant threat to the northern long-eared bat, especially throughout the Northeast where the species has declined by up to 99% from pre-white-nose syndrome levels at many hibernation sites (hibernacula; USDOJ USFWS 2013a). White-nose syndrome has spread rapidly throughout the East and is currently spreading through the Midwest. Although the disease, caused by the fungal species *Pseudogymnoascus destructans*, has not yet spread throughout the northern long-eared bat's entire range (white-nose syndrome is currently found in at least 22 of 39 states where the northern long-eared bat occurs), it continues to spread. Other threats to the species include wind energy

development, habitat destruction or disturbance (e.g., vandalism to hibernacula, roost tree removal), climate change, and contaminants. Although no significant population declines have been observed due to these threats, they may now be important factors affecting this bat's ability to persist while experiencing dramatic declines caused by white-nose syndrome.

The northern long-eared bat was proposed for listing as an endangered species by the USFWS on October 2, 2013. The USFWS also determined that critical habitat for the northern long-eared bat is not determinable at this time.

6.2.1.2 Distribution

The northern long-eared bat is found across much of the eastern and northcentral United States and all Canadian provinces from the Atlantic coast west to the southern Northwest Territories and eastern British Columbia (USDOI USFWS 2013a).

Historically, the species has been most frequently observed in the northeastern United States and in Canadian Provinces, Quebec and Ontario, with sightings increasing during swarming and hibernation. However, throughout the majority of the species' range it is patchily distributed, and historically was less common in the southern and western portions of the range than in the northern portion of the range.

Although they are typically found in low numbers in inconspicuous roosts, most records of northern long-eared bats are from winter hibernacula surveys. More than 780 hibernacula have been identified throughout the species' range in the United States, although many hibernacula contain only a few (1 to 3) individuals. Eleven hibernacula sites with one or more winter records are known from Minnesota.

The northern long-eared bat is commonly encountered in summer mist-net surveys throughout the majority of the Midwest and is considered fairly common throughout much of the region. However, the species is often found infrequently and in small numbers in hibernacula surveys throughout most of the Midwest. In northeastern Minnesota, this species has been detected in St. Louis, Lake, and Cook Counties based on records in the MDNR Natural Heritage Information System database of element occurrences (MDNR 2014a). In Minnesota, the Tower/Soudan Underground Mine State Park in St. Louis County contains a large number of individuals, possibly over 3,000; however, this is a very rough estimate because the majority of the mine cannot be safely accessed for surveys (Nordquist et al. 2006, USDOI USFWS 2013b). The mine is about 15 miles northwest of the Project area.

Additionally, northern long-eared bats have been detected in six caves along the North Shore of Lake Superior. These caves are within the Superior National Forest proclamation boundary but outside of federal surface ownership. Mist-net surveys conducted by Superior National Forest biologists confirmed the presence of northern long-eared bats at five of the eight sites surveyed in St. Louis and Lake Counties during the summer of 2013 (Grandmaison et al. 2013). While these data are far from providing an estimate of abundance on the Superior National Forest, they do suggest that northern long-eared bats can be detected, albeit at low numbers, across much of the forest where surveys are conducted.

6.2.1.3 Life History

Hibernation

The northern long-eared bat hibernates during the winter months to conserve energy from increased thermoregulatory demands and reduced food resources. In general, northern long-eared bats arrive at hibernacula in August or September, enter hibernation in October and November, and leave the hibernacula in March or April. Northern long-eared bats have shown a high degree of philopatry (using the same site multiple years) for a hibernaculum, although they may not return to the same hibernaculum in successive seasons.

Typically, northern long-eared bats are not abundant and compose a small proportion of the total number of bats hibernating in a hibernaculum. Although usually found in small numbers, the species typically inhabits the same hibernacula with large numbers of other bat species, and occasionally are found in clusters with these other bat species. Other species that commonly occupy the same habitat include little brown myotis, big brown bat, eastern small-footed bat, tri-colored bat, and Indiana bat.

Northern long-eared bats often move between hibernacula throughout the winter, which may further decrease population estimates. Though northern long-eared bats fly outside of the hibernacula during the winter, they do not feed; hence the function of this behavior is not well understood. However, it has been suggested that bat activity during winter could be due in part to disturbance by researchers. Northern long-eared bats exhibited significant weight loss during hibernation. Whitaker and Hamilton (1998:101) reported a weight loss of 41 to 43% over the hibernation period for northern long-eared bats in Indiana.

Migration and Homing

While the northern long-eared bat is not considered a long-distance migratory species, short migratory movements between summer roost and winter hibernacula between 35 to 55 miles have been documented. Several studies show a strong homing ability of northern long-eared bats in terms of return rates to a specific hibernaculum, although bats may not return to the same hibernaculum in successive winters.

Summer Roosts

During the summer, northern long-eared bats typically roost singly or in colonies underneath bark or in cavities or crevices of both live trees and snags. Northern long-eared bats switch roosts often. In Missouri, the longest time spent roosting in one tree was 3 nights; however, up to 11 nights spent roosting in a man-made structure has been documented. Bats switch roosts for a variety of reasons, including, temperature, precipitation, predation, parasitism, and ephemeral roost sites. Timpone et al. (2010:118) radiotracked 13 northern long-eared bats to 39 roosts and found the mean distance between the location where captured and roost tree was 1.1 miles.

Some studies have found tree roost selection to differ slightly between male and female northern long-eared bats. Male northern long-eared bats have been found to more readily use smaller diameter trees for roosting than females, suggesting males are more flexible in roost selection than females. In New Brunswick, Canada, Broder and Forbes (2004:606-607) found that there was spatial segregation between male and female roosts, with female maternity colonies typically occupying more mature, shade-tolerant deciduous tree stands and males occupying more conifer-dominated stands. In northeastern Kentucky, males do not use colony roosting

sites and are typically found occupying cavities in live hardwood trees, while females form colonies more often in both hardwood and softwood snags.

Reproduction

Breeding occurs from late July in northern regions to early October in southern regions and commences when males begin to swarm hibernacula and initiate copulation activity. Copulation occasionally occurs again in the spring. Hibernating females store sperm until spring, exhibiting a delayed fertilization strategy. Ovulation takes place at the time of emergence from the hibernaculum, followed by fertilization of a single egg, resulting in a single embryo. Gestation is approximately 60 days.

Maternity colonies, consisting of females and young, are generally small, numbering from about 30 to 60 individuals, although one group of 100 adult females was observed in Vermilion County, Indiana. Adult females give birth to a single pup. Birthing within the colony tends to be synchronous, with the majority of births occurring around the same time. Female roost site selection, in terms of canopy cover and tree height, changes depending on reproductive stage. Relative to pre- and post-lactation periods, lactating northern long-eared bats have been shown to roost higher in tall trees situated in areas of relatively less canopy cover and tree density.

Adult longevity is estimated to be up to 18.5 years, with the greatest recorded age of 19 years. Most mortality for northern long-eared and many other species of bats occurs during the juvenile stage.

Foraging Behavior and Home Range

The northern long-eared bat has a diverse diet including moths, flies, leafhoppers, caddisflies, and beetles. The most common insects found in the diets of northern long-eared bats are lepidopterans (moths) and coleopterans (beetles), with arachnids (spiders) also being a common prey item.

Foraging techniques include hawking (catching insects in flight) and gleaning in conjunction with passive acoustic cues. Northern long-eared bats have the highest frequency call of any bat species in the Great Lakes area. Gleaning allows this species to gain a foraging advantage for preying upon moths because moths are less able to detect these high frequency echolocation calls. Emerging at dusk, most hunting occurs above the understory, 3 to 10 feet above the ground, but under the canopy. This coincides with data indicating that mature forests are an important habitat type for foraging northern long-eared bats. Occasional foraging also takes place over forest clearings and water, and along roads. Foraging patterns indicate a peak activity period within 5 hours after sunset followed by a secondary peak within 8 hours after sunset.

Female home range size may range from 47 to 425 acres. Owen et al. (2003:353) estimated average maternal home range size to be 161 acres. Home range size of northern long-eared bats in this study site was small relative to other bat species, but this may be due to the study's timing (during the maternity period) and the small body size of northern long-eared bat.

6.2.1.4 Habitat

Winter Habitat

Northern long-eared bats predominantly overwinter in hibernacula that include caves and abandoned mines. Hibernacula used by northern long-eared bats are typically large, with large passages and entrances, relatively constant, cooler temperatures (32 to 48 degrees Fahrenheit), and with high humidity and no air currents. The sites favored by northern long-eared bats are often in very high humidity areas, to such a large degree that droplets of water are often observed on their fur. Caire et al. (1979:405) and Whitaker and Mumford (2009:208) commonly observed individuals exiting caves with mud and clay on their fur, also suggesting the bats were roosting in tighter recesses of hibernacula. They are also found hanging in the open, although not as frequently as in cracks and crevices.

To a lesser extent, northern long-eared bats have been found overwintering in other types of habitat that resemble cave or mine hibernacula, including abandoned railroad tunnels, more frequently in the northeast portion of the range. In 1952, three northern long-eared bats were found hibernating near the entrance of a storm sewer in central Minnesota (Goehring 1954:435).

Summer Habitat

During the summer, northern long-eared bats typically roost singly or in colonies underneath bark or in cavities or crevices of both live trees and snags. Males and non-reproductive females' summer roost sites may include cooler locations, including caves and mines. Northern long-eared bats have also been observed roosting in colonies in man-made structures, such as buildings, barns, a park pavilion, sheds, cabins, under eaves, behind window shutters, and in bat houses.

The northern long-eared bat appears to be somewhat opportunistic in tree roost selection, selecting varying roost tree species and types of roosts throughout its range, including tree species such as black oak, northern red oak, silver maple, black locust, American beech, sugar maple, sourwood, and shortleaf pine. Northern long-eared bats most likely are not dependent on a certain species of trees for roosts throughout their range; rather, certain tree species will form suitable cavities or retain bark and the bats will use them opportunistically.

Many studies have documented the northern long-eared bat's selection of live trees and snags, with a range of 10 to 53% selection of live roosts found. In tree roosts, northern long-eared bats are typically found beneath loose bark or within cavities and have been found to use both exfoliating bark and crevices to a similar degree for summer roosting habitat.

Canopy coverage at northern long-eared bat roosts has ranged from 56% in Missouri to greater than 84% in Kentucky. Studies in New Hampshire and British Columbia have found that canopy coverage around roosts is lower than in available stands. Females tend to roost in more open areas than males, likely due to the increased solar radiation, which aids pup development. Fewer trees surrounding maternity roosts may also benefit juvenile bats that are starting to learn to fly. However, in southern Illinois, northern long-eared bats were observed roosting in areas with greater canopy cover than in random plots. Roosts are also largely selected below the canopy, which could be due to the species' ability to exploit roosts in cluttered environments; their gleaning behavior suggests an ability to easily maneuver around obstacles.

Female northern long-eared bats typically roost in tall, large-diameter trees. Studies have found that the dbh and height of northern long-eared bat roost trees was greater than random trees. Lacki and Schwierjohann (2001:486) have also found that northern long-eared bats roost more often on upper and middle slopes than lower slopes, which suggests a preference for higher elevations due to increased solar heating.

6.2.1.5 Factors Affecting the Welfare of Northern Long-eared Bat

Several factors affect northern long-eared bats. These include: 1) modification to hibernacula, human disturbance during hibernation, loss of summer roosting habitat, and loss of habitat from other disturbance factors, including mining projects and prescribed burning; 2) loss of bats due to diseases such as rabies and encephalitis, and from contaminants; 3) predation from hawks, raccoons, skunks, and snakes; 4) lack of federal, state, and local regulations to address threats to northern long-eared bats, although the northern long-eared bat is a species of special concern in Minnesota; 5) wind energy development; and 6) climate change. However, these activities alone are not likely to have significant population-level effects (USDOJ USFWS 2013b). PolyMet would follow the USFWS northern long-eared bat interim guidance for removal of marketable timber across the Project (USFWS 2014). Disturbance from noise and vibration is discussed in Section 6.2.2.1.

The most severe and immediate threat to the long-term persistence of this species is the infectious disease known as white-nose syndrome. White-nose syndrome is responsible for unprecedented mortality rates observed in the northeastern United States and poses an increasing threat to bat populations throughout North America. White-nose syndrome has spread rapidly throughout the northeast where an estimated 5.7 to 6.7 million bats have died, and is currently spreading through the Midwest. The causative fungal species for white-nose syndrome, *Pseudogymnoascus destructans*, is known to occur in Minnesota, including the Tower/Soudan Underground Mine State Park, which is 15 miles northwest of the Project area and serves as the largest known hibernaculum for Myotis bats in Minnesota.

White-Nose Syndrome

Since its first documented appearance in New York in 2006, white-nose syndrome has spread rapidly throughout the Northeast and is expanding through the Midwest. As of August 2013, white-nose syndrome has been confirmed in 22 States (Alabama, Connecticut, Delaware, Georgia, Illinois, Indiana, Kentucky, Maine, Maryland, Massachusetts, Missouri, New Hampshire, New Jersey, New York, North Carolina, Ohio, Pennsylvania, South Carolina, Tennessee, Vermont, Virginia, and West Virginia) and 5 Canadian provinces (New Brunswick, Nova Scotia, Ontario, Prince Edward Island, and Quebec). Four additional States (Arkansas, Iowa, Minnesota, and Oklahoma) are considered suspect for white-nose syndrome based on the detection of the causative fungus on bats within those States, but with no associated disease to date. U.S. Fish and Wildlife Service biologists and partners estimate that at least 5.7 million to 6.7 million bats of several species have now died from white-nose syndrome.

The pattern of spread has generally followed predictable trajectories along recognized migratory pathways and overlapping summer ranges of hibernating bat species. Therefore, Kunz and Reichard (2010:12) assert that white-nose syndrome is spread mainly through bat-to-bat contact; however, evidence suggests that fungal spores can be transmitted by humans, and bats can also become infected by coming into contact with contaminated cave substrate. Six North American hibernating bat species (little brown myotis, Indiana bat, northern long-eared bat, eastern small-footed bat, big brown bat, and tri-colored bat), are known to be affected by white-nose syndrome.

White-nose syndrome is caused by the recently described psychrophilic (cold-loving) fungus, currently known as *Pseudogymnoascus destructans*. *Pseudogymnoascus destructans* may be non-native to North America, and only recently arrived on the continent. The fungus grows on and within exposed tissues of hibernating bats, and the diagnostic feature is the white fungal growth on muzzles, ears, or wing membranes of affected bats, along with epidermal (skin) erosions that are filled with fungal hyphae (branching, filamentous structures of fungi). Bats that are found in more humid regions of hibernacula may be more susceptible to white-nose syndrome.

In addition to the presence of the white fungus, initial observations showed that bats affected by white-nose syndrome were characterized by some or all of the following: 1) Depleted fat reserves by mid-winter; 2) a general unresponsiveness to human disturbance; 3) an apparent lack of immune response during hibernation; 4) ulcerated, necrotic, and scarred wing membranes; and 5) aberrant behaviors, including shifts of large numbers of bats in hibernacula to roosts near the entrances or unusually cold areas, large numbers of bats dispersing during the day from hibernacula during mid-winter, and large numbers of fatalities, either inside the hibernacula, near the entrance, or in the immediate vicinity of the entrance.

Although the exact process by which white-nose syndrome leads to death remains undetermined, it is likely that the immune function during torpor compromises the ability of hibernating bats to combat the infection. Other factors that could cause death include loss of fat stores during winter, alternation of normal arousal cycles in hibernating bats, and loss of wing-dependent physiological functions.

Due to white-nose syndrome, the northern long-eared bat has experienced a sharp decline in the northeastern part of its range, as evidenced in hibernacula surveys. The northeastern United States is very close to saturation (white-nose syndrome found in majority of hibernacula) for the disease, with the northern long-eared bat being one of the species most severely affected by the disease. In hibernacula surveys in New York, Vermont, Connecticut, and Massachusetts, hibernacula with larger populations of northern long-eared bats experienced greater declines, suggesting a density-dependent decline due to white-nose syndrome.

Long-term (including pre- and post- white-nose syndrome) summer data for the northern long-eared bat are somewhat limited; however, the available data parallel the population decline exhibited in hibernacula surveys. Summer data can corroborate and confirm the decline to the species seen in hibernacula data. Summer surveys from 2005 to 2011 near Surry Mountain Lake in New Hampshire showed a 99% decline in capture success of northern long-eared bats post- white-nose syndrome, which is similar to the hibernacula data for the State (a 95% decline).

Because white-nose syndrome has already had a substantial effect on northern long-eared bats in the core of its range and is likely to spread throughout the species' entire range within a short time, the USFWS considers white-nose syndrome to be the predominant threat to the species rangewide.

6.2.2 Analysis of Direct and Indirect Effects to Northern Long-eared Bat

6.2.2.1 Effects to Northern Long-eared Bat within the Action Area

As discussed in Section 6.2.1.5, the USFWS identified several factors affecting the welfare of northern long-eared bat. Of these, loss of habitat from the Project could be a direct effect to northern long-eared bats. Forest management activities, including timber harvest and prescribed burning, could occur on federal and non-federal lands in the reasonably foreseeable future under the Proposed Action and could result in cumulative effects to northern long-eared bats due to habitat modification.

In addition, the Forest Service (USDA Forest Service 2013b) has identified three analysis indicators for northern long-eared bat:

1. acres of upland forest (MIH 1),
2. presence of known hibernacula, and
3. presence of known summer roost sites.

Analysis indicators 2 and 3 are not evaluated in this BA because there are no known hibernacula or summer roost sites on the federal or non-federal lands. The 2014 Forest Service surveys indicated that summer roost sites may be present on the Mine Site; however, there have been no field surveys to identify roost trees in the Project area.

Federal Lands

Northern long-eared bats have been found in the winter in Minnesota in natural caves, sand mines, and deep iron mines, but these habitats are not found on the federal or non-federal lands. During warmer months of the year, northern long-eared bats primarily roost and forage in forests, especially more mature forests and forests near wetlands. There are approximately 233 acres of young, 540 acres of immature, and 557 acres of mature upland forest habitat (MIH 1), and 3,737 acres of wetlands, within the federal lands that could provide roosting, foraging, and drinking habitat for northern long-eared bat.

The 2014 Forest Service surveys confirmed that northern long-eared bats utilize the Mine Site for foraging and travel to and from foraging and roost sites. The 2014 Forest Service surveys also suggested that the Mine Site may contain roost sites; however, there have been no surveys specifically conducted for the identification of roost sites. Bats were also observed using wetlands in the vicinity of the Mine Site, although they were not identified to species (AECOM 2011a). The Project would result in the loss of about 532 acres of upland forest habitat (MIH 1) and 634 acres of wetlands due to mining. Based on the mine closure plan, about 397 acres of the habitat lost to mining would be reclaimed as grassland/herbaceous (54%), wetland and/or grassland/herbaceous (27%), and wetland (18%). Wetland habitat created would have lesser habitat value for northern long-eared bat. The West Pit would not be reclaimed, but would remain as a 321-acre open pit lake (MDNR et al. 2013). Young upland forest habitat could occur on reclaimed lands about 10 years after mine reclamation. As this forest habitat matures, it could be used by northern long-eared bats. Because northern long-eared bats can utilize trees with a minimum diameter of 3", the time to maturation of basic usable forest habitat would be approximately 10-15 years. Wetland and open water habitat on reclaimed lands could be used for foraging and drinking by northern long-eared bats; however, in general wetland habitats are less utilized by northern long-eared bats.

Transportation and Utility Corridors

The Dunka Road and Utility Corridor is approximately 108 acres and the Railroad Connection Corridor is approximately 12 acres. Because of prior use during the former LTVSMC taconite mining operation, the Dunka Road and Utility Corridor is now defined as having a "disturbed" cover type (94 acres). The remaining MDNR GAP land cover types that are not disturbed include cropland/grassland (10 acres), shrubland (8 acres), and smaller acreages of the remaining types, including 5 acres of upland forest and 3 acres of aquatic habitat

(MDNR et al. 2013). The 2014 Forest Service surveys confirmed that northern long-eared bats utilize the upland forest habitats for foraging.

Plant Site

Of the 4,515 acres at the Plant Site Area, 2,756 acres have been disturbed by LTVSMC taconite mining operations. Of the remaining 1,760 acres, approximately 648 acres are upland deciduous forest, 637 acres are aquatic habitat, 334 acres are shrubland, 100 acres are upland coniferous forest, and 42 acres are lowland coniferous forest (totals don't add because acreages are rounded). About 48% of the Plant Site would be impacted by plant construction and operations, with only about 422 acres of forest habitat remaining after construction. It is assumed that the majority of this forested habitat meets the minimum criteria for roosting and/or foraging value for northern long-eared bat. Construction of the processing facilities would have little impact on bat habitat, as over half of the site has been previously disturbed by LTVSMC taconite mining operations (MDNR et al. 2013). The 2014 Forest Service surveys confirmed that northern long-eared bats utilize the Plant Site for foraging. Driving transects identified the northern long-eared bat being present near the forest/open edge to the east of the Tailings Basin and southwest of the former LTVSMC processing buildings, but this species was not identified to be present within the Tailings Basin itself (Forest Service 2014a, Figure 4). The surveys found no evidence of roost sites at the Plant Site.

Non-federal Lands

Under the Proposed Action, approximately 7,075 acres of non-federal lands would be transferred to the Forest Service. The Forest Service has not determined the suitability of these lands to provide habitat for northern long-eared bat. However, wildlife habitat surveys conducted on these lands have shown that bats forage and drink on the non-federal lands, although bats were not identified to species during the surveys (AECOM 2011b, c). There are 591 acres of mature and 2,104 acres of young and immature upland forest habitat (MIH 1) on the non-federal lands that could provide habitat for northern long-eared bats. The non-federal lands would not be affected by the Project, but should benefit from Forest Service management that favors longer harvest rotations than typically occurs on private forestlands and from activities that promote development of snags. There are approximately 4,254 acres of wetlands on the non-federal lands that could provide habitat for northern long-eared bats.

Wetland Mitigation Sites

Under the Proposed Action approximately 2,169 acres of Wetland Mitigation Site lands would be purchased by PolyMet as compensatory mitigation for impacts to wetlands and other waters of the U.S.. These lands are used for sod production, but under the Proposed Action would be restored to native wetland and upland vegetation. After restoration, the combined total of wetland and upland acreage for these sites would be about 1,603 acres and 197 acres, respectively. These sites could provide habitat for northern long-eared bats and would be privately owned (Pylka 2013b).

Other

Noise and Vibration

Existing ambient steady equivalent noise levels for most of the Mine Site are in the range of 35 to 45 decibels (dBA), which is a range comparable to secluded woods or a quiet bedroom (MPCA 1999). The Peter Mitchell

Mine, north of the Mine Site, and traffic along Dunka Road and the existing railway, along the south edge of the Mine Site, also contribute brief, episodic noise impacts.

The primary sources of Project noise from the Mine Site would be blasting, haul trucks, and train horns, with noise levels ranging from 89-115 dBA. Equipment such as graders, bull dozers, and support trucks would be less dominant sources of noise, ranging from 75-95 dBA (Environmental Protection Agency 1971). Blasting at the Mine Site is expected to occur once every two to three days. Typically, rock blasting generates a single event noise level ranging from 111- 115 dBA at 50 feet from the blasting site (Table 5.5-7 of Madera County 2005). Within most of the Mine Site, the sound from the blast would be similar to a loud clap of thunder.

Noise associated with mining activities, including noise from vehicle and rail traffic, would likely have some effect on the behavior of northern long-eared bats. These effects would vary depending on the distance between the noise source and any roost trees in use at the time. Construction and routine operational noise would have a lesser impact on northern long-eared bats, because these noise sources would be more continuous and lower volume. Effects due to acute noise (such as blasting) are not well studied, but may cause northern long-eared bats to startle and may interrupt roosting activities; however, blasting would be more episodic and less continuous than other noise sources, and would therefore be a less-frequent impact. Noise and blasting effects may extend beyond the proposed Mine Site to nearby northern long-eared bat roost sites. However, noise and blasting effects on roosting would be ameliorated by the fact that northern long-eared bats typically utilize several spatially-distinct roosting tree areas (Kunz and Lumsden 2003). As a result, bats startled by noise from one roost area would likely move to another nearby known roost area (Kunz and Lumsden 2003). Section 6.3.2.1 provides further discussion on the noise levels for the NorthMet Project area. Though northern long-eared bats are likely to be sensitive to changes in noise levels, there are no local, national, or international standards or limits that are applicable to the NorthMet Project Proposed Action.

Hazardous Materials

Mishandling of hazardous materials or wastes could result in spills, accidental release, or discharge into the environment, which could pose risks to northern long-eared bats. Sections 5.2.13 and 5.3.13 of the FEIS discuss the risks posed to the public and the environment from the transport, handling, storage, and use of hazardous materials. Mitigation measures to prevent releases in transportation, storage, and handling or use of these materials are described in several hazardous material management plans necessary to comply with various regulatory requirements for the Project and in the FEIS. Based on this analysis, and limited use by northern long-eared bats of the areas where these materials would be used, risks to northern long-eared bats would be negligible and should not result in harm or death to northern long-eared bats (MDNR et al. 2013).

Potential Indirect Effects from Project Stormwater and Process Water Ponds

As previously mentioned, the northern long-eared bat primarily forages in forested areas on moths, flies, leafhoppers, caddisflies, and beetles. Occasional foraging in small forest canopy gaps, over forest clearings, riparian areas of waterways (with preference for streams protected by canopy closure), and along roads has also been observed. In a forest-agriculture landscape it was found that northern long-eared bats avoided the large agricultural openings (fields) and had preferential travel patterns that followed wooded streams and wooded edges including hedgerows (Henderson and Broders 2008). The same researchers found that foraging areas for the northern long-eared bat were typically within the forested parcels along creeks, providing a higher concentration of prey species and drinking areas than in upland open areas such as agricultural fields (Henderson and Broders 2008). Sources of drinking water for northern long-eared bat include open water areas

within forested areas such as woodland vernal pools (Francl 2005, 2008) and open water areas in wetlands (e.g., beaver ponds) (Taylor 2006).

A portion of the Mine Site would be cleared of vegetation to accommodate the mine pits and associated infrastructure (e.g., haul roads, stockpile, stormwater ponds, waste water ponds) and would become a large open area during operations. The existing Plant Site is primarily an open area dominated by the LTVSMC Tailings Basin and would continue as an open area during Project operations. As a forest specialist, the northern long-eared bat is unlikely to use large upland open areas (Henderson and Broders 2008; Jantzen 2012). Chapman et al. (2014) identify that the northern long-eared bat seldom forages outside the forest or over water bodies and Jantzen (2012) identified that most bat activity occurs within 40 meters of the forest edge, with a maximum distance from the forest edge of about 120 meters. Francl (2005, 2008) identifies the importance of palustrine habitats (bogs, fens, beaver ponds) for bat species usage and that woodland vernal pools are an important drinking water source for several species including the northern long-eared bat. Overall, the peer-reviewed literature identifies the northern long-eared as an obligate forest species (Ford et al. 2005; Buckman-Sewald et al. 2014) that has a strong preference to forage and roost and drink within the forest area (Henderson and Broders 2008; Francl 2008; Chapman et al. 2014) and that it is rare for this species to roost in man-made structures (Henderson and Broder 2008).

The 2014 Forest Service bat surveys indicated that northern long-eared bats were present and foraging at the Plant Site, with driving transect data identifying this species as being present at the forest/open edge area to the east of the Tailings Basin (within 50 meters of the road) and near the LTVSMC process buildings, but not within the Tailings Basin itself (USDA Forest Service 2014a, Figure 4). Currently, forest vegetation at the east side of the Tailings Basin is more than 300 meters from the existing pond. Emergence surveys indicated the northern long-eared bat was also present in areas adjacent to the existing LTVSMC process buildings, with forest vegetation being within about 140 to 150 meters on the west side of the concentrator building and within 30 to 50 meters southeast of the coarse crusher building (USDA Forest Service 2014a, Figure 5).

While other bat species may use open upland areas for foraging and ponds in open terrain for drinking (e.g., little brown bat), it seems unlikely for the northern long-eared bat to use these areas (Jantzen 2012; Chapman et al. 2014). Based on the 2014 Forest Service bat survey data (e.g., driving transects) and the weight of evidence in the peer-reviewed literature, it seems unlikely for the northern long-eared bat to use the open areas at the Tailings Basin or the cleared Mine Site, or the ponds within those open areas, to any great extent because they do not meet its habitat and foraging requirements. Therefore, the northern long-eared bat is likely to have a low potential exposure to water in mining-related ponds and minimal consumption of aquatic insects that may use the stormwater or process water ponds at the Mine Site or the Plant Site during operations, and no significant indirect effects to this species from the Project are likely to occur.

The Project's water management further limits the potential exposure of the northern long-eared bat to indirect effects from the various water features at the Plant Site or Mine Site and consumption of insects that may use these water features. Project water features include stormwater ponds, process water ponds, water in active mine pits, constructed wetlands, the Hydrometallurgical Facility pond (operations), the Flotation Tailings Basin Pond and wetland (reclamation and long-term closure), and the West Pit lake (long-term closure). Each water feature is qualitatively evaluated for potential indirect effects to northern long-eared bats.

1. Stormwater from precipitation and runoff would be directed to sedimentation ponds to remove total suspended solids (TSS) prior to being discharged off-site. Water in the ponds prior to

discharge is expected to reflect background concentrations of water quality parameters (including metals and mercury) and any aquatic insects inhabiting stormwater ponds should have metal and mercury concentrations that reflect background conditions, and therefore, similar to existing conditions. Therefore, any consumers of aquatic insects (including the northern long-eared bat) from Project stormwater ponds should not be exposed to metal or mercury concentrations in those insects above background levels.

2. Process water would be collected and stored in a number of ponds at the Mine Site (e.g., Overburden Storage and Laydown Area Pond) and the Flotation Tailings Basin Pond and Hydrometallurgical Residue Facility Pond at the Plant Site and be actively managed for re-use. The probability of insects inhabiting or using a process water pond as a source of drinking water is expected to be low because: 1) these ponds would tend to be turbid and limit the establishment and growth of plants and in turn limit organic materials and the establishment of macroinvertebrates (Nelms et al. 2012); 2) mining-related water is low in organic carbon (Berndt and Bavin 2012) and nutrients and would limit growth and reproduction of algae, macroinvertebrates, and other biota (Nelms et al. 2012; Seger et al. 2012) ; 3) the use of liners and/or compacted bottoms to maximize water retention would not likely provide a suitable substrate for the larval stages of most aquatic insects (Flake and Cieminski 1996); and 4) fine mineral sediments that have little silt or clay are poor media for plant establishment and growth (Nelms et al. 2012) and further limits the presence of aquatic insects that require organic materials for food (Seger et al. 2012). The above listed factors likely limit the aquatic life in process water ponds and insects from Project process water ponds would likely represent a very small percent of the diet of consumers of aquatic insects. Limited pond productivity and the preference of the northern long-eared bat for forest areas further reduces the potential effect of process water ponds on this bat species.

Similar to taconite processing, mercury in process water sent to the Flotation Tailings Basin Pond and the Hydrometallurgical Residue Facility Pond is expected to be associated with the solids and sequestered with those solids in the respective ponds and result in relatively low concentrations of mercury in the water column (Barr Eng. 2007b; PolyMet 2015). Mercury associated with solids such as tailings is sequestered within the basin and is typically not released from the basin (Berndt 2003) and not readily bioavailable. The continual deposition of solids in these ponds is likely to limit sediment-dwelling organisms (Nelms et al. 2012), as would the lack of organic material for food (Flake and Cieminski 1996; Nelms et al. 2012). Limited pond productivity, sequestration of mercury with solids, and the preference of the northern long-eared bat for forest areas also reduces the potential effect of process water ponds on this species.

3. Mine pit dewatering would occur during Mine Years 1 through 20 and this water would be routed to the Waste Water Treatment Facility for initial treatment and then pumped to the Flotation Tailing Basin Pond for use in ore processing (Poly Met 2014c). A minimal amount of water is expected to be present in an active mine pit, therefore the probability of aquatic insects inhabiting or using a sump area is low. The continual removal of water is likely to limit the presence of aquatic organisms (Nelms et al. 2012), as would the lack of organic material for food (Flake and Cieminski 1996; Nelms et al. 2012). Limited productivity and the preference of the northern long-eared bat for forest areas reduces the potential effect of mine pit watering on

this species.

4. As part of reclamation, some stormwater ponds and process water ponds would be filled and converted to terrestrial habitat (.e.g., Hydrometallurgical Residue Facility Pond) (Poly Met 2014b; 2014e; 2014f). Ponds filled and reclaimed to terrestrial vegetation would have the potential to produce runoff water that would be expected to reflect background conditions. Reclaiming ponds to terrestrial vegetation is not expected to produce runoff that would adversely affect aquatic insects.

A part of the East Pit (after backfilling is completed) and some stormwater and process water ponds would be converted to wetlands (Poly Met 2014b, 2014c, 2014d). These constructed wetlands are expected to receive precipitation and stormwater runoff. The accumulating water should reflect background concentrations for various parameters (including mercury). Any aquatic insects inhabiting a constructed wetland or using it as a source of drinking water should have metal or mercury concentrations that reflect background conditions. Therefore, any consumers of these aquatic insects (including the northern long-eared bat) should not be exposed to metal or mercury concentrations in those insects above background levels.

In regard to the backfilling of the East Pit, the water level would be maintained below the level of the fill material to facilitate truck hauling (Poly Met 2014b). No visible ponding of water is expected during backfilling. Therefore, backfilling of the East Pit would have no potential to affect aquatic organisms.

The Flotation Tailings Basin Pond would be present after Mine Year 20 and a wetland would be constructed around the perimeter of the pond. The pond and wetland are expected to be present into long-term closure. After Mine Year 20, the Beneficiation Plant and Mine Site would no longer contribute water and the largest source of water to the pond would be precipitation and runoff (PolyMet 2015). In long-term closure, the water in the pond would be primarily from precipitation and runoff (PolyMet 2015) and would be expected to reflect background conditions and parameter concentrations (including mercury). Any aquatic insects inhabiting the Flotation Tailings Basin Pond or using it as a source of drinking water during long-term closure should have metal or mercury concentrations that reflect background conditions. Therefore, any consumers of these aquatic insects (including the northern long-eared bat) should not be exposed to metal or mercury concentrations in those insects above background levels.

5. The depth of the West Pit at the end of mining will be more than 600 feet. Flooding of the pit would result in rapid water level increases that are predicted to average about 17 feet per year (PolyMet 2014g). Rapidly rising water levels likely limits the aquatic life that would inhabit the lake during the years of pit flooding (Nelms et al. 2007). In addition, the probability of the northern long-eared bat, an obligate forest species (Jantzen 2012; Chapman et al. 2014), to use a body of water more within a large open area is very low. Therefore, the potential exposure of the northern long-eared bat to any insects that might inhabit or use the West Pit lake during the early years of flooding is likely very low.

The majority of water used to flood the West Pit would be primarily from precipitation and stormwater runoff (Poly Met 2014g) and as the pit fills the parameter concentrations in the

upper portion of the water column (i.e., the epilimnion) should reflect background (including mercury). Flooding of the West Pit would produce a pit lake that is approximately 320 acres in size with a maximum depth of 630 feet (Poly Met 2014b). As an oligotrophic system with a small littoral area, aquatic insects diversity and numbers in the West Pit lake would be limited (Nelms et al. 2012; Gray et al. 2012). Data for pit lakes identifies they have low densities and diversity of invertebrates (MDNR 1989). In addition, pit lake waters are typically low in phosphorus, limiting primary production (MDNR 1989). For the above reasons, overall, the potential population of aquatic insects in the West Pit lake is expected to be small. In addition, these insects would likely represent only a small portion of the diet of consumers of aquatic insects. Therefore aquatic insects inhabiting the West Pit lake or using it as a source of drinking water would likely have no significant effect on insect consumers such as the northern long-eared bat.

With regard to mercury, the West Pit lake is estimated to have a total mercury concentration of 0.3 to 0.9 ng/L during flooding and in long-term closure (Poly Met, 2014g). Because precipitation would be the main input of water to the West Pit lake, metal concentrations in long-term closure would likely reflect background conditions. Therefore, any aquatic insects inhabiting the West Pit lake or drinking from the West Pit lake would be exposed to background concentrations. Any consumers of these aquatic insects (including the northern long-eared bat) should not be exposed to metal or mercury concentrations in those insects above background levels.

Because existing wetlands at the Plant Site (e.g., north of the tailings basin) and the Mine Site (e.g., 100 Mile Swamp) would be providing an abundant supply of insects, the northern long-eared bat and other consumers of insects would likely be focused in these areas and would not likely be relying on the Project water features for any significant portion of their food supply. Therefore, any insects inhabiting Project water features or using them as sources of drinking water are not expected to have a significant effect on the consumers of insects. Overall, no adverse indirect effects on the northern long-eared bat from the Project's water features are anticipated.

6.2.3 Effects of Interrelated and Interdependent Actions

No known activities are interrelated or interdependent to the Project that would have the potential to affect northern long-eared bat. It is possible that future specific programs or projects may have relevant interrelated and interdependent actions (e.g., expansion of the Mine Site due to discovery of new ore bodies) and they would be considered in the context of consultations for those actions.

6.2.4 Cumulative Effects

The methods used to analyze cumulative effects, and the temporal and spatial domains, are the same for northern long-eared bat as for lynx, as discussed in Section 6.1.4. Forest management and habitat fragmentation are reasonably foreseeable future actions that could affect northern long-eared bat.

6.2.4.1 Habitat Management and Fragmentation

Forest Management and Habitat Fragmentation

Forest management activities, such as timber harvest and road building, could occur on the federal and non-federal lands in the reasonably foreseeable future and these activities could result in habitat modification and fragmentation.

Northern long-eared bats roost predominantly in trees and to a lesser extent in man-made structures. Although there is still much to learn about the effects of forest removal on northern long-eared bats and their associated summer habitat, studies to date have found that the northern long-eared bat shows a varied degree of sensitivity to forest management practices. Several studies have found that the species uses a wide range of tree species for roosting, suggesting that forest succession may play a larger role in roost selection (than tree species). Studies have found that female bat roosts are more often located in areas with partial harvesting, which may be due to trees located in more open habitat receiving greater solar radiation and therefore speeding development of young. In the Appalachians of West Virginia, diameter-limit harvests (70 to 90 year-old stands, with 30 to 40% of the basal area removed in the past 10 years) rather than intact forest was the habitat type most selected by northern long-eared bats. Cryan et al. (2001:49) found several northern long-eared bat roost areas in recently harvested (less than 5 years) stands in the Black Hills of South Dakota, although the largest colony (n=41) was found in a mature forest stand that had not been harvested in over 50 years.

It is possible that this flexibility in roosting habits allows northern long-eared bats to be adaptable in managed forests. However, the northern long-eared bat has shown a preference for contiguous tracts of forest cover for foraging. Jung et al. (2004:333) found that it is important to retain snags and provide for recruitment of roost trees during selective harvesting in forest stands that harbor bats. If roost networks are disturbed through timber harvesting, there may be more dispersal and fewer shared roost trees, which may lead to less communication between bats in addition to less disease transmission. In the Appalachians, Ford et al. (2006:20) assessed that northern long-eared bats may be a suitable management indicator species for assessing mature forest ecosystem integrity, because they found male bats using roosts in mature forest stands of mostly second growth or regenerated forests.

Perry and Thill (2007:225) found that male northern long-eared bats seem to prefer more dense stands for summer roosting, with 67% of male roosts occurring in unharvested sites versus 45% of female roosts. The greater tendency of females to roost in more open forested areas than males may be due to greater solar radiation experienced in these openings, which could speed growth of young in maternity colonies. Lacki and Schwierjohann (2001:487) stated that silvicultural practices could meet both male and female roosting requirements by maintaining large-diameter snags, while allowing for regeneration of forests. However, Broders and Forbes (2004:608) found that timber harvest may have negative effects on female bats because they use forest interiors at small scales (less than 1.2 miles from roost sites). They also found that males are not as limited in roost selection and they do not have the energetic cost of raising young; therefore males may be less affected than females. Henderson et al. (2008:1,825) also found that forest fragmentation affects northern long-eared bats at different scales based on sex; females require a larger unfragmented area with a large number of suitable roost trees to support a colony, whereas males are able to use smaller areas (more fragmented).

The Project would result in habitat loss and fragmentation on about 1,166 acres at the Mine Site for about 20 years (until the Project is reclaimed). Impacts from habitat and fragmentation may continue beyond the onset of

reclamation, but these impacts would be expected to diminish as the target reclamation habitats develop along the expected successional trajectories. High-quality forested vegetation would begin to return to the site over the long-term successional trajectory (approximately 30 years), except in areas where trees and other deep-rooted vegetation would be excluded to protect stockpile liners.

Under the Proposed Action, PolyMet would acquire the federal lands from the Forest Service and would manage lands outside of the Mine Site for wildlife habitat, including some timber management. The non-federal lands would be managed for General Forest, General Forest-Longer Rotation, Riparian Areas, and Candidate Research Natural Areas (MDNR et al. 2013). If new roads are constructed on the federal or non-federal lands, they would likely be temporary and used to support timber management. Although these actions would result in some short-term loss of habitat for northern long-eared bats, long-term protection and management of forests would retain and promote high-quality forest habitat for northern long-eared bats that should result in a long-term cumulative benefit.

Prescribed Fire

Prescribed fire could be used on federal and non-federal lands to reduce hazardous fuels in the reasonably foreseeable future. Eastern forest-dwelling bat species, such as the northern long-eared bats, likely evolved with fire management of mixed-oak ecosystems. A recent review of prescribed fire and its effects on bats (U.S. Forest Service 2012:182) generally found that fire had beneficial effects on bat habitat. Fire may create snags for roosting and creates more open forests conducive to foraging on flying insects, although gleaners such as northern long-eared bats may readily use cluttered understories for foraging. Cavity and bark roosting bats, such as northern long-eared bat, use previously burned areas for both foraging and roosting. In Kentucky, the abundance of prey items for northern long-eared bats increased after burning, and more roosts were found in post-burn areas. Burning may create more suitable snags for roosting through exfoliation of bark, mimicking trees in the appropriate decay stage for roosting bats. Low-intensity burns may not kill taller trees directly but may create snags of smaller trees and larger trees may be injured, resulting in vulnerability of the tree to pathogens that cause hollowing of the trunk, which provides roosting habitat. Prescribed burning also opens the tree canopy, providing more canopy light penetration, which may facilitate faster development of juvenile bats.

Under the Proposed Action, prescribed fire would be used on a limited basis, primarily on non-federal lands administered by the Forest Service, and should have long-term benefit on forest health and habitat availability for northern long-eared bat.

6.3 Gray Wolf

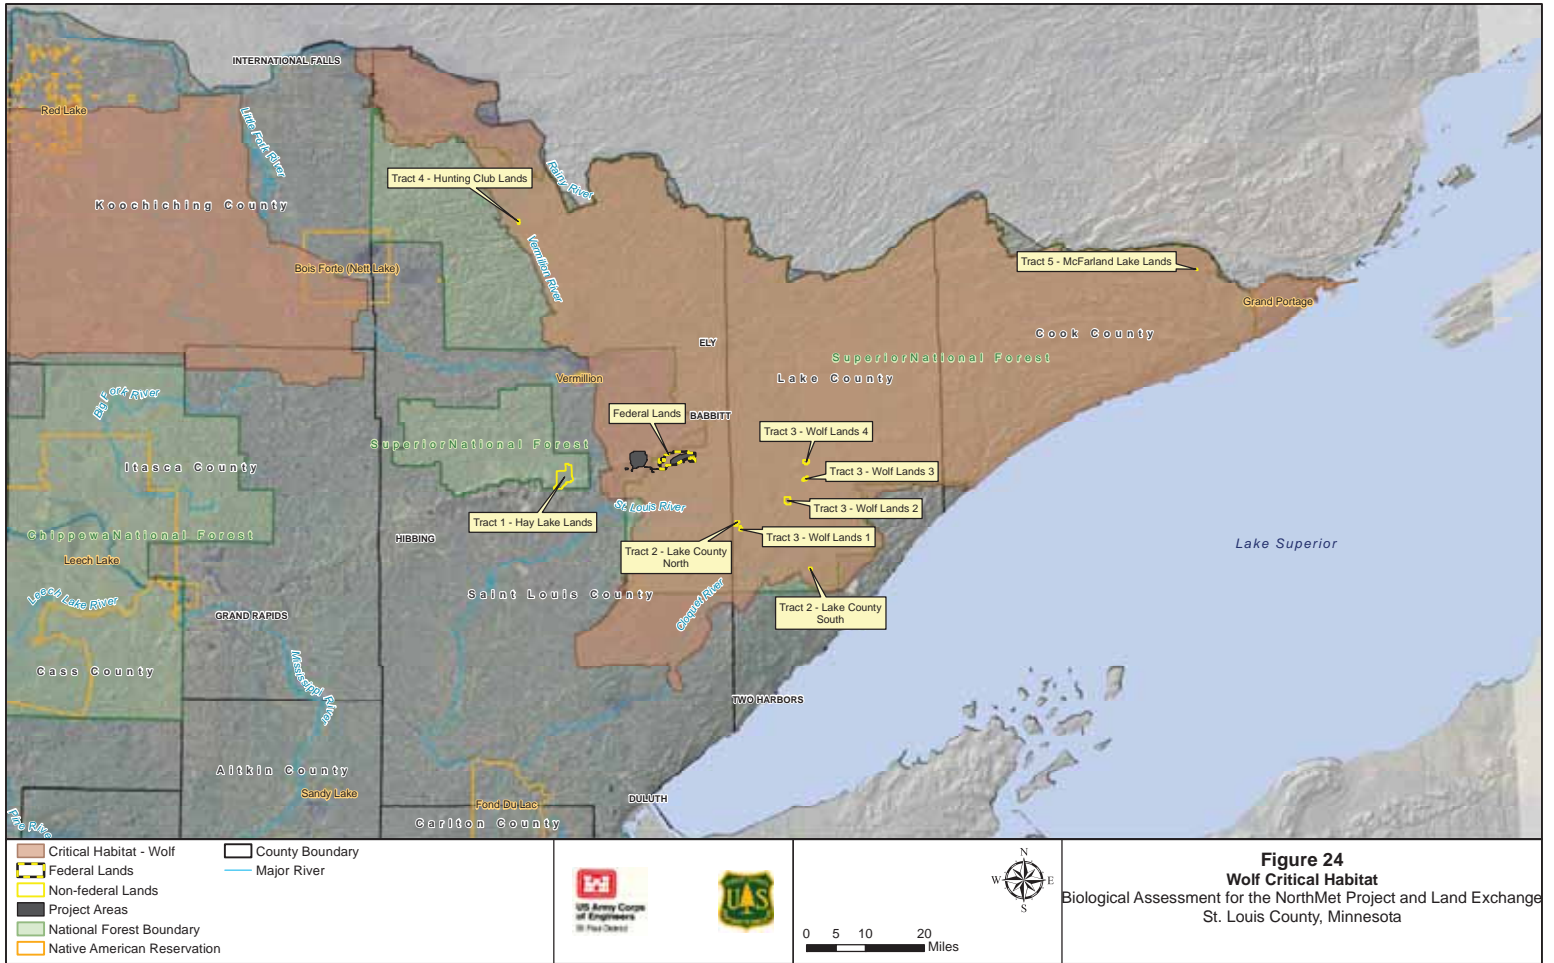

6.3.1 Environmental Baseline

6.3.1.1 Species Description and Status and Critical Habitat Status

Gray wolves are the largest wild members of the dog family (Canidae) with adults ranging from 40 to 175 pounds, depending on sex and subspecies (Mech 1974). Wolves have a gray fur coat that can vary from pure white to coal black. Wolves may look similar to coyotes and some domestic dogs, such as the Siberian husky (*C. familiaris*; USDOI USFWS 2003b). Currently, three wolf species are recognized with ranges in the conterminous U.S.—*Canis lupus*, *Canis lycaon*, and *Canis rufus*. *Canis lycaon* is primarily found in Canada and the western Great Lakes, and *C. rufus* in the southeastern U.S. *Canis lupus* is found in the western Great Lakes and western U.S. The ranges of *C. lupus* and *C. lycaon* overlap in the western Great Lakes region.

In response to their vastly declining numbers, the gray wolf was determined to be endangered in 1967 (USDOI USFWS 1967) under the Endangered Species Preservation Act of 1966. In 1974, the species was formally listed as endangered through the authority of the ESA (USDOI USFWS 1974), and the Minnesota population was reclassified to threatened in 1977 (USDOI USFWS 1977). In 1978, critical habitat was designated for the Eastern DPS of gray wolf (USDOI USFWS 1978). That rule (50 C.F.R. § 17.95[a]) identified critical habitat at Isle Royale National Park, Michigan, and Minnesota wolf management zones 1, 2, and 3, as delineated in 50 C.F.R. § 17.40(d)(1). Wolf management zones 1, 2, and 3 comprise approximately 9,800 mi² in northeastern and northcentral Minnesota and include all of the Superior National Forest and portions of the Chippewa National Forest. Hunting Club Lands and McFarland Lake Lands are in Zone 1, while the federal lands, and other non-federal lands are in Zone 2. The Wetland Mitigation Sites are outside the wolf zones (**Figure 24**).

In April 2003, gray wolf populations in the U.S. were separated into three DPS' (USDOI USFWS 2003b) to more effectively manage the species; the Minnesota population was a designated portion of the Eastern DPS. In March 2006, the USFWS proposed to designate gray wolves in the Western Great Lakes region as a DPS under the ESA and to remove wolves in Minnesota, Wisconsin, and Michigan from listing under the ESA. The Western Great Lakes DPS included Minnesota, Wisconsin, and Michigan as well as parts of North Dakota, South Dakota, Iowa, Illinois, Indiana, and Ohio (USDOI USFWS 2006b). In March 2007, the USFWS removed the gray wolf from the endangered species list (USDOI USFWS 2007).

In September 2008, the U.S. District Court for the District of Columbia overturned the USDOJ's decision to remove the Great Lakes DPS of the gray wolf from federal ESA protection; the USFWS issued a rule in December 2008 to comply with court orders reinstating regulatory protections for the gray wolf in the western Great Lakes and northern Rocky Mountains (USDOJ USFWS 2008b). In April 2009, the USFWS issued a rule to identify the Western Great Lakes DPS of the gray wolf, and to remove this DPS from the list of threatened and endangered species (USDOJ USFWS 2009b). In July 2009, the USFWS withdrew its request to delist the Western Great Lakes DPS and in September 2009 the USFWS reinstated protections for the Western Great Lakes DPS (United States District Court for the District of Columbia 2009, USDOJ USFWS 2009c). In May 2011, the USFWS again proposed to identify and remove the Western Great Lakes DPS of gray wolf from federal ESA protection. The USFWS also proposed to remove federal designation of critical habitat for the species in Minnesota and Michigan, and to remove the gray wolf special rule in Minnesota, which defined the circumstances when gray wolves can be taken in Minnesota (USDOJ USFWS 2011b).

On December 28, 2011, the USFWS revised the 1978 listing of the Minnesota population of gray wolf to conform to statutory and policy requirements. The USFWS renamed what was previously listed as the Minnesota population of the gray wolf as the Western Great Lakes DPS, and delineated the boundaries of the expanded Minnesota population segment to include all of Minnesota, Wisconsin, and Michigan and portions of the adjacent states. The USFWS removed the Western Great Lakes DPS from the list of endangered and threatened wildlife. The USFWS took this action because the best available scientific and commercial information indicated that the Western Great Lakes DPS does not meet the definitions of threatened or endangered under the ESA. This final rule also removed the designated critical habitat for the wolf in Minnesota and Michigan and the special regulations under Section 4(d) of the ESA for wolves in Minnesota. On December 19, 2014, a federal court reversed the USFWS decision to delist the gray wolf, restoring federal threatened status and critical habitat designation in Minnesota.

6.3.1.2 Distribution

The gray wolf historically occurred across most of North America, Europe, and Asia. The only areas of the conterminous U.S. that apparently lacked gray wolf populations since the last ice age are parts of California and portions of the eastern and southeastern U.S. (an area occupied by the red wolf; *Canis lupus rufus*). Wolf research and the expansion of wolf range over the last 3 decades have shown that wolves can successfully occupy a wide range of habitats, and they are not dependent on wilderness areas for their survival. In the past, for instance, wolf populations occupied nearly every type of habitat north of mid-Mexico that contained large ungulate prey species, including bison, elk, white-tailed deer, mule deer, moose, and woodland caribou. Inadequate prey density or high levels of human-caused mortality appear to be the only factors that limit wolf distribution (USDOJ USFWS 2011b).

Widespread persecution of wolves began following European settlement of North America (Boitani 1995). Poisons, trapping, and shooting spurred by federal, state, and local government bounties extirpated this once widespread species from more than 95% of its historic range. In the late 1960s, a diminished population (several hundred) of wolves was known to occur in northeastern Minnesota and on Isle Royale, Michigan; a few scattered wolves also may have occurred in Michigan's Upper Peninsula, Montana, and the southwest U.S. Today, wolves have expanded their range to include much of the U.S, including the Pacific Northwest, Northern Rockies, Upper Midwest, and eastern U.S. Wolves that comprised the Western Great Lakes DPS are found in Minnesota, Wisconsin, and Michigan.

6.3.1.3 Population Status in North America

Wolves once occupied all of North America, and today occupy only between 5 and 10% of this historic range. The wolves occupying Minnesota are part of a meta-population of 60,000 to 80,000 covering most of Canada, the Lake States of Minnesota, Wisconsin, and Michigan, portions of the northern Rocky Mountains, with smaller reintroduced populations in Wyoming (Yellowstone National Park), central Idaho, and Arizona/New Mexico (USDA Forest Service 2011b).

6.3.1.4 Life History

Wolves are carnivorous predators that prefer a diet of medium and large mammals. Wild prey species in Minnesota include white-tailed deer, moose, beaver, and snowshoe hare, with small mammals, birds, and large invertebrates sometimes being taken (Mech 1974, Wisconsin DNR 1999). Wolves are habitat generalists that do not depend on the type, age, or structure of vegetation, instead, they are indirectly influenced by vegetative condition through the distribution of their primary prey species.

Wolves are social animals, normally living in packs of 2 to 30 wolves, although about 15% of the population may be composed of loners and dispersers (Fuller 1989). In Minnesota, packs range in size from 4.9 to 5.6 (Erb and Benson 2004, Erb 2008). Packs are primarily family groups consisting of a breeding pair, their pups from the current year, offspring from the previous year, and occasionally an unrelated wolf. Packs typically occupy, and defend from other packs and individual wolves, territories of 42 to 100 mi² in the Great Lakes region and about 40 mi² in Minnesota (Fuller 1989, Erb and Benson 2004, Erb 2008).

Normally, only the top-ranking (alpha) male and female in each pack breed and produce pups. Litters are born from early April to May and range from 1 to 11 pups, but generally include 4 to 8 pups (Fuller 1989, Michigan DNR 1997, USDOJ USFWS 1992). Normally a pack has a single litter annually, but the production of two or three litters in 1 year has been documented in Yellowstone National Park (USDOJ USFWS et al. 2002). Yearling wolves frequently disperse from their natal packs, although some remain with their natal pack. Yearlings may range over large areas as lone animals after leaving their natal pack or they may locate suitable unoccupied habitat, pair with a member of the opposite sex, and begin their own pack. Dispersal distances of over 500 miles have been documented (Fritts 1983); individual wolves have recently traveled from central Wisconsin to east-central Indiana (400 miles) and northern Illinois, from the Upper Peninsula of Michigan to northern Missouri (600 miles), and from the Minnesota-Wisconsin-Michigan population to east central Nebraska.

6.3.1.5 Wolf Habitat, including Prey Habitat

Potential and favorable wolf habitat is defined by several elements such as human population density, sufficient prey density, road density, vegetation cover, and special landscape patterns (Mladenoff et al. 1995). Gray wolves are generalists that can live in most any habitat that supports ungulate prey. Wolf densities are directly related to the densities of their primary ungulate prey (Fuller 1989), thus forested areas occupied by white-tailed deer and moose are critical. Additionally, the habitat should be suitable for smaller prey such as beaver and snowshoe hare which may be seasonally important (Mech 1970). Moose, deer, and snowshoe hare tend to forage in areas of regenerating upland forest, and coniferous forest is an important component of thermal cover for all. Riparian trembling aspen forest is important for beavers. Patch structure is only important in that it may alter prey densities or include areas of high road and human densities thereby indirectly altering wolf distribution (Fuller 1997).

Wolf density is heavily dependent on prey availability (Fuller 1989). Conservation of primary wolf prey, such as white-tailed deer, is clearly a high priority for the MDNR, which typically manages ungulates to ensure a harvestable surplus for hunters and non-consumptive users, and to minimize conflicts with humans. To ensure a harvestable surplus for hunters, the agency must account for all sources of natural mortality, including loss to wolves, and adjust hunter harvest levels when necessary.

White-tailed deer, moose, and beaver, the primary prey species for wolf, are closely associated with forage from young upland forest less than 10 years old. White-tailed deer and moose rely on upland immature (10 to 80 years old) and mature (80+ years old) conifer for thermal and hiding cover.

Moose Populations

Population estimates from aerial surveys in northeastern Minnesota, conducted since 1959, suggest that the moose population gradually began to increase in the 1970s and 1980s to a peak of 6,900 in 1988, then dropped to 3,700 by 1990, and then stabilized between 3,500 and 4,000 animals, or approximately 0.7 moose/mi², between 1996 and 2001. Due to a change in MDNR survey methods in 2004, population estimates from surveys conducted in 2005 and afterwards are not directly comparable to prior surveys. An estimated 8,106 moose occurred in northeastern Minnesota in 2005, 7,890 in 2008, 5,700 in 2010, but only 2,760 moose occurred in January 2013, a 52% decline between 2010 and 2013. Both the cow to calf ratio and the percent calves has exhibited a steady decline over the past 9 years (DelGiudice 2013). There is currently a moratorium on moose hunting in Minnesota due to low population numbers (MDNR 2013a).

There is no documentation expressing a correlation between the wolf and moose population fluctuations on the Superior National Forest, although as discussed below for white-tailed deer, there has been a decline in wolf populations concurrent with declines in white-tailed deer and moose populations in recent years.

White-tailed Deer Populations

Land management carried out by other public agencies and by private landowners in Minnesota's wolf range, including timber harvest and prescribed fire, improves habitat for white-tailed deer, the primary prey for wolves in the State. The success of these measures is apparent from the continuing high white-tailed deer densities in the Forest Zone of Minnesota, and with a white-tailed deer harvest averaging about 215,000 deer over the last 5 years. However, numbers of white-tailed deer harvested has declined slowly since a peak harvest of 290,000 deer in 2003 (MDNR 2012). Approximately one-half of the Minnesota deer harvest is in the Forest Zone, which encompasses most of the occupied wolf range in the State. The decline in white-tailed deer numbers may be depressing wolf abundance in Minnesota's core wolf range, as wolf numbers have declined statewide from 2,900 in 2009 to about 2,200 in 2012 (Erb and Samson 2013). Since 2007, Minnesota's Forest Zone white-tailed deer population is estimated to have declined by 25% (Grund and Walberg 2012). Erb and Samson (2013) believe that reduced prey density largely explains the 13% increase in wolf pack territory size they observed during the 2012-13 wolf survey, the first such increase in territory size since surveys began, and the decline in wolf populations in Minnesota. The harvest of wolves in Minnesota may also explain some of the decline in wolf populations. Nevertheless, current estimated density remains near the upper end of densities reported from other regions of North America where density of self-sustaining wolf populations has been estimated over a large area.

6.3.1.6 Human Access and Disturbance and Wolf Mortality

Human settlement and roads are considered to be major determinants in gray wolf distribution. These activities have multiple effects, including increased human presence causing an increase in illegal poaching and legal predator control, increased chance of introduced diseases and parasites via pets (e.g., canine parvovirus), and potential deterrence to colonization of otherwise suitable habitat (Mech 1995, Gogan et al. 1997).

Road Density

To a large extent, road density has been adopted as the best predictor of habitat suitability for wolves in the Midwest due to the connection between roads and human-related wolf mortality. Recent studies have used road density to predict probabilities of persistent wolf pack presence in an area. Areas with road densities less than 0.7 miles/mi² are estimated to have a greater than 50% probability of wolf pack colonization and persistent presence, and areas where road density exceeds 1 mile/mi² have less than a 10% probability of occupancy (Mladenoff et al. 1995, 1999).

Studies of wolf populations in Minnesota, Michigan, and Wisconsin indicate that wolf populations usually fail to sustain themselves in areas where rural roads open to the public have densities exceeding 0.93 linear miles of road/mi². The Wolf Recovery Plan recommends that density of higher standard roads remain below 1 mile/mi² in critical habitat to limit the extent of associated effects to wolves (USDOJ USFWS 1992).

Roads lead to wolf-vehicle collisions and an increase in access by hunters and trappers, and can be barriers to movement (USDOJ USFWS 1992). However, wolves may tolerate road densities as high as 1.2 miles/mi² if roaded areas are adjacent to large roadless areas, such as the Superior National Forest.

The Wolf Recovery Plan addresses the impact of low standard roads, but does not recommend a density threshold for such roads. Low standard roads may have a greater potential for human impact on wolves than high standard roads due to the potential for human access for trapping and shooting. These roads typically are accessed by recreational motor vehicles or on foot. Illegal killing of wolves may result from a variety of reasons. Some of these killings are accidental (e.g., wolves are hit by vehicles, mistaken for coyotes and shot, or caught in traps set for other animals) and may be reported to state, tribal, and federal authorities. Most illegal killings, however, likely are intentional and are never reported to authorities (Mech 1995). The MDNR receives approximately two to six reports of wolves killed by vehicle collision annually. While human habitation and the associated network of roads and vehicle traffic increase, wolf mortality from vehicle collisions is expected to continue both in actual numbers and as a percent of total diagnosed mortality in Minnesota.

As wolf populations have continued to expand, however, the road density threshold has been questioned. Wolves can be expected to expand their range into areas with more roads and humans, “as more tolerant attitudes toward wolves increase and depredations by wolves are controlled.” “Given the current status of wolves, reducing current levels of high standard road access is not necessary to increase either wolf density or distribution. However, in areas of sufficient size to sustain one or more wolf packs, land managers should be cautious about adding new road access that could exceed a density of 1 mile/mi² without considering the potential effect on wolves” (MDNR 2001 *in* USDA Forest Service 2011b). Thus, the focus of wolf protection is now on maintaining large blocks of habitat relatively free of human access even in areas where the road density exceeds 1 mile/mi².

Human-caused Mortality Factors

A study conducted in between 1980 to 1986 within northcentral Minnesota found human-caused mortality occurred at a rate of 29%, a figure which includes 2% mortality from legal depredation control actions (Fuller 1989). The MDNR conducted a radiotelemetry study of wolves and white-tailed deer, and of 32 wolves fitted with radio collars between 1993 and 2005, 11 of 16 documented mortalities were attributed to humans (USDA Forest Service 2011b). This includes one wolf accidentally snared, two vehicle collisions, and eight that were shot.

A smaller mortality dataset is available from a 1987 to 1991 study of wolves in and adjacent to Minnesota's Voyageurs National Park. Natural causes of mortality among radiomarked wolves included intraspecific strife (n = 4) and starvation (2). Confirmed human-induced causes of mortality among radiomarked wolves included shooting (2), trapping or snaring (2), and unknown method (2). Natural causes of mortality among non-radiomarked wolves included intraspecific strife (1) and starvation (1). Confirmed human-induced causes of mortality among non-radiomarked wolves included automobile collisions (3), shooting (3), and trapping or snaring (2). All mortalities within the boundaries of Voyageurs National Park were attributed to natural causes. Six of eight confirmed mortalities among instrumented wolves and eight deaths of non-instrumented wolves beyond the boundaries of Voyageurs National Park were human caused (Gogan et al. 2004).

The USDA Animal and Plant Health Inspection Service Wildlife Services found that from 1996 to 2009, an average of 146 wolves were taken annually for depredation control in Minnesota (USDA Forest Service 2011a).

Illegal mortality can often be estimated through radiotelemetry studies (Fuller 1989), however only a few radiotelemetry studies have taken place in Minnesota. Northcentral Minnesota data from 16 diagnosed mortalities of radiocollared wolves over a 12-year period (1994 to 2005) show that human-causes resulted in 69% of the diagnosed mortalities (USDA Forest Service 2011b).

Minnesota's wolves transitioned from federal protection under the ESA to state management by the Minnesota Department of Natural Resources on January 27, 2012. Minnesota's Wolf Management Plan will ensure the wolf's long-term survival. The plan gives owners of livestock and domestic pets more protection from wolf depredation. It splits the state into two management zones with more protective regulations in the northern third, considered the wolf's core range. The MDNR has not established a maximum population goal and wolves are allowed to naturally expand their range. A statewide winter population of 1,600 wolves is the minimum goal. If Minnesota's wolf population falls below this minimum, the MDNR will take immediate and appropriate management actions to reverse the decline and restore the population to its minimum level in the shortest possible time. The MDNR implemented a conservative and regulated hunting and trapping season in fall 2012. Hunters and trappers harvested 413 wolves in 2012 (MDNR 2013b). The MDNR expects the 2013 season to follow a similar framework with a harvest goal of 220 wolves (MDNR 2013c).

The MDNR (2001) and the Forest Service (2004b) use a variety of methods to encourage and support education of the public about the history and ecology of wolves in the state and the effects wolves on livestock, wild ungulate populations, and human activities. Public outreach efforts have been in effect for years in Minnesota, and while these efforts may not further reduce illegal take of wolves from existing levels, these measures may be crucial in ensuring that illegal mortality does not increase. Illegal take of wolves is likely

related to road and human population densities, but changing attitudes towards wolves may provide for their survival in areas where road and human densities were previously thought to be too high (Fuller et al. 2003). It is important to note that despite the difficulty in measuring the extent of illegal killing of wolves, all sources of wolf mortality, including legal (e.g., depredation control, hunting, trapping) and illegal human-caused mortality, have not been of sufficient magnitude to stop the growth of the wolf population in Minnesota, or for Minnesota to have a hunting season for wolves.

6.3.1.7 Disease

Disease such as canine distemper, canine parvovirus, Lyme's disease, mange, and blastomycosis have been observed in Minnesota wolves. However, the usual high annual replacement of dying wolves by a high number of pups produced (Mech 1977 *in* Mech 2002) may be attenuated by canine parvovirus mortality of young pups (Mech and Goyal 1995 *in* Mech 2002). On the Superior National Forest, wolf population density has been stable or increasing for many years probably indicating that the main effect of canine parvovirus is to reduce the number of dispersing wolves (Mech 2002).

Wolves in Minnesota may have been exposed to canine parvovirus as early as 1973 (Mech and Goyal 1993, 1995). The population impacts of canine parvovirus are believed to be via diarrhea-induced dehydration leading to abnormally high pup mortality (Wisconsin DNR 1999). Despite the presence of canine parvovirus, wolf abundance and range in Minnesota have stabilized above recovery goal levels and there is no evidence that canine parvovirus has caused a population decline in the Minnesota wolf population. In the Superior National Forest, Mech and Goyal (1995) found high canine parvovirus prevalence during the same years in which wolf pup numbers were low, however they concluded that these pup mortalities only replaced deaths that would have occurred from other causes, particularly starvation. They theorized that canine parvovirus prevalence would cause a wolf population decline when 76% of the adult wolves consistently test positive for canine parvovirus exposure. Their data indicate that canine parvovirus prevalence in adult wolves in their study area increased by an annual average of 4% during 1979 to 1993 and was at least 80% during the last 5 years of their study.

6.3.1.8 Population Numbers and Dynamics in Minnesota and Great Lakes Distinct Population Segment

In the western Great Lakes region, wolves in the densely forested northeastern corner of Minnesota have expanded into the more agricultural portions of central and northwestern Minnesota, northern and central Wisconsin, and the entire Upper Peninsula of Michigan. Habitats currently being used by wolves span the broad range from the mixed coniferous/deciduous forest wilderness area of northern Minnesota, through sparsely settled, but similar habitats in Michigan's Upper Peninsula and northern Wisconsin, and into more intensively cultivated and livestock-producing portions of central and northwestern Minnesota and central Wisconsin.

Five comparable surveys of wolf numbers and range in Minnesota have been carried out since 1979. These surveys estimated that in Minnesota there were 1,235 wolves in 1979; 1,500 to 1,750 in 1989; 2,440 in 1998; 3,020 in 2004; and 2,920 in 2008 (Berg and Kuehn 1982, Fuller et al. 1992, Erb 2008). The 1998 and later surveys revealed that the number of wolves in Minnesota was 2 times greater than the planning goal (1,400 wolves) as specified in the Recovery Plan for Minnesota. However, the 2012 survey showed that wolf numbers have declined statewide from 2,900 in 2008 to about 2,200 in 2012 (Erb and Samson 2013).

Based on analysis of 34 radiomarked wolves, average territory size was about 62 mi² in 2012, an increase from 54 mi² during the previous two surveys. Wolf observations were greatest in the vicinity of the Chippewa National Forest, in the Superior National Forest near Virginia, Minnesota, and in Voyageurs National Park (Erb 2008, Erb and Sampson 2013). The Superior National Forest's wolf population was estimated to be about 484 wolves, or about one wolf per 10 mi² (one wolf per 25.9 km²; 0.04 wolf per km²), based on radiotelemetry studies during 2003 to 2008 (Mech 2004, 2008, USDA Forest Service 2004b, 2011b). Both Forests are operated and managed through the 2004 Forest Plan in conformance with standards and guidelines that follow the 1992 Wolf Recovery Plan's recommendations for the wolf.

As wolves increased in numbers, they also expanded their range. In the early 1950s, the wolf range was approximately 12,000 mi², or 14% of the state. By the late 1990s, it was estimated at 34,000 mi², or about 40% of the state, with an occupied range of about 27,612 mi², but since then has shown little expansion (Erb 2008, Erb and Sampson 2013).

Wolves were considered to have been extirpated from Wisconsin by 1960, and no formal attempts were made to monitor that state's wolf population from 1960 until 1979. During that time, individual wolves and an occasional wolf pair were reported. There is no documentation, however, of any wolf reproduction occurring in Wisconsin, and the wolves that were reported may have been animals dispersing from Minnesota. Wolf population monitoring by the Wisconsin DNR began in 1979 and a statewide population of 25 wolves was estimated at that time. This population remained relatively stable for several years, and then declined to approximately 15 to 19 wolves in the mid-1980s. In the late 1980s, the Wisconsin wolf population began an increase that has continued to date. In 2002, wolf numbers in Wisconsin alone surpassed the planning goal as specified in the Wolf Recovery Plan for a second population near Minnesota (100 wolves for a minimum of 5 consecutive years; geographically isolated populations should have 200 wolves for a minimum of 5 years). Approximately 540 wolves were in Wisconsin in 2008 and 815 in 2012 (Wydeven and Wiedenhoeft 2008, Wisconsin DNR 2012).

Michigan wolves were extirpated as a reproducing population long before they were listed as endangered in 1974. Before 1991, and excluding Isle Royale, the last known breeding population of wild Michigan wolves occurred in the mid-1950s. As wolves began to reoccupy northern Wisconsin, the Michigan DNR began noting single wolves at various locations in the Upper Peninsula of Michigan. In the late 1980s, a wolf pair was verified in the central Upper Peninsula and was known to have produced pups in 1991. Since that time, wolf packs have spread throughout the Upper Peninsula, with immigration occurring from both Wisconsin to the west and Ontario to the east. They now are found in every county of the Upper Peninsula. When the wolf population estimates of Wisconsin and Michigan are combined, the total population has exceeded the second population recovery goal, as specified in the Wolf Recovery Plan, of 200 wolves for 5 consecutive years for a geographically isolated wolf population. The two state wolf population, excluding Isle Royale wolves, has exceeded 200 wolves since late winter 1995-1996. An estimated 510 wolves were in Michigan in 2007 and 687 in 2010 (Michigan Department of Natural Resources 2008, USDO I USFWS 2013c).

6.3.1.9 Observations of Gray Wolf in the Vicinity of the Project

Gray wolf tracks, scat, and signs of wolf kills were seen during wildlife studies on the federal lands, Transportation and Utility Corridors, and Plant Site during 2000, 2004, 2008, and 2009 (ENSR 2000, 2005, AECOM 2009b, 2011a). Tracks were commonly seen on the Dunka Road, on mine exploration roads, along railroad grades and utility rights-of-ways, and north of the Mine Site on Northshore Mine roads

during all seasons. In addition, several wolves responded to calls from the Mine Site during 2004. The wolves were located to the south of the calling station, and likely south of the property boundary based on call intensity and direction.

Gray wolf tracks and scat were recorded on Hay Lake Lands, Wolf Lands 3 and 4, and Lake County Lands North during the surveys. Wolf scat was seen on several abandoned logging roads. No wolves or their sign were seen on the other non-federal lands, although conditions for surveys were not favorable for detecting tracks and scat at Hunting Club Lands.

Until 2012, International Wolf Center posted on their website a database summary of wolf radiotelemetry observations in northeastern Minnesota. Of the over 11,000 records in the monitoring database between 1994 and 2010, 10 records were for wolves recorded on the federal lands; however, there were no records for the Plant Site or Transportation and Utility Corridors (International Wolf Center 2012). Radiocollared wolves have been recorded on the townships of Hay Lake Lands. A wolf was observed in Section 6 of Township 58 North, Range 16 West in September 1994, just south of Hay Lake. Wolves were observed in Sections 1, 19, 22, and 23 of Township 59 North, Range 16 West, in and around Hay Lake Lands, between 1994 and 1997. Radiocollared wolves have been recorded in the vicinity of Wolf Lands 2 and 3. There are no recorded observations of wolves in the township of McFarland Lake Lands, although McFarland Lake Lands and other non-federal lands that would be involved in the land exchange or Wetland Mitigation Sites are within the current range of the wolf (Erb and Sampson 2013).

6.3.2 Analysis of Direct and Indirect Effects to Gray Wolf

6.3.2.1 Effects to Gray Wolf within the Action Area

The Wolf Recovery Plan (USDOJ USFWS 1992) and the *Minnesota Wolf Management Plan* (MDNR 2001) identify habitat factors considered as essential for a recovering and recovered wolf population (including maintenance or improvement of critical habitat). Those that may be affected by the Project are prey habitat and human access and disturbance. In addition, disease can impact wolf populations. The Project would result in both beneficial and adverse direct and indirect impacts to factors of importance to wolves.

Factors Affecting Prey Habitat

Federal Lands

The primary impacts to gray wolf prey habitat from the Project would result from habitat loss and disturbance. The Forest Service manages the Mine Site as a General Forest and General Forest – Longer Rotation Management Area. The General Forest – Longer Rotation Management Area emphasizes land and resource conditions that provide a wide variety of goods, uses, and services. These include wood products, other commercial products, scenic quality, developed and dispersed recreation opportunities, and habitat for a diversity of terrestrial and aquatic wildlife and fish species (USDA Forest Service 2004a). The characteristics and use of the General Forest Management Area are similar to the General Forest – Longer Rotation Management Area, except that harvests are more frequent, more uniform in age, and more extensive. The General Forest Management Area has the highest amount of young forest and the largest sized timber harvest units.

The Forest Service identified young upland forest that is less than 10 years old as providing important foraging habitat for wolves (USDA Forest Service 2004b). Based on Forest Service and MDNR cover type mapping criteria and wildlife assessments done on the federal lands, only about 271 acres on the federal lands provide these habitats, although some suitable coniferous stands are found in mixed coniferous/deciduous forest habitats (**Table 11**; MDNR et al. 2013). Immature and mature coniferous forest habitat provides important cover habitat for wolves. There are about 5,393 acres of cover habitat on the federal lands (MDNR et al. 2013). The typical home range for gray wolf is approximately 161 square kilometers, or just under 40,000 acres (MDNR 2014b). The area of disturbance at the Mine Site is 1,719 acres, which is less than 10% of a gray wolf's home range. There is also abundant suitable habitat adjacent to the Mine Site.

Wolves used the federal lands, and wolf calls were heard to the south of the Mine Site during 2004 surveys (ENSR 2000, 2005). Wolf packs with radiocollared individuals have been observed several miles to the north and northeast of the Mine Site. It is likely that the federal lands include much of the territory of a wolf pack comprised of three or more individuals. Wolf tracks were seen along Dunka Road. Interestingly, wolf tracks were not observed on the study area during January 2000, when a drill rig was operating, but only during March 2000 and June 2004, when the rig was not in operation. Thus, noise and activity associated with drilling activities may have discouraged wolves from using the area in the immediate vicinity of the exploration area. Wolf tracks were seen along trails in the federal lands surrounding the Mine Site, and carcasses of two deer were found on these lands that appeared to be wolf kills (AECOM 2009b, 2011a).

White-tailed deer are common on the Mine Site. White-tailed deer tracks were primarily observed in the western and southern portions of the Mine Site during field studies in 2000 and 2004, especially in recently logged areas and shrublands near mixed coniferous/deciduous and coniferous immature/mature and mature forest habitats. White-tailed deer were common on the federal lands surrounding the Mine Site. White-tailed deer tracks and droppings were commonly found on the Project area in virtually all habitat types, and several white-tailed deer were seen along roads within the land. White-tailed deer tracks were primarily observed in the western portion of the federal lands surrounding the Mine Site during 2008 surveys.

Moose sightings were common in logged areas with abundant shrubs and near mature forest habitat, and in sedge and willow wetlands. Moose primarily used the western half of the federal lands (ENSR 2005, AECOM 2011a). Moose populations in the Superior National Forest have fluctuated considerably since the early 1900s and have shown their greatest increases during periods of intense timber harvest (Huempfer 1978). As noted above, however moose populations have declined by about 52% in Minnesota since 2010.

Beaver are common residents on the federal lands. Many large open water and emergent wetlands on the federal lands are the result of beavers damming streams on the site. Beavers also block culverts under road and railroad grades to create lake habitat. Beaver lodges and tree cuttings are common in areas used by beavers.

Based on a cover type mapping of the Mine Site, about 181 acres of wolf foraging habitat and 1,333 acres of wolf cover habitat would be lost on the Mine Site. Loss of this habitat would reduce the amount of prey and cover available to gray wolf traveling through the Project area. Loss of habitat would also make it less likely that a gray wolf pack would establish a territory within the Project area, especially areas directly impacted by the Project.

About 397 acres would be reclaimed after mine closure, but it would be 10 or more years before re-vegetation resulted in much suitable habitat for wolves.

Table 11
Gray Wolf Habitat on the Federal and Non-federal Lands

Lands	Foraging Habitat	Cover Habitat
Federal Lands	271	5,393
Non-federal Lands		
Hay Lake	534	3,720
Hunting Club	27	93
Lake County Lands North	24	220
Lake County Lands South	43	49
McFarland Lake	0	30
Wolf Lands 1	2	114
Wolf Lands 2	8	684
Wolf Lands 3	130	97
Wolf Lands 4	10	360
Net Gain (Loss) to Forest Service after Land Exchange	507	(26)

Source: MDNR et al. (2013).

Transportation and Utility Corridors

The Dunka Road and Utility Corridor is approximately 108 acres and the Railroad Connection Corridor is approximately 12 acres. Because of prior use during the former LTVSMC taconite mining operation, the Dunka Road and Utility Corridor is now defined as having a “disturbed” cover type (94 acres). The remaining MDNR GAP land cover types that are not disturbed include cropland/grassland (10 acres), shrubland (8 acres), and smaller acreages of the remaining types, including 5 acres of upland forest and 3 acres of aquatic habitat (MDNR et al. 2013).

Plant Site

Of the 4,515 acres at the Plant Site Area, 2,756 acres have been disturbed by LTVSMC taconite mining operations. Of the remaining 1,760 acres, approximately 648 acres are upland deciduous forest, 637 acres are aquatic habitat, 334 acres are shrubland, 100 acres are upland coniferous forest, and 42 acres are lowland coniferous forest (totals do not add because acreages are rounded). About 48% of the Plant Site would be impacted by plant construction and operations, with only about 422 acres of forest habitat remaining after construction. Construction of the processing facilities would have little impact on wolf habitat, as over half of the site has been previously disturbed by LTVSMC taconite mining operations (MDNR et al. 2013).

Non-federal Lands

Under the Proposed Action, approximately 7,075 acres of non-federal lands would be transferred to the Forest Service. The Forest Service has not determined the suitability of these lands to provide habitat for wolves or their prey. However, wildlife habitat surveys conducted on these lands give an indication of the suitability of these lands for wolves. Portions of the non-federal lands have been harvested for timber during the past 20 years, with much of the harvest occurring on Lake County Lands North, Lake County Lands South, and Wolf Lands 2 and 3; there are about 778 acres of wolf foraging habitat on the non-federal lands. In addition, the non-federal lands contain about 5,366 acres of upland immature and mature forest greater than 9 years old that can provide cover for wolf prey (**Table 7**; MDNR et al. 2013).

Wolf howling surveys were conducted at night on Hay Lake Lands and McFarland Lake Lands. No gray wolves were heard during howling surveys, but sign of gray wolf was seen on Hay Lake Lands. Wolf scat was seen on several abandoned logging roads. Radiocollared wolves have been recorded on Hay Lake Lands (AECOM 2011b).

Gray wolf tracks were seen on Wolf Lands 3 and 4 and Lake County Lands North during the surveys. A review of the International Wolf Center (2012) Minnesota Wolf Telemetry Database revealed that radiocollared wolves have been recorded in the vicinity of Wolf Lands 2 and 3 (AECOM 2011c).

Beaver dams or sign of beaver were found on or near all the lands. Several beaver dams were observed on Hunting Club Lands and Lake County Lands South. Open water bodies on the lands were created by beaver dams, and beaver lodges were also seen on large water bodies (AECOM 2011c).

Beaver dams were found in several ponds and wetlands, and along the Pike River, on Hay Lake Lands, with recent cuttings found at several locations. Several large open water bodies on the site were created by beaver dams, and beaver lodges were seen on large water bodies. Beaver cuttings were also seen on McFarland Lake Lands near McFarland Lake (AECOM 2011b).

White-tailed deer are common on the non-federal lands. White-tailed deer tracks and droppings were commonly found in the study areas in virtually all habitat types, and several white-tailed deer were seen along roads, in shrublands, and bedding along the Pike River on Hay Lake Lands. Deer were especially common in recently logged areas and shrublands near mixed coniferous/deciduous and coniferous immature and mature forest habitats (AECOM 2011b).

Moose sign (droppings, tracks, and evidence of browsing) were observed on Hay Lake Lands in areas with abundant shrubs and in shrub swamp speckled alder wetlands. Moose sign were also observed on Wolf Lands 3 and 4 and Lake County Lands South in areas with abundant upland shrubs and in shrub swamp speckled alder wetlands (AECOM 2011c).

Wetland Mitigation Sites

Under the Proposed Action approximately 2,169 acres of Wetland Mitigation Site lands would be purchased by PolyMet as compensatory mitigation for impacts to wetlands and other waters of the U.S. These lands are used for sod production, but under the Proposed Action would be restored to native wetland and upland vegetation. After restoration, the combined total of wetland and upland acreage for these sites would be about 1,603 acres and 197 acres, respectively. These sites could provide habitat for wolves and would be privately owned (Pylka 2013b).

Summary of Prey Habitat Impacts to Wolves

Numerous habitat and human-disturbance factors influence wolf and wolf prey use of an area. Factors most important in the study area include timber management, mining activity, and habitat fragmentation. The mine project would remove forestlands, reduce the amount of available habitat for wolves and their prey, and increase habitat fragmentation; some of this habitat would be reclaimed after mine closure. However, large tracts of land associated with the Superior National Forest and adjacent to the mine project would be managed to provide wolf habitat. These lands would also help to maintain wolf travel corridors between areas of suitable habitat.

Despite the presence of wolf tracks on the Mine Site, there is little suitable foraging habitat for wolves, and it appears that only a few wolves use the Mine Site at any one time. Thus, the loss of habitat on the Mine Site may have little impact on wolves. To conserve wolves in the area, PolyMet would reclaim the Mine Site, maintain vegetated buffers around the Project area, close the Project area to public access, minimize the number of roads constructed in the Project area and reclaim roads after mine closure, and educate workers on the need to observe speed limits and take measures to protect wolves and other wildlife.

The land adjacent to the Mine Site would not be directly impacted by the Proposed Action. However, noise, light, and other disturbances at the Mine Site could limit use of the area by wolves and their prey. Wolves have been recorded using this area, and appeared to have preyed upon white-tailed deer in the western portion of the federal lands. Still, based on number of tracks observed during field studies, few wolves appear to use the land at any one time (AECOM 2009b, 2011a). Thus, the Project may have little direct impact on wolf use of this area.

Wolves have been recorded on most of the non-federal lands based on radiotelemetry and wildlife studies. The Forest Service would gain additional lands that would provide habitat for wolves under the Proposed Action. However, given that these lands would not be directly or indirectly impacted by the Project, would likely not be developed, and would remain mostly in timber production with limited recreational use, there would likely be little or no adverse or beneficial effects to wolves using the non-federal lands with or without the Proposed Action.

Although the Forest Service would administer additional habitat for wolves under the Proposed Action, there would still be a net loss of habitat to wolves and their prey from the Project. If the land exchange does not take place, and non-federal lands are not acquired by PolyMet and remain privately owned, non-federal lands would likely be managed primarily for timber production, and some recreational use (hunting, fishing, and cabins). Much of the habitat on the non-federal lands is wetland and is not suitable for most types of development. At this time, there also appears to be little interest in mining these lands or conducting other large scale surface disturbance. Thus, these lands would continue to provide similar acres of habitat for wolves and their prey with or without the land exchange.

No wolf surveys were conducted on or near the Wetland Mitigation Sites. These sites are agricultural farms that would be restored to wetland and upland habitat. They could provide habitat for wolves in the future, but the beneficial effects to wolves from acquisition of these lands would be minor.

Human Access and Disturbance

Federal Lands and Plant Site

Human-related Disturbance

The Project would generate as many as 500 full-time workers over an 18-month during peak construction period, and about 360 full-time workers during operation. It is estimated that about 80% of construction workers, but only about 25% of operations workers, would commute from population centers such as Duluth, Hibbing, and Virginia to the Project area on a daily or weekly basis, while remaining workers would be local hires. The Project would employ about 360 full-time workers during operation. When accounting for family members, the total population influx from direct, indirect, and induced employment would be about 400 people. A small number of workers would be needed during mine closure (MDNR et al. 2013). New housing

and other infrastructure would be required to support many of these new workers and could indirectly affect wolves through loss of habitat and human disturbance. However, new housing for workers may be constructed in nearby municipalities, such as Hoyt Lakes, Aurora, and Babbitt. It is not anticipated that new housing centers would be constructed that would result in additional townships exceeding a human density of more than four humans per square kilometer (2.5 humans per square mile). The MDNR criteria for a wolf-occupied township is a human density of fewer than four humans per square kilometer and a road density of fewer than 0.7 kilometers per square kilometer (0.4 miles per square mile). The Mine Site and Federal Lands are located within Township 59 North (35 square miles) and there are 3.3 miles of Forest Road 113 and 77.5 miles of other Forest Service roads and trails within the township. The road density for Township 59 North is 0.1 mile per square mile, considering only Forest Road 113, and 2.2 miles per square mile considering all roads and trails.

Disturbance associated with the facility and associated transportation corridors would include lights, glare, and noise. The Project is expected to operate 24 hours a day, 365 days a year, for a minimum of 20 years. Lights and glare would primarily be associated with the Mine Site, Plant Site, and Transportation and Utility Corridors. Wolves traveling through the study area would likely avoid areas that are active and well lit.

Noise

Sources of noise during the construction phase include trucks, bulldozers, rock drills, jack hammers, graders, backhoes, air compressors, and cranes. The loudest noise sources during the operational phase of the project include blasting, haul trucks, and train horns at the Mine Site, and crushers at the Plant Site. Estimated noise levels from blasting at receptors located 50 feet from the noise source are estimated to range from 111 to 115 a-weighted decibels (dBA; MDNR et al. 2013), while noise levels for drill rigs, excavators, and crushers range from 109 to 121 dBA near the noise source. Noise from the Mine Site and Plant Site could impact wolves residing in or traveling through the Project area. The impacts of noise on wolves and other wildlife are largely unknown and the assessment of impacts remains subjective. Wildlife are receptive to different sound frequency spectrums, many of which may be inaudible to humans. Wildlife are also known to habituate to noise, especially noises that are steady or continuous, such as noises that would occur at the Project. For example, wolves have been seen within about a quarter mile of loud noise sources and other human disturbance at Northshore Mine facilities north of the Mine Site.

Under the Proposed Action, the areas not disturbed by the Project on the lands adjacent to the Mine Site would be managed for wildlife habitat, including timber management. During mine operations, few, if any wolves would use this area due to noise and other disturbance associated with the adjacent Mine Site. After mine closure, wolf use of this area could return to the current level of use. But with a large area of new mine disturbance between much of this area and areas to the east where wolves are more common, it is unlikely that wolf use of this area would increase from current levels.

Roads

Impacts to wolves on and surrounding the Project may include mortality from vehicle collisions and trains. Construction and operation of the project, and the influx of workers to the area, would mean an increase in the number of roads and rail lines, as well as an increase in vehicular traffic volume along transportation corridors. The FEIS estimates that the Project would generate a total of up to 1,316 miles per day of vehicle traffic near the Project site, including trips between the Mine Site and the Plant Site, and trips between the Plant Site and the Area 1 Shop. Vehicle traffic would consist primarily of light trucks and maintenance vehicles traveling

between 30 and 45 miles per hour (mph), and a few large fuel, waste/supply, and haul trucks traveling between 25 and 40 mph. The Project would also generate 418 total miles of train traffic each day during mine operations. Trains would operate at 15 to 25 mph (MDNR et al. 2013).

Harm or loss of wolves from collisions with vehicles or trains traveling within the Project boundaries cannot be discounted, but the risk would be very small as there is currently little use of the Project area by wolves, and use of the site by wolves would decrease substantially during project operations due to loss of habitat and noise and disturbance associated with Project activities.

The potential for wolves to be killed from vehicle/rail collisions was estimated using the methodology described in Section 6.1.2.1 for lynx. Assuming that there is about 0.04 wolf/km² (see Section 6.2.1.8), that vehicle/rail collisions could occur along the 8-mile Transportation and Utility Corridors and railroad, and that vehicles and rail traffic have equal potential for collisions with wolves, it was estimated that approximately 0.05 wolf could be killed annually by vehicle/train traffic between the Mine Site and Plant Site, or about one wolf during the estimated 20-year life of the Project (assuming that mortalities due to collisions with vehicles and trains were twice the estimated level).

Using the same assumptions and methodology used to estimate wolf mortality on Project roads and railroads, approximately 0.3 wolf could be killed annually by vehicle/train traffic on off-Project access roads/rail lines to the Plant Site, or about six wolves during the estimated 20-year life of the Project (assuming that mortalities due to collisions with vehicles and trains were twice the estimated level).

These losses are probably overestimated, however, based on wolf mortality estimates done for other projects in northern Minnesota by the USFWS. Thus, although risk of loss of wolves due to a collision with a Project-related vehicle or train traffic is very small, it could occur during the life of the Project.

In addition to potential harm from vehicle/train/wolf collisions, road density influences wolf use of habitat. The Wolf Recovery Plan recommends that density of higher standard roads remain below 1 mile/mi² in critical habitat to limit the extent of associated effects to gray wolves (USDOI USFWS 1992, 2011a). However, wolves may tolerate road densities as high as 1.2 miles/mi² if roaded areas are adjacent to large roadless areas, such as the Superior National Forest. Current road density is 0.5 miles of road/mi² for the Mine Site. After mine operations cease, temporary roads would be closed and reclaimed and would remain closed to the public.

Temporary roads have been constructed on the federal lands to support timber harvest activities and within a ROW to support powerline maintenance. Except for recently constructed roads, temporary roads are now overgrown in places with vegetation and are generally only suitable for foot, all-terrain vehicle, and snowmobile travel. Vegetation within the ROW is maintained at a low height for safety purposes, and the ROW is accessible to all-terrain vehicles and snowmobiles. Temporary roads may be constructed to support future management, but roads would be likely closed after their intended use and allowed to revegetate; it is unlikely that permanent roads would be constructed. The number of miles of temporary roads would likely remain at or below current levels, to the benefit of wolves. These roads would be privately owned and closed to the public after mine closure.

Non-federal Lands and Wetland Mitigation Sites

The non-federal lands would be transferred to the Forest Service. The non-federal lands are currently managed primarily for timber and recreation, similar to how these lands would be managed by the Forest Service. The

Wetland Mitigation Sites would be restored to wetland and upland wildlife habitat. Wolf observations are rare near the Wetland Mitigation Sites and wolf use of the sites after restoration would be infrequent. Thus, there would be few beneficial effects to wolves from the land exchange and wetland mitigation.

Access onto most of the non-federal lands is by secondary roads that branch off Forest Service or county roads. Most secondary roads were constructed to support timber harvest activities, and wolves were observed using these roads on several lands. There is no road access onto Hunting Club Lands and Wolf Lands 4. Access to McFarland Lake Lands is controlled by a locked gate. If acquired by the Forest Service, the lands would be managed for General Forest, General Forest-Longer Rotation, Riparian Areas, and Candidate Research Natural Areas. If new roads are constructed on the lands, they would likely be temporary and used to support timber management. There would likely be little change in the number of miles of backcountry roads and trails on the non-federal lands, and the number of miles may decrease if existing roads are closed and re-vegetated or allowed to re-vegetate naturally, benefitting wolves.

Other

Hazardous Materials

Mishandling of hazardous materials or wastes could result in spills, accidental release, or discharge into the environment, which could pose risks to wolves. Sections 5.2.13 and 5.3.13 of the FEIS discuss the risks posed to the public and the environment from the transport, handling, storage, and use of hazardous materials. Mitigation measures to prevent releases in transportation, storage, and handling or use of these materials are described in several hazardous material management plans necessary to comply with various regulatory requirements for the Project and in the FEIS. Based on this analysis, and limited use by wolves of the areas where there materials would be used, risks to wolves would be negligible and should not result in harm or death to wolves (MDNR et al. 2013).

6.3.2.2 Effects to Wolf Critical Habitat

Overview

Primary Constituent Elements of Wolf Critical Habitat

No specific primary constituent elements (PCE) have been formalized for the gray wolf. However, in general, primary constituent elements for gray wolf may include the following:

1. space for population growth;
2. normal behavior, nutritional or physiological requirements;
3. shelter and breeding habitats, and
4. habitats representing appropriate species distribution.

In addition, the USFWS (1992) has identified five main factors critical to the long-term survival of gray wolf:

1. large tracts of wild land with low human densities and minimal accessibility by humans
2. ecologically sound management
3. availability of adequate wild prey;
4. adequate understanding of wolf ecology and management, and
5. maintenance of populations that are either free of, or resistant to, parasites and diseases new to wolves or are large enough to successfully contend with their adverse effects.

Additional detail on the presence of general PCEs and factors critical to the long-term survival of gray wolf is provided in Section 6.3.1, Gray Wolf Environmental Baseline. Potential impacts to the general PCEs and to factors critical to the long-term survival of gray wolf are described in Section 6.3.2, Analysis of Direct and Indirect Effects to Gray Wolf. Further detail on impacts to gray wolf prey habitat is provided below.

The Forest Service identified quantitative indicators in the 2004 Forest Plan BA, and in the *Programmatic Biological Assessment: Gray Wolf, Canada Lynx, and Their Critical Habitats for the Superior National Forest* (USDA Forest Service 2011b), to analyze the impacts of those risk factors that have the most substantive impacts on wolf habitat. These indicators have been used to assess impacts to wolf critical habitat, if it was implemented in Minnesota in the future, in this BA. **Table 12** lists risk indicators and identifies those that apply to the Project.

Risk Analysis Indicators

Prey Habitat

The Forest Service has identified two risk analysis indicators to measure the effects to prey habitat that would apply to the Project. Parameters used by the Forest Service to identify suitable wolf prey habitat were given in the *Federally Listed Threatened and Endangered Species for the Revised Forest Plans: Chippewa and Superior National Forests* (USDA Forest Service 2004b) and *Programmatic Biological Assessment: Gray Wolf, Canada Lynx, and Their Critical Habitats for the Superior National Forest* (USDA Forest Service 2011a).

Indicator 1 – Acres and Percent of Young Upland Forest < 10 Years Old

This indicator represents potential habitat for moose, white-tailed deer, and beaver, important prey items for wolves, by acres of young upland forest. Acreage dedicated to coniferous plantations, clearcuts, areas of prescribed burns, and shelterwood harvests all provide significant forage biomass. Lowland conifer is not included. Even though the correlation between habitat and populations appears to be weak, this indicator provides an overall analysis of potential prey forage habitat.

There are about 271 acres of young upland forest on the federal lands (**Figure 9, Table 7**). Based on Management Indicator Habitat mapping done by the Forest Service, about 181 acres of young upland forest would be lost to mining. Although young upland forest vegetation would be lost on the Mine Site, the lands adjacent to the Mine Site would still provide young upland forest for wolf prey even though lands would be owned by PolyMet, as these lands would be managed to provide wildlife habitat and would not be developed. About 10 or more years after mine reclamation, approximately 397 acres of young upland forest could be available to wolf prey, although it is uncertain if wolf prey would move from areas outside of the Mine Site to suitable habitat on the Mine Site.

Collectively, the non-federal lands have about 778 acres (11% of available habitat) of young upland forest. Under the Proposed Action, this habitat would be administered by the Forest Service. Wetland Mitigation Sites would provide additional young upland forest. Based on young upland forest losses at the federal lands, and gains from the non-federal lands, there would be a net gain of 507 acres of young upland forest under Forest Service administration under the Proposed Action (MDNR et al. 2013).

Table 12
Wolf Risk Analysis Indicators

Risk Analysis Indicators¹	Analyzed	Rationale for Exclusion
1. Acres and Percent of Young Upland Forest <10 years Old (MIH 1, Young)	Yes	
2. Acres and Percent of Upland Conifer (Spruce and Pine) > 9 years Old on All Uplands (MIH 5, All but Young)	Yes	
3. Miles of High Standard Roads (OML 3, 4, and 5)	No	Miles of high standard roads would not change under the Proposed Action.
4. Cross-country Use Policy for Designated All-terrain Vehicle and Snowmobile Trails	No	Policy would not change under the Proposed Action. There are 0 miles of designated trails on the federal lands, and 0.3 miles on the non-federal lands.
5. Miles of Temporary and OML 1 and 2 Roads	No	There would be little or no change in the miles of Temporary and OML 1 and 2 roads on federal and non-federal lands under the Proposed Action (Ryan 2013a).

Source: USDA Forest Service (2004b).

Indicator 2 – Acres and Percent of Upland Forest > 9 Years Old on all Uplands

This indicator represents potential winter thermal and hiding cover for white-tailed deer and moose provided by relatively dense occurrence of immature and mature coniferous forest in planted/seeded stands. Coniferous forest also provides important summer thermal cover (from heat) for moose.

There are about 5,393 acres of immature and mature upland coniferous forest on the federal lands (**Figure 19, Table 7**). About 1,333 acres of immature and mature upland coniferous forest would be lost to mining based on Management Indicator Habitat mapping done by the Forest Service. Although forest vegetation would be lost on the Mine Site, the federal lands would still provide immature and mature upland coniferous forest for wolf prey even though lands would be owned by PolyMet, as these lands would be managed to provide wildlife habitat and would not be developed. About 20 or more years after mine reclamation, approximately 397 acres of immature and mature upland coniferous forest could be available to wolf prey for cover, although it is uncertain if wolf prey would move from areas outside of the Mine Site to suitable habitat on the Mine Site.

Collectively, the non-federal lands have about 5,366 acres (76% of available habitat) of immature and mature upland coniferous forest. Under the Proposed Action, this habitat would be administered by the Forest Service. Wetland Mitigation Sites would provide additional immature and mature upland coniferous forest. Based on immature and mature upland coniferous forest losses at the federal lands, and gains from the non-federal lands, there would be a net loss of 26 acres of immature and mature upland coniferous forest under Forest Service administration under the Proposed Action.

Human Access and Disturbance

The Forest Service identified three indicators that apply to human access and disturbance. These are:

Indicator 3 – Miles of High Standard Roads (OML 3, 4, and 5)

Indicator 4 – Cross-country Use Policy for Designated All-terrain Vehicle and Snowmobile Trails

Indicator 5 – Miles of Temporary and OML 1 and 2 Roads

Indicators 4 and 5 were not analyzed for reasons given for Indicators 7 and 9 for lynx. Indicator 3 was not analyzed because there are no High Standard Roads (OML 3, 4, and 5) on the federal and non-federal lands, and none are proposed to be built under the Proposed Action. Objective Maintenance Level 3 roads are those roads open and maintained for travel by a prudent driver in a passenger car. User comfort and convenience are not considered priorities. Roads are typically low speed, single lane with turnouts and have only spot surfacing. Objective Maintenance Level 4 roads provide a moderate degree of user comfort and convenience at moderate travel speeds. Most roads are double lane and aggregate surfaced. Objective Maintenance Level 5 roads provide a high degree of user comfort and convenience. The roads are normally double lane, paved facilities (USDA Forest Service 2004a).

Under the Proposed Action, PolyMet would gain control of the federal lands. There are approximately 5.9 miles of temporary and OML 1 and 2 roads on the federal lands. Most temporary roads were built to support historic timber management and mine exploration on the proposed Mine Site and would be lost to mine development. Access to the federal lands would be strictly controlled during mine operations.

These roads would likely have little impact on wolves as wolves would not likely use the federal lands during mining due to noise and other disturbances. After mine closure, roads would be reclaimed (except for a short road from the Dunka Road to the Waste Water Treatment Facility; Pylka 2013b) and closed to vehicle access. Temporary roads may be constructed on the lands adjacent to the Mine Site to support forest management activities, but number of miles of temporary backcountry roads and trails on the lands should be similar to, or less than, existing miles of backcountry roads and trail on the lands. After mine closure, the federal lands would remain in private ownership and the public would not be allowed to use the roads to access the lands (Pylka 2013b).

The Forest Service would manage the non-federal lands for timber production and recreation. If new roads are constructed on the lands, they would likely be temporary and used to support timber management. There would likely be little or no change in the number of miles of backcountry roads and trails on the non-federal lands, and the number of miles may decrease if existing roads are closed and re-vegetated or allowed to re-vegetate naturally, benefitting wolves.

6.3.3 Effects of Interrelated and Interdependent Actions

No known activities are interrelated or interdependent to the Project that would have the potential to affect gray wolves. It is possible that future specific programs or projects may have relevant interrelated and interdependent actions (e.g., expansion of the Mine Site due to discovery of new ore bodies) and they would be considered in the context of consultations for those actions.

6.3.4 Cumulative Effects

The methods used to analyze cumulative effects, and the temporal and spatial domains, are the same for wolves as for lynx, as discussed in Section 6.1.4.

6.3.4.1 Prey Habitat

The types of cumulative effects to wolf prey habitat and habitat fragmentation, and to wolf travel corridors, would be similar to those effects to lynx as discussed in Section 6.1.4. However, given that more wolves are found in the CESA, more wolves could be impacted than lynx. Although the Project would result in habitat loss and fragmentation on about 1,719 acres at the Mine Site for about 20 years (until the Project is reclaimed), in the context of available habitat, and habitat that would be available to wolves in the reasonably foreseeable future, cumulative effects of the Project on habitat loss and fragmentation would be minor.

6.3.4.2 Human Access and Disturbance

Human Access and Traffic

The Project and other nearby proposed projects would increase the amount of human access and disturbance in the area. Effects from loss of habitat and disturbance associated with human activities from the Project are discussed above. However, increased human populations in the Project area may also lead to increased risk to wolves from collisions with vehicles and trains, increased levels of recreation activities and use of backcountry roads and trails, and increased mortality from illegal hunting and trapping.

See Section 6.1.4.2, Human Access and Traffic, for a discussion of the road system in the area. Given that the number of miles of roads associated with the federal and non-federal lands after mining is expected to be similar to or less than current levels, impacts associated with road mileage are not expected to accumulate from the Project.

Trapping and Legal and Illegal Taking

An influx of worker and their families into the region to support the Project and other development would increase the potential for illegal harvest of wolves. The USDA Animal and Plant Health Inspection Service Wildlife Services maintains records on the legal taking of wolves in Minnesota. From 1996 to 2009, an average of 146 wolves was taken annually as a result of depredation control in Minnesota (USDA Forest Service 2011b).

Hunting and trapping of wolves would not be allowed on lands administered by PolyMet. Thus, there should be no illegal or accidental take due to the Project. Loss of wolves to illegal trapping and hunting should remain near current levels on the non-federal lands, while the number of wolves harvested on non-federal lands during legal hunting and trapping seasons will vary based on wolf population levels. Thus, there should be negligible or no cumulative effect to legal, illegal, and accidental take of wolves from the Project and land exchange.

7.0 Conservation Measures

Seven conservation measures are recommended to reduce potential impacts to lynx, northern long-eared bat, and wolf from the Project. These measures are based, in part, on conservation measures identified by the Forest Service during its review of the Project, measures in the *Lynx Conservation Assessment and Strategy* (Ruediger et al. 2000) that are applicable to lynx populations throughout the contiguous U.S. and could therefore apply to lynx in and around the Project area; measures identified in the *Endangered and Threatened Wildlife and Plants; 12-Month Finding on a Petition To List the Eastern Small-Footed Bat and the Northern Long-Eared Bat as Endangered or Threatened Species; Listing the Northern Long-Eared Bat as an Endangered Species; Proposed Rule* (USDOJ USFWS 2013b); and measures identified in the *Minnesota Wolf Management Plan* (MDNR 2001) that can benefit wolves in Minnesota.

7.1 Reclaim Project Area

PolyMet would reclaim about 397 acres to wetland and upland habitat at the Mine Site, including the Waste Rock Stockpiles, the Overburden Storage and Laydown Area, and the Ore Surge Pile. The stockpiles would be revegetated using a mixture of native grasses and forbs. Areas revegetated with grasses and forbs would initially provide little habitat value for lynx, northern long-eared bat, and wolf and their prey, primarily due to lack of hiding cover. Over time, reclaimed areas may be used by lynx, northern long-eared bats, and wolves and their prey as coniferous and deciduous forests establish on the sites through plant succession. Lynx tracking surveys at waste rock stockpiles east of the Project found that lynx hunt for snowshoe hare that reside in early successional shrubland and forestland habitats that have established on waste rock stockpiles. As disturbed areas are reclaimed, they would also improve habitat connectivity with forestlands in the vicinity of the Project.

When feasible, PolyMet should progressively reclaim disturbance areas to allow reclaimed areas to revegetate sooner than if the areas were not reclaimed until after mine operations cease.

7.2 Maintain Vegetated Buffers

The facility should be designed to reduce impacts to lynx, northern long-eared bats, and wolves by minimizing the disturbance area and new road construction, and reclaiming any areas where Project activities cease. Where feasible, a vegetative buffer should be retained around the perimeter of the facility to reduce light and noise effects on lynx, northern long-eared bat, and wolf. In addition, existing and newly constructed roads (built to access the Project area) should be reclaimed or obliterated after facility closure, where feasible.

7.3 Limit Public Access to Project Area

Public access to the Project area should be limited to the extent possible during development, operation, and reclamation. Users of any snowmobile or all-terrain vehicle trails on public lands near the Project area should be encouraged to stay on the trail and avoid travel into other areas. After closure and reclamation, activities that compact snow should be minimized.

7.4 Minimize Road Construction and Reclaim Unused Roads

Where feasible and appropriate, dirt and gravel roads traversing lynx and wolf habitat within the Project area should not be paved or otherwise upgraded (e.g., straightening of curves, widening of roadway, etc.) in a

CONSERVATION MEASURES

manner that is likely to lead to significant increases in traffic speeds or increased width of the cleared ROW, or would foreseeably contribute to development or increases in human activity in lynx and wolf habitat within the Project area.

Plowed roads and groomed over-the-snow routes may allow competing carnivores such as coyotes to access lynx and wolf habitat in the winter, increasing competition for prey (Buskirk et al. 2000). However, plowed or created snow roads would be necessary to access the facility during construction and operation, and are necessary to access other lands within the vicinity of the Project.

Several studies suggest that lynx may not avoid roads, except at high traffic volumes. Therefore, at this time, there is no compelling evidence to recommend management of road density to conserve lynx. There is evidence, however, that road density can impact wolf use of an area. Thus, the number of new roads constructed in support of the Project should be minimized and roads reclaimed/obliterated where feasible and appropriate.

7.5 Educate Workers and Public

Direct mortality from vehicular collisions has been detrimental to lynx and wolf in northern Minnesota. It is unlikely that lynx and wolves would travel close to the Project area due to disturbance and lack of habitat. Still, to benefit lynx, wolf, and other wildlife, speed limits should be enforced along access roads to reduce the risk of wildlife-vehicle collisions. Workers should be given training to make them aware of the importance of the area to wildlife, to request that employees report sick or dying wildlife along roads or at facilities, to ensure that employees do not dump wastes or other harmful materials off the site, and to make employees aware of other actions that could be harmful to wildlife or their habitats.

Lynx and wolf may be mistakenly trapped or shot outside the legal wolf hunting season by legal predator hunters seeking bobcats or other furbearers. Prey species, such as snowshoe hares, may also be affected by legal and illegal trapping and shooting. To reduce or eliminate the incidence of illegal trapping and shooting of lynx and wolf, PolyMet could work with the MDNR and local conservation groups to initiate information and education efforts to protect the lynx and wolf and to ensure that trappers check their traps at frequent intervals and release lynx and wolf that are still alive. Trailhead posters, magazine articles, and news releases could be used to inform the public of the possible presence of lynx and wolf within or near the Project area.

7.6 Lynx Monitoring

Because limited research has been conducted on lynx in the contiguous U.S., PolyMet would continue to follow studies of lynx conducted by the Forest Service, NRRRI, MDNR, and other conservation agencies and groups to better understand lynx use of the study area during the Project's construction and operation, and to identify specific reclamation measures that could be implemented to restore lynx habitat to the area after facility closure.

7.7 Preserve and Protect Habitat

Lynx, northern long-eared bat, and wolf would benefit from habitat protection on lands adjacent to the Mine Site. These lands would be managed by PolyMet and provide habitat for use by lynx, northern long-eared bat, wolf, and other wildlife.

Forestlands in this area would likely be harvested periodically, but could be managed to provide early successional habitat favored by snowshoe hare, while wetlands could be left relatively untouched. Wetlands and forestlands could be used by lynx and wolf as a travel corridor between lands to the east and west of the Mine Site, and for foraging and roosting habitat by northern long-eared bat. Based on observations of lynx and wolf on and near disturbance areas at the Northshore Mine, lynx and wolf could use this area as a travel corridor during mine operations, and would likely use this area as a travel corridor after mine operations cease.

8.0 Determination of Effects

Lynx and wolf have been observed on and near the federal lands, and at several of the non-federal lands. The northern long-eared bat has been observed on the federal lands. Bats have been observed on the non-federal lands, although they were not identified to species. The primary effects to lynx and their critical habitat, and to wolf, would be from loss and fragmentation of habitat, to habitat connectivity, and from fatalities associated with vehicle and rail traffic on the Mine Site, Transportation and Utility Corridors, Plant Site, and access roads and railroads to the Project area. The primary effect to northern long-eared bat would be loss of habitat.

Collision with vehicles and trains is a documented cause of lynx and wolf mortality in Minnesota. Vehicle and rail traffic would include road and rail access to and within the Project area. Increased traffic is expected in the vicinity of the Project area. Although there is little likelihood that lynx or wolf would be killed by vehicle and rail traffic associated with the Project, based on studies at several other mine sites, this risk of the loss of lynx and wolf cannot be discounted.

Critical habitat for the lynx has been designated in the Project area. The Mine Site and a portion of the Dunka Road and Utility Corridor are within lynx critical habitat. Not all areas within the mapped boundaries of designated habitat are considered critical habitat. Only areas that contain the primary constituent elements required by the species are considered critical habitat. Primary constituent elements are the physical and biological features of a landscape that a species needs to survive and reproduce (USDOJ USFWS and NMFS 1998). The Mine Site contains habitat elements that facilitate lynx survival and reproduction.

Habitat loss and fragmentation would be unavoidable effects to lynx, northern long-eared bat, and wolf from the Project, and additional impacts from other proposed projects in the area are expected. In addition, Project noise and other disturbances could disrupt lynx and wolf use of travel corridors near the Project area. The types of habitat that provide suitable habitat for lynx and their prey and would be lost to the Project are common in northeastern Minnesota, however, and lands along the Iron Range are already highly fragmented.

The Project would affect about 0.03% of lynx critical habitat in Minnesota, including Primary Constituent Elements (PCEs) of lynx critical habitat. Less than 0.03% of wolf critical habitat, including PCEs for wolf, would be directly affected by mining. In addition, of the 1,719 acres that would be directly affected by mining, about 397 acres (23%) would be reclaimed to habitats that could be used by lynx and wolf about 10 or more years after reclamation. It is unlikely that habitat loss and fragmentation resulting from the Project would represent a significant impact to lynx and wolf habitat from a regional perspective.

Based on the analysis in this BA, the Project would affect lynx, and those effects would not be insignificant or discountable. Thus, the Project **is likely to adversely affect** Canada lynx. As noted above, the Project would directly impact only about 0.03% of lynx critical habitat, including PCEs of lynx habitat. Some of this habitat would be reclaimed and available for use by lynx and their prey about 10 or more years after reclamation. However, not all of the reclaimed areas would restore the lost PCEs nor would they likely return to the quality of the habitat removed from the site. Thus, the Project **is likely to adversely affect** Canada lynx critical habitat.

Based on analysis in this BA, the Project is **likely to adversely affect** the continued existence of northern long-eared bat. This is because of the loss of available summer roost habitat. Impacts on northern long-eared bats from the Project would not preclude both the survival and recovery of the population as a whole.

CONSERVATION MEASURES

Based on the analysis in the BA, the Project would affect gray wolves, and those effects would not be insignificant or discountable. Thus the Project **is likely to adversely affect gray wolves**. The Project would directly impact only 0.03% of wolf critical habitat, including PCEs, in Minnesota. Some of this habitat would be reclaimed and available for use by gray wolves and their prey about 10 or more years after reclamation. Thus, the Project **is likely to adversely affect** gray wolf critical habitat.

APPENDIX A

Common and Scientific Names of Plants and Animals Given in this Biological Assessment

Common Name	Scientific Name
Plants	
American Beech	<i>Fagus grandifolia</i>
Balsam Fir	<i>Abies balsamea</i>
Beaked Hazel	<i>Corylus cornuta</i>
Black Ash	<i>Fraxinus nigra</i>
Black Locust	<i>Robinia pseudoacacia</i>
Black Oak	<i>Quercus velutina</i>
Black Spruce	<i>Picea mariana</i>
Blueberry	<i>Vaccinium angustifolium</i>
Bog Birch	<i>Betula pumila</i>
Bog Labrador-tea	<i>Ledum groenlandicum</i>
Canada Bluejoint	<i>Calamagrostis canadensis</i>
Cattail	<i>Typha</i> spp.
Club Moss	<i>Lycopodium</i> spp.
Eastern White Pine	<i>Pinus strobus</i>
Jack Pine	<i>Pinus banksiana</i>
Leatherleaf	<i>Chamaedaphne calyculata</i>
Lodgepole Pine	<i>Pinus contorta</i>
Narrow-leaved Cattail	<i>Typha latifolia</i>
Northern Red Oak	<i>Quercus rubra</i>
Northern White Cedar	<i>Thuja occidentalis</i>
Paper Birch	<i>Betula papyrifera</i>
Pussywillow	<i>Salix discolor</i>
Raspberry	<i>Rubus</i> spp.
Red-osier Dogwood	<i>Cornus stolonifera</i>
Red Pine	<i>Pinus resinosa</i>
Sedge	<i>Carex</i> spp.
Shining Club Moss	<i>Lycopodium lucidulum</i>
Shortleaf Pine	<i>Pinus echinata</i>
Silver Maple	<i>Acer saccharinum</i>
Small-fruited Bog Cranberry	<i>Vaccinium oxycoccus</i>
Sourwood	<i>Oxydendrum arboreum</i>
Speckled Alder	<i>Alnus rugosa</i>
Sphagnum Moss	<i>Sphagnum</i> spp.
Subalpine Fir	<i>Abies lasiocarpa</i>
Sugar Maple	<i>Acer saccharum</i>
Tamarack	<i>Larix laricina</i>

APPENDIX A (Cont.)

Common and Scientific Names of Plants and Animals Given in the Report

Common Name	Scientific Name
Plants (Cont.)	
Trembling Aspen	<i>Populus tremuloides</i>
White Pine	<i>Pinus strobus</i>
White Spruce	<i>Picea glauca</i>
Willow	<i>Salix</i> spp.
Woolgrass	<i>Scirpus cyperinus</i>
Animals	
Beaver	<i>Castor canadensis</i>
Big Brown Bat	<i>Eptesicus fuscus</i>
Bison	<i>Bison bison</i>
Bobcat	<i>Lynx rufus</i>
Canada Lynx	<i>Lynx canadensis</i>
Coyote	<i>Canis latrans</i>
Eastern Red Bat	<i>Lasiurus borealis</i>
Eastern Small-footed Myotis	<i>Myotis leibii</i>
Elk	<i>Cervus canadensis</i>
Fisher	<i>Martes pennanti</i>
Gray Wolf	<i>Canis lupus</i>
Hoary Bat	<i>Lasiurus cinereus</i>
Indiana Bat	<i>Myotis sodalis</i>
Keen's Long-eared Myotis	<i>Myotis keenii</i>
Little Brown Myotis	<i>Myotis lucifugus</i>
Moose	<i>Alces alces</i>
Mountain Lion	<i>Puma concolor</i>
Mule Deer	<i>Odocoileus hemionus</i>
Northern Flying Squirrel	<i>Glaucomys sabrinus</i>
Northern Long-Eared Bat	<i>Myotis septentrionalis</i>
Pine Marten	<i>Martes americana</i>
Porcupine	<i>Erethizon dorsatum</i>
Red Squirrel	<i>Tamiasciurus hudsonicus</i>
Ruffed Grouse	<i>Bonasa umbellus</i>
Siberian Husky	<i>Canis familiaris</i>
Silver-haired Bat	<i>Lasionycteris noctivagans</i>
Snowshoe Hare	<i>Lepus canadensis</i>
Spruce Budworm	<i>Choristoneura fumiferana</i>
Tri-colored Bat	<i>Perimyotis subflavus</i>
Western Long-eared Myotis	<i>Myotis evotis</i>

APPENDIX A (Cont.)**Common and Scientific Names of Plants and Animals Given in the Report**

Common Name	Scientific Name
Animals (Cont.)	
White-tailed Deer	<i>Odocoileus virginianus</i>

Executive Summary

Poly Met Mining Inc. (PolyMet) proposes to construct an open pit mine in northern Minnesota to extract low- to medium-quality copper-nickel-PGE minerals with low sulfide content. This project, called the NorthMet Project (Project), is located in St. Louis County on the eastern end of the Mesabi Iron Range, about 60 miles north of the City of Duluth, and 6 miles south of the City of Babbitt, Minnesota. The Project areas include the Mine Site (3,015 acres), Plant Site (4,515 acres), and Transportation and Utility Corridors (120 acres) that connect the Mine Site to the Plant Site.¹

PolyMet plans to mine and process polymetallic ore from the northwestern portion of the Duluth Complex, a rock formation that forms much of the bedrock of northeastern Minnesota. The ore contains copper, nickel, gold, platinum, palladium, and cobalt. The Project would mine ore for approximately 20 years, using open pit mining methods similar to those currently in use at ferrous metallic mining operations on the Iron Range. The Plant Site was previously used as a taconite processing facility by the LTV Steel Mining Company (LTVSMC). PolyMet would upgrade existing facilities and construct new facilities to produce copper concentrates, nickel concentrates, and base and precious metal precipitates for off-site shipment and treatment. Tailings from ore processing would be placed in a tailings basin built atop the existing LTVSMC taconite tailings basin.

About 1,719 acres of the Mine Site would be directly disturbed by mining activities. Of these, 1,667 acres are administered by the Forest Service and 52 acres are privately owned. Habitats on the federally administered lands that would potentially be affected by the project include upland coniferous forest (including black spruce², jack pine, and balsam fir), upland deciduous forest (including trembling aspen and paper birch), upland mixed coniferous/deciduous forest, coniferous bogs (including black spruce and tamarack), open bogs (including leatherleaf and Labrador tea), coniferous swamps (including black spruce, tamarack, and northern white cedar), hardwood swamps (including black ash), shrub swamps (including speckled alder, willows, and dogwoods), marshes (including cattails), and sedge and wet meadows (including sedges and grasses). A variety of plants and animals, including several species of concern, have been observed on or near the Mine Site. A 2014 Forest Service study confirmed that northern long-eared bats and little brown bats utilize the Mine Site and adjacent Project areas (USDA Forest Service 2014a).

Of the approximately 3,015 acres on the Mine Site, approximately 2,719 acres are owned by the United States (U.S.) Government (Government) and administered by the U.S. Department of Agriculture (USDA) Forest Service (Forest Service). In addition, about 3,776 acres adjacent to the Mine Site are owned by the Government and administered by the Forest Service.

The Forest Service is considering transferring these approximately 6,495 acres (federal lands) to PolyMet in exchange for lands (non-federal lands) of similar value that have been offered for consideration by PolyMet. All

¹ Acreages given in this report are based on Geographic Information System (GIS) analysis. Acreages associated with the legal descriptions of the lands are based on original surveys performed by the Bureau of Land Management, Government Land Office (GLO) surveyors between 1858 and 1907. As such, GLO acreages are used as part of the project description for the Final Environmental Impact Statement (FEIS) being prepared for the Project and would also be used to define the real estate transaction if the Land Exchange Proposed Action was approved. The analysis of effects presented in this Biological Evaluation (BE) is based upon GIS data. GIS values indicate the actual size of the parcels discussed in this BE, which may be different than the GLO legal acreage.

² Common and scientific names of plants and animals given in this report are provided in **Appendix A**.

lands potentially involved in the land exchange would be independently appraised according to the Uniform Appraisal Standards for Federal Land Acquisitions. The appraisals would determine the market value of the properties. Information collected during wildlife and wetland functions and values studies would be used by the Forest Service in the land exchange appraisal, and would be used to evaluate impacts to wetlands, and wildlife and their habitats, for a Final Environmental Impact Statement (FEIS) for the Project and land exchange.

Assuming a land exchange occurs, the portions of the Mine Site, Dunka Road and Utility Corridor, and lands adjacent to the Mine Site that are administered by the Forest Service would no longer be part of the National Forest and therefore would not be subject to Forest Service management plans and policies. A land exchange for land adjustment is consistent with the 2004 *Land and Resource Management Plan for the Superior National Forest* (2004 Forest Plan).

To fulfill land exchange requirements, PolyMet is proposing to purchase and transfer all or a portion of 7,075 acres of non-federal lands to the Forest Service. The non-federal lands consist of the Hay Lake Lands (4,926 acres), Hunting Club Lands (160 acres), Lake County Lands (382 acres), McFarland Lake Lands (31 acres), and Wolf Lands (1,576 acres). All lands are dominated by second-growth deciduous and coniferous forest habitats and a variety of plants and animals, including several species of concern, have been observed on or near the non-federal lands.

Assuming a land exchange occurs, the non-federal lands would be administered by the Forest Service. The non-federal lands are associated with four Forest Plan Management Areas, as designated by the Forest Service, which include General Forest, General Forest – Longer Rotation, Riparian Emphasis Area, and Candidate Research Natural Areas. If all or portions of the non-federal lands are acquired by the Forest Service, they would be administered by the Forest Service to meet the goals of these management areas.

The Project could adversely impact plant and animal species of concern found on or near the federal lands. The 2004 *Forest Plan Revision Final Environmental Impact Statement for Chippewa and Superior National Forests* (2004 Forest Plan EIS) assessed plant and animal species identified by the Regional Forester for which population viability was a concern as evidenced by:

- Significant current or predicted downward trends in population numbers or density.
- Significant current or predicted downward trends in habitat capability that would reduce a species' existing distribution (Forest Service Manual 2670.5).

Based on the 2004 Forest Plan EIS and subsequent updates, the Regional Forester identified 12 non-vascular plants, 46 vascular plants, 2 aquatic invertebrates, 6 insects, 4 fish, 1 reptile, 8 birds, and 5 mammals as Regional Forester Sensitive Species (RFSS). Of these, eight vascular plants, and six (and possibly nine as unidentified bat species have been reported on the federal lands) animals have been reported on the federal exchange lands, while two vascular plants and two (and possibly up to five as unidentified bat species have been found on the non-federal exchange lands) animals have been reported on the non-federal lands.

This Biological Evaluation (BE) was prepared to document RFSS populations and habitat use on or near the federal and non-federal lands, and potential direct, indirect, and cumulative impacts to these species from the Project. This BE complies with Forest Service Manual Directives 2671.1 through 2672.43 and the National

Forest Management Act of 1976. The Forest Service Manual Directive 2672.42 objectives for completing BEs for proposed Forest Service programs and activities are to:

- ensure that Forest Service actions do not contribute to loss of viability of any native or desired non-native plant or animal species,
- ensure that Forest Service activities do not cause any species to move toward federal listing, and
- incorporate concerns for sensitive species throughout the planning process, reducing negative impacts to species and enhancing opportunities for mitigation.

In addition to addressing impacts to RFSS from the Proposed Action, which includes the Project and land exchange, this BE also addresses impacts to RFSS from two alternatives also considered in the FEIS:

- Land Exchange Alternative B (Alternative B) - under Alternative B, the Forest Service would transfer 4,753 acres of federal lands, which comprise 2,719 acres at the Mine Site and a smaller amount of federal land surrounding the Mine Site, to PolyMet in exchange for the 4,926-acre Hay Lake Lands. This land exchange would involve the transfer of a similar acreage, would provide wetlands to the Forest Service, and Hay Lake Lands would have a higher-per-acre value than the federal lands.
- Land Exchange No Action Alternative (No Action Alternative) - under the No Action Alternative, mine construction, development, and operation would not occur and no lands would be exchanged. The Government would not convey federal lands to PolyMet, and the Forest Service would continue managing these federal lands.

Based on the analyses for this BE, the Forest Service has determined that the Proposed Action and Alternative B would have **no impact** to the following RFSS:

Plants

Alpine milkvetch	Lanceleaf grapefern	Scotch false asphodel
<i>Arctoparmelia centrifuga</i>	Largeleaf sandwort	Short sedge
<i>Arctoparmelia subcentrifuga</i>	Little goblin moonwort	Smooth woodsia
Braun's holly fern	Long-leaved arnica	Sticky locoweed
Creeping rush	Maidenhair spleenwort	Triangle grapefern
Chilean sweet-cicely	Moschatel	Wain's cup lichen
Douglas' hawthorn	Nodding saxifrage	
Encrusted saxifrage	Oakes' pondweed	

Animals

Lake sturgeon	Nipigon cisco	Shortjaw cisco
---------------	---------------	----------------

EXECUTIVE SUMMARY

The Forest Service determined that the Proposed Action and Alternative B **may impact individuals but are not likely to cause a trend to federal listing or loss of viability** for the following RFSS:

Plants

American shoreweed	<i>Cetraria aurescens</i>	New England sedge
American waterawlwort	Cloudberry	Pale moonwort
Appalachian clubmoss	Common moonwort	Peppered moon lichen
Auricled twayblade	Fairy slipper	Quill spikerush
Barren strawberry	Fan lichen	Ram's head lady slipper
Beard lichen	Floating marsh marigold	Roughfruit fairybells
Bog muhly	Honeycombed lichen	Selwyn's scalewort
Bog white violet	Least moonwort	Small beggarticks
<i>Caloplaca parvula</i>	Leiberg's waterlily	Snowline wintergreen
Canada ricegrass	Linear-leaved sundew	Ternate grapefern
Canada yew	Michigan moonwort	Western Jacob's-ladder
Cartilage lichen	Moor rush	Yellow specklebelly

Animals

Bald eagle	Freija's grizzled skipper	Northern long-eared bat
Bay-breasted warbler	Gray wolf	Olive-sided flycatcher
Black sandshell	Great gray owl	Quebec emerald dragonfly
Boreal owl	Headwaters chilostigman caddisfly	Taiga alpine
Connecticut warbler	Little brown myotis	Three-toed woodpecker
Creek heelsplitter	Northern brook lamprey	Tri-colored bat
Eastern heather vole	Northern goshawk	Wood turtle
Ebony boghaunter		

EXECUTIVE SUMMARY

The Forest Service determined that the Proposed Action and Alternative B would have **no beneficial impact**, and **would not likely impact individuals or result in a trend to federal listing or loss of viability**, for any RFSS discussed in this BE.

Finally, the Forest Service determined that the No Action Alternative would have **no impact** on RFSS discussed in this BE.

A separate Biological Assessment (BA) was prepared to evaluate project effects to Canada lynx, a federally listed threatened species, and its critical habitat; northern long-eared bat, a RFSS species that was recently federally listed as threatened; and gray wolf, a RFSS species that was previously federally listed as threatened in 1977, delisted in 2011, and relisted December 19, 2014, following a federal court reversal of the USFWS decision to delist the gray wolf.

1.0 Introduction

1.1 Overview

Poly Met Mining Inc. (PolyMet) proposes to construct an open pit mine in northern Minnesota to extract low- to medium-quality copper-nickel-PGE minerals with low sulfide content. This project, called the NorthMet Mining Project (Project), is located in St. Louis County on the eastern end of the Mesabi Iron Range, about 60 miles north of the City of Duluth, and 6 miles south of the City of Babbitt, Minnesota. The Project areas include the Mine Site (3,015 acres), Plant Site (4,515 acres), and Transportation and Utility Corridors (120 acres) that connect the Mine Site to the Plant Site³ (**Figure 1**).

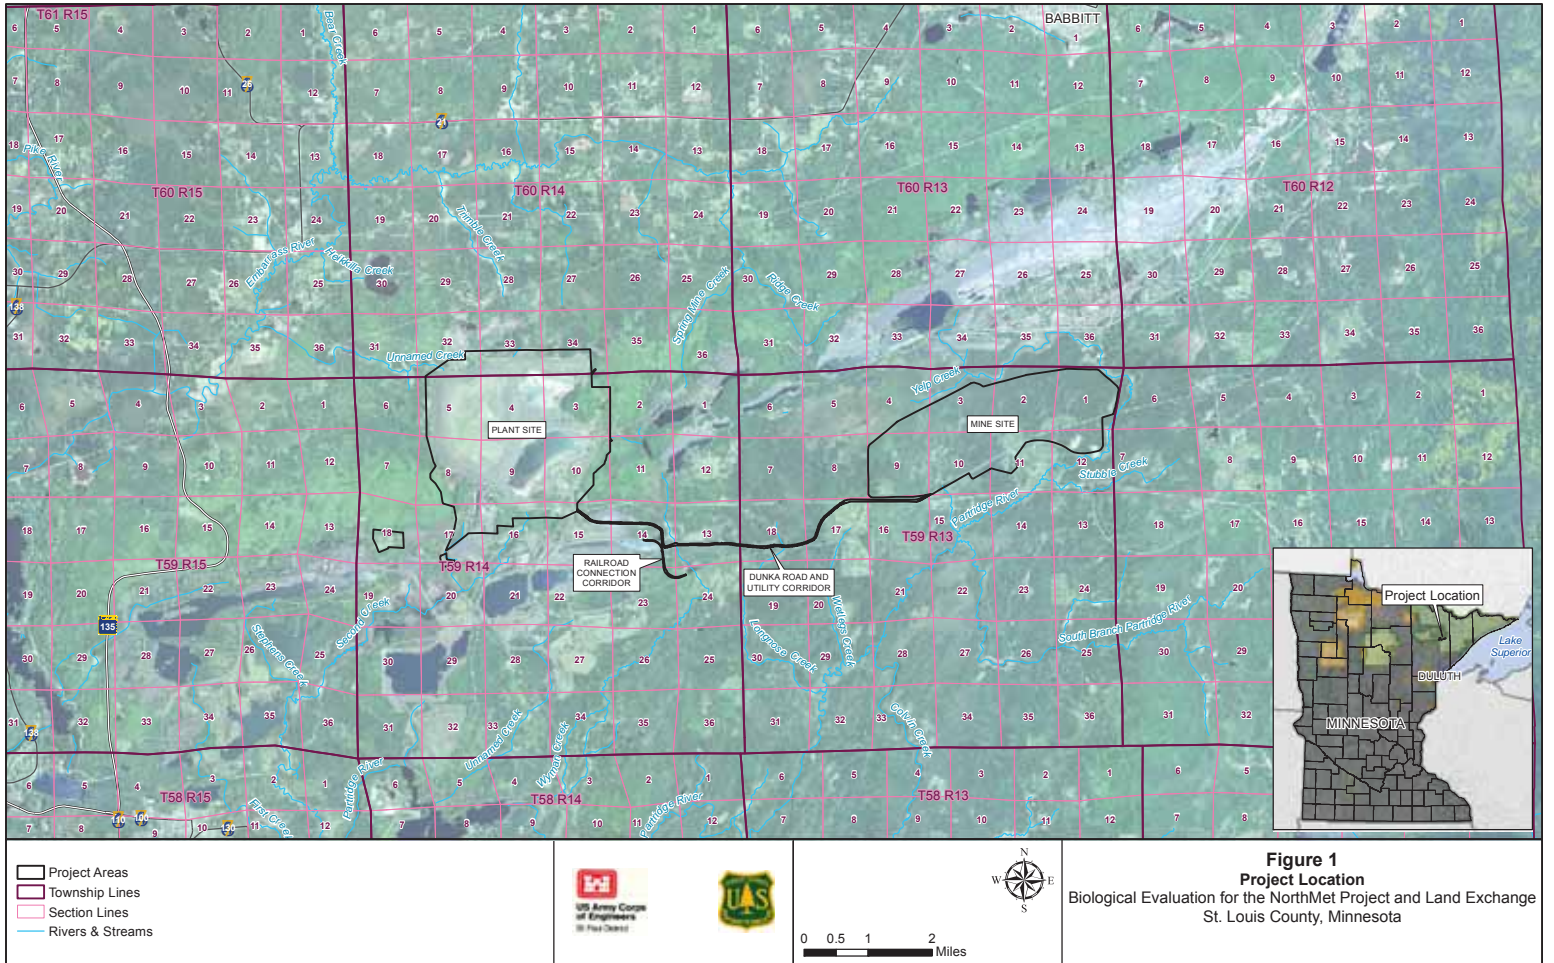

PolyMet plans to mine and process polymetallic ore from the northwestern portion of the Duluth Complex. The Duluth Complex is an ore complex that forms much of the bedrock of northeastern Minnesota. The ore contains copper, nickel, gold, platinum, palladium, and cobalt. The Plant Site was previously used as a taconite processing facility by the LTV Steel Mining Company (LTVSMC). PolyMet would upgrade existing facilities and construct new facilities to produce copper concentrates, nickel concentrates, and base and precious metal precipitates for off-site shipment and treatment. Because the Plant Site has been operated as an industrial facility for decades, the Project would not have significant new effects on wildlife habitat at the Plant Site.

About 1,719 acres of the Mine Site would be directly disturbed by mining activities. Of these, 1,667 acres are administered by the Forest Service and 52 acres are privately owned. Habitats on the federally administered lands that would potentially be affected by the project include upland coniferous forest (including black spruce⁴, jack pine, and balsam fir), upland deciduous forest (including trembling aspen and paper birch), upland mixed coniferous/deciduous forest, coniferous bogs (including black spruce and tamarack), open bogs (including leatherleaf and Labrador tea), coniferous swamps (including black spruce, tamarack, and northern white cedar), hardwood swamps (including black ash), shrub swamps (including speckled alder, willows, and dogwoods), marshes (including cattails), and sedge and wet meadows (including sedges and grasses). A variety of plants and animals, including several species of concern, have been observed on or near the Mine Site.

Of the approximately 3,015 acres on the Mine Site, approximately 2,719 acres are owned by the United States (U.S.) Government (Government) and administered by the U.S. Department of Agriculture (USDA) Forest Service (Forest Service). In addition, about 3,776 acres adjacent to the Mine Site are owned by the Government and administered by the Forest Service.

³ Acreages given in this report are based on Geographic Information System (GIS) analysis. Acreages associated with the legal descriptions of the Lands are based on original surveys performed by the Bureau of Land Management, Government Land Office (GLO) surveyors between 1858 and 1907. As such, GLO acreages are used as part of the project description for the Final Environmental Impact Statement (FEIS) being prepared for the Project and would also be used to define the real estate transaction if the land exchange was approved. The analysis of effects presented in this Biological Evaluation (BE) is based upon GIS data. The GIS values indicate the actual size of the Lands discussed in this BE, which may be different than the GLO legal acreage.

⁴ Common and scientific names of plants and animals given in this report are provided in **Appendix A**.

INTRODUCTION

The Forest Service is considering transferring these approximately 6,495 acres (federal lands) to PolyMet in exchange for lands (non-federal lands) of similar value that have been offered for consideration by PolyMet (**Figures 2 and 3**). Assuming a land exchange occurs, the portions of the Mine Site, Dunka Road and Utility Corridor, and lands adjacent to the Mine Site that are administered by the Forest Service would no longer be part of the National Forest and therefore would not be subject to Forest Service management plans and policies. A land exchange for land adjustment is consistent with the 2004 *Land and Resource Management Plan for the Superior National Forest* (2004 Forest Plan; USDA Forest Service 2004a).

To fulfill land exchange requirements, PolyMet is proposing to purchase and transfer all or a portion of 7,075 acres of non-federal lands to the Forest Service under the Proposed Action (**Figure 2**). The non-federal lands consist of the Hay Lake Lands (4,926 acres), Hunting Club Lands (160 acres), Lake County Lands (382 acres), McFarland Lake Lands (31 acres), and Wolf Lands (1,576 acres). All lands are dominated by second-growth deciduous and coniferous forest habitats and a variety of plants and animals, including species of concern, have been observed on or near the non-federal lands.

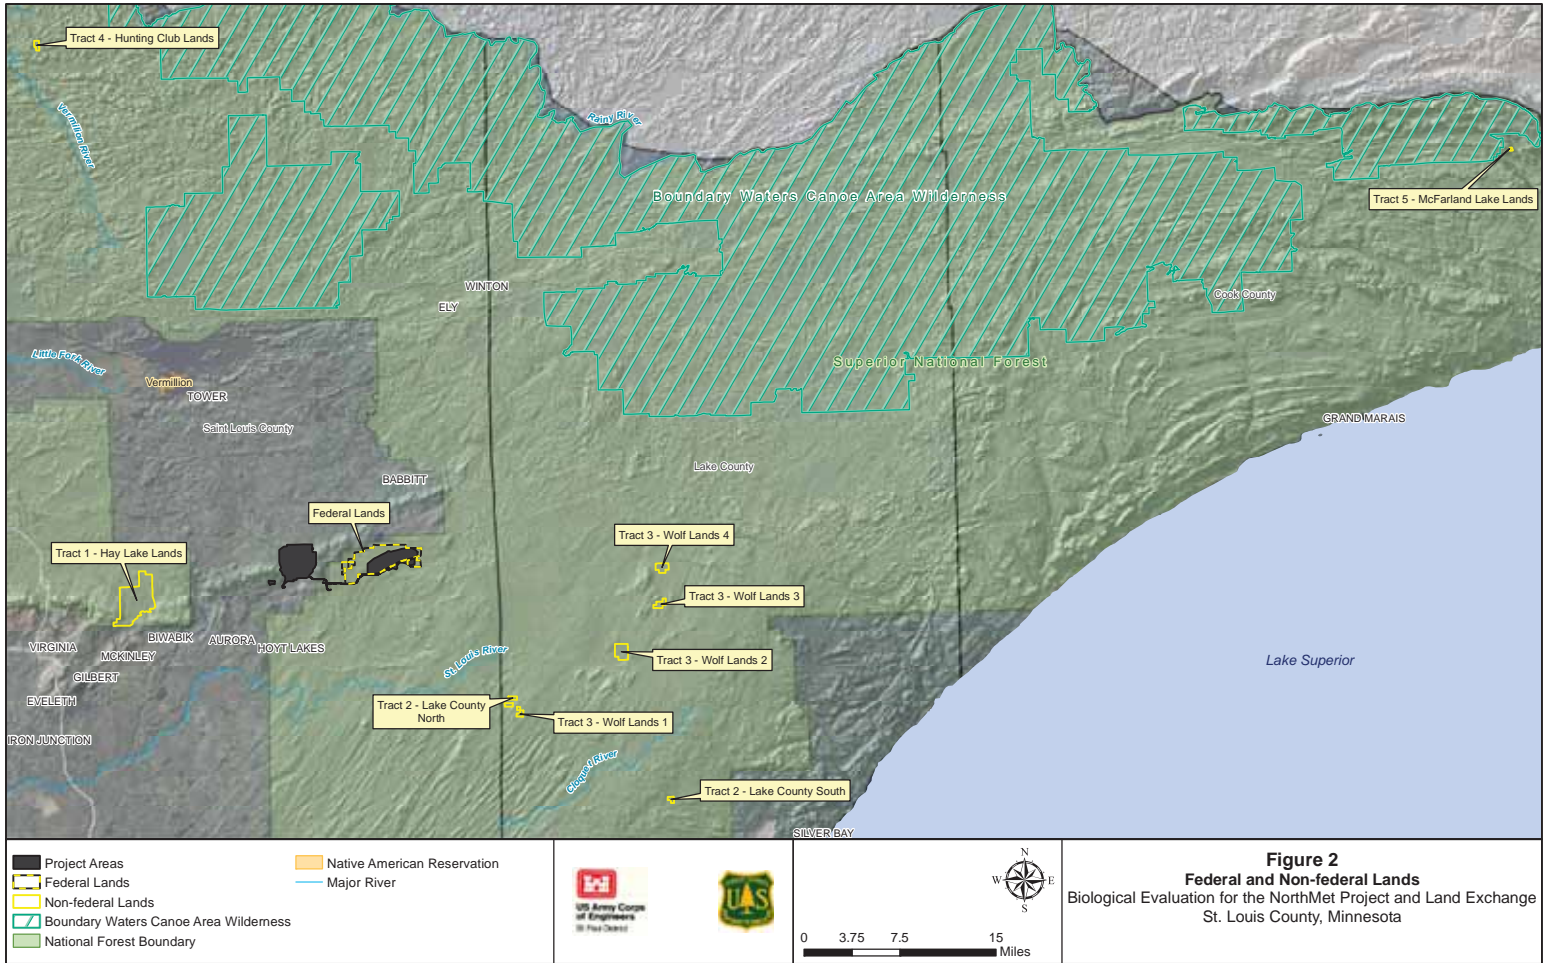

Assuming a land exchange occurs, the non-federal lands would be administered by the Forest Service. The non-federal lands are associated with four Forest Plan Management Areas, as designated by the Forest Service, which include: General Forest, General Forest – Longer Rotation, Riparian Emphasis Area, and Candidate Research Natural Areas. If all or a portion of the non-federal lands are acquired by the Forest Service, they would be administered by the Forest Service to meet the goals of these management areas (USDA Forest Service 2004a).

The Regional Forester or other authorized officer must decide if the proposed land exchange complies with the 2004 Forest Plan (USDA Forest Service 2004a), is a fair value exchange, and is in the public interest. All lands potentially involved in the land exchange would be independently appraised according to the Uniform Appraisal Standards for Federal Land Acquisitions. The appraisals would determine the market value of the properties. Information collected during wildlife and wetland functions and values studies would be used by the Forest Service in the land exchange appraisal, and would be used to evaluate impacts to wetlands, and wildlife and their habitats, for a *NorthMet Mining Project and Land Exchange Final Environmental Impact Statement* (FEIS) for the Project and land exchange (Minnesota Department of Natural Resources [MDNR] et al. 2015).

The Project could adversely impact plant and animal species of concern found on or near the federal lands. The 2004 *Forest Plan Revision Final Environmental Impact Statement for Chippewa and Superior National Forests* (2004 Forest Plan EIS; USDA Forest Service 2004b) assessed plant and animal species identified by the Regional Forester for which population viability was a concern as evidenced by:

- Significant current or predicted downward trends in population numbers or density.
- Significant current or predicted downward trends in habitat capability that would reduce a species' existing distribution (Forest Service Manual Directive 2670.5; USDA Forest Service 2000a).

Table 1 provides information on species occurrence and habitat availability for the Regional Forester Sensitive Species (RFSS) on the federal and non-federal lands. Based on the 2004 Forest Plan EIS and

-  Project Areas
-  Federal Lands - Proposed Action
-  Federal Lands - Alternative B
-  Section Lines

Figure 3
Land Exchange - Proposed Action and Alternative B
 Biological Evaluation for the NorthMet Project and Land Exchange
 St. Louis County, Minnesota

subsequent updates, the Regional Forester identified 12 non-vascular plants, 46 vascular plants, 2 aquatic invertebrates, 6 insects, 4 fish, 1 reptile, 8 birds, and 5 mammals as RFSS (Ryan 2011). Of these, eight vascular plants, and six (and possibly nine as unidentified bat species have been found on the federal exchange lands) animals have been reported on the federal lands, while two vascular plants and two (and possibly up to five as unidentified bat species have been found on the non-federal lands) animals have been reported on the non-federal exchange lands (**Table 1**). If the known and potential habitat and species occurrences are listed as “No” for a RFSS in **Table 1**, the RFSS was not analyzed in this Biological Evaluation (BE).

In accordance with Forest Service Manual Directives 2671.1 through 2672.43 (USDA Forest Service 2000a) and the National Forest Management Act of 1976, the Forest Service is required to prepare a BE to:

- ensure that Forest Service actions do not contribute to loss of viability of any native or desired non-native plant or animal species,
- ensure that Forest Service activities do not cause any species to move toward federal listing, and
- incorporate concerns for RFSS throughout the planning process, reducing negative impacts to species and enhancing opportunities for mitigation.

In addition to addressing impacts to RFSS from the Proposed Action, which includes the Project and land exchange, this BE also addresses impacts to RFSS from two alternatives also considered in the FEIS:

- Land Exchange Alternative B (Alternative B) - under Alternative B, the Forest Service would transfer 4,753 acres of federal lands, which comprise 2,719 acres at the Mine Site and a smaller amount of federal land surrounding the Mine Site, to PolyMet in exchange for the 4,926-acre Hay Lake Lands (**Figure 3**). This land exchange would involve the transfer of a similar acreage, would provide wetlands to the Forest Service, and Hay Lake Lands would have a higher-per-acre value than the federal lands.
- Land Exchange No Action Alternative (No Action Alternative) - under the No Action Alternative, mine construction, development, and operation would not occur and no lands would be exchanged. The Government would not convey federal lands to PolyMet, and the Forest Service would continue managing these federal lands.

This BE was prepared to document RFSS populations and habitats on or near the federal and non-federal lands, and likely direct, indirect, and cumulative impacts to these species from the Project. A separate Biological Assessment (BA) was prepared to evaluate project effects to Canada lynx, a federally listed threatened species, and its critical habitat; northern long-eared bat, a RFSS species that was recently federally listed as threatened; and gray wolf, a RFSS species that was recently re-listed as federally threatened, and its critical habitat (U.S. Army Corps of Engineers [USACE] and USDA Forest Service 2013). While the Canada lynx, northern long-eared bat, and gray wolf are discussed in this BE, the *NorthMet Mining Project and Land Exchange Biological Assessment Draft* provides additional details on these species (USACE and USDA Forest Service 2013).

Table 1
Regional Forester Sensitive Species Occurrence and Habitat Availability on the Federal and Non-Federal Lands

RFSS Species		Species and Habitat Occurrence				Habitat Characteristics
Scientific Name	Common Name	Known Species Occurrence on/near Federal Lands	Potential Habitat Present on/near Federal Lands	Known Species Occurrence on/near Non-federal Lands	Potential Habitat Present on/near Non-federal Lands	
Non-vascular Plants						
<i>Arctoparmelia centrifuga</i>	Arctoparmelia Lichen	No	No	No	No	Sunny rocks and open talus slopes.
<i>Arctoparmelia subcentrifuga</i>	Arctoparmelia Lichen	No	No	No	No	Sunny rocks and open talus slopes.
<i>Caloplaca parvula</i>	Unnamed Lichen	No	No	No	Yes	Smooth bark of young black ash in moist, humid old-growth black ash stands.
<i>Cetraria (=Ahtiana) aurescens</i>	Unnamed Lichen	No	Yes	No	Yes	Conifer bark in lowland conifer swamps (old cedar/black spruce).
<i>Cladonia wainioi</i>	Wain's Cup Lichen	No	No	No	No	On rock outcrops and thin soil and exposed sites with lots of light.
<i>Frullania selwyniana</i>	Selwyn's Scalewort	No	Yes	No	Yes	Lowland cedar swamps on bark of northern white cedar.
<i>Menegazzia terebrata</i>	Honeycombed Lichen	No	Yes	No	Yes	Cedar swamps, especially old growth, often at base of cedar trees.
<i>Peltigera venosa</i>	Fan Lichen	No	Yes	No	Yes	Soil and moist cliffs and on exposed root wads.
<i>Pseudocyphellaria crocata</i>	Yellow Specklebelly	No	Yes	No	Yes	Mossy rocks and trees in partially shaded, moist, frequently foggy habitats.
<i>Ramalina thrausta</i>	Cartilage Lichen	No	Yes	No	Yes	Cedar swamps, and especially old growth forest.
<i>Sticta fuliginosa</i>	Peppered Moon Lichen	No	Yes	No	Yes	On hardwoods in humid, old growth cedar or ash bogs.
<i>Usnea longissima</i>	Beard Lichen	No	Yes	No	Yes	On old conifers in moist situations, often in or near a conifer or hardwood swamps.

Regional Forester Sensitive Species Occurrence and Habitat Availability on the Federal and Non-Federal Lands

RFSS Species		Species and Habitat Occurrence				Habitat Characteristics
Scientific Name	Common Name	Known Species Occurrence on/near Federal Lands	Potential Habitat Present on/near Federal Lands	Known Species Occurrence on/near Non-federal Lands	Potential Habitat Present on/near Non-federal Lands	
Vascular Plants						
<i>Adoxa moschatellina</i>	Moschatel	No	No	No	Yes	Shaded damp cliffs and slopes in upland mature northern hardwood forests on North Shore of Lake Superior.
<i>Arnica lonchophylla</i>	Long-leaved Arnica	No	No	No	No	Cool and moist cliffs and ledges along North Shore of Lake Superior.
<i>Asplenium trichomanes</i>	Maidenhair Spleenwort	No	No	No	Yes	In crevices of moist, mostly east-facing cliffs, ledges, and talus; Rove formation.
<i>Astragalus alpinus</i>	Alpine Milkvetch	No	No	No	No	Found on rocky, gravelly margins of shallow groundwater-fed ponds; herbaceous cover is typically sparse.
<i>Bidens discoidea</i>	Small Beggarticks	No	Yes	No	Yes	Wet habitats. Silty shores and hummocks in floating mats and swamps; also partly submerged logs.
<i>Botrychium lanceolatum</i>	Triangle Grapefern	No	Yes	Yes	Yes	Northern hardwood forest, old fields, old logging roads, and trails.
<i>Botrychium lanceolatum</i> var. <i>angustisegmentum</i>	Lanceleaf Grapefern	No	Yes	No	Yes	Prefers moist, shady, mature northern hardwood forests, particularly in low areas.

**Table 1 (Cont.)
Regional Forester Sensitive Species Occurrence and Habitat Availability on the Federal and Non-Federal Lands**

RFSS Species		Species and Habitat Occurrence				Habitat Characteristics
Scientific Name	Common Name	Known Species Occurrence on/near Federal Lands	Potential Habitat Present on/near Federal Lands	Known Species Occurrence on/near Non-federal Lands	Potential Habitat Present on/near Non-federal Lands	
<i>Botrychium lunaria</i>	Common Moonwort	No	Yes	No	Yes	Prefers open habitats such as gravelly banks, rocky ledges, and talus. It has also been found in open, sparsely vegetated habitats with grasses and scattered shrubs, and open habitats such as old log landings, sawmill sites, and building sites.
<i>Botrychium michiganense (hesperium)</i>	Michigan Moonwort	Yes	Yes	No	Yes	Open habitats such as old log landings, old dirt roads, gravel pits, powerline corridors, borrow pits, beach ridges, old fields, trails, and dredge spoil dumps.
<i>Botrychium mormo</i>	Little Goblin Moonwort	No	No	No	No	Occurs in mature mesic hardwood forests where the dominant trees are sugar maple with lesser amounts of northern white cedar; canopy must be intact to maintain shaded and moist conditions.
<i>Botrychium pallidum</i>	Pale Moonwort	Yes	Yes	No	Yes	Full to shady exposure and edge of alder thickets.
<i>Botrychium rugulosum</i>	Ternate (St. Lawrence) Grapefern	Yes	Yes	No	Yes	Disturbed habitats, fields, open woods, and forests.
<i>Botrychium simplex</i>	Least Moonwort	Yes	Yes	No	Yes	Full to shady exposure at edge of alder thickets and along forest roads.
<i>Caltha natans</i>	Floating Marsh Marigold	Yes	Yes	No	Yes	Shallow water in ditches and streams, alder swamps, shallow marshes, and beaver ponds

Table 1 (Cont.)
Regional Forester Sensitive Species Occurrence and Habitat Availability on the Federal and Non-Federal Lands

RFSS Species		Species and Habitat Occurrence				Habitat Characteristics
Scientific Name	Common Name	Known Species Occurrence on/near Federal Lands	Potential Habitat Present on/near Federal Lands	Known Species Occurrence on/near Non-federal Lands	Potential Habitat Present on/near Non-federal Lands	
<i>Calypso bulbosa</i>	Fairy Slipper	No	Yes	No	Yes	Hummocks in northern white cedar swamps, moist to wet lowland coniferous swamps, and to lesser extent in upland coniferous forests.
<i>Carex novae-angliae</i>	New England Sedge	No	Yes	No	Yes	Moist woods with sugar maple, also with yellow birch, trembling aspen, white spruce dominated forest, and tall shrubs.
<i>Carex rossii</i>	Short Sedge	No	No	No	No	Rocky summits, dry exposed cliff faces, and rocky slopes, in east Border Lakes subsection.
<i>Crataegus douglasii</i>	Douglas' Hawthorn	No	No	No	No	North Shore of Lake Superior rocky and gravelly streambeds/banks and open areas, and rocky borders of woods.
<i>Cypripedium arietinum</i>	Ram's head Lady Slipper	No	Yes	No	Yes	Wide variety of forests, both upland and lowland, but in Minnesota predominantly in northern white cedar swamps; also in forests dominated by jack pine, red pine, or white pine.
<i>Drosera linearis</i>	Linear-leaved Sundew	No	Yes	No	Yes	One of a small group of rare plant species that are restricted to high-quality, undisturbed examples of a peatland type called patterned fens.
<i>Eleocharis nitida</i>	Quill Spikerush	Yes	Yes	No	Yes	Full exposure and moist ditches.
<i>Huperzia appalachiana</i>	Appalachian Clubmoss	No	No	No	Yes	Shelves and crevices on cliff/talus/rock outcrops, and shrub-dominated talus piles.

**Table 1 (Cont.)
Regional Forester Sensitive Species Occurrence and Habitat Availability on the Federal and Non-Federal Lands**

RFSS Species		Species and Habitat Occurrence				Habitat Characteristics
Scientific Name	Common Name	Known Species Occurrence on/near Federal Lands	Potential Habitat Present on/near Federal Lands	Known Species Occurrence on/near Non-federal Lands	Potential Habitat Present on/near Non-federal Lands	
<i>Juncus stygius</i>	Moor Rush	Yes	Yes	No	Yes	Open-patterned peatlands, rich and poor fens, and northern black spruce bogs.
<i>Juncus subtilis</i>	Creeping Rush	No	No	No	No	Sandy lakeshore; only known occurrence is in the Boundary Waters Canoe Area Wilderness (BWCAW).
<i>Listera auriculata</i>	Auricled Twayblade	No	Yes	No	Yes	On alluvial or lake-deposited sands or gravels, with occasional seasonal flooding; associated with riparian alder or black spruce/balsam fir forest.
<i>Littorella uniflora</i> (= <i>L. americana</i>)	American Shoreweed	No	Yes	No	Yes	Shallow margins of nutrient-poor lakes and seepage lakes; sandy substrates and may have fine gravel/organic soil; fluctuating water level up to about 3 feet.
<i>Moehringia macrophylla</i>	Largeleaf Sandwort	No	No	No	Yes	Cliffs/rock outcrops, talus, and conifer sites on shallow soils; pine plantation with rocky outcrops; usually semi-open shrub or tree canopy.
<i>Muhlenbergia uniflora</i>	Bog Muhly	No	Yes	No	Yes	Wet sandy beaches and floating peat mats.
<i>Nymphaea leibergii</i>	Leiberg's Water-lily	No	Yes	No	Yes	Slow moving streams, rivers, and beaver impoundments 3 to 6 feet deep; occurs at outer margin of emergent vegetation.
<i>Osmorhiza berteroi</i>	Chilean Sweet-cicely	No	No	No	No	Northern hardwood forest dominated by sugar maple on North Shore of Lake Superior.

<i>Perimyotis subflavus</i>	Tri-colored Bat	No	Yes	Potential	Yes	Hibernate in caves, mines, and tunnels during winter, roost in trees during summer. Maternity colonies found in trees, rock crevices, and barns or other buildings.
<i>Phenacomys ungava</i>	Eastern Heather Vole	No	Yes	No	Yes	Forest, brushland, or clearcuts with bilberry and rocks.

2.0 Description of the Proposed Action and Alternatives

2.1 Proposed Action (Alternative A)

2.1.1 Overview

The USACE and the USFS have separate proposed actions on which consultation is occurring. The USACE has an application under the Clean Water Act to impact wetlands and other waters of the U.S. associated with the construction and operation of the NorthMet mine. The USFS is evaluating a land exchange of federal and non-federal lands. For convenience, the impacts are described in terms of the Project and its associated activities.

PolyMet proposes to construct an open pit mine in northern Minnesota to extract low- to medium-quality copper-nickel-PGE minerals with low sulfide content. This Project is located in Sections 5, 6, 8, 9, 13, 14, 15, 16, 17, 23, and 24, Township 58 North, Range 14 West; Sections 1, 2, 3, 4, 9, 10, 11, 12, 15, 16, 17, and 18, Township 59 North, Range 13 West; Sections 3, 4, 5, 8, 9, 10, 11, 13, 14, 15, 16, 17, 20, 23, 24, 29, and 32, Township 59 North, Range 14 West; and Sections 32, 33, and 34, Township 60 North, Range 14 West, in St. Louis County on the eastern end of the Mesabi Iron Range, about 60 miles north of the City of Duluth, and 6 miles south of the City of Babbitt, Minnesota (**Figure 1**).

This section describes specific Project features that could have potential effects on RFSS and their habitats. Additional Project features that are not relevant to potential effects on RFSS and their habitats are listed in this section, but are not described in detail. Full Project details are available in the FEIS (MDNR et. al. 2015).

Ore would be excavated at the Mine Site and hauled by railroad approximately 8 miles west to the Plant Site for processing. Corridors for roads, railroad, utilities, and water pipelines would connect the Mine Site and the Plant Site. The four Project areas are shown on **Figure 1** and include:

- Mine Site
- Plant Site
- Dunka Road and Utility Corridor
- Railroad Connection Corridor

2.1.2 Mine Site

The Mine Site, approximately 3,015 acres, would be developed at a greenfield site that has previous disturbance from logging and mining exploration activities. The Project would develop open mine pits (up to 528 acres), stockpiles (up to 794 acres), and supporting infrastructure (up to 397 acres). The location and dimensions of Mine Site features are shown on **Figure 4**. The Project features at the Mine Site would include:

- mine pits;
- ore storage and handling facilities, including an Ore Surge Pile and a Rail Transfer Hopper;

DESCRIPTION OF THE PROPOSED ACTION AND ALTERNATIVES

- stockpiles for overburden and waste rock with engineered systems to manage potential water resource impacts (such as liners, covers, and the Category 1 Waste Rock Stockpile Groundwater Containment System);

<ul style="list-style-type: none"> Mine Site Year 1 Mine Pits Year 11 Mine Pits Year 1 Stockpiles Year 11 Stockpiles 	<ul style="list-style-type: none"> Haul Roads Treated Water Pipeline Dunka Road Existing Private Railroad Proposed Railroad Track 			<p>Figure 4 Mine Site Plan Biological Evaluation for the NorthMet Project and Land Exchange St. Louis County, Minnesota</p>
---	--	--	--	--

DESCRIPTION OF THE PROPOSED ACTION AND ALTERNATIVES

- a Waste Water Treatment Facility and process water collection systems to collect and treat water from the mine pits, waste rock stockpiles, ore handling facilities, and haul roads;
- a Central Pumping Station and Treated Water Pipeline to transport water from the Mine Site to the Plant Site; and
- supporting infrastructure (such as roads, electrical supply, rail connections, and fueling and maintenance facilities).

2.1.2.1 Pre-production Mine Development

Mine Site infrastructure would be constructed during the estimated 12 to 18 months of pre-production mine development. Pre-production mine development would be followed by a gradual ramp-up of ore output over 6 to 12 months. The following Project features would be constructed during pre-production mine development:

- Roads - site access roads, haul roads, and Dunka Road upgrades.
- Railroad infrastructure - the Rail Transfer Hopper, the rail spur connecting the Rail Transfer Hopper with Cliffs Erie railroad track, and the rail spur between the Cliffs Erie railroad track and PolyMet railroad track that serves the Coarse Crusher Building.
- Surface water management features - dikes ditches, water collection ponds, and sumps.
- Overburden Storage and Laydown Area.
- Stockpile liners and containment systems.
- Waste Water Treatment Facility, Treated Water Pipeline, and Central Pumping Station.
- Substation drop from the 138 kilovolt (kV) Minnesota Power transmission line and a 13.8 kV Mine Site power distribution system.
- Mine Site Fueling and Maintenance Facility.

2.1.2.2 Mining Activities

PolyMet expects to mine a total of 533 million tons of waste rock and ore over 20 years, which would include 225 million tons of ore and 308 million tons of waste rock. Mining activities include overburden removal, open pit mining, drilling and blasting, excavation and haulage, ore storage and loading for transport to the Process Plant, waste rock stockpiling, and mine site water management.

Overburden Removal

The marketable timber would be cleared and the overburden removed from the footprints of the mine pits, the Ore Surge Pile, and the waste rock stockpiles, as necessary. Overburden has been defined for this Project as the material that lies on top of the underlying bedrock.

Overburden would be stripped incrementally as needed for mine development in order to minimize the amount of bedrock exposed at any one time. After removal of overburden from the initial mining area, additional overburden stripping could take place concurrently with the mining of ore and waste rock. Approximately 32% of the required overburden stripping for the pit development would be done in the first 2 years of mine operation. All of the overburden that needs to be stripped from the pits would be removed by the end of Mine Year 11.

Open Pit Mining

The Project would use open pit mining methods similar to those used at ferrous metallic mining operations on the Iron Range. The mine would consist of three separate open pits known as the East, Central, and West pits. For approximately the first 10 years of operations, mining would take place in the East and West pits simultaneously, with the East Pit mining ending in Mine Year 11. The Central Pit mining would occur between Mine Years 11 and 16. During Central Pit mining, the East and Central pits would converge into one pit which would then be referred to as the East Pit.

At its maximum size, each pit is projected to have the approximate maximum area and depth shown in **Table 2**.

Table 2
Maximum Pit Dimensions

Mine Pit	Area (acres)	Maximum Depth (feet below ground surface)
East	155	696
Central	52	356
West	321	630

Drilling and blasting would be conducted to remove waste rock and extract ore. Two conventional electric or diesel powered rotary drilling rigs would be used. Blasting of ore and waste rock is anticipated to take place approximately every 2 to 3 days.

After being drilled and blasted, the ore would be loaded by excavators into haul trucks that would haul the ore to the Rail Transfer Hopper or to the Ore Surge Pile for temporary storage, and haul the waste rock to the stockpiles or the East Pit. Up to nine haul trucks would be in service with a maximum speed of 34 miles per hour loaded, however their speed would typically be lower.

Mining operations would be supported by mine auxiliary vehicles (in other words [e.g.], water trucks, dozers, graders) traveling on access and haul roads within the Mine Site.

Ore Storage and Loading

Ore would be loaded for transport to the Plant Site at the Rail Transfer Hopper. The Rail Transfer Hopper would consist of a raised platform from which haul trucks dump into a hopper over a pan feeder into rail cars. The Rail Transfer Hopper would be located to the south of the mine pits and would be connected to the existing Cliffs Erie main line track by a new spur line (**Figure 4**).

An Ore Surge Pile would be constructed adjacent to the Rail Transfer Hopper to allow for temporary storage of ore until it could fit into the processing schedule or as required by operational delays. Drainage from the Ore

DESCRIPTION OF THE PROPOSED ACTION AND ALTERNATIVES

Surge Pile would be collected on a liner and routed to a sump for pumping to the Waste Water Treatment Facility.

Stockpiling

Waste rock and overburden would be managed according to its geochemical properties as determined using a sampling and analysis program approved by the MDNR. PolyMet has categorized waste rock into four categories defined according to its sulfur content, in ascending order of reactivity. These waste rock categories are summarized in **Table 3**.

The Category 1 Waste Rock Stockpile would be the only permanent stockpile for the Project. During Mine Years 1 through 11, Category 2, 3 and 4 waste rock would be placed on the temporary Category 2/3 or Category 4 Waste Rock Stockpiles (**Figure 4**). When at its maximum size, each stockpile is projected to have the approximate area, height, and elevation shown in **Table 4**.

**Table 3
Waste Rock Properties**

Waste Rock Categorization	Sulfur Content (percent)¹	Approximate Percent of Total Waste Rock Produced during Mining (percent)
Category 1	≤ 0.12	70
Category 2	> 0.12 to ≤ 0.31	24
Category 3	> 0.31 to ≤ 0.60	3
Category 4	> 0.6	3

¹In general, the higher the rock’s sulfur content, the higher it’s potential for generating acid rock drainage or leaching heavy metals.

**Table 4
Maximum Stockpile Dimensions - Approximate**

Stockpile	Mine Year of Maximum Footprint	Maximum Footprint (acres)	Maximum Height (feet)	Maximum Elevation (feet above sea level)
Category 1 waste rock	6/21 ¹	508/526 ¹	280	1,880
Category 2/3 waste rock	6	180	200	1,770
Category 4 waste rock	3	57	180	1,790
Ore Surge Pile	NA ²	31	120	1,690

¹The Category 1 Waste Rock Stockpile has a maximum footprint of 508 acres while active. It would reach this size by Mine Year 6. The stockpile would be re-graded as part of the reclamation with a final footprint of 526 acres.

²The Ore Surge Pile would have ore moving in and out as needed to meet mine and plant operations.

All waste rock stockpiles would be engineered to manage water resource impacts. The temporary Category 2/3 and Category 4 Waste Rock Stockpiles, which have the potential to generate acid rock drainage, would have liner systems to capture water passing through the stockpile. The permanent Category 1 Waste Rock Stockpile, which does not have the potential to generate acid rock drainage, would be constructed with a groundwater containment system to collect stockpile drainage from around the entire stockpile.

Progressive Reclamation

Reclamation of the East Pit and the temporary waste rock stockpiles would begin during operations. The temporary Category 2/3 and Category 4 Waste Rock Stockpiles would be relocated to the East Pit starting in Mine Year 11. The infrastructure associated with the temporary stockpiles (pipes, pumps, liners, etc.) would be removed and the footprint of each area would be reclaimed.

After the temporary stockpiles are reclaimed, all future Category 2, 3, and 4 waste rock would be placed in the East Pit. Most of the Category 1 waste rock mined after Mine Year 12 would also be placed in the East Pit. Ultimately, approximately 45% of the total waste rock mined would be backfilled to the East Pit.

The East Pit would be flooded to keep the waste rock in a subaqueous environment to reduce the environmental impact associated with further oxidation and dissolution of sulfide minerals. If natural inflow of water into the East Pit is insufficient to keep the waste rock submerged, water could be pumped from the Waste Water Treatment Facility. During periods of high precipitation or during spring snowmelt, dewatering (to the Waste Water Treatment Facility and ultimately to the Flotation Tailings Basin) may be required to allow safe placement of the waste rock.

Reclamation of the Category 1 Waste Rock Stockpile would also begin during operations. A cover system would be added incrementally after Mine Year 13 to limit infiltration through the stockpile. The stockpile would be sloped and graded, an engineered geomembrane system would be installed, soil would be placed on top of the cover, and vegetation would be planted to meet the requirements of Minnesota Rules, part 6132.2200, subpart 2, item B. The cover system would be designed to promote runoff with minimal erosion.

Mine Site Water Management

This section summarizes information from the Water Management Plan - Mine, which would become part of the MDNR Permit to Mine and Water Appropriations permits and Minnesota Pollution Control Agency (MPCA) National Pollutant Discharge Elimination System/State Disposal System permit. These plans include water management system designs, operating and maintenance plans, water quality monitoring plans, reporting requirements, and adaptive management approach.

In addition to the stockpile liners, the stockpile cover, and the groundwater containment system, water management at the Mine Site would include pit dewatering, stormwater dikes and ditches, and the Waste Water Treatment Facility that would treat water that comes in contact with mining features. During operations, there would be no direct discharge of treated waste water to public waters.

It would be necessary to dewater the pits during mining to remove groundwater flow and precipitation runoff. These waters would be directed to low areas in the pits where it would be collected in sumps and pumped to the Waste Water Treatment Facility.

Non-contact stormwater, the result of precipitation that falls on natural or reclaimed vegetated surfaces, would be routed through sedimentation ponds prior to discharge to a small watercourse that flows to the Partridge River. A system of dikes and ditches constructed at the Mine Site perimeter would minimize the amount of surface water flowing onto the site and into the mine pits, manage the amount of water that comes into contact with mining features, and control non-contact stormwater flowing off the site.

During operations, the Waste Water Treatment Facility would treat water that comes into contact with the waste rock stockpiles, haul roads, Ore Surge Pile, and mine pits. For the first approximately 10 years, all Waste Water Treatment Facility effluent would be pumped to the Plant Site Flotation Tailings Basin Pond for reuse in the beneficiation process. Reuse of the Mine Site process water at the Plant Site would eliminate the need to discharge any process water to surface waters during operations. Starting in Mine Year 11, some Waste Water Treatment Facility effluent would be sent to the East Pit to augment flooding as the pit is backfilled, with the remainder of the effluent continuing to go to the Flotation Tailings Basin. The purpose of the Waste Water Treatment Facility is to maintain water quality in the Flotation Tailings Basin pond at concentrations that do not have an adverse impact on Beneficiation Plant operations or future reclamation of the Flotation Tailings Basin.

Mine Site water would be managed in accordance with a future MPCA National Pollutant Discharge Elimination System/State Disposal System permit, which would include a Stormwater Pollution Prevention Plan. The Stormwater Pollution Prevention Plan would identify and describe Best Management Practices for the Mine Site to minimize the discharge of potential pollutants in stormwater runoff.

2.1.2.3 Fueling and Maintenance Facilities

The Mine Site Fueling and Maintenance Facility would consist of two buildings, one for fueling mobile equipment, and one for minor service and repair of mobile equipment. Major scheduled maintenance and repair work lasting several days on most mobile equipment would be done in the refurbished and reactivated former LTVSMC Area 1 Shop. Stationary or slow-moving equipment such as excavators, dozers, drill rigs, and light plants would be fueled in the field using mobile fuel tankers.

The former LTVSMC Area 2 Shop, about 1 mile east of the Process Plant, would be reactivated to provide office space for mining and railroad operations supervision and management, as well as clothes changing facilities, toilets, lunch rooms, first aid facility, emergency response center, and training and meeting rooms for mining and railroad crews. The Area 2 Shop facilities would include a Locomotive Fueling Station, Locomotive Service Building, and Mine Reporting Building.

2.1.3 Plant Site

The Plant Site was previously used as a taconite processing facility by the LTVSMC. The location and dimensions of Plant Site features are shown on **Figure 5**.

At the Plant Site, the Project would upgrade existing facilities (Beneficiation Plant, Tailings Basin, Area 1 Shop, sewage collection system, rail connections, access roads) and construct new facilities (Hydrometallurgical Plant, Hydrometallurgical Residue Facility, Concentrate Dewatering/Storage Building, Sewage Treatment System Ponds, and Waste Water Treatment Plant) within an existing brownfield facility. The Flotation Tailings would be stored atop the existing LTVSMC Tailings Basin by staged construction of new dams. The Plant Site also includes supporting infrastructure (e.g., roads, electrical supply, rail connections, Area 1 Shop, and Area 2 Shop).

Plant Site environmental controls would include: cover systems to limit infiltration of oxygen and water through the Flotation Tailings Basin dams, beaches, and pond bottom, and seepage capture systems to collect seepage from the Flotation Tailings Basin. Most water used in processing would be recycled for use. A Waste Water Treatment Plant would be constructed, including reverse osmosis or similar membrane separation technology, to treat any water that could not be recycled prior to discharge to the environment. If makeup water is needed for

Figure 5
Plant Site Layout
 Biological Evaluation for the NorthMet Project and Land Exchange
 St. Louis County, Minnesota

processing, it may be provided via the Colby Lake Water Pipeline. No new construction is required for the Colby Lake Water Pipeline.

2.1.3.1 Ore Processing

A Beneficiation Plant and Hydrometallurgical Plant would process the ore at the Plant Site to recover base metals, gold, and platinum group metals. The purpose of the beneficiation process would be to produce final separate concentrates. One of the separate concentrates would be a copper concentrate. The other separate concentrates would be differing grades of nickel concentrate. The concentrates could be shipped to customers, used as a feedstock to the hydrometallurgical process, or divided for both uses. PolyMet expects that the Beneficiation Plant would be operational several years before the Hydrometallurgical Plant and during that period all concentrates would be shipped to customers. Once the Hydrometallurgical Plant becomes operational, some or all of the nickel concentrates would be feedstock to the hydrometallurgical process. The decision to ship or process concentrates would be based on equipment maintenance schedules, customer requirements, and overall Project economics.

Beneficiation Plant

The Beneficiation Plant processes would include ore crushing, grinding, flotation, dewatering, storage, and shipping. Crushing and grinding would occur in the existing Coarse Crusher Building, Fine Crusher Building, and Concentrator Building. Flotation would occur in a new Flotation Building located on previously disturbed ground immediately to the west of the Concentrator Building. Dewatering, storage, and shipping would occur in a new Concentrate Dewatering/Storage Building located on previously disturbed ground.

Hydrometallurgical Plant

Hydrometallurgical processing technology would be used for the treatment of nickel concentrates. This process would involve high pressure and temperature autoclave leaching followed by solution purification steps to extract and isolate platinum group metals, precious metals, and base metals. All equipment used in the hydrometallurgical process would be located in a new Hydrometallurgical Plant Building. Should spillage of process fluids occur, it would remain within the Hydrometallurgical Plant Building and be returned to the appropriate process streams.

Plant Site Infrastructure

Plant Site infrastructure that exists at this site includes:

- County Road 666 ends at the Main Gate for the industrial area that includes the Process Plant, Area 1 Shop, and Area 2 Shop.
- The Canadian National Railroad serves the industrial area that would include the Process Plant. The PolyMet railroad would connect to the Area 1 Shop and the Area 2 Shop.
- Three Minnesota Power Company 138 kV transmission lines serve the Project substation.

- The existing mechanical Sewage Treatment Plant would be replaced with new Sewage Treatment System Ponds, and the existing sewage collection system would be upgraded to meet current construction and performance standards and sized as appropriate.
- The Process Plant potable water treatment plant located near the Plant Reservoir would be refurbished and reactivated. The potable water distribution system extends to the Area 1 Shop and Area 2 Shop. This water would be used for showers and sinks and would be treated (chlorinated) to be drinkable. However, bottled water would be brought in for drinking as well.
- Area 1 Shop and Area 2 Shop.

2.1.3.2 Flotation Tailings Basin

Flotation Tailings from the flotation process at the Beneficiation Plant would be pumped to the Flotation Tailings Basin, which would be constructed on top of cells 1E and 2E of the existing LTVSMC Tailings Basin. Treated water from the Waste Water Treatment Facility would also be pumped to the Flotation Tailings Basin, enabling it to serve as the primary collection and distribution point for water used in the beneficiation process.

The existing LTVSMC Tailings Basin is unlined and was constructed in stages beginning in the 1950s. It has been inactive since January 2001, except for reclamation activities consistent with a MDNR-approved Closure Plan currently managed by Cliffs Erie.

The future Flotation Tailings Basin perimeter dams would be raised using upstream construction methods. The dams would be constructed using compacted LTVSMC tailings borrowed from the existing Tailings Basin. Once the LTVSMC tailings supply has been completely used for dam construction, offsite borrow from MDNR-approved sources would be utilized. Material from LTVSMC Area 5 would be a likely source, but other sources could also be considered.

Emergency overflow channels would be provided to protect the dams in the unlikely event that freeboard within the Flotation Tailings Basin is not sufficient to contain all water from an extreme storm event. Even though there is a low likelihood of overflow, it is standard practice in dam design to accommodate overflows in a manner that protects the integrity of the dams.

Seepage from the Flotation Tailings Basin would be collected by the Flotation Tailings Basin Containment System located around the northern, western, and portions of the eastern sides of the Tailings Basin and the Flotation Tailings Basin South Surface Seepage Management System located south of Tailings Basin Cell 1E. These two systems are collectively referred to as the Flotation Tailings Basin Seepage Capture Systems. The Flotation Tailings Basin Containment System would include a low permeability cutoff wall so that it can collect seepage (from up-gradient), but avoid drawing in water from down-gradient wetlands.

2.1.3.3 Hydrometallurgical Residue Facility

The Hydrometallurgical Residue Facility would be constructed to manage residues generated by the hydrometallurgical process. The Hydrometallurgical Residue Facility would consist of a one-lined cell located adjacent to the southwest corner of Tailings Basin, on previously disturbed ground (**Figure 5**).

The Hydrometallurgical Residue Facility liner system would be a double liner system consisting of two barrier layers separated by a leakage collection layer. This system would substantially remove all hydraulic head from the lower liner, virtually eliminating leakage from the Hydrometallurgical Residue Facility.

Residue from the Hydrometallurgical Plant would be pumped to the Hydrometallurgical Residue Facility as slurry. A pond would be maintained within the Hydrometallurgical Residue Facility so that the solids in the slurry would settle out. Most of the liquid would be recovered by a pump system and returned to the plant for reuse.

2.1.3.4 Plant Site Water Management

This section summarizes information from the Water Management Plan - Plant, which is a support document for the MDNR Permit to Mine and Water Appropriations permits and MPCA National Pollutant Discharge Elimination System/State Disposal System permit. These plans include water management system designs, operating and maintenance plans, preliminary water quality monitoring plans, preliminary reporting requirements, and adaptive management approach. Final water quality monitoring and reporting requirements would be determined in the permits.

Water management features at the Plant Site would include the Flotation Tailings Basin and seepage capture systems, Hydrometallurgical Residue Facility, stormwater dikes and ditches, drainage swale, Waste Water Treatment Plant, and stream augmentation. With the exception of the Flotation Tailings Basin seepage containment system, all Plant Site water management features would be located on previously disturbed areas.

Waste Water Treatment Plant

The Waste Water Treatment Plant would treat any water collected by the Flotation Tailings Basin seepage capture systems that cannot be reused as process water. It would include a reverse osmosis unit or similar membrane separation technology designed to achieve an effluent sulfate concentration that meets the sulfate standard for waters used for the production of wild rice (10 milligrams per liter (mg/L)). Water would be treated to meet appropriate discharge limits, then discharged along the west, northwest, and north perimeter of the Flotation Tailings Basin, beyond the Flotation Tailings Basin Containment System, and to Second Creek at the south end of the Flotation Tailings Basin to replenish the flow to the surrounding wetlands and streams. This discharge strategy would limit the potential for indirect wetland impacts due to reduced seepage from the Tailings Basin to the wetlands.

Stream Augmentation

Construction of the Flotation Tailings Basin Containment System would reduce the amount of seepage that is currently leaving the existing Tailings Basin. Consequently, the stream flow in the four tributaries around the Tailings Basin (Unnamed Creek, Second Creek, Trimble Creek, and Mud Lake Creek) would be reduced from current levels. Flow to Unnamed Creek, Second Creek, and Trimble Creek would be augmented by treated water from the Waste Water Treatment Plant. Flow to Mud Lake Creek would be augmented by construction of a drainage swale east of the Flotation Tailings Basin.

2.1.4 Transportation and Utility Corridors

The remaining Project components are linear corridor features, including the following:

- Dunka Road and Utility Corridor
- Railroad Connection Corridor
-

This section describes Project features in the Transportation and Utility Corridors and presents information on the types of traffic that would result from the Project.

2.1.4.1 Dunka Road and Utility Corridor

Dunka Road is an existing, compacted-gravel, private road that extends from near the LTVSMC Plant Site to the Mine Site, then continues roughly northeast toward Babbitt, Minnesota (**Figure 6**). The portion of Dunka Road that connects the Plant Site to the Mine Site would be widened. The Treated Water Pipeline would be constructed parallel and adjacent to the Dunka Road in the Utility Corridor to transport treated water from the Mine Site to the Plant Site. The distance along Dunka Road from the Plant Site gate to the Mine Site gate is approximately 6.4 miles. Including the road segments located within the Plant Site and the Mine Site, the total distance from the ore processing area at the Plant Site to the ore loading area at the Mine Site is approximately 8.5 miles.

Traffic on Dunka Road would include light trucks and automobiles, sport utility vehicles (SUVs), fuel trucks, supply and waste trucks, and haul trucks needing maintenance.

- Automobiles, light trucks, or SUVs transporting employees would travel between the Area Two Shops and the Mine Site each day, at speeds of 30 to 45 miles per hour.
- Trucks carrying fuel and blasting agents would travel to the Mine Site every day, at speeds of 25 to 40 miles per hour. These trucks would travel from County Highway 666 to Dunka Road.
- Trucks transporting supplies and waste to and from the Waste Water Treatment Plant and the Waste Water Treatment facility would travel between the Plant Site and the Mine Site each day, at speeds of 25 to 40 miles per hour.
- Haul trucks would travel from the Mine Site to the Area 1 Shop for maintenance occasionally, at a maximum speed of 35 miles per hour.

2.1.4.2 Railroad Connection Corridor

The railroad route from the Mine Site to the Plant Site would be from a new spur at the Rail Transfer Hopper, to the existing track on the Cliffs Erie private railroad, to a new approximately 1.1 mile connecting railroad track between the Cliffs Erie railroad track and existing PolyMet track railroad that serves the Coarse Crusher Building at the Process Plant (**Figure 6**).

Each ore train would consist of 16 to 20 100-ton side dumping ore cars and one diesel-electric “Gen-Set” or “Multi-Engine” locomotive. Ore trains would make approximately 22 roundtrips per day delivering ore from the Mine Site to the Plant Site, traveling between 15 to 25 miles per hour.

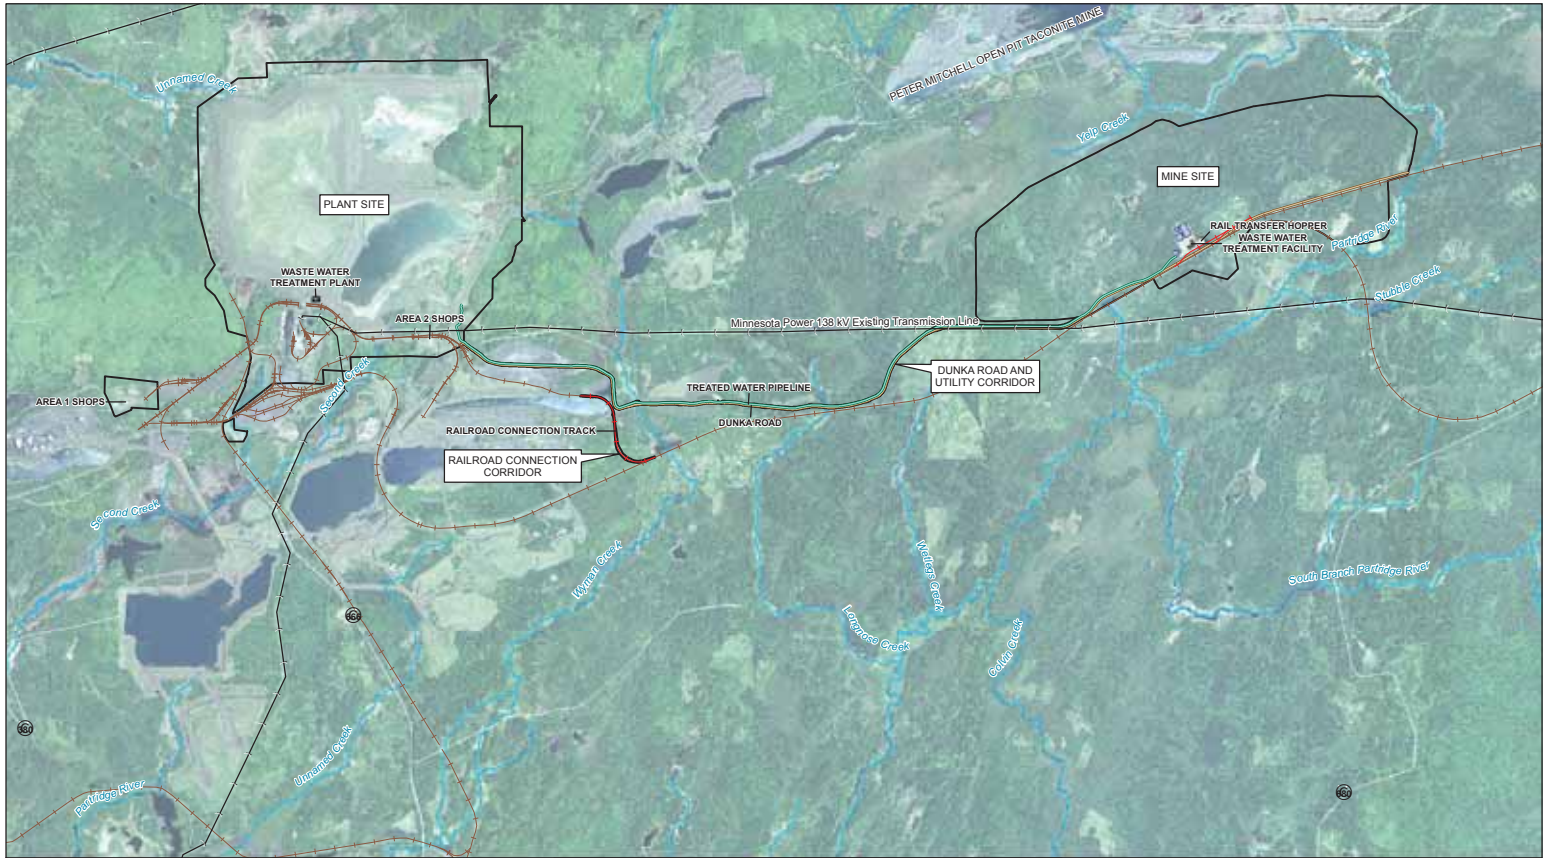

Figure 6
Transportation and Utility Corridor
 Biological Evaluation for the NorthMet Project and Land Exchange
 St. Louis County, Minnesota

To minimize the amount of ore that escapes from rail cars, ore would be loaded into the center of the car so that fines would be located at the center of the car and the larger ore pieces would be at the edge. The result would be that fines would be kept from reaching the edge of the car where they would be subject to spillage through the hinge gaps. Large pieces that extend over the edge of the rail car would be pushed into the center of the car using a rubber-tired dozer or a front-end loader. In the event that a large ore piece would fall over the top edge of the cars during transit, it would be recovered during routine track maintenance.

In order to guard against possible adverse impacts from spilled ore, monitoring and mitigation activities can be developed. It is expected that the surface water quality sampling in the two streams traversed by the rail line would be included in permit monitoring. Mitigation measures could include alterations to the stream crossings (bridges or culverts) to collect any spilled material or the physical collection of spilled ore from the top of the rail ballast.

2.1.5 Traffic

Transportation of Project consumables and products would result in traffic on public roads and commercial railroads. Public roads would also have additional traffic from employees and service providers.

2.1.5.1 Transport of Consumables and Products

Process consumables and products would be transported to and from the Plant Site by truck and by rail. This section describes the traffic on public roads and commercial railroad lines that would result from the Project.

Trucks transporting raw materials needed for the beneficiation process and the hydrometallurgical process would make approximately 80 round trips per month, entering the Plant Site from Highway 135. Trucks transporting copper and nickel concentrates would make up to approximately four round trips per day, also entering the Plant Site from Highway 135.

A locomotive, similar to the locomotives that would be hauling ore from the Mine Site to the Plant Site, would transfer loaded and empty cars carrying process consumables and concentrates to and from the interchange location with the Canadian National Railroad. Cars carrying process consumables and concentrate would meet railroad common carrier requirements.

Product shipment would require an approximately 100-car train once per month and a 30-car train 4 times per month, year-round. Process consumables would require an approximately 100-car train once per week, April through October. It is expected that outgoing PolyMet products would go by rail from the Plant Site to Virginia, Minnesota, with about half going south to Duluth, Minnesota, and the other half going north to International Falls, Minnesota. Product transport beyond Virginia is likely to be a part of the existing commercial rail traffic, with limited potential to generate additional commercial train trips. Process consumables would arrive at the Plant Site from the south from Duluth through Virginia. This movement is likely to be a part of the existing commercial rail traffic, with limited potential to generate additional commercial train trips.

2.1.5.2 Traffic from Employees and Service Providers

The Project would employ as many as 500 full-time workers over an 18-month period during peak construction period, and about 360 full-time workers during operation. There would be approximately 38 employee vehicles per day and 4 service vehicles per day entering the Main Gate (from County Road 666). In

addition, there would be approximately 113 employee vehicles per day and 36 service vehicles per day entering the North Gate (from Highway 135).

2.1.6 Project Reclamation

Mining is expected to be completed approximately 20 years after operations begin. This section summarizes information from the Reclamation Plan, which is a support document for the MDNR Permit to Mine, and focuses on those aspects of Project Reclamation that have potential effects on RFSS. Additional information on Project reclamation is available in the FEIS (MDNR et al. 2015).

In general, Project facilities have been designed and would be operated to allow for progressive reclamation, or “mining in a manner that creates areas that can be reclaimed as soon after initiation of the operation as practical and as continuously as practical throughout the life of operation” (Minnesota Rules, part 6132.0100). This would leave a smaller portion of the Project area needing to be reclaimed after closure. Project features that would be progressively reclaimed include the Waste Rock Stockpiles, the East Pit, exterior slopes of the Flotation Tailings Basin, and the Hydrometallurgical Residue Facility. The Waste Water Treatment Facility and the Waste Water Treatment Plant would remain operative during reclamation and long-term closure⁵.

2.1.6.1 Building and Structure Demolition and Equipment Removal

The buildings and structures would be removed and foundations razed. All mining, dewatering, and electrical equipment would be removed from the mine pit and scrapped, decommissioned, or sold. Debris and equipment would be removed from the Mine Site and Plant Site. Most roads, parking areas, or storage pads built to access these facilities would be demolished. Utility tunnels would be sealed and reclaimed in place. After demolition, these areas would be reclaimed and vegetated according to Minnesota Rules, part 6132.2700. All areas would be stabilized as required for stormwater management.

Demolition waste from structure removal would be disposed of in the existing on-site demolition landfill located northwest of the Area 1 Shop. Most concrete from demolition would be crushed and used for structural fill, placed in the basements of the Plant Site buildings, or placed in the existing on-site industrial landfill. Asphalt from paved surfaces would be removed and recycled or properly disposed of. Railroad track and ties that were not used by common carriers would be removed and recycled. All disturbed areas would be reclaimed and vegetated.

Any roads, including Mine Site access roads that may develop into unofficial off-road vehicle trails, would require a variance from MDNR reclamation rules to allow a 15-foot-wide unpaved, unvegetated track down the centerline of the road. Such approvals would also be coordinated with the St. Louis County Mine Inspector’s Office.

Special materials would be disposed of appropriately during reclamation:

- Any ore remaining in the Rail Transfer Hopper, the Ore Surge Pile, or anywhere else in the

⁵ “Long-term closure” is defined as being the time period when the West Pit has filled with water and the Waste Water Treatment Facility is discharging water to the outlet channel to the Upper Partridge River. This will likely occur during the post-closure maintenance period of reclamation.

vicinity of the Rail Transfer Hopper, as well as sediment removed from ditches and process water ponds, would be placed in the East Pit.

- Asbestos-containing materials would be removed intact, properly packaged, and disposed of in the on-site demolition landfill. The locations of asbestos-containing materials in the landfill would be noted on the property deed. Any asbestos-containing materials found in utility tunnels would be sealed before the utility tunnel is sealed.
- Fluorescent and sodium halide bulbs, nuclear sources, oil-stained concrete, and partially used paint, chemical, and petroleum products would be removed and recycled or properly disposed of.
- Any materials remaining in storage tanks would be sent to appropriate recycling or waste disposal facility. All storage tanks would be cleaned, disassembled, and recycled or disposed of appropriately. Tank foundations would be removed and all disturbed areas would be vegetated.
- Material remaining in the equipment and process piping would be properly disposed of in the Hydrometallurgical Residue Facility or other MPCA-approved locations.
- On-site sewer and water systems, powerlines, pipelines, and culverts would be closed according to regulatory requirements.

2.1.6.2 Reclamation of Mine Site

Mine Site reclamation would include building and structure demolition and equipment removal, mine pit reclamation, stockpile reclamation and watershed restoration. Mine Site reclamation would begin as soon as practical throughout operations, with reclamation of the East Pit and Waste Rock Stockpiles commencing before mining activities cease.

Mine Pit Reclamation

Mine pit reclamation would include pit flooding, construction of overflows and outlet control structures, sloping and vegetation of pit walls, and fencing to control access to the pits. East Pit reclamation would begin during operations, while West Pit reclamation would commence when mining activity ceases.

Mine pit dewatering systems would be removed from the pits and the pits would be allowed to flood with water. All areas disturbed during pipe removal would be graded and revegetated. Some temporary pumps may remain in the pits for dewatering that would be performed during pit flooding.

East Pit flooding would start in Mine Year 11 and be completed by Mine Year 20. Overflow from the East Pit would flow to the West Pit through a new ditch. An East Pit outlet structure would be built, which would establish the steady-state water level in the East Pit. The East Pit would be revegetated with wetland vegetation, resulting in approximately 207 acres of wetland (**Figure 7**).

Upon completion of mining operations, the West Pit would begin to flood naturally with groundwater, precipitation, and surface runoff from the tributary watershed. West Pit flooding would be accelerated with treated and untreated water from the Plant Site. With the addition of water pumped from the Plant Site to the

Figure 7
Mine Site Plan Long-term Closure
 Biological Evaluation for the NorthMet Project and Land Exchange
 St. Louis County, Minnesota

West Pit, West Pit flooding is projected to be completed between Mine Years 40 and 45. The West Pit would remain an open pit lake (MDNR et al. 2013).

When the West Pit is full, discharge would be prevented by pumping West Pit water to the Waste Water Treatment Facility for treatment. The Waste Water Treatment Facility would be upgraded to include reverse osmosis or similar membrane separation technology to achieve an effluent concentration that meets the sulfate standard for waters used for the production of wild rice (10 mg/l). After the upgrade, effluent would be discharged through Dunka Road into an existing wetland and eventually into the Partridge River through an existing tributary channel.

The overburden portions of the pit walls would be sloped, graded, and vegetated in accordance with Minnesota Rules, part 6132.2300. Lift heights would be selected based on the need to protect public safety, the location of the pit wall in relation to the surrounding land uses, the soil types and their erosion characteristics, the variability of overburden thickness, and the potential use of the pit following mining.

A pit perimeter fencing system would be installed consisting of fences, rock barricades, ditches, stockpiles, and berms. The barrier system plan would be submitted to the St. Louis County mine inspector for review and approval before installation. Safe access would be provided to the bottom of each mine pit via selected haul roads built during pit development. The access road would be selected such that, as pit water level rises, there would always be a clear path to the water surface. A gated entrance would be placed at each pit access location.

Stockpile Reclamation

Stockpile reclamation would begin during operations. Upon full reclamation of the Category 1 Waste Rock Stockpile, runoff from the top and sides of the stockpile would be classified as non-contact stormwater and discharged into the natural drainage system. The Category 1 Waste Rock Stockpile Groundwater Containment System would continue to collect drainage from the stockpile during reclamation, with drainage treated at the Waste Water Treatment Facility.

Watershed Restoration

During mining operations, stormwater runoff from reclaimed stockpile areas and natural (undisturbed) areas would be routed via dikes and ditches to stormwater sedimentation ponds. During reclamation, dikes and ditches that were no longer needed would be removed or filled and ponds would be filled. The reclaimed surfaces would then be scarified, topsoil placed on the surface, and the area revegetated with native species.

Surface runoff inflows would be routed to the mine pits using a combination of existing and new ditches. Some portions of the pit rim dikes may be left in place, if needed, to prevent an uncontrolled flow to or from the pits and potential erosion (head cutting) of the pits walls.

All stormwater ponds, the Overburden Storage and Laydown Area process water pond, haul road process water ponds, and all stockpile sumps and overflow ponds would be filled with overburden and peat (that was removed from the site during construction and stored in the Overburden Storage Area), and covered with topsoil and revegetated or converted into wetlands. If the process water ponds were converted into wetlands, any sedimentation that occurred within the pond would be evaluated to determine if removal of sediment or covering of the pond would be necessary prior to restoration. Stormwater pond outlet control structures would remain in place as necessary to manage water flows.

2.1.6.3 Reclamation of Plant Site

Plant Site reclamation would include building and structure demolition and equipment removal, Flotation Tailings Basin reclamation, and Hydrometallurgical Residue Facility reclamation. Similar to the Mine Site,

Plant Site facilities have been designed and would be operated to allow for progressive reclamation. Features that would remain at the Plant Site are shown on **Figure 8**.

The Waste Water Treatment Plant, Flotation Tailings Basin Seepage Management Systems, and Hydrometallurgical Residue Facility Leakage Collection System would continue to operate during reclamation, although seepage rates would be progressively reduced. Seepage would be recycled back into the Flotation Tailings Basin Pond or treated at the Waste Water Treatment Plant and pumped to the Mine Site to aid in West Pit flooding, or discharged.

Flotation Tailings Basin Reclamation

Permanent vegetation would be established on the Flotation Tailings Basin to control fugitive dust. Flotation Tailings Basin exterior dam surfaces would be reclaimed progressively, while interior areas would be seeded and mulched after closure.

Infiltration would be reduced through the dam faces, beaches, and pond bottom of the Flotation Tailings Basin by bentonite amendment. The exterior faces of the dams would be reclaimed progressively, with a bentonite layer added as they are constructed to limit oxygen diffusion. The exposed beaches and dam tops would be amended with a bentonite layer to limit oxygen diffusion. The pond bottom would be covered with a bentonite layer to maintain a permanent pond that would limit oxygen diffusion.

During reclamation, several sources of water from the Flotation Tailings Basin would require management. The sources and a summary of the type of management needed are described as follows:

- Pounded water within the Flotation Tailings Basin – a pond and wetland would remain in the Flotation Tailings Basin. The pond and wetland would receive surface water runoff from the crest and beaches of the basin and natural terrain adjacent to the Flotation Tailings Basin. The pond and wetland would continue to lose water via seepage, but at a reduced rate as compared to during operations as a result of the bentonite augmentation of the Flotation Tailings Basin pond bottom. Excess water would be pumped from the Flotation Tailings Basin pond to the Waste Water Treatment Plant for treatment prior to discharge.
- Stormwater management would include grading to provide a gently sloping surface that effectively routes surface water runoff to the interior of the Flotation Tailings Basin, and to accommodate future differential settlement of the underlying Flotation Tailings.
- An emergency overflow channel would be constructed to carry stormwater from the pond to the adjacent wetland in case of an extreme storm or snowmelt event after reclamation. The conceptual location of the emergency overflow channel is from the combined Cell 1/2E to the adjoining land.

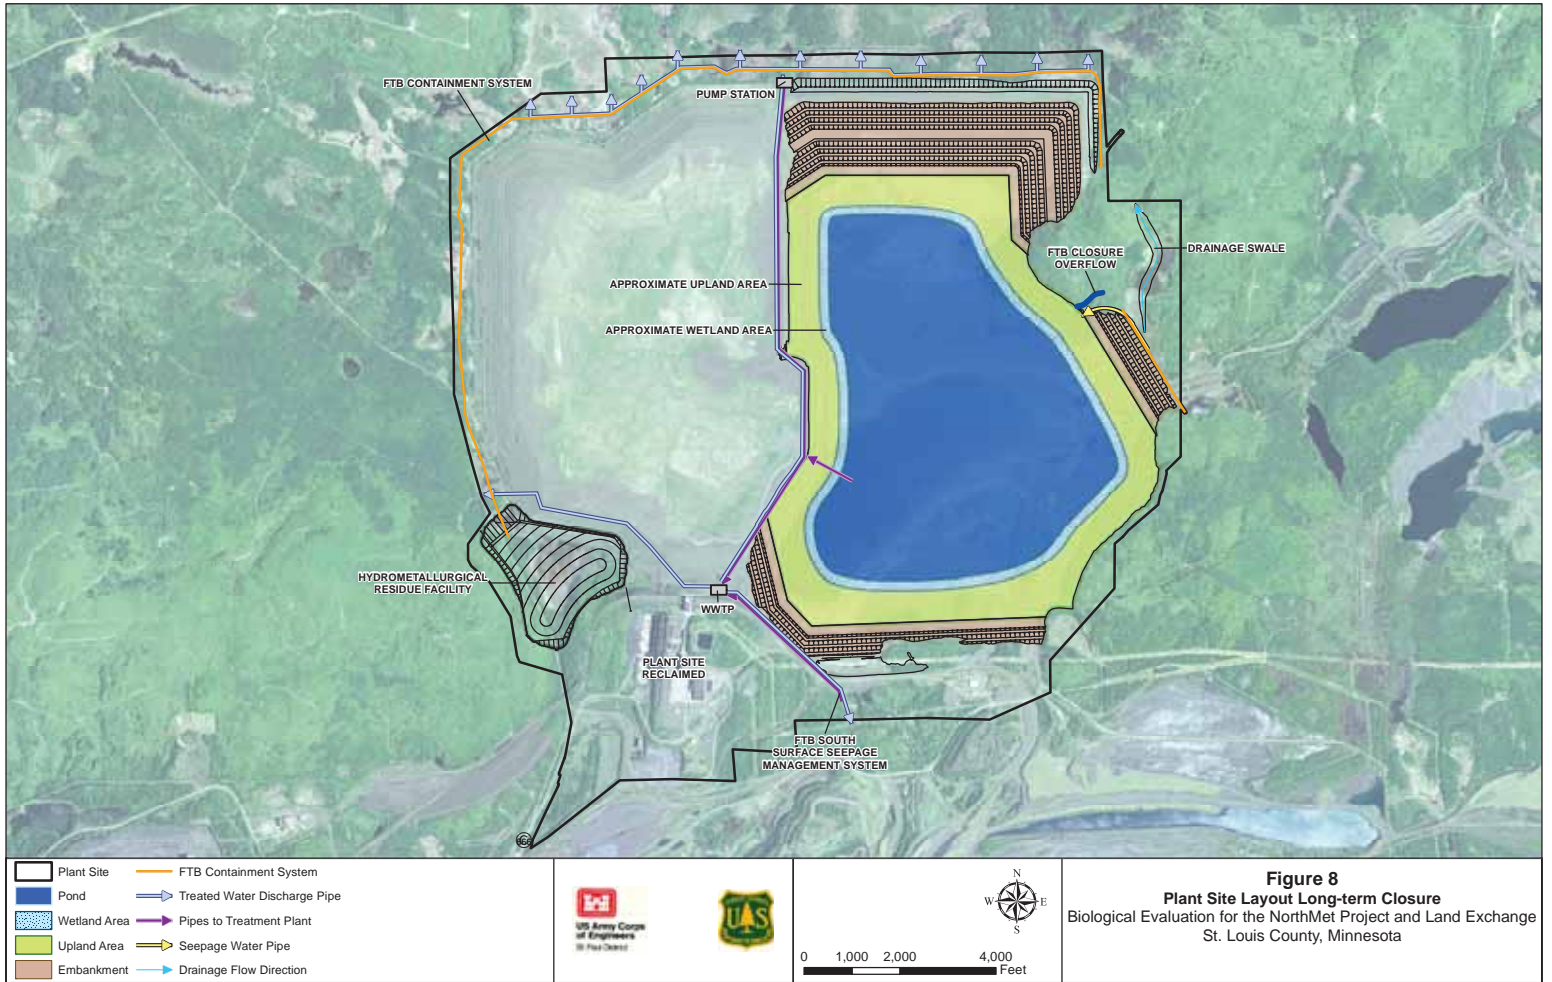

Figure 8
Plant Site Layout Long-term Closure
 Biological Evaluation for the NorthMet Project and Land Exchange
 St. Louis County, Minnesota

Hydrometallurgical Residue Facility Reclamation

Hydrometallurgical Residue Facility reclamation would include removal of ponded water from the Hydrometallurgical Residue Facility cell surface, removal of pore water from the residue, construction of the cell cover system, establishment of vegetation, and surface water runoff controls.

Ponded water remaining in the cell would be removed and treated at the Waste Water Treatment Plant. Drainage would be collected from the base of the cell at the geocomposite drainage system and managed as described for ponded water. The rate of drainage would decrease over time as the pore water within the Hydrometallurgical Residue Facility was collected and removed.

The hydrometallurgical cell area would be graded into a gently sloping surface, and an engineered cover system would be installed to limit infiltration. Permanent vegetation would be established over the cover system. The turf and final cover would be inspected, mowed once per year or as needed, fertilized if vegetation growth is poor, and repaired as needed.

The cover would slope gently toward the site perimeter to accommodate natural drainage of the runoff. Final cover slopes on the cell interior would be relatively shallow to minimize surface water runoff flow velocity and the associated erosion. Runoff channeled along the cell perimeter would be routed downslope via rip-rapped drainage swales or plug-resistant inlet structures and piping systems. Once runoff was conveyed down the cell exterior dam slope, it would be routed to the surrounding natural drainage system. All runoff would be from reclaimed cover or dam exterior slopes, which would be constructed of MDNR-approved material.

2.1.6.4 Long-Term Closure Activities

Mechanical water treatment systems (the Waste Water Treatment Facility and the Waste Water Treatment Plant) would continue to operate during long-term closure. The water collected by the Category 1 Waste Rock Stockpile Groundwater Containment System and the West Pit water would be treated using the Waste Water Treatment Facility (upgraded to reverse osmosis or similar membrane separation technology) to ensure that the discharge meets applicable water quality discharge limits. The Waste Water Treatment Plant would treat water collected by the Flotation Tailings Basin seepage capture systems, Hydrometallurgical Residue Facility Leakage Collection System, and excess Flotation Tailings Basin pond water, to meet applicable water quality discharge limits. Inspection, water treatment maintenance, and reporting activities would continue while the mechanical treatment systems operated during long-term closure.

Surface water and groundwater quality would be monitored. These long-term closure activities would be expected to be ongoing until such time as the various facility features are deemed environmentally acceptable, in a self-sustaining and stable condition.

Other long-term closure activities would include repair of stockpile and Flotation Tailings Basin dam slope erosion, up-keep of constructed wetlands and outflow structures, removal of shrubs and trees from the Hydrometallurgical Residue Facility and Category 1 Waste Rock Stockpile cover systems, and on-going operation/maintenance and inspection of the seepage capture systems at the Category 1 Waste Rock Stockpile and Flotation Tailings Basin.

When PolyMet has completed all reclamation and long-term closure activities required under the Permit to Mine, a Request for Release per Minnesota Rules, part 6132.1400 would be submitted to the MDNR. This

request would provide the Commissioner of the MDNR with detailed information on the final closure status of the Project.

2.1.7 Federal and Non-federal Lands

2.1.7.1 Land Exchange Process

As part of the Project, the Forest Service is considering transferring approximately 6,495 acres of federal lands to PolyMet in exchange for non-federal lands of similar value that have been offered for consideration by PolyMet (**Figures 2 and 3**).

The federal lands are in St. Louis County, approximately 60 miles north of the City of Duluth, 20 miles south of the Boundary Waters Canoe Area Wilderness (BWCAW), and 6 miles south of the City of Babbitt, Minnesota. The federal lands are bounded on the north by the Northshore taconite mine and on the south by the Dunka Road and Utility Corridor.

The proposed land exchange between the Government, acting through the Forest Service, and PolyMet is an assembled land exchange. The land exchange is proposed under the authority of the Weeks Act of March 1, 1911 as amended; General Exchange Act of March 20, 1922; Federal Land Exchange Facilitation Act of 1988; and the Federal Land, Policy and Management Act of October 21, 1976.

The proposed land exchange complies with the 2004 Forest Plan (USDA Forest Service 2004a). The federal lands are located within the General Forest and General Forest - Longer Rotation Management Area. The theme of the General Forest – Longer Rotation Management Area emphasizes land and resource conditions that provide a wide variety of goods, uses and services. The characteristics and use of the General Forest Management Area are similar to the General Forest – Longer Rotation Management Area, except that harvests are more frequent, more uniform in age, and more extensive. The General Forest Management Area has the highest amount of young forest and the largest-sized timber harvest units. Forested habitats on the federal lands can be categorized using the Forest Service’s Management Indicator Habitat (MIH), which describes dominant species, stand age class (young, immature, and mature), and stand condition (USDA Forest Service 2010a).

Land ownership adjustment direction for the General Forest and General Forest - Longer Rotation Management Area allows for the exchange of federal lands, with the desired condition described as “Land ownership patterns (federal, state, county, corporation and private) are consolidated, promote efficient administration and reduce the costs of managing resources.”

2.1.7.2 Federal Lands

The federal lands include approximately 2,719 acres of the 3,015-acre Mine Site and 3,776 acres of lands surrounding the Mine Site that are owned by the Government and administered by the Forest Service (**Figure 3**). The federal lands are located in Township 59 North, Range 12 West, Sections 6 and 7; Township 59 North, Range 13 West, Sections 1-12, 17, and 18; and Township 60 North, Range 13 West, Sections 33, 34, and 35 (**Figure 1**). Most of the federal lands are part of the General Forest – Longer Rotation Management Area, while the remainder is within the General Forest Management Area.

The federal lands include a portion of One Hundred Mile Swamp, a large black spruce, tamarack, and northern white cedar wetland, and Mud Lake. Yelp Creek and the Partridge River flow through the federal lands on the north, east, and southeast. Management of the 3,776 acres of federal lands surrounding the Mine Site may include some upland timber management to enhance wildlife habitat, however, wetland areas would be maintained in their natural state for the foreseeable future.

2.1.7.3 Non-federal Lands

PolyMet has acquired non-federal lands for transfer to the Government that encourage efficient land ownership patterns, with the desired condition of consolidating federal, state, county, corporate and private ownership to promote efficient administration and reduce the cost of managing resources to the Forest Service. The non-federal lands would be incorporated with adjacent federal ownership and managed in accordance with 2004 Forest Plan direction for that particular area (USDA Forest Service 2004a). Lands with obvious recreational values would be managed to enhance those public recreation opportunities. The non-federal lands assembled include five different lands totaling approximately 7,075 acres that are comprised primarily of forest and wetland habitat (**Figure 2**).

Hay Lake Lands

Hay Lake Lands are in central St. Louis County, Minnesota, and are approximately 3 miles west of Biwabik, Minnesota. The lands, located at the eastern end of the Mesabi Iron Range, include approximately 4,926 acres in all or portions of Sections 9, 16, 19, 20, 21, 27, 28, 29, 30, 31, and 32 in Township 59 North, Range 16 West. The lands are moderately hilly and consist predominantly of second- or third-growth deciduous and coniferous forest uplands and emergent, shrub swamp, and forested wetlands. Approximately 59% (2,931 acres) of the Hay Lake Lands consists of wetlands. The lands include Hay Lake, identified as a Wild Rice Water by the MDNR, and Little Rice Lake, and are bordered on the east by the Pike River. The Superior National Forest borders the lands to the north, east, and west. Forest Service lands adjacent to Hay Lake Lands are managed as General Forest and Candidate Research Natural Areas. Research Natural Areas are areas that the Forest Service has designated to be permanently protected and maintained in natural condition. These protected natural areas include unique ecosystems or ecological features; rare or sensitive species of plants and animals and their habitat; and/or high-quality examples of widespread ecosystems. Candidate Research Natural Areas are those areas which are in various stages of review for possible establishment as a Research Natural Area.

Hunting Club Lands

Hunting Club Lands are in northern St. Louis County, Minnesota, and include approximately 160 acres in Section 17, Township 66 North, Range 17 West. The lands are nearly level and consist predominantly of second- or third-growth deciduous and mixed coniferous/deciduous forest uplands and emergent, shrub swamp, and forested wetlands. Approximately 40% (64 acres) of Hunting Club Lands consists of wetlands. The lands are bordered by Forest Service and county lands. Nearby Forest Service lands are managed as General Forest – Longer Rotation.

Lake County Lands

Lake County Lands consist of approximately 382 acres, with 265 acres in Sections 5 and 6, Township 57 North, Range 11 West (Lake County Lands North), and 117 acres in Section 17, Township 56 North, Range 9 West (Lake County Lands South) in Lake County, Minnesota. The lands are administered by Lake County. The lands

are nearly level and consist predominantly of second- or third-growth mixed coniferous/deciduous forest uplands and bog, emergent, shrub swamp, and forested wetlands. Much of Lake County Lands South was recently logged. Approximately 74% (283 acres) of Lake County Lands consists of wetlands. The lands are bordered by the Superior National Forest. Forest Service lands near Lake County Lands North are managed as Riparian Emphasis Area and General Forest – Longer Rotation. Forest Service lands near Lake County Lands South are managed as General Forest – Longer Rotation. In Riparian Emphasis Areas, riparian ecological functions are actively restored, protected, and enhanced in areas where ecosystem processes are sensitive to degradation. This includes maintaining and restoring native vegetation communities; maintaining and restoring riparian/hydrologic functions such as shoreline stability, wildlife habitat, coarse woody debris recruitment to aquatic and riparian ecosystems, and temperature regulation; and controlling non-native invasive species. Restoration focuses on components of the ecosystem that are not functioning at or within the range of desired conditions. Those components that are functioning properly are protected. These areas are also managed for recreational opportunities and visual quality adjacent to bodies of water.

McFarland Lake Lands

McFarland Lake Lands are approximately 31 acres in Section 9, Township 64 North, Range 3 East, in Cook County, Minnesota. The lands are approximately 3 miles west of the U.S. - Canada border and 10 miles north of Hovland, Minnesota. The lands are mostly on a hillslope and consist of second- or third-growth deciduous and coniferous upland forest. McFarland Lake is an entry point to the BWCAW. There are no wetlands on the lands. The lands are bordered by Forest Service lands, which are managed as General Forest – Longer Rotation.

Wolf Lands

Wolf Lands total 1,576 acres and are comprised of 126 acres in Section 8, Township 57 North, Range 11 West (Wolf Lands 1); 769 acres in Sections 15 and 22, Township 58 North, Range 10 West (Wolf Lands 2); 277 acres in Sections 30 and 31, Township 59 North, Range 9 West (Wolf Lands 3); and 405 acres in Sections 7, 8, 15, 17, and 18, Township 59 North, Range 9 West (Wolf Lands 4) in Lake County, Minnesota. The lands are nearly level and consist predominantly of second- or third-growth mixed coniferous/deciduous forest uplands and bog, emergent, shrub swamp, and forested wetlands. Much of Wolf Lands 3 has been recently logged. Approximately 88% (1,393 acres) of Wolf Lands consists of wetlands. Forest Service lands border portions of all of Wolf Lands and are managed as General Forest (Wolf Lands 2, 3, and 4) and General Forest – Longer Rotation (Wolf Lands 1). Wolf Lands would supplement National Forest ownership by reducing federal exterior boundaries and would eliminate several private in-holdings.

2.2 Land Exchange Alternative B (Alternative B)

Alternative B was derived from the Mine Site Exchange-Only Alternative Proposed Action (refer to Sections 3.3.3.2 and 3.3.3.3.4 of the FEIS) that was developed to address concerns raised during scoping. This alternative would convey fewer acres of federal lands to the Government for fewer acres of non-federal land from PolyMet.

Land exchanges are based on equal value. Because there would be fewer federal acres available to be conveyed by the Government, there would be fewer acres of private land that would be acquired by the Government. The Government would convey approximately 4,753 acres of federal lands to PolyMet, and the Forest Service would no longer administer these lands. The Government would acquire approximately 4,926 acres of Hay Lake Lands (identified as Tract 1 – Hay Lake Lands in the FEIS). Hay Lake Lands were selected for this alternative for the following reasons:

- they would be almost equal in size to the smaller federal lands,
- they would provide wetlands, and
- it is likely that Hay Lake Lands would have a higher per-acre value than the federal lands because of their access to a county road and its potential for riparian lots.

The configuration of the smaller federal lands is the smallest acreage that would meet the Purpose and Need for the Land Exchange (**Figure 2**). Under Alternative B, approximately 1,742 acres to the west of the Mine Site would remain under federal ownership. These remaining federal lands would become an isolated piece of federal land with limited or difficult access through private property. As with the Land Exchange Proposed Action, the Forest Service would reserve ownership of 181 acres of mineral rights scattered across the federal lands. These minerals are located outside of the mine pits.

2.3 Land Exchange No Action Alternative (No Action Alternative)

Under the No Action Alternative, the Project would not occur and no lands would be exchanged. The Government would not convey federal lands to PolyMet and the Forest Service would continue administering these lands as has been done in the past. The level of development and acceptable activities would continue to be regulated by Forest Service and Superior National Forest policies. Management would include vegetation management, mineral exploration, recreation, wildlife, watershed, and other uses identified in the 2004 Forest Plan. These lands are in General Forest – Longer Rotation and the General Forest Management Areas. Furthermore, under the No Action Alternative, the Government would not acquire the five tracts of non-federal lands and the non-federal lands would remain as private lands.

At the Mine Site, PolyMet would be required under exploration approvals to reclaim surface disturbance associated with exploratory and development drilling activities. Other existing surface uses would be allowed to continue consistent with 2004 Forest Plan.

No further upgrades or new segments would be constructed along the existing power transmission line, railroad, or Dunka Road, which would continue to be used by their private owners.

At the brownfield Plant Site, Cliffs Erie would be required to complete closure and reclamation activities required under an existing MDNR- and MPCA-approved reclamation program. This would include completing activities for the localized affected areas under the Minnesota Voluntary Investigation and Cleanup Program, removal of the former Plant Site building, and management of seepage at the Flotation Tailings Basin embankment.

3.0 Description of the Lands Affected by the Project

3.1 Federal Lands

Federal lands under the Proposed Action include approximately 2,719 acres at the 3,015-acre Mine Site and 3,776 acres surrounding the Mine Site that are owned by the Government and administered by the Forest Service (**Figure 3**). For Alternative B, the federal lands would include the 2,719 acres at the Mine Site and 2,034 acres surrounding the Mine Site.

The Forest Service designates and maintains data regarding MIH types on federal lands (USDA Forest Service 2004a: Appendix C, 2010a). The MIHs are based on forest type, including dominant species, stand age class, and stand condition. There are 14 MIHs, of which 13 MIHs pertain to forest habitats and 1 MIH pertains to aquatic habitats. A subset of these MIH types was used for the analysis of effects in the BE, including upland forest types (MIH 1; jack pine, red pine, white pine, balsam fir/trembling aspen-paper birch, black spruce-balsam fir, black spruce-jack pine, northern hardwoods, including oak and maple, trembling aspen, paper birch, and trembling aspen-black spruce-balsam fir); upland coniferous forest (MIH 5; all upland conifer and conifer-dominated mixed forest types); lowland black spruce-tamarack forest (MIH 9; all lowland conifer and lowland mixed conifer types dominated by black spruce or tamarack); and aquatic habitats (MIH 14; lakes, rivers, streams, pond, marshes or pools [permanent, intermittent, or seasonal]). The MIH types for the federal lands are shown on **Figure 9**, and for the non-federal lands are shown on **Figures 10 and 11**. **Tables 5 and 6** provide a summary of MIH type acreage on the federal and non-federal lands and gains and losses of MIH type acreage that would be administered by the Forest Service under the Proposed Action and Alternative B.

The MDNR developed the Gap Analysis Program (GAP) to identify land cover types (MDNR et al. 2013). The GAP land cover system is a hierarchical land classification system that organizes vegetation communities into 1-acre blocks. The GAP land cover types for the federal lands are shown on **Figure 12**, and for the non-federal lands on **Figures 13 and 14**. **Tables 5 and 7** provide a summary of GAP cover type acreage on the federal and non-federal lands and gains and losses of GAP cover type acreage that would be administered by the Forest Service under the Proposed Action and Alternative B.

Wetlands on the federal and non-federal lands were identified using the Eggers and Reed (1997) community types. Forest wetland types include coniferous bog, coniferous swamp, and hardwood swamp. Non-forested wetlands types include deep marsh, open bog, open water (includes shallow, open water and lakes), sedge/wet meadow, shallow marsh, and speckled alder thicket and shrub-carr. Wetland community types for the federal lands are shown on **Figure 15**, and for the non-federal lands on **Figures 16 and 17**. **Table 8** provides a summary of wetland community type acreage on the federal and non-federal lands and gains and losses of wetland cover type acreage that would be administered by the Forest Service under the Proposed Action and Alternative B.

3.1.1 Mine Site

The Mine Site encompasses 3,015 acres; 2,719 acres are Government owned while 296 acres are privately owned (**Figure 3**). The Mine Site has little topographic relief. The site consists of a mosaic of slightly elevated upland areas surrounded by wetlands, with the northern portion of the site sloping toward the east-northeast and the remainder of the site sloping to the south-southwest, in the direction of the Partridge River. About 57% of the Mine Site is upland habitat, and 43% is wetland habitat (PolyMet 2014a).

Sources: MDNR et al. (2013), PolyMet (2013, 2014).

Most upland habitat is associated with the central portion of the Mine Site. One Hundred Mile Swamp, which borders much of the Mine Site, is the dominant feature on the landscape. The Partridge River flows along and outside the northeastern and eastern boundary of the Mine Site (**Figure 3**).

Habitat observed on the Mine Site is typical of habitats associated with much of the Iron Range. Forest vegetation dominates the Mine Site (**Figures 9 and 12**). Most forest stands contain trees that are 12 inch diameter-at-breast-height (dbh) or less.

The site can be divided into three general areas. The northwestern area is dominated by lowland black spruce, with scattered stands of trembling aspen and balsam fir/trembling aspen; tamarack is also scattered throughout these stands (ENSR 2000, 2005). Most trees are estimated to be 60 years or older (USDA Forest Service 2000b). Interspersed within forest stands are brush/young tree stands in areas that were recently logged and that provide habitat for deer and moose. Several wetlands are found in the northwest area, with One Hundred Mile Swamp comprising most of the western and northern portions of this area, including the federal lands surrounding the Mine Site.

The northeastern area is dominated by nearly equal amounts of jack pine and black spruce, with scattered trembling aspen stands and speckled alder swamps (ENSR 2000, 2005). Although there are scattered black spruce stands containing trees greater than 60 years in age, most trees, especially jack pine, are 30 to 70 years in age (USDA Forest Service 2000b). There are a few recently logged areas within this area. Several large wetlands are found in this area. Most shrub/young tree habitat is associated with these wetlands and drainages.

The southern area contains a nearly equal mix of lowland and upland black spruce, jack pine, and trembling aspen, with some balsam fir and paper birch (ENSR 2000, 2005). Most tree stands are from 40 to 80+ years of age, although jack pine tree stands along Dunka Road are from 20 to 40 years of age.

Vegetation in the recently logged areas consists of grasses and ferns with trembling aspen saplings and speckled alder (ENSR 2000, 2005). The areas of more mature upland forests consist of jack pine, balsam fir, and trembling aspen, with lesser amounts of paper birch, red pine, and white pine. The mature lowland areas consist mainly of black spruce and tamarack growing on a bed of sphagnum moss and club moss with speckled alder, bog Labrador-tea, and leatherleaf. The open wetland areas consist of grasses, sedges, cattails, speckled alder, and pussywillow.

Approximately 1,719 acres of the Mine Site would be affected by the Project. **Table 9** shows the cover types that would be affected by the Project.

3.1.2 Federal Lands Surrounding the Mine Site

Federal lands surrounding the Mine Site encompass about 3,776 acres surrounding the Mine Site to the west, north, and east. This area has little topographic relief. The lands consist of a mosaic of slightly elevated upland areas surrounded by wetlands, and slope toward the east-northeast, in the direction of the Partridge River. Most (76%) of the area is wetland habitat, including a portion of One Hundred Mile Swamp, although upland habitat (24%) is an important component in the western portions of the area (**Figures 12 and 15, Table 6**). Yelp Creek flows from One Hundred Mile Swamp, joining the Partridge River, which flows around the northern, eastern, and southeastern edges of the federal lands, outside of the Mine Site (AECOM 2011a).

DESCRIPTION OF LANDS AFFECTED BY PROJECT

Forest vegetation dominates the federal lands. Most forest stands contain trees that are 12 inches dbh or less. The area can be divided into three general parts (AECOM 2011a). The eastern portion is dominated by the Partridge River. Large stands of lowland black spruce with scattered northern white cedar and tamarack are found in low areas associated with the river. Emergent and speckled alder wetland is adjacent to most of the river. Stands of immature (trees from 5 to 11 inches dbh, and from about 10 to 80 years of age) and mature (trees greater than 11 inches dbh and over 80 years of age) mixed coniferous/deciduous forest, coniferous forest dominated by jack pine, and smaller patches of immature deciduous forest, are found at higher elevations (USDA Forest Service 2000b).

The northern portion of the federal lands surrounding the Mine Site includes a portion of One Hundred Mile Swamp. The swamp is comprised of some young (trees less than 5 inches dbh and less than 10 years of age), but mostly immature and mature black spruce, northern white cedar, and tamarack forests (AECOM 2011a). Northern white cedar is prevalent in the northcentral portion of the northern area, while black spruce and tamarack are more common in the remaining areas. Scattered stands of speckled alder are associated with the swamp, as are bog and emergent wetlands, especially along the Partridge River. There are scattered “islands” of mature deciduous and mixed coniferous/deciduous forest. Most of the forest stands are 90 years or older, with many of the remaining stands 70 to 90 years of age (USDA Forest Service 2000b).

The western portion of the federal lands surrounding the Mine Site are dominated by lowland immature black spruce forest in its center, bordered by bog wetlands and wetlands dominated by speckled alder and red-osier dogwood (AECOM 2011a). A large area dominated by cattail is associated with the transmission line rights-of-way (ROW). Upland immature and mature deciduous and mixed coniferous/deciduous forest, with scattered stands of coniferous forest, surrounds the centrally located black spruce forest. Clearings comprised of grasses, forbs, and shrubs are associated with the transmission line ROW, while scattered low areas, dominated by emergent and shrub swamp wetland vegetation, are interspersed within upland forest habitats.

Table 9
GAP Cover Types Affected by the Project at the Mine Site

Source: MDNR et al. (2013).

3.2 Plant Site and Transportation and Utility Corridors

The Plant Site encompasses about 4,515 acres, which include the former LTVSMC processing plant, existing LTVSMC Tailings Basin, Area 1 Shop, Hydrometallurgical Residue Facility, and administration buildings. There is no federal land at the Plant Site.

The southwestern corner of the Plant Site, the former LTVSMC processing plant, has almost entirely been disturbed by past mining activities. No wetlands are present within this portion of the Plant Site, although there is a plant reservoir east of the concentrator that is not regulated as a wetland (PolyMet 2014a). The regulated wetlands within the Plant Site include a total of 52 wetlands covering approximately 245 acres. Using the MDNR GAP land cover types, approximately 61% (2,756 acres) of the Plant Site is disturbed and supports little vegetation. The remaining areas consist of trembling aspen and trembling aspen-paper birch forest (14%), aquatic habitat (14%), grass/brushland (7%), upland coniferous forest (2%), and lowland coniferous forest (1%; MDNR et al. 2013).

The Dunka Road and Utility Corridor is approximately 108 acres and the Railroad Connection Corridor is approximately 12 acres. There is no federal land in the Railroad Connection Corridor; however there is some federal land in the Dunka Road and Utility Corridor (**Figure 3**). Because of prior use during the former LTVSMC taconite mining operation, the Dunka Road and Utility Corridor is now defined as having a “disturbed” cover type. The remaining MDNR GAP land cover types that are not disturbed include cropland/grassland (8%), shrubland (6%), and smaller acreages of the remaining types. A total of 25 wetlands, encompassing approximately 7 acres, have been identified within the Dunka Road and Utility Corridor (MDNR et al. 2013).

3.3 Non-federal Lands

3.3.1 Hay Lake Lands

Hay Lake Lands are approximately 4,926 acres and have moderate topographic relief. The lands consist of a mosaic of slightly elevated upland areas surrounded by wetlands, and slope toward the east-northeast, in the direction of the Pike River (AECOM 2011b).

Most (59%) of Hay Lake Lands is wetland habitat, although upland habitat (41%) is an important component in the central and western portions of the lands (**Figure 16**). The Pike River, Hay Lake, and Little Rice Lake are dominant features of the landscape. The Pike River flows along the eastern boundary of the lands.

Forest vegetation dominates Hay Lake Lands. Nearly all forest stands contain trees that are 12 inches dbh or less, and most of the upland trees are 8 inches dbh or less. The lands can be divided into four general habitats. The eastern portion is dominated by the Pike River. Floodplain associated with river is dominated by emergent wetland with sedge and grass habitat, and shrub swamp wetland with speckled alder habitat. Wetland areas to the west of the river are dominated by lowland black spruce forest, with scattered northern white cedar and tamarack, and shrub swamp wetlands, especially in areas with evidence of past disturbance by logging activities.

Higher elevations in the northern, central, and western portions of the lands are dominated by upland deciduous and mixed coniferous/deciduous forest. Upland forest stands in the northern, central, and southwestern portions of the lands are immature to mature in size and age, while stands in the western portion of the lands are young to immature in size and age, having been harvested in recent years. Most trees are estimated to be 60 years or

younger. Two transmission line ROWs are found on the lands. Emergent wetland and upland grassland/shrubland vegetation dominates the ROWs. Abandoned logging roads are also found on the lands. Low areas along roads are dominated by emergent wetland vegetation consisting of sedges and grasses, while upland portions of roads are dominated by grasses and forbs.

3.3.2 Hunting Club Lands

Hunting Club Lands are approximately 160 acres, of which about 64 acres are wetland (**Figure 17, Table 5**). The lands drain to the north and then northeast via an unnamed creek. Several beaver dams are found along the creek. From this low area, the lands slope upward to the east and west. The lands consist primarily of shrub swamp wetland, with lesser amounts of emergent wetland, and upland immature and mature deciduous forests (AECOM 2011c).

Beaver ponds and dams are the dominant wetland features on the lands. Open water habitat is typical near the dams. Emergent vegetation, consisting of Canada bluejoint, narrow-leaved cattail, and sedges, is found in water from 12 to 24 inches deep, while shrub swamp is found near ponds at water depths from 6 to 18 inches. Speckled alder makes up to 80% of the cover in the shrub swamp wetlands. A large immature black spruce forest is found in the middle of Hunting Club Lands. The midstory consists of speckled alder, while leatherleaf, bog Labrador-tea, and sphagnum moss are found below the speckled alder. Immature black ash is found in a drainage leading to wetlands on the lands.

Habitat in the northwestern and northeastern portions and near the southern boundary of the lands is comprised of upland mature mixed coniferous/deciduous forest, dominated by eastern white pine to 24 inches dbh, and paper birch and trembling aspen to 12 inches dbh. The midstory consists primarily of balsam fir, while beaked hazel is found in the shrub layer.

The eastern and southern portions of the lands consist of patches of upland young and immature trembling aspen. The midstory consists of beaked hazel, with scattered black spruce and balsam fir. There is little ground cover. An “island” of trembling aspen-eastern white pine forest is found within the young and immature trembling aspen forest. It consists of young mature forest comprised of trembling aspen and eastern white pine to 16 inches dbh and black spruce to 12 inches dbh. There are many downed trees and much woody debris on the ground.

3.3.3 Lake County Lands

Lake County Lands consist of Lake County Lands North and Lake County Lands South.

3.3.3.1 Lake County Lands North

Lake County Lands North is approximately 265 acres, of which about 209 acres are wetland (**Figure 16, Table 5**). The lands have moderate topography, with the terrain generally sloping toward the southwest and Pine Lake. Lake County Lands North consists of two small areas to the north, and a single, small area to the south that is adjacent to Wolf Lands 1. The lands are comprised of mostly wetland habitat, except for areas of upland habitat on the northern portion of the northern area and on portions of the southern area. Portions of the lands have recently been logged. Wetland habitat consists mostly of immature coniferous forest, with lesser amounts of mature mixed coniferous/deciduous forest and shrubland. Upland habitat is dominated by mature deciduous and immature deciduous forests (AECOM 2011c).

Wetlands are comprised primarily of immature northern white cedar and black spruce with lesser amounts of tamarack, although several drainages also contain black ash. The midstory consists of balsam fir and black spruce, while speckled alder, leatherleaf, and bog Labrador-tea are found in the shrub layer. Club moss and sphagnum moss cover most of the ground.

Shrub swamp and emergent wetland habitats are also found on the lands. Shrub swamp habitat is associated with several drainages, a beaver pond, a bog area, and recently logged areas, while emergent wetland habitat was found near the beaver pond and on recently logged areas. Shrub swamp wetlands are dominated by speckled alder. Vegetation in the emergent wetlands consists of sedges and Canada bluejoint, with scattered black spruce, northern white cedar, tamarack, and speckled alder.

Upland habitats are comprised of immature and mature paper birch and black spruce, while recently logged areas supported young paper birch stands or shrub habitat. The midstory cover is comprised of balsam fir, black spruce, and beaked hazel. Young paper birch with scattered young trembling aspen and scattered immature paper birch are in areas that had been recently logged.

Older forests contain large amounts of downed woody material; this material is mostly absent in logged areas. Tree wind-throw is common in forest stands adjacent to the clearcuts, and walking in these forests is difficult due to downed trees and woody debris, and the dense stand of balsam fir, black spruce, and northern white cedar in the midstory.

3.3.3.2 Lake County Lands South

Lake County Lands South is approximately 117 acres, of which about 74 acres are wetland (**Figure 16, Table 5**). The lands are relatively flat in the northwest, rise in elevation to the northeast, and fall in elevation to the southeast. Water flows from west to east. A series of beaver dams and ponds dominate the landscape. Several areas have been recently logged and the dominant upland habitat is shrubland (AECOM 2011c).

Forested wetlands dominate the western and southeastern portions of the lands and are comprised of immature and mature black spruce and northern white cedar, although immature tamarack is found in some forest stands and immature black ash is an important component of several drainages. The midstory consists of balsam fir and black spruce. Speckled alder, leatherleaf, bog Labrador-tea, and red-osier dogwood are common shrubs, while sphagnum moss covered most of the ground. Forests in the northwestern portion contain a dense mix of northern white cedar and black spruce with scattered black ash in the drainages. The northwestern area of the northwestern portion is dominated by immature and mature northern white cedar.

Five beaver ponds were found on the lands. These ponds are comprised of open water with scattered dead spruce surrounded by emergent wetland dominated by sedges, narrow-leaved cattail, woolgrass, and Canada bluejoint, or by dense stands of speckled alder in shallow-water areas. Shallower-water drainages, especially in areas that have been logged, are covered by speckled alder, sedges, and narrow-leaved cattail.

Most upland areas have been recently clear-cut, with the exception of the southwestern section of the lands. This area has been partially thinned, leaving areas where mature paper birch, black spruce, jack pine, eastern white pine, and northern white cedar trees remain, ranging from 12 to 24 inches dbh. Balsam fir and beaked hazel are found in the midstory, while forbs and grasses cover the ground layer. Because of recent logging activity, woody debris and large downed trees are abundant.

3.3.4 McFarland Lake Lands

McFarland Lake Lands are about 31 acres on a hillslope that rises from 1,483 feet above mean sea level at McFarland Lake to 1,778 feet above mean sea level on the western boundary of the lands. Rocky cliffs, about 150 feet in height, are found at the top of the hillslope and large boulders are found on the hillslope (AECOM 2011c).

McFarland Lake Lands are dominated by deciduous and mixed coniferous/deciduous forest habitats (**Figure 17, Table 5**). Tree sizes and ages range from immature to mature. Some logging has occurred at the top of the hillslope along the western boundary of the lands.

3.3.5 Wolf Lands

Wolf Lands total 1,576 acres and consist of four parcels, Wolf Lands 1, 2, 3, and 4.

3.3.5.1 Wolf Lands 1

Wolf Lands 1 is approximately 126 acres, of which about 90 acres are wetland (**Figure 16, Table 5**). Most upland habitat consists of mature coniferous and deciduous forest, while most wetland habitat consists of immature coniferous forest. The lands are relatively flat but slope gently downward toward the southwest. The lands are adjacent to Lake County Lands North (AECOM 2011c).

Wetland communities are comprised primarily of young and immature forests in nearly equal amounts. Young forests are comprised of black spruce, with scattered northern white cedar and tamarack. Young forests have characteristics of more open bogs, as tree cover is sparse, trees are short, and most of the ground is covered by bog Labrador-tea and leatherleaf, and sphagnum moss. In immature forests, the canopy is dominated by 6 to 10 inches dbh black spruce, with tamarack and northern white cedar also present. The midstory consists of balsam fir and black spruce, while speckled alder, leatherleaf, bog Labrador-tea, and red-osier dogwood dominate the shrub layer. Club moss and sphagnum moss cover most of the ground (AECOM 2011c).

Upland mixed coniferous/deciduous immature and mature forest is found in the southwestern portion of the lands. Paper birch and trembling aspen cover about half of the area, and the midstory consists of mostly balsam fir; beaked hazel, and red-osier dogwood.

3.3.5.2 Wolf Lands 2

Wolf Lands 2 is approximately 769 acres, of which about 706 acres are wetland (**Figure 16, Table 5**). The lands consist of gently undulating terrain and slope toward the southwest. Water generally flows to the southwest and to Mary Ann Creek, Wenho Creek, and Greenwood Lake. The lands consist primarily of wetlands comprised of immature black spruce and northern white cedar forest, while shrub swamp comprised of speckled alder also is common. Black spruce is the dominant tree in wetlands in the northern and eastern portions of the lands, while northern white cedar is more prevalent in other portions of the lands (AECOM 2011c). Several drainages are dominated by speckled alder or have a black ash component, while emergent wetland habitat is associated with beaver ponds. Most upland habitat consists of immature mixed coniferous/deciduous forest.

Wetland immature forests are of three types: black spruce dominant, a mix of black spruce and northern white cedar, or northern white cedar dominant. Canopy trees range from 4 to 8 inches dbh. The midstory consists of

young black spruce, northern white cedar, and balsam fir. Bog Labrador-tea comprises 10 to 30% of the low shrub cover, while sphagnum moss often covers more than 80% of the ground.

Several drainages are dominated by shrub swamp vegetation. These drainages generally have a sparse overstory of black spruce, northern white cedar, and tamarack. Speckled alder and young trees are in the midstory while low shrub cover consists of bog Labrador-tea.

Beaver dams and ponds are found in the southeastern portion of the lands. Typically, open water is adjacent to the dams, with emergent wetland surrounding the open water and shrub swamp wetland upstream of the dams.

Upland habitat in the northern portion of the lands consists of an overstory of young and immature mixed coniferous/deciduous forest over a shrub layer of beaked hazel. Some of the upland area on the northern portion of the lands has been logged. Upland habitat is also found in the southern portion of the lands and is comprised of paper birch, trembling aspen, and black spruce, over a midstory of balsam fir and shrub layer of beaked hazel.

3.3.5.3 Wolf Lands 3

Wolf Lands 3 is approximately 277 acres, of which about 233 acres are wetland (**Figure 17, Table 5**). The lands are relatively flat and Coyote Creek begins its northward flow within the lands. Wetlands are dominated by shrub swamp and immature coniferous forest habitat, while uplands consist of mostly shrubland and immature deciduous forest (AECOM 2011c).

About half of the lands have been recently logged. Logged wetlands are dominated by grasses, forbs, and low growing shrubs, including red-osier dogwood and speckled alder. In shrub swamp wetlands, speckled alder dominates. Bog Labrador-tea is often thick in areas where there is a dense cover of speckled alder. Vegetation on logged uplands includes grasses, forbs, and beaked hazel.

In the unlogged areas, wetland forests are comprised of immature black spruce. In the northern portion of the lands, black spruce is co-dominant with tamarack; in the rest of the lands, tamarack is present in the canopy but in much lower amounts. The midstory consists of balsam fir and black spruce, while the shrub layer is dominated by bog Labrador-tea, over a ground layer of nearly continuous sphagnum moss with scattered grasses and forbs. There are numerous downed trees and much woody debris associated with tree wind-throw in areas adjacent to the clearings.

Coyote Creek is bordered by emergent sedge meadow wetland comprised of sedges, narrow-leaved cattail, and Canada bluejoint. There are also scattered young tamarack and northern white cedar, as well as scattered patches of speckled alder and bog Labrador-tea. The emergent wetland is bordered by dense speckled alder. Water depth in the emergent and shrub swamp wetlands is about 18 to 24 inches.

Upland areas within the lands have been logged recently. Most of these areas have few trees remaining, though some areas still support paper birch up to 16 inches dbh and scattered balsam fir. The upland habitat along the boundary of the lands consists of both young and mature paper birch with scattered black spruce and northern white cedar, over an understory comprised of balsam fir.

3.3.5.4 Wolf Lands 4

Wolf Lands 4 is approximately 405 acres, of which about 363 acres are wetland (**Figure 17, Table 5**). Coyote Creek bisects the lands, while the Stony River is found about 2,000 feet northwest of the lands. Timber harvests have recently occurred along the western border of the lands. Wetland habitats are dominated by immature coniferous forest and shrub swamp, while upland habitat consists primarily of mature deciduous forest (AECOM 2011c).

Coniferous forest dominates the wetland habitat. Black spruce forest dominates in the northern half of the lands, while northern white cedar is more prevalent in the southern half of the lands. Immature-size trees prevail over most of the lands, but patches of young black spruce are more common in the northeastern portion of the lands, and young northern white cedar and black spruce are more common in the southwestern portion of the lands. Emergent communities comprised of sedges and Canada bluejoint, and shrub swamp communities comprised primarily of speckled alder, are found in floodplains that border Coyote Creek.

Immature black spruce and black spruce/northern white cedar wetlands are dominated by trees ranging from 4 to 8 inches dbh. Scattered young and immature tamarack is also found in these wetlands. The low shrub layer is nearly continuous, and is comprised of leatherleaf, bog Labrador-tea, and other vegetation. Sphagnum and club mosses cover most of the ground.

Shrub swamp is dominated by speckled alder, with scattered black spruce, tamarack, and northern white cedar in the overstory. Leatherleaf and bog Labrador-tea cover comprise about 40 to 50% of the shrub layer.

Upland habitat consists of immature and mature paper birch and some black spruce. Trees are up to 18 inches dbh, although a 30 inches dbh jack pine and several large red pines to 24 inches dbh are found on the lands. Balsam fir is common in the midstory, while beaked hazel and raspberry are dominant in the shrub layer. In areas that have been logged recently, young paper birch is common over a shrub layer of beaked hazel, raspberry, and bog Labrador-tea.

4.0 Biological Evaluation Methodology

This section discusses the methods and references used for the literature review, database inquiries, consultations, field studies, and effects determination for the BE. This information is used in Section 5.0 for the analysis and determination of effects for all RFSS plants and animals.

4.1 Literature Review

4.1.1 Biological Evaluations

Several recent BEs have been prepared for proposed actions on or near the federal and non-federal lands and provided information that is used in this BE and include:

- *Forest Plan Revision Chippewa and Superior National Forests Regional Forester Sensitive Plants Biological Evaluation* (USDA Forest Service 2004c) and *Forest Plan Revision Chippewa and Superior National Forests Regional Forester Sensitive Animals Biological Evaluation* (USDA Forest Service 2004d; collectively 2004 Forest Service BEs) – evaluated potential effects to RFSS plants and animals from proposed vegetation management activities in the Chippewa and Superior National Forests, including federal lands.
- *Whyte Forest Management Project Laurentian Ranger District, Superior National Forest Biological Evaluation Region 9 Regional Forester Sensitive Species* (USDA Forest Service 2006) – evaluated potential effects to RFSS plants and animals from proposed forest management activities in Lake County.
- *Tracks Forest Management Project Laurentian Ranger District, Superior National Forest Biological Evaluation Region 9 Regional Forester Sensitive Species* (Tracks Project BE; USDA Forest Service 2010b) – evaluated potential effects to RFSS plants and animals from proposed forest management activities on the Tracks Forest Management Project (Tracks Project) area east of Hoyt Lakes and north of Brimson, Minnesota, in Lake and St. Louis Counties, and near the Project area. The Track Project area encompasses about 152,000 acres of land of which approximately 78,000 acres are in the Superior National Forest.
- *Regional Forester Sensitive Species Biological Evaluation for the Federal Hardrock Mineral Prospecting Permits Final EIS Appendix I Superior National Forest* (USDA Forest Service 2012) – evaluated potential effects to RFSS plants and animals from proposed hardrock mineral prospecting activities in the Superior National Forest, including the federal lands.

4.1.2 Other Sources of Information

- *Winter 2000 Wildlife Survey for the Proposed NorthMet Mine Site, St. Louis County, Minnesota* (ENSR 2000).
- *Land and Resource Management Plan for the Superior National Forest* (USDA Forest Service 2004a).
- *NorthMet Mine Summer Fish and Wildlife Study* (ENSR 2005).
- *2009 NorthMet Mine/Forest Additional Parcel Northern Goshawk and Owl Survey – Final Report* (AECOM 2009).

- *2008 NorthMet Mine/Forest Service Additional Parcel Summer Wildlife and Wetland Assessment – Final Report* (AECOM 2011a).
- *2009 Hay Lakes Parcel and McFarland Lake Parcel Summer Wildlife and Wetland Assessment Final Report* (AECOM 2011b).
- *Hunting Club, Lake County, and Wolf Land Parcels Fall 2010 Wildlife and Wetland Assessment Final Report* (AECOM 2011c).
- *NorthMet Mining Project and Land Exchange Draft Supplemental EIS* (MDNR et al. 2013).
- *Superior National Forest Bat Monitoring: Summary of 2013 Survey Effort* (Grandmaison et al. 2013).
- *Summary of Acoustic and Emergence Surveys for Bats in the NorthMet Project Area* (USDA Forest Service 2014a).
- *Summary of the 2014 Minnesota Northern Long-eared Bat Summer Habitat Use in Minnesota Project (Preliminary Report)* (USDA Forest Service 2014b).

4.2 Database Inquiries

The MDNR Natural Heritage Information System (NHIS) Rare Features database was queried for sightings of RFSS within the federal and non-federal lands (MDNR 2014a).

4.3 Consultation with Biologists with Local Knowledge of the Species

Telephone and in-person interviews were conducted with agency and other personnel with knowledge of RFSS in the region, including staff with the MDNR, Forest Service, and University of Minnesota.

4.4 Field Studies

4.4.1 Federal Lands

Several studies have been conducted for RFSS plants and animals on the federal lands. Three rare plant surveys were conducted on the proposed Mine Site during July 2004 (Johnson-Groh 2004, Pomroy and Barnes 2004, Walton 2004). A variety of habitats were surveyed and Global Positioning System (GPS) was used to record the locations of rare plant occurrences. Photographs were taken of specimens in their habitats, and representative specimens were collected, pressed, dried, and analyzed in the laboratory. Characteristics of the habitat were recorded at each location where RFSS plants were observed.

Surveys for moonworts, which are rare ferns, were conducted in July 2004 on the Mine Site using protocol developed by Johnson-Groh (2004) for the Forest Service. Areas with high potential for having moonworts were searched on hands and knees using the timed meander search approach.

Barr Engineering Company (Barr; 2007a) conducted surveys for ternate grapefern in late August and early September 2007. Surveys were conducted along the Dunka Road and other roads for the Project. The majority

of vegetation cover types on the Project area do not provide suitable habitat for St. Lawrence grapefern. Characteristics of the habitat were recorded at each location where RFSS plants were observed.

ENSR conducted studies of wildlife use of the proposed Mine Site in 2000 (winter study) and 2004 (summer study; ENSR 2000, 2005). In addition to determining general wildlife use of the area during January and March 2000 and June 2004, the study also determined the presence of RFSS wildlife species and important habitats used by RFSS and other wildlife species. These studies involved: 1) reviewing federal and state agency and conservation group databases for known and historic occurrences of RFSS species in the proposed Mine Site area; 2) reviewing previous plant and animal surveys conducted on or near the proposed Mine Site; 3) consultation with agency and conservation group biologists; 4) field surveys to record wildlife and their habitats on the site; and 5) calling surveys for wolf, raptors, and several species of woodpeckers, including RFSS species. In addition, a vegetation cover type map was prepared showing the habitat types on the site, including disturbed, wetland, and upland habitats. Within the wetland and upland habitat types, open water, emergent and bog wetland, grassland, shrubland, and deciduous, mixed deciduous/coniferous, and coniferous forest habitat types were recorded.

In October 2004, David Heath conducted studies of the freshwater mussel fauna in two reaches of the Partridge River, one reach of the Embarrass River, and one reach of Trimble Creek (Heath 2004). Mussels were collected by hand using Self-contained Underwater Breathing Apparatus (SCUBA) and snorkeling equipment.

In February 2005, Dan Breneman conducted a stream and wetland biological survey in the Project area (Breneman 2005). The survey was conducted on four stream sites and two wetland sites. Fish and macroinvertebrate community composition, habitat characteristics, and water chemistry parameters were examined to establish biological condition at these sites. Fish were sampled by electrofishing in streams, and with 24-hour trap net sets in wetlands. Macroinvertebrates were collected with D-frame kick nets and Hess, Ekman, or Petite Ponar dredge sampling gear. Total number of fish and total length per species were determined within each stream reach to estimate catch-per-unit effort. Macroinvertebrates were identified and enumerated, and the relative abundance and taxa richness per site were determined. Stream habitat characteristics and water quality parameters at each site were summarized by point estimates along randomly spaced transects.

Wetlands on the Mine Site were initially mapped in June 2004 by ENSR based on a general field survey of the area for wetland and upland habitats (ENSR 2005). The location and boundaries of wetlands were determined based primarily on vegetative and hydrologic characteristics of the sites (wetland boundaries were not mapped using GPS).

Between 2004 and 2012, Barr evaluated wetlands across the federal lands, including the Mine Site. Barr conducted wetland delineations across several Project areas between 2004 and 2006 (PolyMet 2013, 2014). In 2007, Barr evaluated wetlands on approximately 2,420 acres of the federal lands surrounding the Mine Site that were not evaluated as part of the 2004 to 2006 studies (Barr 2007b). Wetlands in this area were identified from field studies and aerial interpretation. Along the Dunka Road and other possible transportation routes, Barr conducted field studies to determine wetland boundaries, vegetation cover types, and plant species composition of wetlands identified in this area. For areas outside of the Dunka Road and possible transportation routes, wetlands were mapped primarily based on the presence of photographic signatures with limited field-truthing and GPS-locating. Barr also assessed wetland functions and values for these wetlands.

In September 2007 and August 2008, Barr assessed plant species of concern on portions of the federal lands surrounding the Mine Site (Barr 2007a, 2009a, 2011).

In August 2008, AECOM conducted studies of wildlife use of lands surrounding the Mine Site (AECOM 2011a). The study also determined the presence of RFSS wildlife species and important habitats used by RFSS and other wildlife species, and followed protocols used during 2000 and 2004 surveys of the Mine Site. In April 2009, AECOM conducted calling surveys for northern goshawk and owls, and made observations of other wildlife, on the federal lands surrounding the Mine Site (AECOM 2009).

The USFS Superior National Forest staff conducted surveys for the northern long-eared bat and little brown bat at three general locations in the Project area in July and August 2014 (Smith et al. 2014). The three Project locations included the Mine Site, the Plant Site, and the Dunka Road and Utility Corridor. Survey methods utilized passive sonic (Anabat) detectors on the Mine Site and Dunka Road and Utility Corridor. At the Plant Site, the methods were primarily direct observation of bat species, supplemented by passive sonic detectors when feasible.

4.4.2 Non-federal Lands

In June 2009, AECOM evaluated wildlife and their habitats and conducted northern goshawk, owl, bat, and gray wolf surveys on about 4,760 acres of non-federal lands on Hay Lake Lands and McFarland Lake Lands (AECOM 2011b). In November 2010, wildlife and their habitats, and wetland functions and values, were evaluated on the Lake County Lands, Hunting Club Lands, and Wolf Lands (AECOM 2011c). During both wildlife surveys, AECOM also mapped upland and wetland habitats on the lands and evaluated wetlands for their functions and values. Survey protocols were similar to those used by ENSR and AECOM for the federal lands.

An assessment of RFSS plant species was not conducted for the non-federal lands as these lands would not be disturbed by the Project. Information on RFSS occurrence on or near the lands was obtained from the MDNR (2014) NHIS database and from Forest Service observations on and near the lands. However, these sources do not provide the same level of detail as the plant surveys conducted on the federal lands, so lack of occurrence data does not conclusively indicate that an RFSS plant species is not present on the non-federal lands. Should these lands be acquired by the Forest Service under the land exchange, the Forest Service would conduct RFSS surveys prior to conducting ground-disturbing activities, such as road building and timber harvesting.

4.5 Determination of Effects

4.5.1 Types of Effects and Assessment Factors

Section 5.0 includes background information and an analysis of the effects of the Project on the RFSS listed in **Table 1**, which are species that have occurred or are likely to occur, and/or have habitat or are likely to have potential habitat, on the federal and/or non-federal lands. For each RFSS, background information on species abundance and distribution and habitat requirements is presented. Potential beneficial and adverse direct and indirect effects to the species that are related to the proposed action and alternatives, and that may result from the Proposed Action or alternatives, are presented. Effects of future actions on RFSS, and that are reasonably likely to occur in the areas considered in this BE, or cumulative effects, are also discussed. These effects are defined as follows:

- Beneficial – Effects of an action that are wholly positive, without any adverse effects, on a RFSS or designated habitat. Determination that an action will have beneficial effects is a “may impact” situation.
- Direct – The direct or immediate effects of the Project on a RFSS or its habitat. Direct effects result from the proposed action including the effects of interrelated actions and interdependent actions.
- Indirect – Effects caused by or resulting from the proposed action, which are later in time, and are reasonably certain to occur. Indirect effects may occur outside of the area directly affected by the action.
- Cumulative – Include the effects of future state, tribal, local, or private actions that are reasonably certain to occur in the cumulative effects study area (CESA) and are considered in this BE.

The effects assessment is based on the following factors:

- the dependency of the species on specific habitat components,
- habitat abundance,
- population levels of the species,
- the degree of habitat impact, and
- the potential to mitigate for an adverse effect.

4.5.2 Cumulative Effects

Cumulative effects include the effects of future state, tribal, local, or private actions that are reasonably certain to occur in the CESA considered in this BE.

The CESA includes the Nashwauk and Laurentian Uplands ecological subregions within the Arrowhead Region of Minnesota. This area totals approximately 1.38 million acres in the northeast corner of Minnesota (**Figure 18**; Emmons and Olivier Resources, Inc. 2006). The period for analysis of cumulative effects in this BE was from pre-settlement (approximately 1890) through closure and reclamation of Project facilities (approximately 40 years).

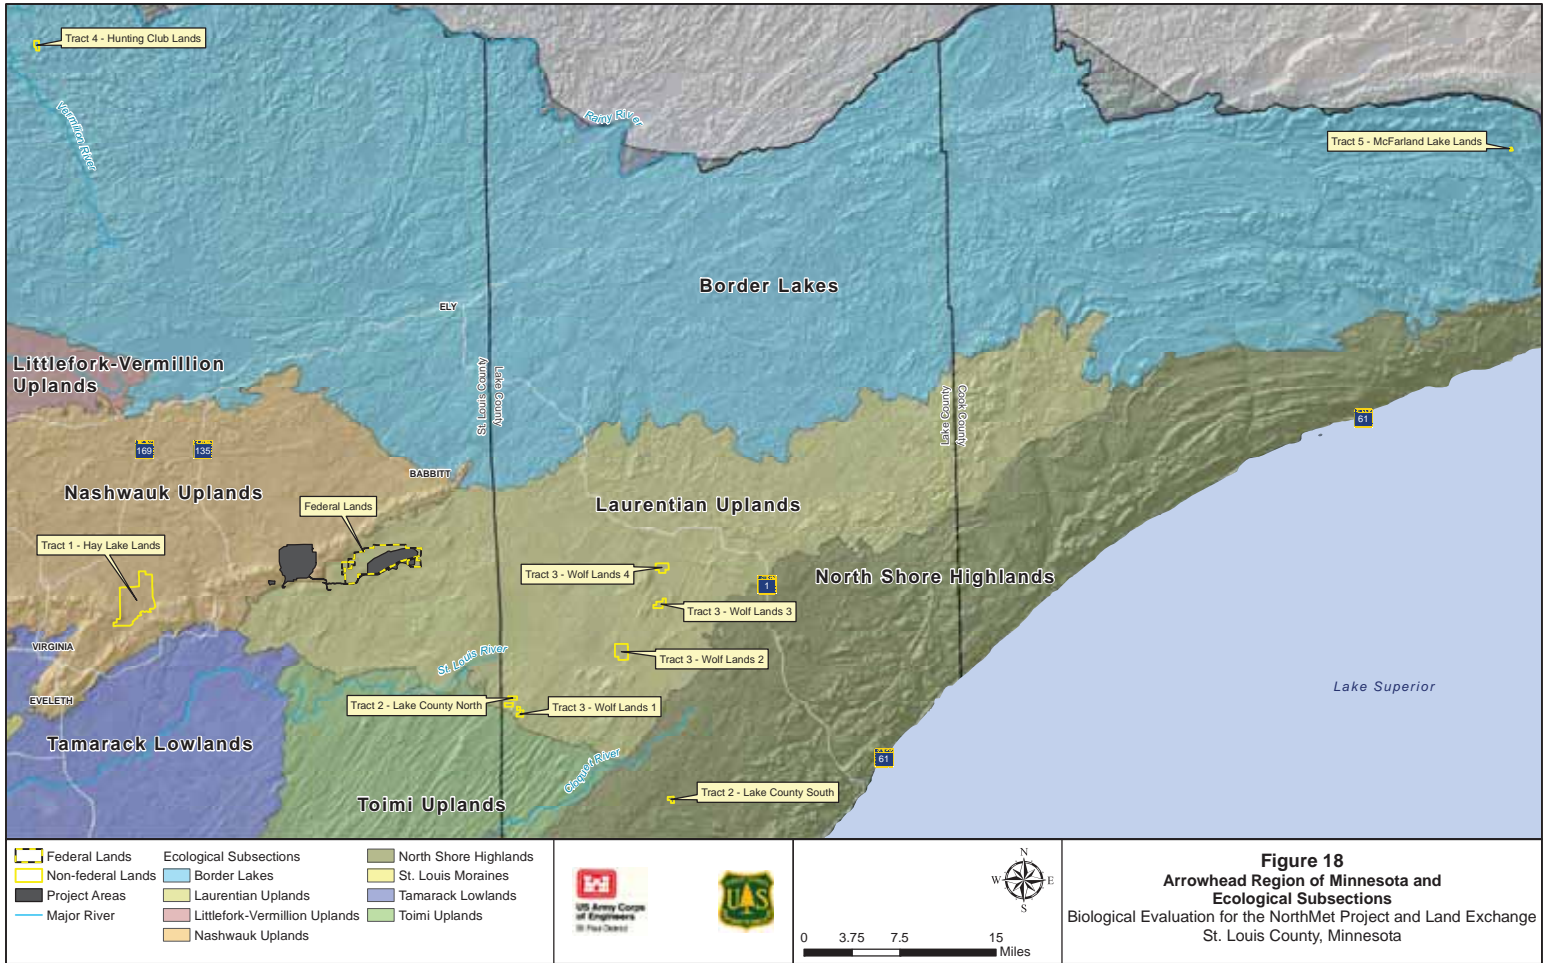

Cumulative effects to plants and animals are discussed in Chapter 6 of the FEIS (MDNR et al. 2015). The effects discussed in that section were based on an analysis conducted for a 2006 MDNR report titled *Cumulative Effects Analysis on Wildlife Habitat and Travel Corridors in the Mesabi Iron Range and Arrowhead Regions of Minnesota* (Emmons and Olivier Resources, Inc. 2006), and a report titled *Cumulative Effects Analysis of Wildlife Habitat and Threatened and Endangered Wildlife Species* (Barr 2009b).

In accordance with Council on Environmental Quality guidance on June 24, 2005 (Council on Environmental Quality 2005), past actions associated with the Project are addressed through their current aggregate effects and have not been provided as a list of individual projects in this BE. The FEIS identifies a number of proposed projects that should be considered reasonably foreseeable future actions and that may contribute to cumulative effects to plants and animals. These include mining and other land development activities, and land management activities such as timber harvest, prescribed fire, and road construction that may be authorized or carried out on nearby federal, state, and private lands and that are likely to have both positive and negative effects to RFSS.

Based on analysis conducted by Emmons and Olivier Resources, Inc. (2006:30, 38), approximately 1,700 acres of wildlife habitat were lost from the Nashwauk and Laurentian Uplands ecological subregions between 1890 and the 1990s, with loss due to forestry and mining accounting for 89% of the loss. In most of the region, forest communities have transitioned from predominately pine- and tamarack-dominated forests to trembling aspen and other non-pine community-dominated forest species. Forest composition has changed, and the Minnesota Forest Resource Council (2003) concluded that forest fragmentation has increased, with decreased forest stand sizes and more miles of forest edge.

Barr (2009b) estimated habitat loss due to mining at about 17,000 acres over the next 25 to 30 years. In the future, the rate of habitat loss due to mining would decrease as vegetation establishes on disturbed lands. Potential disturbances to habitat within the Laurentian Uplands ecological subsection would be primarily due to timber harvest and mining, and habitat types most likely to be affected include upland and lowland coniferous forest, upland deciduous forest, and upland shrub/woodland. Within the Nashwauk Uplands ecological subsection, mining activities and urban development would be more likely to affect habitat, with upland deciduous forests and upland shrub/woodland habitats most affected (Emmons and Olivier, Inc. 2006).

Although more land would be impacted by timber management than mining in the future, forestry management offers a greater range of options for RFSS to co-exist with the practice, as it can mimic natural disturbances, whereas mining represents a complete land conversion that could affect long-term RFSS habitat availability. Between 2005 and 2014, within the Laurentian Uplands ecological subregion, an average of approximately 1,034 forest acres were (or would be) harvested annually on state lands (0.2% of the subregion). Between 2010 and 2019 within the Nashwauk Uplands ecological subregion, an average of approximately 1,189 forest acres were (or would be) harvested annually on state lands (0.1% of the subregion). On average, 1% of timber land in the Superior National Forest is harvested annually (MDNR et al. 2013). Private timber harvest data are generally not available.

5.0 Analysis and Determination of Effects

This section discusses all RFSS plants and animals that are known or suspected to occur on the federal and/or non-federal lands, or that may have habitat on the lands, as identified in **Table 1**. Primary sources of information used to describe the environmental baseline condition are the *NorthMet Mining Project and Land Exchange Draft SEIS* (MDNR et al. 2013 and references cited therein), *Tracks Project BE* (USDA Forest Service 2010b and references cited therein), MDNR Rare Species Guide (MDNR 2008 and references cited therein), MDNR NHIS Rare Features Database (MDNR 2014a), and Bell Museum of Natural History (2013) Scientific Collections database.

Plant habitat cover types and acreages used in the description of habitat conditions and for Project effects analysis are based on MDNR (2006) for GAP cover types, USDA Forest Service (2010a) for MIH cover types, and MDNR et al. (2013) and PolyMet (2013,2014) for wetland habitat cover types.

Plant population numbers correspond to the MDNR Element Occurrence within the NHIS database (MDNR 2014a). According to the 2014 MDNR NHIS training notes, Element Occurrences may have multiple observations in a given area, but are considered one population if they are “within close enough proximity to one another to allow for gene flow and there are no known barriers to movement.” These clusters of observations are described here as colonies for given populations. An individual is defined as a single plant of a species. A colony is a group of individual plants of one species in a distinct geographic location. A population is a group of individuals or colonies of one species that may be separated geographically, but are close enough to interbreed and persist over time.

Other sources of information for the BE are provided in Section 4.0. Information in Section 5.0 may be assumed to be from one of these sources. Any additional information that is not from one of these sources is cited in the text.

5.1 Vascular and Non-vascular Plants

5.1.1 Plants Not Evaluated in the Biological Evaluation

As shown in **Table 1**, there is no suitable habitat on the federal or non-federal lands for alpine milkvetch, *Arctoparmelia centrifuga*, *Arctoparmelia subcentrifuga*, creeping rush, Chilean sweet-cicely, Douglas’ hawthorn, little goblin moonwort, long-leaved arnica, nodding saxifrage, Oakes’ pondweed, Scotch false asphodel, short sedge, smooth woodsia, and Wain’s cup lichen. The Proposed Action, Alternative B, and No Action Alternative would have **no impact** to individuals of these species, and they will not be addressed further in this BE.

5.1.2 Plants of Non-forested Wetlands, Shallow Water, and Riparian Areas (Habitat Group 1)

5.1.2.1 Environmental Baseline

Habitat Group 1 RFSS favor non-forested wetland habitat, shallow water, and riparian areas. The following Habitat Group 1 RFSS either occur on, and/or have suitable habitat on, the federal and/or non-federal lands—small beggarticks, floating marsh marigold, linear-leaved sundew, quill spikerush, moor rush, auricled twayblade, American shoreweed, bog muhly, Leiberg’s waterlily, American waterawlwort, and bog white violet.

Of these species, floating marsh marigold, quill spikerush, and moor rush are found on the federal lands. No Habitat Group 1 RFSS have been reported on the non-federal lands.

Species Conditions

Small Beggarticks (*Bidens discoidea*)

In Minnesota, small beggarticks is restricted to a relatively few lakes in the northeast counties, including St. Louis and Cook Counties, where it is found along boggy shorelines and floating mats in partial to full sunlight (Minnesota Wildflowers 2013).

Small beggarticks has not been reported on the federal or non-federal lands, or on the Tracks Project area. As discussed in Section 4.1.1, the Tracks Project area is east of Hoyt Lakes and north of Brimson, Minnesota, in Lake and St. Louis Counties, and near the Project area. The Tracks Project area encompasses about 152,000 acres of land of which approximately 78,000 acres are administered by the Forest Service.

Floating Marsh Marigold (*Caltha natans*)

Floating marsh marigold was first collected in Minnesota in 1889 from Vermilion Lake in St. Louis County. All subsequent collections have been from St. Louis County, including the federal lands and Tracks Project area. Very few populations are known in Minnesota. Habitat loss is the primary reason behind recent local extirpations of this species in Minnesota.

Floating marsh marigold is a perennial aquatic forb and occurs within shallow open water or on moist mud within northern ponds, lakes, slow-moving rivers, streams, ditches, and wet meadows. Floating marsh marigold is found in relatively stable aquatic systems and may be sensitive to disturbances, including alteration of hydrology or hydro-period, water quality, water chemistry, and non-native species invasion, although a few populations are found on disturbed habitats.

Of the 12 known populations statewide, 3 populations, totaling 22 individuals, occur on the federal lands north of the Mine Site along the Partridge River. The populations would not be disturbed by mining. Nine additional populations of floating marsh marigold occur on privately owned lands south of the Mine Site, and along Dunka Road. One of these populations would be directly affected by a Waste Rock Stockpile.

Floating marsh marigold has not been reported on the non-federal lands.

Linear-leaved Sundew (*Drosera linearis*)

In Minnesota, linear-leaved sundew has been found in Lake County, but not in St. Louis or Cook Counties. It is one of a small group of rare plant species that are restricted to a high-quality, undisturbed, type of peatland called patterned fens. These fens tend to develop at the core of large peatland complexes in northern Minnesota. Like all sundews, linear-leaved sundew is a small, inconspicuous plant with one outstanding feature; the leaves are covered with mucilage-tipped tentacle-hairs that are adapted to trap insects. Protection of fen habitat is essential to the survival of this species.

Linear-leaved sundew has not been reported on the federal or non-federal lands, or on the Tracks Project area.

Quill Spikerush (*Eleocharis nitida*)

Quill spikerush distribution in Minnesota is limited to the northeastern counties of the Arrowhead region and west to Itasca County. Quill spikerush was first collected in Minnesota in 1946 from various wetland habitats in Cook and St. Louis Counties. Despite the long collection record for this species in Minnesota, relatively few populations have been documented and little is known about the overall distribution of the species throughout the state.

Quill spikerush occurs within various wetland habitats of northern Minnesota, including acid bog pools, small streams, areas of seasonal water drawdown (mucky/peaty flats), disturbed wetland edges, and along roads and trails. This rooted perennial species may be intolerant of hydrologic fluctuations and alterations to water quality and chemistry associated with landscape and wetland alteration and development. However, roadside distributions suggest the species may be semi-tolerant to disturbance and at least mild alterations in water quality in the short term.

Of the 49 known populations in the state, 1 population occurs within the federal lands, on the Mine Site, and would be affected by the Project. There are an additional 13 locations of this species on private lands located along Dunka Road and the railroad tracks south of the Mine Site. Project activities would directly affect four of these populations.

Quill spikerush has not been reported on the non-federal lands. It has been reported on the Tracks Project area.

Moor Rush (*Juncus stygius* var. *americanus*)

Moor rush is distributed across the northern and northeastern Arrowhead counties in large patterned peatlands and calcareous fens. It was first documented in St. Louis County in 1886. In 2003, it was reported in Carlton County (one occurrence), Koochiching County (five occurrences), and Lake County (four occurrences; USDA Forest Service 2004e). It is generally not a dominant species. Even in ideal, large-patterned peatland settings, it occurs in isolated colonies with scattered individuals.

Moor rush is a perennial graminoid species that occurs in full sun, and generally, it is restricted to narrow wet zones of the margin of a bog pond. Moor rush has very specific hydrology requirements and the principal threats are large-scale disturbances to its peatland habitat and surrounding watersheds. These threats include mineral exploration, peat mining, pollution of watershed waters, alterations of hydrologic regime, and acid rain (USDA Forest Service 2004e and references cited therein).

Of the 30 known populations in Minnesota, 1 population consisting of 67 individuals scattered within a 450-foot radius was found on the federal lands within One Hundred Mile Swamp in bog habitat with scattered black spruce (PolyMet 2013).

Moor rush has not been reported on the non-federal lands. It has been reported on the Tracks Project area.

Auricled Twayblade (*Listera auriculata*)

Auricled twayblade ecology is poorly understood and the species has a very limited distribution. It is found in St. Louis, Lake, and Cook Counties, including along the North Shore of Lake Superior, and at Isle Royale National Park. It is rarely encountered and, until recently, little was known about its distribution and habitat

requirements. The species is very rare in Minnesota, prompting its listing as a state endangered species in 1996. Its persistence is precarious because there are so few populations and most populations have few individuals.

In Minnesota, it is characteristically found along streams or pond margins in low, moist hardwood forests, mixed coniferous/deciduous forest, and shrub swamps (Hoy 2001). Habitat destruction related to high water levels and vegetation succession, either by human alteration or by natural processes is a potential threat.

Auricled twayblade has not been reported on the federal or non-federal lands, or on the Tracks Project area.

American Shoreweed (*Littorella americana*)

American shoreweed occurs in the northeastern U.S. and adjacent Canada, and is considered vulnerable or imperiled across much of its range due to its rarity and threats to its habitat. It currently reaches the westernmost extent of its distribution in the Laurentian Uplands ecological subregion of northeastern Minnesota. The species was first collected in 1886 from Basswood Lake in Lake County. Since that time, 60 additional occurrences have been documented in the state, including in St. Louis, Lake, and Cook Counties, primarily in the BWCAW.

American shoreweed is an aquatic plant primarily occurring in lakes having a sandy, gravel/cobble substrate. In some lakes, plants may become partially or wholly buried in fine organics or silts. Plants are most often observed when they become stranded along the lakeshore.

American shoreweed has not been reported on the federal or non-federal lands. It has been reported on the Tracks Project area.

Bog Muhly (*Muhlenbergia uniflora*)

Bog muhly is a small, fine grass primarily distributed in northeastern North America and ranging as far west as Minnesota. It is found in Lake and Cook Counties, primarily in the BWCAW. The species was first reported in Minnesota from St. Louis County in 1956 and from Lake County the following year. The St. Louis County occurrence near Gilbert has never been located again. It is also questionable whether Lake County location has been located again, in part due to a disputed herbarium label data. Bog muhly subsequently went undocumented in the state until 1987, when it was discovered on the sandy beaches of a lake in the BWCAW. As of 2009, approximately 25 occurrences have been reported, many of which are within 5 miles of each other.

In Minnesota, bog muhly occurs in wetlands and is considered to be a wetland obligate species. It occurs along sandy-gravel shores or cobbly organic shores, in seasonal basins, in peaty depressions, and on low hummocks in rich sedge fens. It is also known to occur in bogs, wet meadows, and lake shores in sandy or peaty, often acidic, soils.

Bog muhly has not been reported on the federal or non-federal lands, or on the Tracks Project area.

Leiberg's waterlily (*Nymphaea leibergii*)

Leiberg's waterlily has a rather limited geographic range and is rare within its geographic range. It has been reported in Cook and Lake Counties and the BWCAW. This aquatic species was first discovered in Minnesota at Bald Eagle Lake (Lake County) in 1914. It was subsequently found at Mulligan Lake (Beltrami County) in 1949, Botany Bog (Itasca County) in 1977, and Stony Creek (Lake of the Woods County) in 1980. The species

was ultimately found in several rivers and streams in two major drainages within the sandy region of the Glacial Lake Agassiz basin, including the western branches of the Rapid River, which drains the Red Lake peatland.

The documented occurrences of Leiberg's waterlily in Minnesota are in shallow, protected bays in lakes and in slow-moving streams, especially streams impounded by beaver dams. One site is in a narrow outlet of a small pond surrounded by a graminoid poor fen. The plants are usually rooted in soft sediments beneath 3 to 7 feet of water, although the water is sometimes deeper. They prefer the outer margin of emergent vegetation, which typically consists of wild rice, arrowhead, bulrush, and cattail. The species frequently occurs with yellow pond-lily.

Leiberg's waterlily has not been reported on the federal or non-federal lands, or on the Tracks Project area.

American Waterarwort (*Subularia aquatica* spp. *americana*)

American waterarwort is a small, aquatic species that inhabits shallow water margins (typically 6 to 18 inches, sometimes as deep as 35 inches). It has a wide distribution in North America, although it is uncommon over most of its range. In Minnesota, it has been found primarily in the littoral zone of large, sandy, oligotrophic lakes in the northeast; there are a few occurrences from silty substrata in non-oligotrophic lakes in north-central Minnesota. When originally listed as state endangered in 1984, American waterarwort was known from only six sites. Between 1984 and 2008, 11 additional populations were discovered. The majority of sites are in the Superior National Forest and the BWCAW, including in St. Louis, Lake, and Cook Counties.

American waterarwort has not been reported on the federal or non-federal lands, or the Tracks Project area.

Bog White Violet (*Viola lanceolata* var. *lanceolata*)

Bog white violet (synonym: lance-leaved violet) occurs in low, moist meadows with a sandy substrate, moist swales in sand dunes and savannas, and occasionally on sandy lakeshores. One recent population was found on dry mud in an old beaver lodge. The majority of the original Minnesota populations probably occurred on the Anoka Sandplain in Sherburne, Isanti, and Anoka Counties. Recently, there have been discoveries of bog white violet in northeastern Minnesota in St. Louis and Lake Counties, including the BWCAW, where it appears to occur sporadically over a relatively large area (Milburn and Husveth 2004).

Bog white violet is typically found in habitats that have experienced some sort of disturbance event, which benefits this species due to its inability to compete with larger species. As competition for light and nutrients increases within the community, the size of the population decreases, and the population waits for the next disturbance event. Following a disturbance event, the species is adapted to quickly germinate from the seed bank or colonize an open area. The greatest threat to bog white violet is loss of habitat due to development, but fire suppression, altered hydrology, and invasive species can also negatively affect this species.

Bog white violet has not been reported on the federal or non-federal lands, or on the Tracks Project area.

Habitat Conditions

There are approximately 4,164 acres of wetlands on the federal lands (**Table 8**). Although coniferous bog and coniferous swamp are the dominant wetland types, there are about 343 acres of non-forested wetland habitat (open bog, sedge/wet meadow, and shallow marsh) and 31 acres of open water associated with the federal lands,

or 6% of the federal lands, that could provide habitat for Habitat Group 1 RFSS. Nearly all of these wetlands are rated high for wetland quality (MDNR et al. 2013).

Mud Lake, the dominant open water feature on the federal lands, is within the One Hundred Mile Swamp. It is approximately 30.5 acres and has approximately 4,550 feet of shoreline. Yelp Creek flows out of One Hundred Mile Swamp to the Partridge River. The Partridge River flows through the northern, eastern, and southeastern portions of the federal lands. Collectively, Yelp Creek and the Partridge River are approximately 5.3 miles in length on the federal lands.

There are approximately 4,670 acres of wetlands on the non-federal lands (**Table 8**). Coniferous swamp and alder thicket or shrub-carr are the dominant wetland types, but there are also 124 acres of non-forested wetland habitat (open bog, sedge/wet meadow, and shallow marsh) and 182 acres of shallow, open water habitat on the non-federal lands, or 4% of the non-federal lands, that could provide habitat for Habitat Group 1 plant species. All wetlands on the non-federal lands are rated high for most wetland functions and values and wetlands on the non-federal lands share similar characteristics to those on the federal lands.

Several lakes and streams with associated riparian zone habitat are found on the non-federal lands. Hay Lake is on Hay Lake Lands and is approximately 96 acres with approximately 9,894 feet of shoreline. Little Rice Lake is also on Hay Lake Lands and is approximately 29 acres with approximately 4,830 feet of shoreline. An unnamed lake between Hay Lake and Little Rice Lake is approximately 4 acres with approximately 1,700 feet of shoreline. McFarland Lake Lands border McFarland Lake, with approximately 990 feet of shoreline along McFarland Lake. There are no other major lakes on the other non-federal lands.

Within Hay Lake Lands, the Pike River flows approximately 8 miles from the southern boundary to the northern boundary of the lands. Riparian habitat is found on both sides of the river for 5.7 miles and is found along one side of the river for 2.4 miles where the Pike River forms the boundary of Hay Lake Lands.

Coyote Creek begins on Wolf Lands 3, then flows north onto Wolf Lands 4 and beyond. The creek is approximately 0.1 mile long on Wolf Lands 3, and 0.9 mile long on Wolf Lands 4. Riparian habitat is found on both sides of the creek.

5.1.2.2 Direct and Indirect Effects

Proposed Action

Species Conditions

Federal Lands

Based on plant surveys of the federal lands, floating marsh marigold and quill spikerush would be directly affected by the Project. Moor rush has been found on the federal lands, but would not be affected by the Project. The remainder of Habitat Group 1 RFSS has not been reported on the federal lands.

Nine floating marsh marigold populations are near, but outside, the Mine Site and federal lands; five of these populations are found along the Partridge River. One population of floating marsh marigold would be directly affected by a Waste Rock Stockpile. The known statewide population for this species is rather small, the Project would affect about 8% of the known population in Minnesota.

Quill spikerush is primarily found in ditches along Dunka Road with gravel or sandy substrates. Of the 49 known populations in the state, 1 population would be affected by the Project (2% affected). An additional 13 populations are found along Dunka Road and the railroad tracks, but they are not on federal lands. The Project would have a direct effect on four of these populations. This species seems to be semi-tolerant of disturbance because it inhabits roadside ditches.

Moor rush has 30 known populations in the state, none of which occur on the Project area. One population, however, is found on the federal lands north of the Mine Site and within One Hundred Mile Swamp. This population would not be affected by the Project.

Non-federal Lands

No Habitat Group 1 RFSS have been reported on the non-federal lands. Under the Proposed Action, the non-federal lands would be transferred to the Forest Service, who would manage the lands for timber production, recreation, nature study, and other values. There would be no direct or indirect effects to Habitat Group 1 RFSS on the non-federal lands from the Project.

Habitat Conditions

Federal Lands

Direct effects to habitat for Habitat Group 1 RFSS on the federal lands would occur from habitat removal or destruction primarily from mining-related activities, including construction of the mine pits, Waste Rock Stockpiles, access roads, and mine facilities.

There are about 343 acres of non-forested wetland and 31 acres of open water within the federal lands that could provide habitat for Habitat Group 1 RFSS (**Table 8**). The Project would affect about 65 acres of non-forested wetland, but 0 acres of open water, or about 17% of the available habitat. The Project would not affect Mud Lake, the large open water area found within One Hundred Mile Swamp, or riparian zone habitat associated with Yelp Creek and the Partridge River.

Habitat for these species could be indirectly affected by dust from mining activities and vehicles, ore spillage, changes in surface and groundwater hydrology from groundwater drawdown, and from changes in water quality related to leakage from stockpiles/mine features and seepage from mine pits. These risks to Habitat Group 1 RFSS, however, should be negligible.

Non-federal Lands

There are about 124 acres of non-forested wetland (open bog, sedge/wet meadow, and shallow marsh) and 183 acres of open water within non-federal lands that could provide habitat for Habitat Group 1 RFSS (**Table 8**). Most of these habitats are found on Hay Lake Lands (263 acres; 86%). Smaller acreages of these habitats are found on Hunting Club Lands (16 acres) and Lake County Lands South (15 acres), with the remainder as scattered, small acreages on the other non-federal lands (**Table 8**). Under the Proposed Action, the Forest Service would survey for Habitat Group 1 RFSS prior to conducting land-disturbing activities and areas of known or potential habitat would be avoided when feasible.

Alternative B

Federal Lands

Effects to Habitat Group 1 RFSS and their habitats under Alternative B would be similar to those under the Proposed Action. Under Alternative B, there are about 291 acres of non-forested wetland (open bog, open water, sedge/wet meadow, and shallow marsh) and 9 acres of open water on the federal lands that could provide habitat for Habitat Group 1 RFSS (**Table 8**). About 74 fewer acres of open bog, open water, sedge/wet meadow, and shallow marsh habitats would be transferred to PolyMet under this alternative than under the Proposed Action, but direct and indirect effects to Habitat Group 1 RFSS species and habitats from the Project activities would remain the same as under the Proposed Action.

Non-federal Lands

Under Alternative B, only Hay Lake Lands would be transferred to the Forest Service. As discussed under the Proposed Action, no Habitat Group 1 RFSS have been reported on Hay Lake Lands. The Forest Service would acquire about 86 acres of non-forested wetland (open bog, open water, sedge/wet meadow, and shallow marsh) and 177 acres of open water habitats that are favored by Habitat Group 1 RFSS, or about 86% of the acreage the Forest Service would have obtained under the Proposed Action (**Table 8**). Effects on these species and their habitats from Forest Service and public use of Hay Lake Lands would be similar to those under the Proposed Action.

No Action Alternative

There would be no direct or indirect effects to Habitat Group 1 RFSS under the No Action Alternative.

5.1.2.3 Cumulative Effects

Timber harvesting, road building, and recreational activities are reasonably foreseeable future actions that could continue to occur on the federal lands and non-federal lands. In addition, there is the potential for homes and cabins to be built on the non-federal lands, including on small portions of wetlands, should the FEIS Record of Decision select the No Action Alternative and the non-federal lands remain under private ownership. These activities could affect the Habitat Group 1 RFSS within the CESA.

Forest management activities could result in Habitat Group 1 RFSS and their habitats being driven over and crushed by timber harvest and road construction/maintenance equipment, and harmed from sedimentation of streams and lakes due to ground disturbance. Timber harvest activities would be conducted during winter in wetlands, however, to reduce the risks of ground disturbance and sedimentation. Prior to implementing ground-disturbing activities, the Forest Service would conduct RFSS surveys to determine if RFSS would be affected by proposed activities. These surveys should help to ensure that RFSS species on non-federal lands are avoided, where feasible.

Lowland road construction and use and wetland draining are the two actions that probably have the largest effect on Habitat Group 1 RFSS within the CESA. Construction and use of roads in lowlands in the CESA, including construction of lowland roads for county, state, and private timber harvest, and for access to mineral exploration and production sites, recreation sites, and homesites, would continue to affect Habitat Group 1 RFSS habitat. However, the amount of suitable habitat affected by these activities should be small. In addition, timber harvest

on Forest Service and other ownerships would not affect this habitat appreciably because it is typically not forested with merchantable trees. The Forest Service would survey proposed timber harvest treatment areas for RFSS and would avoid areas with known or potential habitat for RFSS, where feasible.

Project activities on the federal lands would affect one population of quill spikerush. Project activities on adjacent private lands on the Mine Site would affect an additional four populations of quill spikerush and one population of floating marsh marigold. Approximately 65 acres of habitat could be directly affected on the federal lands that could be used by Habitat Group 1 RFSS. Despite the cumulative effects of the Project, habitat used by Habitat Group 1 RFSS that would be affected by the Project occurs elsewhere in the Superior National Forest, including the Tracks Project area, and would not be affected by the Project or other reasonably foreseeable future activities in the CESA. In addition, there are approximately 67,000 acres of open wetland and water habitat that could be used by Habitat Group 1 RFSS elsewhere in the CESA (Emmons and Olivier Resources, Inc. 2006:30, 38).

5.1.2.4 Summary

Project activities associated with the Proposed Action or Alternative B would have direct, indirect, and cumulative adverse effects on Habitat Group 1 RFSS and their habitat. Other activities in the CESA would contribute to cumulative effects for Habitat Group 1 RFSS. The Proposed Action and Alternative B would have similar effects on Habitat Group 1 RFSS, while there would be no effects to Habitat Group 1 RFSS from the No Action Alternative.

5.1.2.5 Determination

The Proposed Action and Alternative B **may impact individuals but are not likely to cause a trend to federal listing or loss of viability** for floating marsh marigold, quill spikerush, moor rush, small beggarticks, linear-leaved sundew, auricled twayblade, bog muhly, American shoreweed, Leiberg's waterlily, American waterawlwort, or bog white violet. The No Action Alternative would have **no impact** on individuals of Habitat Group 1 RFSS.

5.1.2.6 Mitigation and Recommendations

Mitigation measures for Habitat Group 1 RFSS could include the following:

- Reseed Mine Site and Plant Site impact areas with native species, provided they can perform as effectively as the non-native species. In some areas where erosion control would be critical to prevent slope failures, non-native species may be needed. Temporary stabilization efforts using non-native species should use non-invasive plant species to minimize the long-term risk to surrounding plant communities.
- In the event invasive non-native species are introduced, an additional mitigation measure would be to implement a monitoring and control program for invasive species (including noxious weeds) to ensure these species do not overtake surrounding native communities.
- Additionally, the purchase of an unprotected site with a population of the RFSS species *Caltha natans* should be assessed as mitigation.

5.1.3 Cliff, Talus Slope, and Exposed Rock Habitat (Habitat Group 2)

5.1.3.1 Environmental Baseline

Habitat Group 2 RFSS favor cliffs, talus slopes, and exposed rock habitat. The following Habitat Group 2 RFSS either occur on, and/or have suitable habitat on, the federal and/or non-federal lands —maidenhair spleenwort, largeleaf sandwort, sticky locoweed, and encrusted saxifrage. Habitat Group RFSS 2 habitats are very rare on the federal and non-federal lands. No Habitat Group 2 RFSS have been reported on the federal lands. Encrusted saxifrage has been found on McFarland Lake Lands.

Species Conditions

Maidenhair Spleenwort (*Asplenium trichomanes*)

Maidenhair spleenwort has been found in Cook and Lake Counties, primarily near the North Shore of Lake Superior, and on the BWCAW. Most populations of maidenhair spleenwort occur on moist, north- to east-facing cliffs, particularly on ledges and in crevices. It also occurs in talus at the base of cliffs. Some of the cliffs are associated with large lakes that may provide a needed, climate-modifying effect. At least two populations are known to occur in association with open, exposed southeast-facing cliffs where conditions are warmer, drier, and sunnier. Populations in these more exposed habitats grow in sheltered crannies of cobbly talus.

Maidenhair spleenwort has not been reported on the federal or non-federal lands, or on the Tracks Project area.

Appalachian Clubmoss (*Huperzia appalachiana*)

Appalachian clubmoss may be locally common in moist, sheltered habitats on sandstone ledges. However, the species seems to be rare even where suitable habitat exists. Historic populations documented by herbarium specimens collected in Blue Earth County (1883), in Hennepin County (1902), in Lake County (1943), and in St. Louis County (1949) have presumably been destroyed by human activities. There are very few populations known to currently exist in Minnesota.

Prior to 2000, all Minnesota specimens had been collected from sandstone bluffs and ledges in southeastern Minnesota. Beginning in 2000, the species was found at a number of sites in northeastern Minnesota on diabase cliffs. Sites in the northeast are typically northerly facing, wooded habitats that are moist and well-shaded. Appalachian clubmoss has been found in St. Louis, Lake, and Cook Counties, primarily along the North Shore of Lake Superior, and on the BWCAW. Appalachian clubmoss is found on shelves and crevices on cliff/talus/rock outcrops, and shrub dominated talus piles.

Appalachian clubmoss has not been reported on the federal or non-federal lands, or on the Tracks Project area.

Largeleaf Sandwort (*Moehringia macrophylla*)

In Minnesota, populations of largeleaf sandwort are found in Cook and Lake Counties. Only a few of the historic populations have been relocated, despite considerable effort. All evidence indicates that this is a very rare species with limited distribution and restrictive environmental needs. Furthermore, all known populations are small and occur in fragile habitats. Most of the documented sites of largeleaf sandwort in Minnesota occur on sheltered cliffs of slate and diabase in the Rove Formation. In these habitats, the plants grow in small rock

crevices where organic debris accumulates or where moss mats provide a suitable substrate. Populations are typically associated with cliffs having a northerly aspect, where they are often found near the cliff base on small shelves, cracks, and chutes.

Largeleaf sandwort has not been reported on the federal or non-federal lands, or on the Tracks Project area.

Sticky Locoweed (*Oxytropis borealis* var. *viscida*)

In Minnesota, sticky locoweed (synonym: viscid locoweed) is restricted to a single cliff in Cook County. The population was originally discovered in 1938 and still persists. Such a small, isolated population is vulnerable to a variety of stochastic processes attributable to natural events and human-caused effects. For this reason, sticky locoweed was listed as an endangered species in Minnesota in 1996.

The Minnesota sticky locoweed population occurs on a single, north- to northwest-facing cliff face and at the top of the associated talus slope. Plants occur in both sunny and partially shaded conditions where there is little competition from typical forest species; this is similar to the habitat occupied by the species in the Rocky Mountains. This population is apparently a relic of a wider, preglacial distribution.

Sticky locoweed has not been reported on the federal or non-federal lands, or on the Tracks Project area.

Encrusted Saxifrage (*Saxifraga paniculata*)

Encrusted saxifrage was first documented in Cook County, Minnesota in 1932, and has since only been reported in Cook County, including on the McFarland Lake Lands. Encrusted saxifrage is an arctic-alpine species that reaches the southern end of its range in Minnesota. It typically occurs in rock crevices and on ledges of shaded north-facing cliffs with bedrock of diabase, gabbro/diorite, basalt, or Rove Formation rocks. There is very little suitable cliff habitat for encrusted saxifrage in Minnesota, and threats to the species could include climate change, changes in the biotic community, and recreational exploration of vulnerable cliff faces.

Encrusted saxifrage was found on McFarland Lake Lands, presumably associated with rock outcrops along the western edge of the lands. It has not been reported on the federal lands, other non-federal lands, or the Tracks Project area.

Habitat Conditions

There is very little suitable habitat for Habitat Group 2 RFSS on most of the federal and non-federal lands. There are scattered rock outcrops on the federal lands, and on Hay Lake Lands, Hunting Club Lands, Lake County Lands North, and Lake County Lands South, but no cliffs or talus slopes. Thus, it is unlikely that Habitat Group 2 RFSS would be found on these lands. Cliffs with exposed rock that are about 100 feet high are found in the central portion of McFarland Lake Lands and encrusted saxifrage was reported to occur on the McFarland Lake Lands (MDNR 2006).

5.1.3.2 Direct and Indirect Effects

Proposed Action

Species Conditions

Federal Lands

No Habitat Group 2 RFSS have been reported on the federal lands, and there is very little suitable habitat on the federal lands. Thus, it is unlikely that Habitat Group 2 RFSS would be affected by the Project.

Non-federal Lands

The Forest Service would monitor encrusted saxifrage on McFarland Lake Lands, and seek to protect high quality habitat for this plant species. Under the Proposed Action, the non-federal lands would be transferred to the Forest Service, who would manage the lands for timber production, recreation, nature study, and other values. The Forest Service would monitor Habitat Group 2 RFSS use of these lands, and seek to protect high quality habitat for these species.

Habitat Conditions

Federal Lands

There are no cliffs or talus slopes, and only a few areas with exposed rock, on the federal lands (ENSR 2005, AECOM 2011a). At most, only a few acres of exposed rock would be affected by the Project on the federal lands. Suitable habitat for maidenhair spleenwort, largeleaf sandwort, and encrusted saxifrage could occur on exposed rock outcrops, but it is unlikely that these species would be found on the exposed outcrops. Mining would result in development of a mine pit and associated rock walls and overburden storage piles that would have some exposed rock. These areas could provide habitat for Habitat Group 2 RFSS in the future.

Non-federal Lands

There are scattered rock outcrops on Hay Lake Lands, Hunting Club Lands, Lake County Lands North, and Lake County Lands South, but no cliffs or talus slopes (AECOM 2011b, c). Cliffs with rock outcrops are found on McFarland Lake Lands and total about an acre. Encrusted saxifrage is found on McFarland Lake Lands. Under the Proposed Action, the Forest Service would survey for Habitat Group 2 RFSS and associated habitat prior to conducting land-disturbing activities and areas of known or potential habitat would be avoided when feasible.

Alternative B

Federal Lands

Direct effects to Habitat Group 2 RFSS and their habitats under Alternative B would be similar to those under the Proposed Action. Although exposed rock habitat has not been specifically identified on the federal lands, it likely comprises only a few acres, and is more common in the upland areas on the eastern portion of the federal lands surrounding with the Mine Site (AECOM 2011a).

Non-federal Lands

As discussed under the Proposed Action, no Habitat Group 2 RFSS have been reported on Hay Lake Lands. There are scattered rock outcrops on the lands that could be used by Habitat Group 2 RFSS, but no cliffs or talus slopes (AECOM 2011b). Effects on Habitat Group 2 RFSS and their habitats from Forest Service and public use of Hay Lake Lands would be similar to those under the Proposed Action.

No Action Alternative

There would be no direct or indirect effects to Habitat Group 2 RFSS under the No Action Alternative.

5.1.3.3 Cumulative Effects

As discussed in Section 4.5.2, there has been a cumulative loss of habitat for RFSS from mining, road construction, housing and commercial development, and other land development activities, and from forestry and other land management activities. It is possible that Habitat Group 2 RFSS and/or their habitat have been lost from past and ongoing activities in the CESA, and would be lost in the future from similar reasonably foreseeable future activities.

Although Habitat Group 2 RFSS are rare in Minnesota, populations have been found elsewhere in the Superior National Forest, and on McFarland Lake Lands, and typically occupy areas that are not susceptible to timber harvesting or road building or other development. Given that Habitat Group 2 RFSS have not been reported on the federal lands, and potential habitat for these species on the federal lands is limited to only a few acres, adverse cumulative effects associated with Project actions on federal lands should be negligible.

Under the Proposed Action, the non-federal lands would be transferred to the Forest Service, who would manage the lands for timber production, recreation, nature study, and other values. Prior to implementing ground-disturbing activities, the Forest Service would conduct RFSS surveys to determine if RFSS would be affected by proposed activities. These surveys should help to ensure that RFSS species found on non-federal lands are avoided, where feasible. Due to its proximity to McFarland Lake and several cabins, it is unlikely that the Forest Service would harvest timber or construct roads on McFarland Lake Lands. The steep terrain also makes the lands unsuitable for snowmobile and most recreational uses. Thus, risks to encrusted saxifrage from Forest Service and recreational uses would be negligible, although the plant could be harmed by plant collectors.

5.1.3.4 Summary

Project activities associated with the Proposed Action, Alternative B, or the No Action Alternative should have no direct and indirect adverse effects on individuals of Habitat Group 2 RFSS, and any adverse effects to potential habitat for these species would be limited to a few acres. Other activities in the CESA would also contribute to cumulative effects toward the RFSS plants of this habitat group. The Proposed Action and Alternative B would have similar effects on Habitat Group 2 RFSS, while there would be no effects on Habitat Group 2 RFSS from the No Action Alternative.

5.1.3.5 Determination

The Proposed Action, Alternative B, and the No Action Alternative would have **no impact** to individuals of maidenhair spleenwort, largeleaf sandwort, sticky locoweed, and encrusted saxifrage.

5.1.3.6 Mitigation and Recommendations

No mitigation measures are proposed for Habitat Group 2 RFSS.

5.1.4 Upland Disturbed, Barrens, or Early Successional Forest Habitat (Habitat Group 3)

5.1.4.1 Environmental Baseline

Habitat Group 3 RFSS favor upland disturbed, barrens, or early successional forest habitat. The following Habitat Group 3 RFSS either occur on, and/or have suitable habitat on, the federal and/or non-federal lands—common moonwort, Michigan moonwort, pale moonwort, ternate grapefern, least moonwort, Appalachian clubmoss, and roughfruit fairybells. Michigan moonwort, pale moonwort, ternate grapefern, and least moonwort have been found on the federal lands, and pale moonwort, ternate grapefern, and least moonwort would be directly affected by mining activities. No Habitat Group 3 RFSS have been reported on the non-federal lands.

Species Conditions

Common Moonwort (*Botrychium lunaria*)

Common moonwort is the most widespread of the moonworts and has been found in St. Louis and Cook Counties and several other counties in northern Minnesota, including on the Tracks Project area. Common moonwort appears to prefer open habitats such as gravelly banks, rocky ledges, and talus. It has also been found on open, sparsely vegetated habitats with grasses and scattered shrubs. Along the shore of Lake Superior, common moonwort has been found in fire-dependent forests among mosses and lichens. A Forest Service database reported the habitat for common moonwort as cool/moist conditions, along forest roads and trails, in open areas, lakeshores (sand dunes), and occasionally in forests. Common moonwort has also been reported on sandy soils of old log landings in jack and red pine woods (Chadde and Kudray 2001a and references cited therein).

Common moonwort has not been reported on the federal or non-federal lands.

Michigan Moonwort (*Botrychium michiganense* [*hesperium*])

Across its range, Michigan moonwort (synonym: western moonwort) generally prefers an open habitat and often is found on open early successional habitats that have been disturbed in the past, such as roadside ditches, tailings ponds, gravel pits, log landings, sandy gravel pits, and mine tailings within the Mesabi Iron Range of northeastern Minnesota, including on the federal lands and on the Tracks Project area. Plants have also been found on sand dunes. Soils are often sandy or gravelly. In Minnesota, Michigan moonwort appears to prefer open disturbed habitats. Element occurrence records in St. Louis, Lake, and Cook Counties list habitats as tailings ponds, gravel pits, ditches, an old log landing, and along a weedy roadside (Chadde and Kudray 2001b and references cited therein).

Plant surveys conducted in 2004 identified nine locations of Michigan moonwort within the federal lands. Three of the locations were found on the federal lands within the Mine Site, all of which would be affected by the Project. Six locations of Michigan moonwort were found on private lands within or near the Dunka Road and Utility Corridor (Johnson-Groh 2004); one of these populations would be affected by Project activities.

Michigan moonwort has also been found on the Tracks Project area. Michigan moonwort is sometimes found with other *Botrychium* species in Minnesota including matricary grapefern and pale moonwort.

Michigan moonwort has not been reported on the non-federal lands.

Pale Moonwort (*Botrychium pallidum*)

Pale moonwort (synonym: pale botrychium) was first identified in Minnesota in 1992 and new populations are documented each year in a variety of habitats across northern Minnesota. It occurs in open early successional habitats, log landings, roadsides, sandy gravel pits, and mine tailings within the Mesabi Iron Range of northeastern Minnesota, including on the federal lands and on the Tracks Project area.

This diminutive perennial fern emerges in the late spring, produces spores, and matures within 3 to 4 weeks. Like many of the moonworts, pale moonwort may be sensitive to changes in soil mycorrhizae, herbivory from introduced earthworms, vegetative cover (in other words [i.e.], increased vegetative competition and shading), soil moisture, or other environmental factors affecting suitable microhabitats (Chadde and Kudray 2013a and references cited therein).

Of the 101 known populations statewide, 5 populations totaling 12 individuals were found on the federal lands surrounding the Mine Site; all of these populations would be directly affected by the Project. One of these populations is located south of the West Pit, along the Dunka Road and Utility Corridor. The other four populations are located adjacent to Dunka Road. An additional six locations of pale moonwort were found on private lands immediately adjacent to the federal lands; three of these populations would be affected by Project activities.

Pale moonwort has not been reported on the non-federal lands.

Ternate Grapefern (*Botrychium rugulosum*)

Ternate grapefern (synonym: St. Lawrence grapefern) is a perennial semi-evergreen fern that occurs in the northern and southcentral portions of Minnesota. Relatively little is known about the overall distribution, genetics, and life history requirements of ternate grapefern. In northern Minnesota, ternate grapefern prefers partially shaded mine tailings, sandy coniferous forests and plantations, and shaded vernal pool margins in rich deciduous hardwood forests. It also occurs in wetland areas within habitats subject to past clearing or cultivation. Ternate grapefern is often found in small stands of five to ten individuals, though larger populations can also occur. Disturbance also likely plays an important long-term role in the proliferation of this species (Chadde and Kudray 2013b and references cited therein).

Of the 72 known extant populations in Minnesota, 7 populations totaling 39 individuals occur on the federal lands. One of the seven populations occurring on federal lands would be directly affected by the Project (1% affected). Two additional populations occur on private lands immediately adjacent to the federal lands, neither of which would be affected by Project activities.

Ternate grapefern has not been reported on the non-federal lands, but has been reported on the Tracks Project area.

Least Moonwort (*Botrychium simplex*)

Least moonwort (synonym: little grapefern) occurs throughout northern and central Minnesota. Least moonwort occurs in a variety of natural and disturbed habitats, including brushy fields (often with other species of *Botrychium*), moist or dry woods, edges of forested vernal pools and swamps, mine tailings, and edges of sand/gravel/exposed forest roads. Like the other *Botrychium* species, disturbance likely plays an important role in the proliferation of this species (Chadde and Kudray 2013c and references cited therein).

Of the 213 known populations statewide, 16 populations consisting of at least 354 individuals occur on federal lands within the Mine Site; all but one of these populations would be affected by the Project. There are an additional 19 populations on private lands along the Dunka Road, the railroad, and the transmission line ROW near the Mine Site; 7 of these populations would be affected by Project activities.

Least moonwort has not been reported on the non-federal lands, but has been reported on the Tracks Project area.

Roughfruit Fairybells (*Prosartes trachycarpa* (synonym = *Disporum trachycarpum*))

Roughfruit fairybells has been found near Pigeon River Cliffs in Cook County. The species favors semi-open jack pine forest with aspen, birch, and shallow rocky soils.

Roughfruit fairybells has not been reported on the federal or non-federal lands, or on the Tracks Project area.

Habitat Conditions

Habitat Group 3 RFSS favor upland disturbed, barrens, or early successional ('young' in MIH) forest habitat. There are approximately 64 acres of disturbed habitat and 652 acres of grassland/shrubland on the federal lands, primarily associated with roads and mine exploration sites (**Table 7**). In addition, there are about 271 acres of early successional (young) upland forest habitat (MIH 1 and 5) on the federal lands (**Table 6**).

There are no disturbed areas and approximately 1,878 acres of grassland/shrubland on the non-federal lands (**Table 7**). In addition, there are about 622 acres of early successional upland forest (**Table 6**) that could provide habitat for Habitat Group 3 RFSS on the non-federal lands. Grassland/shrubland habitat is primarily found on Hay Lake Lands and Lake County Lands South, while early successional upland forest is found on Hay Lake Lands, Hunting Club Lands, Lake County Lands North, and Wolf Lands 3.

5.1.4.2 Direct and Indirect Effects

Proposed Action

Species Conditions

Federal Lands

Based on plant surveys of the federal lands, four Habitat Group 3 RFSS would be directly affected by the Project: Michigan moonwort, pale moonwort, ternate grapefern, and least moonwort. All four species have also been found on adjacent private lands along the Dunka Road and Utility Corridor.

Of the 35 populations of Michigan moonwort documented in Minnesota, 3 populations totaling 11 individuals have been found on the federal lands within the Mine Site. Six additional populations totaling 255 individuals have been found on adjacent private lands along the Dunka Road and/or near the railroad tracks. The three populations on federal lands would all be directly affected (9% of statewide populations affected), with one population each being removed by pit excavation, haul road construction, and water pipeline construction. One of the six populations on private lands would be directly affected by Project activities.

Of the 101 known populations of pale moonwort in Minnesota, 5 populations totaling 12 individuals were found on federal lands surrounding the Mine Site. All five populations would be directly affected by the Project, including four locations along Dunka Road (5% of statewide populations affected). Six additional populations totaling 88 individuals were found on adjacent private lands along Dunka Road. Project activities would directly affect three of the six populations. This species, however, appears to be semi-tolerant of disturbance. Therefore, colonies may actually expand into newly disturbed areas along Dunka Road and at the Mine Site (MDNR et al. 2013).

Of the 72 known extant populations of ternate grapefern in Minnesota, 1 population with 19 individuals would be directly affected by construction of the East Pit (1% of statewide populations affected). Six additional populations of ternate grapefern were found within the federal lands, but would not be affected by the Project. Two populations of ternate grapefern, totaling six individuals, were found on private lands along Dunka Road south of the Ore Surge Stockpile and Category 2/3 Stockpile. The Project would have no effect on these two populations.

Of the 213 known populations of least moonwort in Minnesota, 16 populations with at least 356 individuals occur on the Mine site and all but one would be directly affected by mining activities. These include seven populations from stockpiles and mine pits, five populations from haul roads, two populations from water pipelines, and one population from other Project features (7% of statewide population affected). The populations affected by stockpiles, mine pits, and haul roads would be removed, while the populations affected by construction of pipelines or ditches may be reduced in numbers in the short term. Another 19 populations of least moonwort, totaling at least 1,424 individuals, are on adjacent private lands along Dunka Road and the railroad tracks in the vicinity of the Mine Site. The Project would have a direct effect on 7 of the 19 populations on adjacent private lands. Depending on proximity to construction activities, most of these populations of least moonwort would likely recover by growing along the Dunka Road and at the Mine Site post-closure, as this species appears to be semi-tolerant of disturbance (MDNR et al. 2013).

Non-federal Lands

No Habitat Group 3 RFSS have been reported on the non-federal lands, although many of these species were found on the Tracks Project area, which is near Lake County Lands and Wolf Lands. Under the Proposed Action, the non-federal lands would be transferred to the Forest Service, who would manage the lands for timber production, recreation, nature study, and other values. The Forest Service would monitor Habitat Group 3 RFSS use of these lands, and seek to protect high quality habitat for these species.

Habitat Conditions

Federal Lands

Direct effects to Habitat Group 3 RFSS habitat on the federal lands would occur from habitat removal or destruction primarily from mining-related activities, including construction of the mine pits, Waste Rock Stockpiles, access roads, or other mine facilities.

There are 64 acres of disturbed areas and 652 acres of grasslands and shrublands on the federal lands that could provide habitat for Habitat Group 3 RFSS (**Table 7**). The Project would affect about 14 acres of disturbed areas and 204 acres of grasslands and shrublands. In addition, about 260 acres of young upland forest habitat (MIH 1 and 5) would also be lost to mining (**Table 6**).

Habitat for these species could be indirectly affected by dust from mining activities and vehicles, ore spillage, changes in surface and groundwater hydrology from groundwater drawdown, and from changes in water quality related to leakage from stockpiles/mine features and seepage from the mine pits. These risks to Habitat Group 3 RFSS, however, should be negligible.

About 614 acres of grassland/shrubland habitat would be restored during mine reclamation (MDNR et al. 2013). Any remaining individuals in affected portions of the Project area could colonize this habitat. Although the biology of these *Botrychium* species is poorly understood, past mine development activities similar to those proposed by the Project have resulted in creation of habitat conditions favorable to the establishment of several *Botrychium* species, including several RFSS *Botrychium* species. These favorable habitat conditions may perpetuate any populations of these species that may have been missed during Project inventories (USDA Forest Service 2010b).

Non-federal Lands

There are no acres of disturbed habitat and about 1,878 acres of grassland/shrubland that that could provide habitat for Habitat Group 3 RFSS on the non-federal lands (**Table 7**). In addition, there are about 622 acres of early successional upland forest (MIH 1 and 5) that could provide habitat for Habitat Group 3 RFSS on the non-federal lands (**Table 6**). Much of this Habitat Group 3 RFSS habitat is found on Hay Lake Lands. There is no suitable Habitat Group 3 RFSS habitat on the other non-federal lands, although Appalachian clubmoss is found on shelves and crevices on cliff/talus/rock outcrops, which occurs on McFarland Lake Lands. Under the Proposed Action, the Forest Service would survey for Habitat Group 3 RFSS and associated habitat prior to conducting land-disturbing activities and areas of known or potential habitat would be avoided when feasible. Most recreational activity would be confined to trails and roads and could affect Habitat Group 3 RFSS that favor open, disturbed habitats.

Alternative B

Federal Lands

Direct effects to Habitat Group 3 RFSS under Alternative B would be similar to those under the Proposed Action. Based on plant surveys of the federal lands, the four Habitat Group 3 RFSS that could be directly affected by the Project under Alternative B are Michigan moonwort, pale moonwort, ternate grapefern, and least moonwort.

Direct effects to upland disturbed, barrens, or early successional forest habitat from mining and related activities would be similar for the Proposed Action and Alternative B. Under Alternative B, there are 29 acres of disturbed habitat and 439 acres of grassland/shrubland that could provide habitat for Habitat Group 3 RFSS (**Table 7**). In addition, there are about 271 acres of early successional upland forest (MIH 1 and 5) that could provide habitat for Habitat Group 3 RFSS on the non-federal lands (**Table 6**). About 35 fewer acres of disturbed habitat, 213 fewer acres of grassland/shrubland habitat, and the same number of acres of early successional upland forest habitat would be transferred to PolyMet from the Forest Service under Alternative B than under the Proposed Action.

Non-federal Lands

No Habitat Group 3 RFSS have been reported on Hay Lake Lands. There are no acres of disturbed habitat and 1,697 acres of grassland/shrubland that could provide habitat for Habitat Group 3 RFSS on Hay Lake Lands (**Table 7**). In addition, there are about 534 acres of early successional upland forest (MIH 1 and 5) that could provide habitat for Habitat Group 3 RFSS on Hay Lake Lands (**Table 6**). About 86% of early successional upland forest habitat that occurs on the non-federal lands is found on Hay Lake Lands. Thus, the Forest Service would receive much of the land that could provide habitat for Habitat Group 3 RFSS on the non-federal lands under both the Proposed Action and Alternative B.

No Action Alternative

There would be no direct or indirect effects to Habitat Group 3 RFSS under the No Action Alternative.

5.1.4.3 Cumulative Effects

As discussed in Section 4.5.2, it is possible that Habitat Group 3 RFSS and/or their habitat have been lost from past and ongoing activities in the CESA, and would be lost in the future from similar reasonably foreseeable future activities.

The Project could directly affect 35 Habitat Group 3 RFSS populations and about 478 acres of habitat used by Habitat Group 3 RFSS, on the federal lands. Despite the cumulative effects of the Mine Site, Habitat Group 3 RFSS species that would be affected by the Project occur elsewhere in the Superior National Forest, including the Tracks Project area, and in Minnesota, and would not be affected by the Project or other ground-disturbing activities in the CESA. In addition, there are about 33,000 acres of grassland habitat in the CESA (Emmons and Oliver Resources, Inc. 2006:30, 38). About 7% of Forest Service-administered lands are young forest (USDA Forest Service 2011:42), while the percentage of forestlands that are young forest is likely greater for privately owned lands. However, based on a conservative assumption that about 5% of upland forest in the CESA is young forest, about 31,000 acres of early successional upland forest would be available Habitat Group 3 RFSS. In addition, there are about 100,000 acres of disturbed mining areas, some of which could provide habitat for Habitat Group 3 RFSS in the CESA (Emmons and Olivier Resources, Inc. 2006:30, 38).

After mining, about 397 acres would be reclaimed and the federal lands would be privately owned and closed to public access (MDNR et al. 2013). Habitat Group 3 RFSS favor disturbed areas and early successional habitats, the types of habitat associated with recent logging and road-building activity. There is potential for mining activities and mine reclamation to create disturbed areas and early successional habitats that could be colonized by Habitat Group 3 RFSS in the future.

Timber harvesting, road building, and recreational activities could occur on the federal and non-federal lands. Forest management activities could result in Habitat Group 3 RFSS and their habitats being driven over and crushed by timber harvest and road construction/maintenance equipment. No Habitat Group 3 RFSS have been reported on the non-federal lands, but there are about 622 acres of suitable habitat (young age class; **Table 6**) on the lands. The Forest Service would survey for RFSS prior to conducting land-disturbing activities, and would avoid areas with known or potential habitat for RFSS when feasible. Should disturbance activities occur on the non-federal lands, it would result in soil disturbance and creation of early successional habitat that could be colonized by Habitat Group 3 RFSS.

5.1.4.4 Summary

Project activities associated with the Proposed Action and Alternative B would have direct, indirect, and cumulative effects on Habitat Group 3 RFSS, and cause adverse effects on up to 478 acres of known or potential habitat for Habitat Group 3 RFSS on the federal lands. Other activities in the CESA would also contribute to cumulative effects toward the RFSS plants of this habitat group. The Proposed Action and Alternative B would have similar effects on Habitat Group 3 RFSS, while there would be no effects to Habitat Group 3 RFSS from the No Action Alternative.

5.1.4.5 Determination

The Proposed Action and Alternative B **may impact individuals but are not likely to cause a trend to federal listing or loss of viability** for Michigan moonwort, pale moonwort, ternate grapefern, least moonwort, common moonwort, Appalachian clubmoss, and roughfruit fairybells. The No Action Alternative would have **no impact** to individuals of Habitat Group 3 RFSS.

5.1.4.6 Mitigation and Recommendations

No mitigation measures are proposed for Habitat Group 3 RFSS.

5.1.5 Forested Wetland – Black Spruce, Tamarack, and Mixed Conifer Forest Habitat (Habitat Group 4)

5.1.5.1 Environmental Baseline

Habitat Group 4 RFSS favor forested wetlands comprised of coniferous trees such as black spruce, tamarack, and northern white cedar, and deciduous trees such as black ash and yellow birch. The following Habitat Group 4 RFSS either occur on, and/or have suitable habitat on, the federal and/or non-federal lands—fairy slipper, ram's head lady slipper, Selwyn's scalewort, yellow specklebelly, cartilage lichen, cloudberry, peppered moon lichen, honeycombed lichen, western Jacob's-ladder, snowline wintergreen, beard lichen, and two unnamed lichens, *Caloplaca parvula*, and *Cetraria aurescens*. Snowline wintergreen has been found on the federal lands. No Habitat Group 4 RFSS have been reported on the non-federal lands.

Species Conditions

Fairy Slipper (*Calypso bulbosa* var. *occidentalis*)

Fairy slipper is palearctic in distribution, and occurs in 20 of the 48 contiguous states and all of the Canadian provinces. It occurs across the northern third of Minnesota, including St. Louis, Lake, and Cook Counties. It is principally associated with northern white cedar, growing in the shaded duff with little or no herbaceous competition over a metamorphic and igneous bedrock parent material, with calcium accumulated from ground springs (Schmidt 2003a and references cited therein). In bogs, it can occur on stumps, logs, hummocks of drier soil, or slopes, but does not occur in soggy soils. Fairy slipper is also found in closed canopy forest with at least 60% cover and cool soils, and is intolerant of soil temperatures higher than 60 degrees Fahrenheit.

Fairy slipper requires older, closed-canopy cedar stands, so any loss of a viable cedar type affects this species. Limited regeneration due to high deer populations is the primary threat to the cedar community and associated species. Other threats to the community include beaver activity and forest harvesting.

Fairy slipper has not been reported on the federal or non-federal lands, or on the Tracks Project area.

Ram's head Lady Slipper (*Cypripedium arietinum*)

Ram's head lady slipper ranges from Quebec and Saskatchewan south to Maine, New Hampshire, Vermont, Connecticut, and New York, and west to Michigan, Wisconsin, and Minnesota. Ram's head lady slipper has always been considered biologically rare in Minnesota, and the reasons for its rarity are not entirely known. It is known from St. Louis, Lake, and Cook Counties, and elsewhere in central and northern Minnesota. Recently, however, it has suffered a general decline in Minnesota largely as a result of habitat loss from changes in land use, including clear-cutting of jack pine forests.

In Minnesota, populations of Ram's head lady slipper occur in a variety of coniferous forest habitats. Several populations occur in swamps, bogs, or lowland forests dominated by northern white cedar, tamarack, balsam fir, or black spruce. Cool soils seem to define its range; in its southernmost reaches the orchid is found in cold bogs or north-facing cool bluffs near the Great Lakes where cool air drains down ravines. The species also occurs in the drier upland coniferous forests that may be dominated by white pine, red pine, or jack pine (Brzeskiewicz 2000 and references cited therein).

Ram's head lady slipper has not been reported on the federal or non-federal lands, or on the Tracks Project area.

Selwyn's Scalewort (*Frullania selwyniana*)

Selwyn's scalewort is found on lowland northern white cedar swamps on the bark of northern white cedar.

Selwyn's scalewort has not been reported on the federal or non-federal lands, but has been found on the Tracks Project area.

Honeycombed Lichen (*Menegazzia terebrata*)

In the Great Lakes Region, honeycombed lichen has a scattered distribution, mainly associated with bog and cedar swamps, perhaps revealing its oceanic (moist oceanic forests) origin (USDA Forest Service 2002 and references cited therein). In the Great Lakes Region, honeycombed lichen survives in the oldest and wettest

northern white cedar bogs as a few scattered individuals on cedar trunks (estimated 200+ years) in relatively open areas with 50 to 60% canopy cover. In Minnesota, five sites were found on the Superior National Forest within interior portions of old growth northern white cedar bogs. The main short term threat in northern white cedar bogs/swamps is hydrological change from road building and logging.

Honey-combed lichen has not been reported on the federal or non-federal lands, or on the Tracks Project area.

Western Jacob's-ladder (*Polemonium occidentale* spp. *lacustre*)

Western Jacob's-ladder was first documented in St. Louis County, Minnesota in 1944. Prior to that discovery, this subspecies was unknown to science. A total of only five sites in Itasca and St. Louis Counties, Minnesota, have been located since 1944, even after extensive survey efforts.

Habitat requirements for western Jacob's-ladder include open forested wetland communities with associated northern white cedar, tamarack, black spruce, and generally a ground cover of sphagnum moss. Common associated shrub species include speckled alder and bog birch. Within suitable forests, western Jacob's-ladder is found on open and sparsely forested portions of the swamps, as well as in moderately deep shade, usually on hummocks of sphagnum moss. The saturated conditions usually originate from groundwater seepage.

Likely threats would include increased canopy closure, any activity that directly alters the habitat and destroys plants (e.g. slash piles, peat mining, and flooding by beaver dams), or anything that alters groundwater flow. All known locations of this species have a history of logging, ranging from disturbance in the early 1900s to as recent as the 1990s. In all five known populations, western Jacob's ladder blooms most in natural or logging-related openings. In contrast to other species associated with northern white cedar communities, logging appears to be less of a threat (Schmidt 2003b and references cited therein).

Western Jacob's ladder has not been reported on the federal or non-federal lands, or on the Tracks Project area.

Snowline Wintergreen (*Pyrola minor*)

Snowline wintergreen (synonym: small shinleaf) is listed as a species of special concern in Minnesota. The species was first reported in Lake County in 1914 near the North Kawishiwi River. It has since only been documented in Cook, St. Louis, Lake, and Carlton Counties.

Snowline wintergreen is a circumpolar species occurring across Canada and the western U.S. in boreal and alpine habitats. It usually occurs in conifer swamps, including black spruce and northern white cedar swamps, and black spruce-balsam fir forests. Snowline wintergreen can also be found along moist ecotones between wetlands and uplands or between streams and slopes. It may be semi-tolerant of disturbance, because healthy populations exist along well-traveled portage routes and at sites that have experienced timber harvesting around 20 years prior.

Snowline wintergreen has been reported southwest of Mud Lake on the federal lands, within One Hundred Mile Swamp, and approximately 0.7 mile northwest of the Mine Site. Snowline wintergreen has also been found on the Tracks Project area.

Snowline wintergreen has not been reported on the non-federal lands.

Yellow Specklebelly (*Pseudocyphellaria crocata*)

Yellow specklebelly has always been rare in northern Minnesota. It was collected between 1897 and 1902 in St. Louis, Koochiching, Lake, and Cook Counties. In the last 34 years, it has been found only once in St. Louis County, approximately 65 miles northwest of the federal lands. The extensive removal of mature, moist forests across Minnesota's forested landscape has seriously reduced the occurrence of this lichen in the state.

Yellow specklebelly is found in habitats that are moist, shady, and often foggy. Substrates for this lichen are varied, including mossy rocks and a variety of trees, especially northern white cedar in mature hardwood and coniferous forests. When found on trees, this lichen usually occurs 3 to 4 feet above the ground and is at least partially shaded by the tree on which it is growing. All known Minnesota populations of this lichen are near water, and many are on offshore islands.

Yellow specklebelly has not been reported on the federal or non-federal lands, or on the Tracks Project area.

Cartilage Lichen (*Ramalina thrausta*)

Cartilage lichen is found in old growth and other northern white cedar swamps.

Cartilage lichen has not been reported on the federal or non-federal lands, or on the Tracks Project area.

Cloudberry (*Rubus chamaemorus*)

Cloudberry is an arctic and boreal species that is typical of circumpolar bog habitats in North America, Europe, and Asia. The southern limit of its range in North America is poorly defined and is represented by local and discontinuous populations in northern New England and disjunctive sites at Montauk Point, Long Island, and northeastern Minnesota. This species was unknown in Minnesota until 1954 when it was discovered near a research facility on Basswood Lake in the Superior National Forest in Lake County. Since that time, only a few colonies have been located despite targeted surveys. It has been found in St. Louis, Lake, and Cook Counties.

In Minnesota, cloudberry has been found in sphagnum bogs dominated by black spruce or mixed forests of black spruce speckled alder, bog birch, and sometimes northern white cedar. It is often found on deep sphagnum moss hummocks associated with bluejoint, three-seeded bog sedge, creeping snowberry, Labrador tea, and three-leaved false Solomon's seal.

Cloudberry has not been reported on the federal or non-federal lands, or on the Tracks Project area.

Peppered Moon Lichen (*Sticta fuliginosa*)

Peppered moon lichen (synonym: spotted felt lichen) was formerly quite common in Minnesota along the Lake Superior shoreline and around inland lakes and bogs. Today, there are only a few extant populations known in Cook, Lake, and St. Louis Counties; none of these sites are near the federal or non-federal lands. Where it exists, it is found on conifer and hardwood trees in mature, moist forests and bogs. Yellow birch and northern white cedar are preferred substrates. This lichen prefers partial shade in areas that tend to retain moisture, such as northern white cedar swamps, and is often growing on the lower trunks of trees, 3 to 5 feet above the ground (Whitmore 2002a and references cited therein).

Peppered moon lichen has not been reported on the federal or non-federal lands, or on the Tracks Project area.

Beard Lichen (*Usnea longissima*)

Beard lichen is known in Michigan, Wisconsin, and Minnesota. In Minnesota, it has been found in St. Louis, Lake, and Cook Counties, primarily near Lake Superior and in the BWCAW.

Beard lichen is usually found in forests near streams, lakes, or in bogs. The forests are balsam fir, black spruce, or northern white cedar over 100 years old that may be open or quite shady. High humidity and habitat continuity are important for growth, but this species grows better on the upper branches of trees where there is more available light. The recent localities in Superior National Forest are undisturbed balsam fir or northern white cedar stands near water. In one locality (Mark Creek), it apparently began growth in a mature balsam fir forest that has since been killed by insects but the thallus persisted on a dead balsam fir. The extensive logging in the past has eliminated many potential habitats (Wetmore 2002b and references cited therein).

Beard lichen has not been reported on the federal or non-federal lands, or on the Tracks Project area.

Lichen spp. (*Caloplaca parvula*)

Caloplaca parvula was unknown to science when this species was first collected in Minnesota in 1978 near Kettle Falls in St. Louis County. Only two additional specimens have been found in the state since then, both in St. Louis County on Little Long Lake and Echo Lake on the Superior National Forest (Wetmore 2002c and references cited therein). This lichen species occurs in old-age, deciduous-tree swamps, specifically black ash bogs, near open water. In Minnesota, all sites were open black ash bogs with some standing water and without tall grasses, sedges, or brush. These swamps typically have 12 to 14 inches dbh trees, but this lichen species is not found on these trees. Instead, the preferred substrate is 3 to 4 inches dbh young re-growth, near the tree base, within 1 foot of the ground. The forest canopy is fairly open, allowing for lots of sunlight. Humidity in these habitats is high. Groundcover is minimal, typically comprised of just a few sedges.

Caloplaca parvula does not occur on sites with abundant shrubs and groundcover. It is found on sites with some amount of standing water, but has never been found other on a site without standing water. Water is in depressions in the swamp. The young trees or regrowth on which this species is found may themselves be in standing water. All Minnesota sites could be potentially threatened by permanent lake level changes caused by addition or removal of dams (Wetmore 2002c and references cited therein).

Caloplaca parvula has not been reported on the federal or non-federal lands, or on the Tracks Project area.

Lichen spp. (*Cetraria aurescens*)

Cetraria aurescens occurs in old-growth temperate forests and usually grows on pine, on cedar, and occasionally on hardwoods in the southern Appalachians. It has been found in St. Louis, Lake, and Cook Counties, including about 6 miles south of Hoyt Lakes and 5 miles east of Babbitt, Minnesota.

In northern Minnesota, it is restricted to moist habitats near bogs or water in areas of old-growth forest without disturbance, especially within northern white cedar swamps over 100 years old. In the Great Lakes Region, this species seems to require old-growth, moist habitats. In a habitat study in Superior National Forest, this species was found in forest stands with an overstory ranging from 10 to 80% and on trees ranging in age from 118 to

266 years. These localities were usually northern white cedar swamps or black spruce bogs (Wetmore 2002d and references cited therein).

Cetraria aurescens has not been reported on the federal or non-federal lands, or on the Tracks Project area.

Habitat Conditions

Habitat Group 4 RFSS favor forested wetlands comprised of coniferous trees such as black spruce, tamarack, northern white cedar, and deciduous trees such as black ash and yellow birch. Several species, including bearded lichen, fairy slipper, and *Cetraria aurescens* prefer mature wetland forest habitat. Although forested wetland habitat is the most common habitat on the federal and non-federal lands, only one species, snowline wintergreen, was found on the federal lands, and only two species, snowline wintergreen and Selwyn's scalewort, were found on the Tracks Project area; none of the Habitat Group 4 RFSS were reported on the non-federal lands.

There are about 3,270 acres of forested wetland on the federal lands, which represents 79% of all wetland habitat and 50% of all habitat on these lands (**Table 8**). Snowline wintergreen was found within One Hundred Mile Swamp, which is dominated by black spruce, northern white cedar, and tamarack forest, with small patches of open bogs and shrublands. Sphagnum and club mosses cover nearly 100% of the ground, while forest and shrub cover is about 40 to 70%. ENSR (2005) found that about 1% of wetland forest is comprised of young trees, 93% is comprised of immature trees, while about 5% is comprised of mature trees. Of this acreage, only 1% is comprised of deciduous or mixed coniferous-deciduous forest, the remainder was black spruce, northern white cedar, or tamarack forest.

There are about 3,300 acres of forested wetland on the non-federal lands, which represents 71% of all wetland habitat and 47% of all habitat on these lands (**Table 8**). Wetland forest is dominated by black spruce and tamarack, with scattered northern white cedar. Forest and shrub cover ranges from 30 to 60%, while ground cover is 50 to 90% (AECOM 2011b, c). AECOM (2011b, c) found that less than 1% of wetland forest is comprised of mature trees, 4% is comprised of young trees, while 95% is comprised of immature trees. Of this acreage, only 3% is comprised of deciduous or mixed coniferous-deciduous forest, the remainder was black spruce, northern white cedar, and tamarack forest. Black ash is found in small patches on Lake County Lands South, Hunting Club Lands, and Wolf Lands 2, while northern white cedar is most common on Lake County Lands North, Lake County Lands South, Wolf Lands 2, and Wolf Lands 4.

5.1.5.2 Direct and Indirect Effects

Proposed Action

Species Conditions

Federal Lands

Based on plant surveys of the federal lands, one population of snowline wintergreen, consisting of ten individuals, was found northwest of the Mine Site within One Hundred Mile Swamp. The remainder of Habitat Group 4 RFSS have not been reported on the federal lands. The Project would have no direct or indirect effect on the snowline wintergreen population in One Hundred Mile Swamp.

Non-federal Lands

No Habitat Group 4 RFSS have been reported on the non-federal lands. Under the Proposed Action, the non-federal lands would be transferred to the Forest Service, who would manage the lands for timber production, recreation, nature study, and other values. The Forest Service would monitor Habitat Group 4 RFSS use of these lands, and seek to protect high quality habitat for these species.

Habitat Conditions

Federal Lands

Direct effects to Habitat Group 4 RFSS on the federal lands could occur from mining-related activities, including construction of the mine pits, Waste Rock Stockpiles, access roads, and mine facilities. Although no Habitat Group 4 RFSS were found during plant surveys for the federal lands, about 589 acres of forested wetland would be directly affected by mining on the federal lands (**Table 8**).

Habitat for snowline wintergreen, which is found northwest of the Mine Site, and other Habitat Group 4 RFSS, could potentially be indirectly affected by dust from mining activities and vehicles, changes in surface and groundwater hydrology from groundwater drawdown, and from changes in water quality related to leakage from stockpiles/mine features and seepage from mine pits (MDNR et al. 2013). These risks, however, should be negligible.

About 516 acres of wetland habitat would be restored during mine reclamation (MDNR et al. 2013). However, it is unlikely that any Habitat Group 4 RFSS would colonize these areas because nearly all Habitat Group 4 RFSS prefer immature and mature forests and it would likely be 20 or more years before the restored habitat would reach this stage of maturity.

Non-federal Lands

There are about 3,300 acres of forested wetland, or 71% of all wetland habitat and 47% of all habitat, on the non-federal lands (**Table 8**). Under the Proposed Action, the Forest Service would survey for Habitat Group 4 RFSS and associated habitat prior to conducting land-disturbing activities; areas of known or potential habitat would be avoided when feasible. Most recreational activity would be confined to trails and roads and could affect Habitat Group 4 RFSS that favor open, disturbed habitats.

Alternative B

Federal Lands

Direct and indirect effects to Habitat Group 4 RFSS under Alternative B would be similar to those under the Proposed Action. Based on plant surveys for the federal lands, no Habitat Group 4 RFSS would be directly affected by the Project under Alternative B.

Direct and indirect effects to forested wetlands from mining and related activities would be similar for the Proposed Action and Alternative B. Under Alternative B, there are about 2,167 acres of forested wetland (**Table 8**). About 1,103 fewer acres (34%) of forested wetland would be transferred to PolyMet from the Forest Service than under the Proposed Action.

Non-federal Lands

No Habitat Group 4 RFSS have been reported on Hay Lake Lands. There are about 1,962 acres of forested wetland on Hay Lake Lands, which is about 59% of the forested wetland habitat that occurs on the non-federal lands (**Table 8**). Thus, the Forest Service would receive lands that could provide habitat for Habitat Group 4 RFSS on the non-federal lands under Alternative B.

No Action Alternative

There would be no direct or indirect effects to Habitat Group 4 RFSS under the No Action Alternative.

5.1.5.3 Cumulative Effects

As discussed in Section 4.5.2, it is possible that Habitat Group 4 RFSS and/or their habitat have been lost from past and ongoing activities in the CESA, and would be lost in the future from similar reasonably foreseeable future activities.

Because European settlement, timber harvest, wetland drainage, and road construction have affected forested wetlands and reduced the amount and distribution of this habitat within the CESA. More recently, timber sales on federal, state, county, and private lands have changed the age class distribution of lowland black spruce habitats, but have not altered the overall suitability of the habitat for species in this habitat group.

Forest management activities could result in Habitat Group 4 RFSS and their habitats being driven over and crushed by timber harvest and road construction/maintenance equipment, and harmed from sedimentation of streams and lakes due to ground disturbance. Timber harvest activities would be conducted during winter in wetlands, however, to reduce the risks of ground disturbance and sedimentation.

Construction and use of roads in lowlands under the Proposed Action, Alternative B, and No Action Alternative and elsewhere in the CESA would continue to affect suitable habitat. However, the proportion of total suitable habitat affected by these activities would be very small. Timber sales affecting lowlands on state or county lands could change the age class of lowland black spruce forests in the Project area, temporarily making some stands less suitable for Habitat Group 4 RFSS. However, the proportion of total suitable habitat affected by these activities would be very small.

The Project could potentially indirectly affect the habitat of one Habitat Group 4 RFSS population, and directly affect about 589 acres of potential habitat on the federal lands for Habitat Group 4 RFSS (**Table 7**). Despite the potential cumulative effects, RFSS that could be affected by the Project also occur elsewhere in the Superior National Forest, including the Tracks Project area, and elsewhere in Minnesota, which would not be affected by the Project or other ground-disturbing activities in the CESA. In addition, there about 370,000 acres of habitat for Habitat Group 4 RFSS remaining in the CESA (Emmons and Olivier Resources, Inc. 2006:30, 38).

PolyMet would acquire about 2,266 acres of forested wetland on the federal lands surrounding the Mine Site under the proposed land exchange (**Table 8**). Although these lands would remain privately owned, it is likely that some or all of these lands would be managed for timber production and harvested in the reasonably foreseeable future. Timber harvest and associated road construction could directly or indirectly affect Habitat Group 4 RFSS, including snowline wintergreen, unless efforts are taken to avoid Habitat Group 4 RFSS. Effects

from timber management would be mitigated by voluntary adherence to Minnesota Forest Resources Council best management practices (Minnesota Forest Resources Council 1999).

Timber harvesting, road building, and recreational activities could occur on non-federal lands. No Habitat Group 4 RFSS have been reported on the non-federal lands, but there are about 3,300 acres of suitable habitat on the non-federal lands (**Table 8**). The Forest Service would survey for RFSS prior to conducting land-disturbing activities, and would avoid areas with known or potential habitat for RFSS when feasible. Should disturbance activities occur on the non-federal lands, it would take 20 or more years before disturbed lands would be suitable for Habitat Group 4 RFSS.

5.1.5.4 Summary

Project activities associated with the Proposed Action and Alternative B could have indirect effects on individual Habitat Group 4 RFSS, and indirect and cumulative effects on their habitat. Other activities in the CESA would also contribute to cumulative effects toward the RFSS plants of this habitat group. The Proposed Action and Alternative B would have similar effects on Habitat Group 4 RFSS, while there would be no effects to Habitat Group 4 RFSS from the No Action Alternative.

5.1.5.5 Determination

The Proposed Action and Alternative B **may impact individuals but are not likely to cause a trend to federal listing or loss of viability** for snowline wintergreen, fairy slipper, ram's head lady slipper, Selwyn's scalewort, yellow specklebelly, cartilage lichen, cloudberry, peppered moon lichen, honeycombed lichen, western Jacob's-ladder, beard lichen, and two unnamed lichens, *Caloplaca parvula*, and *Cetraria aurescens*. The No Action Alternative would have **no impact** to individuals of Habitat Group 4 RFSS.

5.1.5.6 Mitigation and Recommendations

No mitigation measures are proposed for Habitat Group 4 RFSS.

5.1.6 Mesic Hardwood Forest Dominated Habitat (Habitat Group 5)

5.1.6.1 Environmental Baseline

Habitat Group 5 RFSS favor upland mesic (moderately moist) deciduous forests comprised of sugar maple, basswood, paper birch, and yellow birch. The following Habitat Group 5 RFSS either occur on, and/or have suitable habitat on, the federal and/or non-federal lands—moshatel, Braun's holly fern, triangle grapefern, and lanceleaf grapefern. Triangle grapefern has been found on Hay Lake Lands, but not on the other non-federal lands or federal lands. Moshatel, Braun's holly-fern, and lanceleaf grapefern have not been found on the federal or non-federal lands.

Species Conditions

Moshatel (*Adoxa moschatellina*)

The number of known occurrences of moshatel in Minnesota exceeds 120 populations, including records from St. Louis, Lake, and Cook Counties. The habitat of moshatel in Minnesota is primarily mesic hardwood forests. These are typically mature or old growth communities dominated by sugar maple and basswood. There may also

be significant amounts of paper birch and yellow birch. In the northern part of the state there may be conifers present, particularly northern white cedar and balsam fir.

The narrow geographical and ecological range of those occurrences may be a cause for concern. It appears that the mature mesic hardwood forests where this species occurs are often selectively targeted for intensive forest management in northern Minnesota. In addition to the pressures of the timber industry, mesic forests in southeastern Minnesota tend to be more vulnerable to invasion by non-native species.

Moshatel not been reported on the federal or non-federal lands, or on the Tracks Project area.

Triangle Grapefern (*Botrychium lanceolatum*) and Lanceleaf Grapefern (*Botrychium lanceolatum* var. *angustisegmentum*)

Lanceleaf grapefern is a variety of triangle grapefern and the two are analyzed together in this section. These are small ferns that range across much of the northeastern U.S. and Canada. They are uncommon in Minnesota, but more common in Wisconsin and Michigan, and especially common on the Ottawa National Forest in Michigan's western Upper Peninsula. They are found in St. Louis, Lake, and Cook Counties and several other counties in Minnesota, including on the Tracks Project area. They prefer moist, shady, mature northern hardwood forests, particularly in low areas. They usually occur with sugar maple, yellow birch, green ash, black ash, red oak, basswood, and sometimes northern white cedar. The understory can be rather open.

These ferns probably appear or disappear in accordance with mycorrhizal health due to their obligate relationship with the fungi. Environmental factors that may affect mycorrhizae, like reduction in water availability, are likely to have effects on these ferns, whereas the repeated removal of leaf tissue may have little effect (Chadde and Kudray 2001c and references cited therein).

Triangle grapefern not been reported on the federal lands, but one population was been found near the southwestern portion of Hay Lake Lands (MDNR 2014a). It was not reported on the Tracks Project area.

Lanceleaf grapefern has not been reported on the federal or non-federal lands, but was found on the Tracks Project area.

Goblin Fern (*Botrychium mormo*)

The geographic range of *Botrychium mormo* is confined to forests in portions of three contiguous states: Minnesota, Wisconsin, and Michigan. Most of the records are from north-central Minnesota, particularly Cass County. However, the species is scarce even within its stronghold, and it is becoming increasingly rare. The species requires an intact tree canopy in order to have consistently shaded, moist conditions and the accelerating rate of habitat degradation is the reason for its decline. Concerns over habitat loss and degradation from timber management activities and land clearing prompted the listing of *B. mormo* as a Minnesota special concern species in 1984.

B. mormo occurs in mature mesic hardwood forests where the dominant trees are *Acer saccharum* (sugar maple) with lesser amounts of *Thuja occidentalis* (northern white cedar). The canopy must be intact to maintain shaded, moist conditions. The soils are loamy with large amounts of humus, or organic matter, on the surface.

There is a documented occurrence of goblin fern within a mile of the Hay Lake parcel, where suitable habitat for goblin fern may be present.

Braun's Holly Fern (*Polystichum braunii*)

The geographic range of Braun's holly fern is quite limited and it is generally considered to be rare or local wherever it occurs. It was first found in Minnesota in 1966 during a geological survey of Cook County, and it has since been discovered in adjacent Lake County. Surveys of suitable habitats in northeastern Minnesota have located this species in only a few locations, and it typically occurs in rather localized, small populations.

Most occurrence records place the species in rocky environments, including in soil pockets and fissures in rock outcrops, at the bases of cliffs, among talus, along boulder-strewn water courses, or in rocky woods. But others have found it in environments that may be relatively rock-free, such as floodplain forests and woods with deep loamy soil. Microhabitat seems to be crucial in providing the cooler temperatures needed by this northern species. It is often found in erosion channels where the banks are steeply cut and cool air drains and settles, providing cool and moist conditions throughout the day. Shade, either of steep-sided ravines and gorges, north-facing slopes, or provided by a mature forest canopy or at least a shrub thicket, seems to be a constant. (Brzeskiewicz and Fields 2003 and references cited therein). In Minnesota, Braun's holly fern has been found on small ledges and cracks on the steep walls of river gorges, at the base of cliffs, on shaded rockslides, and in a cobbly, seepy drainage of lowland black ash and northern white cedar. However, most of the populations occur along moist, often rocky draws and ephemeral rocky streams in rich hardwood forests dominated by sugar maple and yellow birch.

Braun's holly fern has not been reported on the federal or non-federal lands, or the Tracks Project area.

5.1.6.2 Habitat Conditions

Habitat Group 5 RFSS favor upland mesic (moderately moist) deciduous forests comprised of sugar maple, basswood, paper birch, and yellow birch. Upland mesic deciduous forest is a component of MIH 1. However, the Forest Service MIH mapping system is too broad to accurately identify acres of this particular forest type. There are about 1,330 acres of upland forest (MIH 1), which includes aspen/aspen-white birch, maple/basswood, and oak forest cover types, on the federal lands and 2,695 acres of upland forest on the non-federal lands (**Table 6**). However, based on plant habitat surveys for the federal lands, mesic deciduous forest comprises only a small portion of upland deciduous forest on the federal and non-federal lands (MDNR et al. 2013).

5.1.6.3 Direct and Indirect Effects

Proposed Action

Species Conditions

Federal Lands

There should be no direct or indirect effects to moshatel, Braun's holly fern, triangle grapefern, or lanceleaf grapefern on federal lands from the Project as they have not been found on the federal lands and there is very little suitable habitat for these species on the federal lands.

Non-federal Lands

The Forest Service would monitor for triangle grapefern near Hay Lake Lands, and seek to protect high quality habitat for this plant species. Under the Proposed Action, the non-federal lands would be transferred to the Forest Service, who would manage the lands for timber production, recreation, nature study, and other values. The Forest Service would monitor Habitat Group 5 RFSS use of these lands, and seek to protect high quality habitat for these species.

Habitat Conditions

Federal Lands

There is very little suitable mesic upland forest habitat for Habitat Group 5 RFSS on the federal lands.

Non-federal Lands

Very little upland mesic upland forest habitat is found on the non-federal lands. Under the Proposed Action, the Forest Service would survey for Habitat Group 5 RFSS and associated habitat prior to conducting land-disturbing activities; areas of known or potential habitat would be avoided when feasible. Most recreational activity would be confined to existing trails and roads and would not likely affect Habitat Group 5 RFSS that favor upland mesic deciduous forests.

Alternative B

Federal Lands

There should be no direct or indirect effects to moshatel, Braun's holly fern, triangle grapefern, or lanceleaf grapefern on federal lands from the Project under Alternative B as these species have not been reported on the federal lands and there is little suitable mesic upland forest habitat for these species on the federal lands.

Non-federal Lands

Triangle grapefern has been found near Hay Lake Lands. Risks to this population and other Habitat Group 5 RFSS populations that could be found on the non-federal lands, and their habitat, would be similar to those under the Proposed Action.

No Action Alternative

There would be no direct or indirect effects to Habitat Group 5 RFSS under the No Action Alternative.

5.1.6.4 Cumulative Effects

As discussed in Section 4.5.2, it is possible that Habitat Group 5 RFSS and/or their habitat have been lost from past and ongoing activities in the CESA, and would be lost in the future from similar reasonably foreseeable future activities.

Forest management activities could result in Habitat Group 5 RFSS and their habitats being driven over and crushed by timber harvest and road construction/maintenance equipment, and from ground disturbance

associated with these activities. Timber harvest and road construction have affected upland forests and reduced the amount and distribution of this habitat within the CESA. Construction and use of roads under the Proposed Action, Alternative B, and the No Action Alternative, and elsewhere in the CESA, would continue to affect suitable habitat. There are about 460,000 acres of upland deciduous forest in the CESA (Emmons and Olivier Resources, Inc. 2006:30, 38), and a portion of this habitat would be mesic hardwood forest and would be available to Habitat Group 5 RFSS.

There should be no effects to Habitat Group 5 RFSS or their habitat from mining, and little upland mesic hardwood forest would be transferred to PolyMet under the land exchange (MDNR et al. 2013). Timber harvesting, road building, and recreational activities could occur on the federal and non-federal lands, depending upon whether the Proposed Action, Alternative B, or No Action Alternative is selected in the Record of Decision. In addition, there is the potential for homes and cabins to be built on the non-federal lands should the FEIS Record of Decision select the No Action Alternative and non-federal lands remain under private ownership. Only one population of triangle grapefern has been found on or near the non-federal lands (Hay Lake Lands) and little suitable habitat is found on the non-federal lands for Habitat Group 5 RFSS. The Forest Service would survey for RFSS prior to conducting land-disturbing activities, and would avoid areas with known or potential habitat for RFSS when feasible.

5.1.6.5 Summary

Project activities associated with the Proposed Action and Alternative B should have no direct or indirect adverse effects on Habitat Group 5 RFSS or their habitat, and would have a negligible contribution toward cumulative effects for Habitat Group 5 RFSS. Other activities in the CESA could also contribute to cumulative effects toward the RFSS plants of this habitat group. The Proposed Action and Alternative B would have similar effects on Habitat Group 5 RFSS, while there should be no effects to Habitat Group 5 RFSS from the No Action Alternative.

5.1.6.6 Determination

There would be **no impacts** to individuals of moshatel, Braun's holly fern, triangle grapefern, or lanceleaf grapefern under the Proposed Action, Alternative B, or No Action Alternative.

5.1.6.7 Mitigation and Recommendations

No mitigation measures are proposed for Habitat Group 5 RFSS.

5.1.7 Dry-mesic Upland Forest: Deciduous, Coniferous, or Mixed Forest Habitat (Habitat Group 6)

5.1.7.1 Environmental Baseline

Habitat Group 6 RFSS favor dry to mesic upland forests. The following Habitat Group 6 RFSS either occur on and/or have suitable habitat on, the federal and/or non-federal lands—New England sedge, fan lichen, Canada yew, Canada ricegrass, and barren strawberry. Fan lichen, although not included as part of any habitat group in the Forest Plan BE, is analyzed with this habitat group in this BE because of its affinity for bare soil habitats such as root wads (USDA Forest Service 2004c). None of these species have been reported on the federal or non-federal lands.

Species Conditions

New England Sedge (*Carex novae-angliae*)

New England sedge has been found at several locations in the Superior National Forest in St. Louis, Lake, and Cook Counties, including on the Tracks Project area. It is found in moist woods with sugar maple, paper birch, trembling aspen, yellow birch, and white spruce dominated forest (Shackleford 2004).

New England sedge has not been reported on the federal or non-federal lands. It has been found on the Tracks Project area.

Fan Lichen (*Peltigera venosa*)

In Minnesota, fan lichen has only been found in Cook County, where it grows on soil and on moist cliffs at a few locations near Lake Superior (Wetmore 2002e and references cited therein). In 1897, Bruce Fink found the species at two localities, while the most recent collections are from 2010. Thorough searches at many localities have yielded no additional records, but some potential habitat remains to be searched. The preferred substrate for fan lichen is rich, not-recently-disturbed soil and mossy rocks. It prefers cool, shady, moist locations, but only where there is little competition from other plants.

Fan lichen has not been reported on the federal or non-federal lands, or on the Tracks Project area.

Canadian Ricegrass (*Piptatherum [=Oryzopsis] canadense*)

Canadian ricegrass is found in St. Louis, Lake, and Cook Counties. This species is known from only eight documented locations in Minnesota. It prefers gravelly/sandy soil associated with red and jack pine plantations.

Canada ricegrass has not been reported on the federal or non-federal lands, but has been found on the Tracks Project area.

Canada Yew (*Taxus canadensis*)

Canada yew is found in northern Minnesota, including St. Louis, Lake, and Cook Counties. Canada yew is a shrub found as an understory species in a wide variety of uplands and lowlands, including northern white cedar/black ash swamps, talus and cliffs, northern hardwoods, and trembling aspen/paper birch forest.

Canada yew has not been reported on the federal or non-federal lands, but has been found on the Tracks Project area.

Barren Strawberry (*Waldsteinia fragarioides*)

In Minnesota, barren strawberry is restricted to forested sites in the northeastern part of the state. The earliest collection of the species is from 1893 in Lake County. It was later collected by Olga Lake at several locations in St. Louis and Lake Counties between 1938 and 1956. Relatively few records were reported in the 1980s but since that time, over 30 observations have been documented, including on the Tracks Project area. Some of these observations are clustered, with sites within a few miles of each other. Separate observations may actually be part of one larger population. Taking this into consideration, there are probably just over 20 populations that have been observed in the state since 1990.

In Minnesota, barren strawberry grows both in fire-dependent forests and in dry mesic hardwood forests. It is often found in forests dominated by pine, including red pine, white pine, and jack pine. It is also found in mixed pine and hardwood forests, often with trembling aspen, as well as in hardwood forests dominated by sugar maple. It is sometimes observed growing in deep shade, but perhaps most often in woodlands with small openings or relatively open tree or shrub canopies. It is also found growing in full sun along roadsides (Hill 2003 and references cited therein).

Barren strawberry has not been reported on the federal or non-federal lands.

Habitat Conditions

Upland forest (MIH 1 and 5) is common on the federal and non-federal lands. There are about 2,582 acres of upland forest on the federal lands, and 2,774 acres of upland forest on the non-federal lands, that could provide habitat for Habitat Group 6 RFSS (**Table 6**). Coniferous forest (MIH 5) makes up about 49% of the upland forest habitat on the federal lands, but only 3% of upland forest on the non-federal lands (**Table 6**). Jack pine, trembling aspen, paper birch, black spruce, and balsam fir are the dominant upland forest species on the federal lands; there are also scattered stands of red and white pine (ENSR 2005, AECOM 2011a). These species are also common on the non-federal lands, although there is less jack pine and more eastern white pine on the non-federal lands than on the federal lands (AECOM 2011b, c). This may be due to higher levels of timber harvesting on non-federal than federal lands, specifically harvesting of coniferous species. Portions of several non-federal lands have been recently logged (Lake County Lands South and Wolf Lands 3, in particular).

5.1.7.2 Direct and Indirect Effects

Proposed Action

Species Conditions

Federal Lands

No Habitat Group 6 RFSS were found during plant surveys on the federal lands, despite the fact that upland forest habitat comprised almost 40% of the federal lands (**Table 6**). Thus, there should be no direct or indirect effects to Habitat Group 6 RFSS from the Project on federal lands.

Non-federal Lands

No Habitat Group 6 RFSS were found during plant surveys on the non-federal lands, despite the fact that upland forest habitat comprised about 39% of the habitat on non-federal lands (**Table 6**). Under the land exchange, the Forest Service would administer the non-federal lands. The Forest Service would monitor Habitat Group 6 RFSS use of these lands, and seek to protect high quality habitat for these species. Some species, such as barren strawberry and Canada ricegrass, seem to tolerate disturbance on opening-up of timber stands.

Habitat Conditions

Federal Lands

There are 2,582 acres of upland forest on the federal lands that can provide habitat for these RFSS (**Table 6**). Upland forest is more prevalent on the portion of the federal lands within the Mine Site, making up 62% (1,694 acres) of the habitat. About 30% of the upland forest on the federal lands is immature or mature forest. The Project would affect about 1,037 acres of upland forest habitat and affected areas would not provide habitat for Habitat Group 6 RFSS for at least 20 years after mining and reclamation, and much longer for Habitat Group 6 RFSS that favor more mature forest habitat.

Non-federal Lands

There are 2,774 acres of upland forest habitat that could be used by Habitat Group 6 RFSS on the non-federal lands (**Table 6**). There is less upland forest habitat (39%), on a percentage basis, on the non-federal lands than on the federal lands. Timber harvest, and road building and recreational activities, could alter or destroy habitat for these species if these lands are transferred to the Forest Service. Under the Proposed Action, the Forest Service would survey for Habitat Group 6 RFSS and associated habitat prior to conducting land-disturbing activities; areas of known or potential habitat would be avoided when feasible. Most recreational activity would be confined to existing trails and roads and would not likely affect Habitat Group 6 RFSS that favor upland forests.

Alternative B

Federal Lands

There should be no direct effects to New England sedge, fan lichen, Canada yew, Canada ricegrass, and barren strawberry on federal lands from the Project as these species have not been reported on the federal lands. Under Alternative B, there are 2,093 acres of upland forest on the federal lands (**Table 6**). About 489 fewer acres of upland forest habitat would be transferred to PolyMet from the Forest Service than would occur under the Proposed Action, but direct and indirect effects to Habitat Group 6 RFSS species and their habitats from the Project activities would remain the same.

Non-federal Lands

There would be no direct effects to New England sedge, fan lichen, Canada yew, Canada ricegrass, and barren strawberry under Alternative B. There are about 2,420 acres of suitable habitat (MIH 1 and 5) on Hay Lake Lands, which is about 87% of the upland forest found on the non-federal lands (**Table 6**). Prior to implementing ground-disturbing activities, the Forest Service would conduct RFSS surveys of Hay Lake Lands to determine if RFSS would be affected by proposed activities. These surveys should help to ensure that RFSS found on the lands are avoided, where feasible. Under Alternative B, however, about 354 acres of upland forest habitat that is found on the other non-federal lands would remain under private ownership (**Table 6**).

No Action Alternative

There would be no direct or indirect effects to Habitat Group 6 RFSS under the No Action Alternative.

5.1.7.3 Cumulative Effects

As discussed in Section 4.5.2, it is possible that Habitat Group 6 RFSS and/or their habitat have been lost from past and ongoing activities in the CESA, and would be lost in the future from similar reasonably foreseeable future activities.

Timber harvest and road construction have affected upland forests and reduced the amount and distribution of this habitat within the CESA. Construction and use of roads in upland forests under the Proposed Action, Alternative B, and No Action Alternative and elsewhere in the CESA would continue to affect suitable habitat. For Canada ricegrass and barren strawberry, however, timber harvest should not have any long-term cumulative effects to habitat for these species because they appear to be able to tolerate some levels of disturbance. Suitable habitat for fan lichen (in the form of tip-ups) would continue to be created by future timber harvests.

There should be no direct or indirect effects to individuals of Habitat Group 6 RFSS from mining. About 1,037 acres of upland forest on the federal lands would be lost to mining and would be an adverse cumulative effect (**Table 6**).

Timber harvesting, road building, and recreational activities could occur in the future on the federal and non-federal lands, depending upon the whether the Proposed Action, Alternative B, or the No Action Alternative is selected in the Record of Decision. In addition, there is the potential for homes and cabins to be built on the non-federal lands, should the FEIS Record of Decision select the No Action Alternative and non-federal lands remain under private ownership. These activities could harm Habitat Group 6 RFSS and their habitats. There are about 31,000 acres of upland deciduous hardwood forest, and about 161,000 acres of upland conifer forest, in the CESA (Emmons and Olivier, Inc. 2006:30, 38), and Habitat Group 6 RFSS are found throughout the Superior National Forest, including on the Tracks Project area. The Forest Service would survey for RFSS prior to conducting land-disturbing activities, and would avoid areas with known or potential habitat for RFSS when feasible on lands they administer.

5.1.7.4 Summary

Project activities associated with the Proposed Action and Alternative B should have no direct or indirect adverse effects on individual Habitat Group 6 RFSS or their habitats because these species have not been found on the Mine Site. The Project would result in the cumulative loss of about 1,037 acres of potential habitat for these species on the federal lands (**Table 6**). Other activities in the CESA would also contribute to cumulative effects toward the RFSS plants of this habitat group. The Proposed Action and Alternative B would have similar effects on Habitat Group 6 RFSS. There should be no effects to Habitat Group 6 RFSS or their habitats from the No Action Alternative.

5.1.7.5 Determination

The Proposed Action and Alternative B **may impact individuals but are not likely to cause a trend to federal listing or loss of viability** for New England sedge, fan lichen, Canada yew, Canada ricegrass, and barren strawberry. The No Action Alternative would have **no impact** to individuals of Habitat Group 6 RFSS.

5.1.7.6 Mitigation and Recommendations

No mitigation measures are recommended for Habitat Group 6 RFSS.

5.2 Animals

5.2.1 Animals Not Evaluated in the Biological Evaluation

As shown in **Table 1**, there is no suitable habitat on the federal and non-federal lands for lake sturgeon, Nipigon cisco, and Shortjaw cisco. The Proposed Action, Alternative B, and No Action Alternative would have **no impact** to individuals of these species, and they will not be addressed further in this BE.

5.2.2 Mussels

Unionid mussels (*Unionidae*) constitute one of the most imperiled major taxa in the U.S. (Master et al. 2000), and 33 unionid species within Minnesota are state-endangered (13 species), threatened (11 species), or species of special concern (9 species). Two of these species, creek heelsplitter and black sandshell, both RFSS, are known to occur in the St. Louis River Watershed. No listed freshwater mussel species were observed on federal during mussel surveys for the Project (Heath 2004, 2011). No listed freshwater mussel species are known to occur on the non-federal lands.

5.2.2.1 Environmental Baseline

Creek Heelsplitter (*Lasmigona compresssa*)

The creek heelsplitter typically occurs in small headwater streams and requires riverine habitat conditions to survive and proliferate. It has also been documented at or near river inlets on lakes on the Superior National Forest. Although the creek heelsplitter is capable of self-fertilization, it relies extensively on host fish species for its parasite life stage (glochidia larvae) and dispersal. Because of its habitat and host fish requirements, the creek heelsplitter may be affected by vegetative management and road construction activities that could potentially increase sedimentation and streamflow, as well as create potential host fish migration barriers at road crossings.

The creek heelsplitter has not been reported on the federal or non-federal lands. It is not known to occur on the Partridge River in the vicinity of the Project area. On Hunting Club Lands, the creek heelsplitter is unlikely to be found as the creek that flows through the lands because the creek does not have a sandy substrate. There are no streams or rivers associated with Wolf Lands 1 and 2, Lake County Lands, or McFarland Lake Lands (AECOM 2011a, b).

There is potential habitat for the species on Hay Lake Lands and Wolf Lands 3 and 4. It has not been reported on Hay Lake Lands, but suitable habitat may exist in the Pike River. This species has been documented 2.3 miles downstream of the Hay Lake Lands at the Sand and Pike Rivers confluence, where the Pike River becomes a fourth-order stream. On the Hay Lake Lands, third-order segments of the Pike River may offer adequate sand substrate and flow to provide habitat for this species.

While the creek heelsplitter is not known to occur within or in the immediate vicinity of Wolf Lands 3 or 4, it has been documented near the eastern and western confluence of the northernmost lake in the chain of McDougal Lakes and in the third-order stretch of the Stony River. Therefore, it could occur in Coyote Creek, which flows from Wolf Lands 3 and 4 into McDougal Lakes, and is near the Stony River. The habitat in Coyote Creek within Wolf Lands 3 and 4 is unknown, but it could display first-order headwater stream characteristics.

The creek heelsplitter is known to occur on the Track Project area in the Cloquet River, and may occur in larger tributaries of the Cloquet River.

Black Sandshell Mussel (*Ligumia recta*)

The black sandshell mussel is primarily a riverine species that requires deep run or glide habitat in wide rivers with moderate current.

The black sandshell mussel is known to occur on the Superior National Forest, although near the edge of this species range. It has been documented in several locations in the St. Louis River system. The black sandshell mussel is not known to occur on the federal or non-federal lands, or within the Tracks Project area. The nearest documented occurrences of this species to the Project area are four locations in the St. Louis River, approximately 9 to 11 miles south to southwest of the federal lands. There is suitable habitat in the Pike River (Hay Lake Lands) and possibly Coyote Creek (Wolf Lands 3 and 4) for the black sandshell mussel. The Langley or Cloquet Rivers (Tracks Project area) may also support individuals or populations and provide habitat for the black sandshell mussel.

5.2.2.2 Direct and Indirect Effects

Proposed Action

There should be no direct effects to creek heelsplitter and black sandshell mussels from the Project as they have not been reported on the federal lands. Because the Project should not result in any measurable changes in habitat quality and flow regimes in the Partridge River, and no change in water quality (for any of the Class B water quality standards), no effects to the habitat for these species are expected within the Partridge River Watershed. Section 5.2.6 of the FEIS provides additional information on anticipated changes to flow regimes.

No creek heelsplitter or black sandshell mussels have been reported on the non-federal lands, although the creek heelsplitter has been documented in the Pike River, about 2.3 miles downstream of Hay Lake Lands, and in the Stony River near Wolf Lands 3 and 4. Under the Proposed Action, the Forest Service would survey for creek heelsplitter and black sandshell mussels and associated habitat prior to conducting land-disturbing activities; areas of known or potential habitat would be avoided when feasible.

Alternative B

Potential effects to creek heelsplitter and black sandshell mussel from Project activities would be similar to those under the Proposed Action. Under Alternative B, PolyMet would administer lands on which the Partridge River flows.

The Forest Service would acquire Hay Lake Lands under Alternative B. The Pike River flows along the eastern boundary of these lands. As noted above, suitable habitat for the creek heelsplitter could be found in the third-order segments of the Pike River, and this species has been found about 2.3 miles downstream of Hay Lake Lands. Creek heelsplitter habitat may occur on Coyote Creek within Wolf Lands 3 and 4 that would remain privately owned.

No Action Alternative

There would be no direct or indirect effects to creek heelsplitter or black sandshell mussel under the No Action Alternative.

5.2.2.3 Cumulative Effects

Substrate quality, channel stability, and host fish migration opportunities are key habitat components for maintaining individuals, populations, and habitat of creek heelsplitter and black sandshell mussel. It is likely that timber harvest, road and trail construction, and poorly designed stream crossings may have affected RFSS mussels and their habitat by altering stream channels and flow, contributing sediment into local streams, increasing stream temperatures, and restricting host fish migration within the CESA (USDA Forest Service 2004a).

Undeveloped federal and non-federal lands could be managed for timber production, and the developed portions of the Mine Site could be managed for timber after reclamation. Use of unclassified roads on federal and non-federal lands may contribute sediment into local streams and potentially threaten RFSS mussels and their habitat, although this input should be minimal if existing roads are used or reclaimed and no new roads are constructed near streams. Road construction and timber management activities could affect individuals, populations, and/or habitat of creek heelsplitter and black sandshell mussel on the Partridge River, Pike River, and Coyote Creek. These activities could potentially increase the inputs of fine sediment into local streams, increase or reroute stream flows, increase stream temperatures, and disrupt existing and/or future habitat unless properly mitigated. These effects could be mitigated by following design criteria to minimize effects to riparian zone habitat, including prohibiting the harvest of trees would occur within certain distances of different types of streams except for the purpose of maintaining or restoring riparian ecological function.

Standards and guidelines in the Forest Plan and best management practices would help to ensure that land management activities would not contribute to cumulative effects (USDA Forest Service 2004a). Provided that best management practices are implemented by landowners and managers, there should be no long-term cumulative effects to creek heelsplitter and black sandshell mussels and habitat from reasonably foreseeable future activities.

There should be no cumulative effects to creek heelsplitter and black sandshell mussel or their habitats from the Project as they have not been reported on or near the federal lands and the Project is not predicted to result in any measurable changes in water flows or water quality within the Partridge River Watershed. Creek heelsplitter has been found near Hay Lake Lands, and would be afforded protection by the Forest Service under both the Proposed Action and Alternative B.

5.2.2.4 Summary

The Proposed Action, Alternative B, and No Action Alternative should have no direct, indirect, or cumulative effects to individuals or habitat of creek heelsplitter or black sandshell mussel.

5.2.2.5 Determination

The Proposed Action and Alternative B **may impact individuals but are not likely to cause a trend to federal listing or loss of viability** creek heelsplitter or black sandshell mussels. The No Action Alternative would have **no impact** to creek heelsplitter or black sandshell mussel individuals.

5.2.2.6 Mitigation and Recommendations

No mitigation measures are recommended for creek heelsplitter or black sandshell mussel.

5.2.3 Insects

Although no RFFS insects have been reported on the federal or non-federal lands, there are six RFSS insects that could have suitable habitat on the federal and/or non-federal lands—headwaters chilostigman caddisfly, ebony boghaunter, Quebec emerald dragonfly, taiga alpine, Nabokov’s blue butterfly, and Freija’s grizzled skipper.

5.2.3.1 Headwaters Chilostigman Caddisfly (*Chilostigma itascae*), Ebony Boghaunter (*Williamsonia fletcheri*), and Quebec Emerald Dragonfly (*Somatochlora brevicincta*)

Environmental Baseline

Headwaters Chilostigman Caddisfly (*Chilostigma itascae*)

Little is known about the headwaters chilostigman caddisfly. It has only been discovered in two locations within Minnesota. In 1994, it was documented in a slow-moving, silt-dominated headwater stream in Itasca State Park and in 2005, in a rich swamp to poor fen habitat at Finland State Forest, which is about 4 miles north of Lake County Lands South.

Observations at Finland State Forest were within a large, acid to minerotrophic peatland complex. These peatlands have a loose to moderately dense canopy of black spruce and tamarack, with some northern white cedar, and a shrub layer of speckled alder and bog birch. Sphagnum mosses, sedges, and several heath species dominate the ground layer. Shallow pools among the hummocks and narrow streamlets are a characteristic feature where adults were observed crawling around on the snow. Adults were also observed in an aspen-mixed coniferous forest on a ridge adjacent to this peatland complex. Presumably these adults wandered from the peatland where larval development took place.

Habitats similar to those at Finland State Forest occur within the One Hundred Mile Swamp on the federal lands. However, because the distribution of this caddisfly appears to be very limited, it is unlikely that this species occurs on the federal or non-federal lands.

Headwaters chilostigman caddisfly has not been reported on the federal or non-federal lands, or the Tracks Project area.

Ebony Boghaunter (*Williamsonia fletcheri*)

The ebony boghaunter uses low elevation sphagnum bogs adjacent to coniferous or mixed coniferous/deciduous forest. It is usually absent from bogs that lack sphagnum. Larvae may develop in shallow pools (6 to 12 inches) in sedge fens or among sphagnum mats that have open pools and are not choked with

heaths. The adult male territorial arenas and adult perching sites are often in small, sun-lit clearings in the forest surrounding the laying habitat, not in completely open upland habitat. The ebony boghaunter has not been identified from benthic macroinvertebrate surveys conducted on and near the federal lands, and it has not been reported on the non-federal lands or Tracks Project area. Habitat likely exists for the ebony boghaunter on the federal and non-federal lands in bogs.

Quebec Emerald Dragonfly (*Somatochlora brevicincta*),

The Quebec emerald dragonfly occurs in lentic habitats typically associated with bogs, fens, and heaths near water-saturated or water-suspended sphagnum moss. The microhabitat is water-suspended or water-saturated sphagnum moss, whether or not associated with open water, and typically having grass-like emergent plants indicating weak minerotrophism. Eggs are laid outside plant tissues on the moss or adjacent water surface, with the larvae likely living within the saturated moss rather than on the water interface. The species has not been observed on open-water peatland ponds. Landforms in which the habitat can develop will generally consist of bedrock or surficial deposits with little mineralizing potential. Habitat may also form adjacent to or within peat bogs or heaths in low relief areas.

The Minnesota Odonata Survey Project found an individual in northern Lake County approximately 30 miles northeast of the Project area in 2006. This RFSS' habitat requirements are not well-understood in Minnesota. Suitable habitat could be present within the federal lands near the bogs associated with the headwater stream, Yelp Creek. It could inhabit poor fens and wet meadow/sedge meadow habitat found on the federal and non-federal lands. However, the likelihood of observing Quebec emerald dragonfly individuals or populations in the vicinity of the federal or non-federal lands is low.

Quebec emerald dragonfly was not found during benthic macroinvertebrate surveys of the federal lands (Breneman 2005, Barr 2011), and has not been reported on the non-federal lands, or the Tracks Project area.

Direct and Indirect Effects

Proposed Action

There should be no direct or indirect effects to headwaters chilostigman caddisfly, ebony boghaunter, or Quebec emerald dragonfly as they have not been reported on the federal lands and sightings have been 30 miles or more from the federal lands. These species favor slow-moving streams, bogs, and fens, which are similar to sedge/wet meadow habitat. There are 2,207 acres of habitat that could be used by these RFSS insects on the federal lands (210 acres of open bog, 1,961 acres of coniferous bog, and 36 acres of sedge/wet meadow; **Table 8**). A total of 547 acres of these habitats (512 acres of open and coniferous bog and 35 acres of sedge/wet meadow) would be disrupted by mining activities.

Because the Proposed Action should not result in any measurable changes in flows or water quality (for any of the Class B water quality standards) in the Partridge River, negligible effects to the headwaters chilostigman caddisfly, ebony boghaunter, or Quebec emerald dragonfly are expected within the Partridge River Watershed from the Project.

The headwaters chilostigman caddisfly, ebony boghaunter, and Quebec emerald dragonfly have not been reported on the non-federal lands, although the headwaters chilostigman caddisfly has been found at Finland State Forest, which is about 4 miles north of Lake County Lands South. There are 7 acres of open bog habitat

that could be used by these RFSS insects on the non-federal lands (**Table 8**). Under the Proposed Action, the Forest Service would survey for chilostigman caddisfly, ebony boghaunter, and Quebec emerald dragonfly and associated habitat prior to conducting land-disturbing activities; areas of known or potential habitat would be avoided when feasible.

Alternative B

Potential effects to headwaters chilostigman caddisfly, ebony boghaunter, or Quebec emerald dragonfly from Project activities would be the same as under the Proposed Action. Under Alternative B, there would be 1,887 acres of habitat that could be used by these RFSS insects on the federal lands (175 acres of open bog, 1,677 acres of coniferous bog, and 35 acres of sedge/wet meadow; **Table 8**). About 320 fewer acres of habitat would be transferred to PolyMet from the Forest Service than under the Proposed Action. Habitat loss to mining activities would be the same under Alternative B as under the Proposed Action.

Under Alternative B, the Forest Service would acquire Hay Lake Lands. No headwaters chilostigman caddisfly, ebony boghaunter, or Quebec emerald dragonfly have been reported on or near Hay Lake Lands. Based on a habitat assessment, there are only 2 acres of open bog habitat on Hay Lake Lands that could provide habitat for these species. About 30% of the available habitat that occurs on the non-federal lands is found on Hay Lake Lands (AECOM 2011b).

No Action Alternative

There would be no direct or indirect effects to headwaters chilostigman caddisfly, ebony boghaunter, or Quebec emerald dragonfly under the No Action Alternative.

Cumulative Effects

Past, present, and reasonably foreseeable future actions from land management and development include federal, state, county, and private road construction and timber management projects, private development, and routine road maintenance and transportation activities. The CESA has mixed ownership with roads crossing from one landowner to the next, and includes multiple jurisdictions. Standards and guidelines in the 2004 Forest Plan help to ensure that Forest Service activities do not contribute to cumulative effects (USDA Forest Service 2004a). In addition to federal standards and guidelines, state, private and local land owners and managers follow established best management practices that should help to minimize cumulative effects.

There should be no cumulative effects to headwaters chilostigman caddisfly, ebony boghaunter, or Quebec emerald dragonfly from the Project as they have not been reported on or near the federal lands. About 547 acres of habitat that could be used by these species on the federal lands would be directly affected by the Project, but given that there are about 368,000 acres of bog, sedge/wet meadow, and lowland conifer habitat within the CESA, habitat loss from the Project would have a negligible cumulative effect (Emmons and Olivier Resources, Inc. 2006:30, 38).

Summary

Project activities associated with the Proposed Action and Alternative B should have no adverse direct or indirect effects on individual headwaters chilostigman caddisfly, ebony boghaunter, or Quebec emerald dragonfly or their habitats, but the Project could cause cumulative effects to these species through loss of

potential habitat for these species on the federal lands. Other activities in the CESA would also contribute to cumulative effects toward this species. There would be no effects to headwaters chilostigman caddisfly, ebony boghaunter, or Quebec emerald dragonfly or their habitats from the No Action Alternative.

Determination

The Proposed Action and Alternative B **may impact individuals but are not likely to cause a trend to federal listing or loss of viability** for headwaters chilostigman caddisfly, ebony boghaunter, or Quebec emerald dragonfly. The No Action Alternative would have **no impact** on individuals of these species.

Mitigation and Recommendations

No mitigation measures are recommended for headwaters chilostigman caddisfly, ebony boghaunter, or Quebec emerald.

5.2.3.2 Taiga Alpine (*Erebia disa mancinus*)

Environmental Baseline

The taiga alpine occurs across northern North America. The taiga alpine's only occurrence in the contiguous U.S. is in Minnesota, where it is known from only a handful of localities in a small area in the northeast part of the state. These locations include the Sand Lake Peatland Scientific and Natural Area, which is about 8 miles north of Lake County Lands North and Wolf Lands 1, 5 miles west of Wolf Lands 2, and 8 miles west of Wolf Lands 3; and the McNair Management Area near Lake County Lands South. Recent surveys in the Glacial Lake Agassiz peatlands have not discovered any occurrences there, suggesting that taiga alpine has highly specialized habitat requirements. Because of the small number of known locations, the taiga alpine is likely vulnerable to habitat destruction and catastrophic events.

In Minnesota, the taiga alpine appears to favor black spruce bogs and swamps where immature black spruce trees form a park-like environment, with small bushy trees dotting the understory. This type of habitat is abundant in northern Minnesota, making the very restricted distribution of the butterfly an enigma. In Canada, where it is more common and widespread, it occurs in a broader range of habitats, most commonly in open black spruce-sphagnum bogs.

The taiga alpine was not searched for during field surveys for the Project and the MDNR NHIS database has no records of taiga alpine occurring on or in the vicinity of the federal or non-federal lands. Taiga alpine was found during surveys of the Tracks Project area.

Direct and Indirect Effects

Proposed Action

Taiga alpine has not been observed on or near the federal lands. There are 3,060 acres of lowland coniferous forest (MIH 9) within the federal lands that could provide habitat for this butterfly (**Table 6**). The Project would affect about 482 acres of lowland coniferous forest.

Taiga alpine has not been reported on the non-federal lands, although it has been found within 8 miles of Lake County Lands North, and Wolf Lands 2 and 3. There are about 3,309 acres of lowland coniferous forest habitat

on the non-federal lands that could provide habitat for taiga alpine (**Table 6**). Under the Proposed Action, the Forest Service would survey for taiga alpine and associated habitat prior to conducting land-disturbing activities; areas of known or potential habitat would be avoided when feasible.

Alternative B

Potential direct and indirect effects to taiga alpine and its habitat from Project activities would be similar to those under the Proposed Action. Under Alternative B, there would be about 2,079 acres of lowland coniferous forest on the federal lands that would be transferred to PolyMet (**Table 6**), or about 982 fewer acres of lowland coniferous forest that be transferred to PolyMet from the Forest Service than under the Proposed Action. In particular, portions of One Hundred Mile Swamp would remain under Forest Service management. Habitat loss due to mining activities would be the same under Alternative B as under the Proposed Action.

Under Alternative B, the Forest Service would acquire Hay Lake Lands. There are about 1,818 acres of lowland coniferous forest on Hay Lake Lands (**Table 6**). About 55% of lowland coniferous forest that occurs on the non-federal lands is found on Hay Lake Lands.

No Action Alternative

There would be no direct or indirect effects to taiga alpine under the No Action Alternative.

Cumulative Effects

As discussed in Section 4.5.2, mature black spruce and tamarack lowland forest has been lost from past and ongoing activities in the CESA, and would be lost in the future from similar reasonably foreseeable future activities.

Because European settlement, timber harvest, mining, wetland drainage, and road construction have affected forested wetlands and reduced the amount and distribution of this habitat within the CESA. More recently, timber sales on federal, state, county, and private lands have changed the age class distribution of lowland black spruce habitats, but have not altered the overall suitability of the habitat for taiga alpine.

Construction and use of roads in lowland forests under the Proposed Action, Alternative B, and No Action Alternative, and elsewhere in the CESA would continue to affect suitable habitat. Timber sales affecting lowland forests on state or county lands could change the age class of lowland black spruce forests in the Project area, temporarily making some stands less suitable for taiga alpine. However, the proportion of total suitable habitat affected by these activities would be very small in relation to habitat availability within the CESA.

The Project should not directly affect taiga alpine. About 482 acres of lowland coniferous forest habitat that could be used by this species on the federal lands would be directly affected by the Project (**Table 6**). Despite the potential cumulative effects of the Project, taiga alpine habitat is common in the CESA and about 356,000 acres of lowland coniferous forest/shrubland would remain in the CESA after the Project (Emmons and Olivier Resources, Inc. 2006:30, 38).

PolyMet would acquire lowland coniferous forest on the federal lands surrounding the Mine Site under the proposed land exchange. Although these lands would remain privately owned, it is likely that some or all of these lands would be managed for timber production and harvested in the reasonably foreseeable future. Timber

harvest and associated road construction could directly or indirectly affect taiga alpine habitat. Effects from timber management would be mitigated by voluntary adherence to best management practices (Minnesota Forest Resources Council 1999).

Under the Proposed Action and Alternative B, all or portions of the non-federal lands would be transferred to the Forest Service, who would manage the lands for timber production, recreation, nature study, and other values. Taiga alpine has not been reported on the non-federal lands, but has been observed within 8 miles of several non-federal lands, and there are about 3,309 acres of lowland coniferous forest on the non-federal lands.

Forest management activities could result in ground disturbance that adversely affects taiga alpine habitat, and possibly even individual butterflies. However, timber harvest activities would be conducted during winter in lowland coniferous forest to reduce the risks of ground disturbance and sedimentation. Should disturbance activities occur on the non-federal lands, it could take 80 or more years before disturbed lands would be suitable for taiga alpine. Prior to implementing ground-disturbing activities, the Forest Service would conduct RFSS surveys to determine if RFSS would be affected by proposed activities. These surveys should help to ensure that RFSS species found on non-federal lands are avoided, where feasible.

Summary

Project activities associated with the Proposed Action and Alternative B should have no adverse direct or indirect effects on individual taiga alpine or their habitat, but the Project could cause cumulative effects to potential habitat for taiga alpine on the federal lands. Other activities in the CESA would also contribute to cumulative effects toward this species. The Proposed Action and Alternative B would have similar effects on taiga alpine, while there would be no effects to this species from the No Action Alternative.

Determination

The Proposed Action and Alternative B **may impact individuals but are not likely to cause a trend to federal listing or loss of viability** for taiga alpine. The No Action Alternative would have **no impact** on individuals of this species.

Mitigation and Recommendations

No mitigation measures are recommended for taiga alpine.

5.2.3.3 Nabokov's Blue (*Lycaeides idas nabokovi*) and Freija's Grizzled Skipper (*Pyrgus centaureae freija*)

Environmental Baseline

Nabokov's Blue (*Plebejus idas nabokovi*)

Populations of Nabokov's blue tend to occur in geographic clusters, or metapopulations, linked by distances of 1 to 2 miles. Fewer than five metapopulations are known to occur in each of the Great Lake States (Michigan, Minnesota, and Wisconsin); several of the most important sites occur on U.S. Forest Service lands (Wolf 2002 and references cited therein). Recent Minnesota records for Nabokov's blue are confined to the three northeastern most counties (St. Louis, Lake, and Cook), including the McNair Butterfly Management Area, which is approximately 23 miles southeast of the federal lands and 9 to 13 miles from Wolf Lands 1 and 2,

respectively (BAMONA 2013). Focused searches in the past few years have discovered several new occurrences of Nabokov's blue, although most appear to be small colonies.

In Minnesota, all known colonies of this butterfly occur at sandy sites, including those with jack pine, but it is recorded on rock outcrops in Michigan. Because the species' preferred habitat is open woodland where the larval host plant, dwarf bilberry, is abundant, forest fires were probably important in creating and maintaining habitat for the species.

Active forest management can play a major role in conservation of these rare species. Encroachment of dense vegetation and woody plants is a major threat to existing populations, especially in the southern part of their geographic range. Fire suppression has likely been responsible for loss of habitat for dwarf bilberry during the past 50 years or longer (Wolf 2002).

Freija's Grizzled Skipper (*Pyrgus centaureae freija*)

The Freija's grizzled skipper has only been observed at a single locality in Minnesota, on the McNair Butterfly Management Area. It could occur at other locations in Minnesota, and the absence of additional records may be explained by its spring flight period, when weather is often unsuitable for butterfly activity, and by the poor understanding of its habitat preferences. At the one known location on the McNair Butterfly Management Area, Freija's grizzled skipper occurs in a large, old clearing on sandy soils dominated by grasses, with some willow, speckled alder, dwarf bilberry, and blueberries. Black spruce and tamarack swamps border the clearing in places.

Direct and Indirect Effects

Proposed Action

No butterfly surveys were conducted on the federal and non-federal lands. Based on observations of Nabokov's blue and Freija's grizzled skipper in Minnesota, however, it is unlikely that they are found on or near the federal lands, and thus there should be no direct or indirect adverse effects to these species from the Proposed Action. These butterflies favor sandy and rocky sites associated with jack pine and other upland coniferous forest, which are rare on the federal lands.

There are 1,252 acres of upland coniferous forest habitat (MIH 5) on the federal lands that could provide habitat for Nabokov's blue and Freija's grizzled skipper (**Table 6**). The Project would affect about 505 acres of upland coniferous forest habitat.

Nabokov's blue and Freija's grizzled skipper have not been reported on the non-federal lands, although they have been found within 23 miles of the federal lands and 9 miles of the non-federal lands. There are about 80 acres of upland coniferous forest on the non-federal lands that could provide habitat for Nabokov's blue and Freija's grizzled skipper (**Table 6**). These lands would not be affected by the Project. Under the Proposed Action, the Forest Service would survey for Nabokov's blue and Freija's grizzled skipper and associated habitat prior to conducting land-disturbing activities; areas of known or potential habitat would be avoided when feasible.

Alternative B

Potential direct and indirect effects to Nabokov's blue and Freija's grizzled skipper and their habitat from Project activities would be similar to those under the Proposed Action. Direct effects to upland coniferous forests from the Project would be similar for both the Proposed Action and Alternative B. Under Alternative B, there are 1,139 acres of upland coniferous forest habitat on the federal lands (**Table 6**). About 114 fewer acres of upland coniferous forest would be transferred to PolyMet from the Forest Service than under the Proposed Action. Habitat loss to mining activities would be the same under Alternative B as under the Proposed Action.

Under Alternative B, the Forest Service would acquire Hay Lake Lands. There are 55 acres of upland coniferous forest habitat on Hay Lake Lands (**Table 6**). About 68% of the upland coniferous forest on the non-federal lands is found on Hay Lake Lands.

No Action Alternative

There would be no direct or indirect effects to Nabokov's blue and Freija's grizzled skipper under the No Action Alternative.

Cumulative Effects

As discussed in Section 4.5.2, upland coniferous forest has been lost from past and ongoing activities in the CESA, and would be lost in the future from reasonably foreseeable future activities. Timber management activities have led to the creation of young upland forest habitat in areas that are suitable habitat for Nabokov's blue and Freija's grizzled skipper over much of the Arrowhead region, especially on private lands that tend to have shorter harvest rotations than federal lands. On the Superior National Forest, projections show decreasing young forest habitat (upland forest younger than 9 years) and greatly increasing immature and mature (upland conifer older than 10 years) forest habitat (USDA Forest Service 2010b). Timber harvest and associated road construction could help to promote habitat for Nabokov's blue and Freija's grizzled skipper.

The Project should not directly affect individual Nabokov's blue and Freija's grizzled skipper or their habitat, but could cumulatively affect these species through loss of potential habitat. About 505 acres of upland coniferous forest habitat that could be used by these species on the federal lands would be directly affected by the Project. Although there are few populations of Nabokov's blue and Freija's grizzled skipper in Minnesota, they are more common outside of Minnesota. There are also about 161,000 acres of upland coniferous forest within the CESA that could provide habitat for Nabokov's blue and Freija's grizzled skipper (Emmons and Olivier Resources, Inc. 2006:30, 38).

Under the Proposed Action and Alternative B, all or portions of the non-federal lands would be transferred to the Forest Service, who would manage the lands for timber production, recreation, and other activities. Forest management activities could result in ground disturbances that adversely affect Nabokov's blue and Freija's grizzled skipper and their habitat. The Forest Service would survey for Nabokov's blue and Freija's grizzled skipper prior to conducting land-disturbing activities, and would avoid areas with known or potential habitat for Nabokov's blue and Freija's grizzled skipper when feasible. Should disturbance activities occur on the non-federal lands, it would take 10 or more years before disturbed lands would be suitable for Nabokov's blue and Freija's grizzled skipper. The Forest Service would conduct RFSS surveys to determine if Nabokov's blue and Freija's grizzled skipper would be affected by any proposed land-disturbance activities. These surveys should help to ensure that these RFSS, if found on Hay Lake Lands, are avoided, where feasible.

Summary

Project activities associated with the Proposed Action and Alternative B should have no adverse direct or indirect effects on Nabokov's blue and Freija's grizzled skipper, but the Project could cause cumulative adverse effects to these species through loss of potential habitat. Other activities in the CESA would also contribute to cumulative effects toward these species. The Proposed Action and Alternative B would have similar effects on Nabokov's blue and Freija's grizzled skipper, while there would be no effects to these species from the No Action Alternative.

Determination

The Proposed Action and Alternative B **may impact individuals but are not likely to cause a trend to federal listing or loss of viability** for Nabokov's blue and Freija's grizzled skipper. The No Action Alternative would have **no impact** to individuals of these species.

Mitigation and Recommendations

No mitigation measures are recommended for Nabokov's blue and Freija's grizzled skipper.

5.2.4 Fish

The only RFSS fish for which there is habitat near the Project area is northern brook lamprey, although they have not been reported on or near the federal lands or non-federal lands. There could be potential habitat for northern brook lamprey within the Partridge River, and within several streams on the non-federal lands.

5.2.4.1 Northern Brook Lamprey (*Ichthyomyzon fossor*)

Environmental Baseline

The northern brook lamprey is a non-parasitic lamprey that is uncommon and has relatively restricted range in Minnesota. They require moderately warm, low-gradient streams with sections of higher gradient (riffle) reaches suitable for spawning. They are most common in streams of medium size, averaging 60-feet wide and 3-feet deep; but can occur in smaller (3- to 10-feet wide) and larger rivers (100- to 325-feet wide). Spawning occurs in May to June in gravel areas near riffles with water depths of about 1 foot. Larval forms (ammocoetes) require soft substrate (approximately 80% sand and silt) for burrowing, often among vegetation at depths of 6 to 20 inches. The diet of ammocoetes consists of diatoms and unicellular algae. Growth is rapid and larvae require organically enriched, sandy substrate until metamorphosis. After a 3- to 6-year growth period, metamorphosis occurs and adults spawn about 3 to 4 months afterwards. As adults, they do not feed and are believed to die a few days after spawning. Northern brook lamprey occurs in medium-size streams in several watersheds on the Superior National Forest.

There are no known occurrences of this species on or near the federal lands. Northern brook lampreys were found at a site south of Cloquet, Minnesota, approximately 75 miles south of the Project area. Since 1986, it has been collected from six other sites in the Lake Superior drainage. Potential habitat near the Project area includes sections of the St. Louis, Cloquet, and Partridge Rivers.

Northern brook lamprey has not been reported on or near non-federal lands, although suitable habitat for the species likely occurs on Hay Lake Lands and Wolf Lands. This species has not been documented on the Tracks Project area.

Direct and Indirect Effects

Proposed Action

There would be no direct or indirect effects to northern brook lamprey from the Project as this species has not been observed on or near the Project area, although suitable habitat for the species could occur in the Partridge River. Because the Project should not contribute sediment, increase stream temperatures, or substantially alter stream flow in the Partridge River, no effects to habitat for this species are expected.

Northern brook lampreys have not been reported on or near non-federal lands, although suitable habitat for the species could occur in the Pike River on Hay Lake Lands and in Coyote Creek on Wolf Lands 4. Under the Proposed Action, the Forest Service would survey for northern brook lamprey and associated habitat prior to conducting land-disturbing activities; areas of known or potential habitat would be avoided when feasible.

Alternative B

There would be no direct or indirect effects to northern brook lamprey from the Project under Alternative B. Under Alternative B, the Forest Service would acquire Hay Lake Lands. The Pike River flows along the eastern boundary of the lands and could provide habitat for northern brook lamprey.

No Action Alternative

There would be no direct or indirect effects to northern brook lamprey under the No Action Alternative.

Cumulative Effects

Historical events, including overfishing, construction of dams, and resource management activities have affected individuals and populations of northern brook lamprey within the CESA. It is possible that historic timber harvest, road and trail construction, and poorly designed stream crossings may have affected northern brook lamprey habitat and ammocoete survival by contributing sediment, increasing stream temperatures, and altering stream flow (USDA Forest Service 2004b).

Use of unclassified roads on federal and non-federal lands may contribute sediment into local streams and potentially threaten RFSS fish and their habitat, although this input should be minimal if existing roads are used and no new roads are constructed near streams. Standards and guidelines in the Forest Plan would help to ensure that Forest Service activities would not contribute to cumulative effects (USDA Forest Service 2004a). In addition to federal standards and guidelines, state, private, and local land owners and managers follow established best management practices that should also contribute to reducing cumulative effects.

There should be no cumulative effects to northern brook lamprey and their habitat from the Project as northern brook lamprey have not been reported on or near the federal lands. The small decrease in the Partridge River flow that is predicted to occur during the Project is not likely to adversely affect the northern brook lamprey.

Under the Proposed Action and Alternative B, most Project roads would be reclaimed after mining. There could be timber management and road construction on the undeveloped portions of the federal and non-federal lands. Because Hay Lake Lands and Wolf Lands 4 could have northern brook lamprey habitat, there could be cumulative effects to potential habitat for northern brook lamprey.

Summary

Project activities associated with the Proposed Action and Alternative B should have no adverse direct, indirect, or cumulative effects on northern brook lamprey or their habitat. The Proposed Action and Alternative B would have similar effects on this species. Under the Proposed Action and Alternative B, the Partridge River (federal lands) and Pike River (non-federal lands) would be exchanged, but Coyote Creek, another stream that could have northern brook lamprey habitat, would not be exchanged under Alternative B. There would be no effects to northern brook lamprey or their habitats from the No Action Alternative.

Determination

The Proposed Action and Alternative B **may impact individuals but are not likely to cause a trend to federal listing or loss of viability** for northern brook lamprey. The No Action Alternative would have **no impact** to individuals of northern brook lamprey.

5.2.4.2 Mitigation and Recommendations

No mitigation measures are recommended for northern brook lamprey.

5.2.5 Reptiles

One RFSS reptile, the wood turtle, has been observed near the federal lands and there could be potential habitat for wood turtles along the Partridge River within the federal lands, and along several streams on the non-federal lands.

5.2.5.1 Wood Turtle (*Glyptemys insculpta*)

Environmental Baseline

The wood turtle's range extends from Virginia to Nova Scotia and westward to Minnesota and northeast Iowa. The Project area is at the western edge of its range in Minnesota. The wood turtle is largely aquatic, preferring small- to medium-sized, fast-moving rivers and streams with adjacent deciduous and coniferous forests. The substrates of wood turtle streams typically consist of sand or gravel. Wood turtles will occupy adjacent alder thickets, forest, and grassland habitat for basking and foraging, typically staying within ¼ mile of the river or stream. Sandy, sparsely vegetated areas that are not prone to flooding and have ample exposure to direct sunlight provide important nesting sites.

The wood turtle occurs just south and west of the Superior National Forest along the St. Louis River and in the south end of the Superior National Forest along the Cloquet River; wood turtles were also found on the Tracks Project area. In the Cloquet River, all known populations use artificial sites such as gravel pits, road shoulders, and a turtle nesting island created in the late 1990s. Populations are isolated and the wood turtles may travel 3 miles along a stream to find nesting sites.

The MDNR NHIS database records indicate the northernmost population of wood turtles in the state occurs immediately south of the federal lands on the Partridge River. However, wood turtles are unlikely to be found on the federal lands because that the portion of the Partridge River within the federal lands does not have the sandy-gravelly morphology and sand bars that wood turtles prefer for hibernating, mating, and nesting.

The MDNR NHIS database did not identify sightings of wood turtles on or within a mile of the non-federal lands. There may be suitable habitat along the Pike River on Hay Lake Lands.

Direct and Indirect Effects

Proposed Action

There would be no direct effects to wood turtles from the Project as this species has not been observed on the federal lands. The small decrease in the Partridge River flow that is predicted to occur during the Project is not likely to affect the river morphology and should not adversely indirectly affect wood turtle habitat.

Should wood turtles occur in the vicinity of the Project area, the potential for indirect effects from contaminants, such as mercury, in ponds or discharge water, is not likely. Because the wood turtle inhabits woodland streams and adjacent habitat (alder thickets, forest, and grassland habitat) within about one-quarter mile of a stream, it is not likely to be found within the large open areas of the Plant Site or Mine Site during operations or near mining-related features such as stormwater and process water ponds associated with the Project. For example, the Tailings Basin Pond and Hydrometallurgical Residue Facility Pond would not have outlets and would be more than a quarter mile from a woodland stream. Similarly, process water ponds at the Mine Site (e.g., Overburden and Storage Laydown Area Pond) would not have outlets and would be more than one-quarter mile from a woodland stream.

The Plant Site and immediately adjacent lands provide no habitat or poor quality habitat for a wood turtle (e.g., lack of forest canopy over streams; slower flow in streams with numerous beaver ponds). During operations, water released from the Plant Site would include stormwater and treated waste water. Stormwater is expected to meet water quality standards after sedimentation ponds remove total suspended solids prior to being released off-site. Water discharged from the Waste Water Treatment Plant would be directed to Unnamed Creek (PM11), Trimble Creek, and Second Creek (at SD026) and would be required to meet water quality standards, including the mercury water quality standard of 1.3 ng/L. During reclamation, some ponds may be converted to wetlands that would receive precipitation and runoff water and this water would meet water quality standards. Other ponds, including the Hydrometallurgical Residue Facility Pond, would be filled and converted to terrestrial vegetation during reclamation and would have no potential to affect the wood turtle.

There could be potential wood turtle habitat along the Partridge River. During operations (Mine Years 1 through 20), there would be no permitted discharges of water from the Mine Site as process water and water accumulating in the mine pits would be pumped to the Plant Site. Stormwater released from the Mine Site is expected to meet water quality standards after sedimentation ponds remove total suspended solids prior to being released off-site. During reclamation, some ponds may be converted to wetlands that would receive precipitation and runoff water and would meet water quality standards. Other ponds, including the Overburden Storage and Laydown Area Pond, would be filled and converted to terrestrial vegetation during reclamation and would have no effect on the wood turtle. In long-term closure the West Pit Lake discharge would be treated at the Waste Water Treatment Facility (or by non-mechanical treatment after it is proven to meet water quality objectives), then discharged to the Upper Partridge River. This discharge channel would provide a riparian habitat that could

be occupied by a wood turtle. Treated water discharged from the West Pit lake would comply with water quality standards, including mercury.

Overall, the potential for indirect effects to a wood turtle inhabiting a woodland stream near the Plant Site or Mine Site would be low and no adverse effects would be expected to occur to a wood turtle inhabiting a stream reach that receives stormwater or treated waste water.

Wood turtles have not been reported on or near the non-federal lands, although suitable habitat for the species could occur in the Pike River on Hay Lake Lands or in Coyote Creek on Wolf Lands 4. Under the Proposed Action, the Forest Service would survey for wood turtles and associated habitat prior to conducting land-disturbing activities and areas of known or potential habitat would be avoided when feasible.

Alternative B

Potential direct and indirect effects to wood turtles from the Project would be similar to those under the Proposed Action. Under Alternative B, the Forest Service would acquire Hay Lake Lands. The Pike River flows along the eastern boundary of the lands and could provide habitat for wood turtles.

No Action Alternative

There should be no direct or indirect effects to wood turtle under the No Action Alternative.

Cumulative Effects

Because of its dependence on forested riverine systems and well-drained soils, the wood turtle was probably never been uniformly distributed in the Upper Great Lakes Region, but was locally abundant in areas with optimal habitat. Throughout its range, many populations have become affected or extirpated by human activities. In Minnesota, factors contributing to its decline include the loss or fragmentation of riverine forests related to agriculture, timber harvest, road construction, and development; siltation of streams caused by excessive runoff; and flooding of nesting areas. Prime wood turtle habitat is attractive to recreationists, leading to increased collection and road kills. In addition, human activity attracts predators into areas because of trash left behind. An increase in predators can in turn affect wood turtle populations, with predators digging up nests or eating young turtles. All of these problems are compounded by the wood turtle's low reproductive potential, resulting in few juveniles recruited into the population (Bowen and Gillingham 2004, MDNR 2008).

Preservation of high-quality wood turtle habitat is dependent upon reasonable floodplain conservation techniques and zoning restrictions, including: maintaining water quality; controlling sedimentation; restricting pesticide use near waterways; enforcing minimum set-back requirements and stream-side buffer zones; and use of best management practices for timber harvest, livestock grazing, and agriculture. Limiting recreational use of streams in prime wood turtle habitat may be necessary to protect the habitat.

There should be no cumulative effects to wood turtles and their habitat from the Project as they have not been reported on the federal lands and mining activities would have no direct effects on the Partridge River, and indirect effects, such as changes in water flow and quality due to mining, should be negligible.

Both PolyMet and the Forest Service could conduct timber management activities on acquired lands. Cumulative effects from timber management should also be minor if the Forest Service follows guidance in its

2004 Forest Management Plan, and PolyMet and/or private landowners follow Minnesota Forest Resource Council (2003) forest management guidelines to protect riparian zones and streambanks.

Summary

Project activities associated with the Proposed Action and Alternative B should have no adverse direct or indirect effects on wood turtles. PolyMet, the Forest Service, and other landowners in the CESA could conduct timber management and other land-use activities in the reasonably foreseeable future that could have adverse cumulative effects on wood turtle habitat within the CESA, but this risk should be negligible if best management practices are followed to protect wood turtle habitat. There would be no direct or indirect effects to wood turtles or their habitats under the No Action Alternative.

5.2.5.2 Determination

The Proposed Action and Alternative B **may impact individuals but are not likely to cause a trend to federal listing or loss of viability** for wood turtle. The No Action Alternative would have **no impact** to individuals of wood turtle.

5.2.5.3 Mitigation and Recommendations

No mitigation measures are recommended for the wood turtle.

5.2.6 Birds

Five RFSS birds have been observed on or near federal and/or non-federal lands and have suitable habitat on or near these lands —bald eagle, northern goshawk, boreal owl, great gray owl and three-toed woodpecker. In addition, these birds have not been observed, but there is suitable habitat for the following three RFSS birds on the federal and/or non-federal lands—olive-sided flycatcher, bay-breasted warbler, and Connecticut warbler.

5.2.6.1 Bald Eagle (*Haliaeetus leucocephalus*)

Environmental Baseline

The bald eagle was removed from the federal threatened species Endangered Species Act (ESA) list on June 28, 2007. After a period of decline due to hunting and widespread use of dichlorodiphenyltrichloroethane (DDT), bald eagle populations in the lower 48 states rose dramatically beginning in 1972. The bald eagle is federally protected by the Bald and Golden Eagle Protection Act and the Migratory Bird Treaty Act.

Forest stands used for nesting (and perching) are typically mature trees within stands with uneven age structure. Second growth forest with 5% to 10% remnant old growth component provides breeding habitat in Minnesota. Nest trees are almost always taller than the surrounding vegetation, probably because it is difficult for such a large bird (especially inexperienced fledglings) to maneuver and take off in dense understories. However, nests are often built below the topmost branches, probably for protection from rain and sun. Bald eagles prefer old growth pine taller than the surrounding forest canopy, and on the Superior National Forest, nearly all nests are in eastern white pine or red pine.

Bald eagles typically use large trees within 500 feet of rivers or large lakes as nest sites and perches to search for fish and other prey. The MDNR NHIS database contains records of 18 nesting areas, some with multiple nests,

within 12 miles of the Project area. Some of these nests were in close proximity and were assumed to be used by a single pair. The five closest bald eagle nesting territories were 6 to 7.5 miles from the Project area and averaged 6 miles apart. No large lakes or large nesting trees are found on or near the Mine Site and it is unlikely that bald eagles would use the Mine Site.

The primary foraging habitats of bald eagles are the shorelines of lakes and rivers. The smallest body of water on which bald eagles were reported to nest was 20 acres on the Chippewa National Forest in Minnesota. Bald eagles nesting on smaller bodies of water may require additional foraging areas nearby. Nesting near small lakes usually means there is a larger lake or several smaller lakes nearby.

Bald eagles generally winter near open water where prey or carrion are available. There are no large open-water lakes on the federal lands. Mud Lake (30.5 acres) is the only open-water area on the federal lands, but it is shallow lake and freezes over during winter. Animal-vehicle collisions on Dunka Road and/or natural white-tailed deer or other wildlife mortality do not appear to produce sufficient carrion to sustain bald eagles on the federal lands (ENSR 2005), although the amount of carrion available to bald eagles during mine operations could increase due to increased levels of vehicle and rail traffic.

Wildlife surveys were conducted during the spring and summer on the federal lands in 2004, 2008, and 2009 (ENSR 2005, AECOM 2009, 2011a). No bald eagle nests were found on the federal lands, although a bald eagle was seen flying over the federal lands. Bald eagles or their nests were not observed on the non-federal lands (AECOM 2011b, c).

Direct and Indirect Effects

Proposed Action

There should be no direct or indirect effects to bald eagles from the Project on the federal lands. There are no large lakes or rivers on the Mine Site that would provide optimal nesting/foraging habitat, although the Partridge River (approximately 0.5 mile south of the federal lands), Mud Lake, and the ponds at the Tailings Basin associated with the Plant Site could provide some, though less-than-optimal, habitat.

The nearest known bald eagle nests to the federal lands are approximately 6 miles from the Project area. The U.S. Department of the Interior (USDOI) U.S. Fish and Wildlife Service (USFWS) *National Bald Eagle Management Guidelines* (USDOI USFWS 2007) suggest that human activity within 2 miles can be seen or heard by eagles and, depending on the level of screening and habituation of individual eagles, may cause them to abandon a nest.

Project noise would potentially have an impact on eagle utilization of habitat in the vicinity of the Mine Site. Existing ambient steady equivalent noise levels for most of the Mine Site are in the range of 35 to 45 decibels (dBA), which is a range comparable to secluded woods or a quiet bedroom (MPCA 1999). The Peter Mitchell Mine, north of the Mine Site, and traffic along Dunka Road and the existing railway, along the south edge of the Mine Site, also contribute brief, episodic noise impacts.

The primary sources of Project noise from the Mine Site would be blasting, haul trucks, and train horns, with noise levels ranging from 89-115 dBA. Equipment such as graders, bull dozers, and support trucks would be less dominant sources of noise, ranging from 75-95 dBA (Environmental Protection Agency 1971). Blasting at the Mine Site is expected to occur once every two to three days. Typically, rock blasting generates a single event

noise level ranging from 111- 115 dBA at 50 feet from the blasting site (Table 5.5-7 of Madera County 2005). Within most of the Mine Site, the sound from the blast would be similar to a loud clap of thunder.

The impacts of noise on bald eagle utilization of habitat near the Mine Site are largely unknown and the assessment of impacts remains subjective. Impacts may also vary between individual eagles. Some eagles may adapt to predictable human activities, so if the activity generally occurs at predictable time periods at the same places or along the same routes, animals may become habituated to the activity (ENSR/AECOM 2006).

Bald eagle nesting territories in Minnesota are, on average, about 10 miles apart. Bald eagle nests near the Project area average about 6 miles apart. This suggests that the area near the Project provides high quality habitat for bald eagles, but there is low likelihood that the area would support many more territories. As eagles become more numerous, any eagles seeking to establish new territories in the area would need to select lower quality habitat and/or move into closer proximity to human activity.

The Forest Service considers MIH 7, which is primarily red and white pine forest, indicative of bald eagle habitat. No stands of MIH 7 were observed on the federal lands or proposed Mine Site, although there are scattered pines on the federal lands.

Surface water contaminants (e.g., mercury) that are absorbed by prey species such as waterfowl could lead to ingestion of contamination by eagles (Marr 2008). However, bald eagles are relatively insensitive to the toxic effect of mercury exposure through their food (Judd 2013). In addition, the potential incremental change in fish mercury concentrations in lakes (e.g., Heikilla, Colby, Sabin, Whitewater, Wynne) potentially associated with the Project's air emissions is estimated to be small (ranges from 0.0006 to about 0.016 parts per million, about 0.2% to 1.6% of background; Barr 2013; Section 10). This potential change in fish mercury concentration would be within the variability of background fish mercury concentrations for the Hoyt Lakes area (Barr 2013: Section 10 and Attachment F). Because the potential change in fish mercury concentrations is estimated to be small and not likely statistically measurable (i.e., no measurable change from existing background conditions), the potential effect of Project-related mercury on the bald eagle would not likely be measurable. Overall, no adverse indirect effects to the bald eagle would be expected from the Project.

Under the land exchange, the Forest Service would acquire potential bald eagle habitat, but no areas with known bald eagle nests. The nearest bald eagle nest to Hay Lake Lands is about 4 miles to the southeast on Cedar Island Lake. Eagle nests have been observed at John Lake and at North Fowl Lake (two nests), about 2 to 3 miles from McFarland Lake Lands. It is likely that eagles use habitat associated with Pine Lake, which is near Wolf Lands 1 and Lake County Lands North; Greenwood Lake, which is near Wolf Lands 2; and the Stony River, which is near Wolf Lands 3 and 4.

Lakes and rivers that could be associated with eagle habitat are present on or near several of the non-federal lands. Hay Lake Lands include the Pike River, Hay Lake (96 acres), and Little Rice Lake (29 acres). Lake County Lands and Wolf Lands are near large lakes such as Pine and Greenwood. McFarland Lake Lands border McFarland Lake, which is connected to other lakes within the BWCAW, and bald eagles have been seen foraging on McFarland Lake (Russ 2010).

There are 2,582 acres of upland forest (MIH 1 and 5), which comprises about 40% of all habitat on the federal lands; 792 acres are mature forest habitat (**Table 6**). There are 2,775 acres of upland forest, which comprises about 39% of all habitat on the non-federal lands; 617 acres are mature forest habitat (**Table 6**). Jack pine, trembling aspen, paper birch, black spruce, and balsam fir are the dominant upland forest species on the federal

lands. These species are also common on the non-federal lands, although there was less jack pine and more eastern white pine on the non-federal lands than on the federal lands.

The Project would affect about 1,037 acres of upland coniferous forest habitat, of which about 182 acres are mature upland forest habitat (**Table 6**). Only about 20% of upland forest stands on the non-federal lands consist of mature forest, which might include trees that could support bald eagle nests. Under the Proposed Action, the Forest Service would survey for bald eagles and associated habitat prior to conducting land-disturbing activities; areas of known or potential habitat would be avoided when feasible.

Alternative B

Potential direct and indirect effects to bald eagles from the Project would be similar to those under the Proposed Action. Under Alternative B, there are 2,093 acres of upland forest on the federal lands (**Table 6**). About 490 fewer acres of upland forest habitat would be transferred to PolyMet from the Forest Service under Alternative B than under the Proposed Action. Habitat loss from mining activities would be the same under Alternative B as under the Proposed Action.

The Forest Service would acquire Hay Lake Lands under Alternative B. There are no bald eagle nests and no known mature coniferous forest habitat on the lands. There are about 2,420 acres of upland forest habitat on Hay Lake Lands, however, only about 2% of this habitat is coniferous (MIH 5) and none of it is mature forest (**Table 6**). About 87% of the upland forest habitat that occurs on the non-federal lands is found on Hay Lake Lands. Thus, the Forest Service would receive most of the land that could provide habitat for bald eagles on the non-federal lands under the Proposed Action and Alternative B. Hay Lake, Little Rice Lake, and the Pike River are on Hay Lake Lands and may provide foraging habitat for bald eagles.

No Action Alternative

There should be no direct or indirect effects to bald eagle under the No Action Alternative.

Cumulative Effects

Human activity is the biggest threat to the bald eagle. Although DDT is no longer a risk factor in the U.S., organophosphates, heavy metals, and other pollutants continue to cause sickness or death in bald eagles. Lead poisoning is also a significant cause of mortality, and oil spills threaten eagles in coastal areas. Bald eagles are occasionally still shot or intentionally poisoned. Additionally, collisions with vehicles and power lines are a growing threat as more land is developed. Vehicle collisions have become more frequent as the bald eagle population has increased in Minnesota, due to the bald eagles habit of feeding on deer carcasses along roads. Land development in wilderness areas and along shorelines destroys breeding habitat and winter roost sites, and increased human activity may cause bald eagles to abandon nesting or winter roosting sites. However, the fact that bald eagles are now successfully nesting in proximity to humans, even in the Twin Cities metropolitan area, indicates that some bald eagles may become habituated to humans if they are not persecuted (USDA Forest Service 2004b).

Modeling to predict future vegetation management activities in Minnesota projected, under all scenarios modeled, that bald eagle nesting, roosting, and perching habitat will increase statewide. Red and eastern white pine forest acres, and the amount of old forests in both these forest types, are expected to increase. Cumulative

effects of forest management on all ownerships should benefit eagles by increasing preferred nesting, roosting, and perching habitat over the next several decades on both public and private lands (Jaakko Poyry 1994).

Adverse effects to bald eagles could occur on lands outside of Forest Service administration. Increases in the potential for human access near bald eagle territories would occur as people buy, subdivide, and develop private lands. New road construction would be needed to access this property. Some of these roads may be developed near to current or future nesting habitat. Development of cabins and second homes next to lakeshores could also decrease high quality eagle habitat through destruction of potential nesting habitat or indirectly through increases in disturbance associated with motorized recreation such as all-terrain vehicles and motorboats. Populations of fish, one of the primary types of prey species for eagle, may decrease on lakes with increased fishing pressure. Increasing fish populations through MDNR stocking would mitigate fish declines in some lakes (USDA Forest Service 2004b).

Relatively high deer populations across the landscape also are likely to pose potential adverse indirect cumulative effect on eagle. High deer populations are a result of factors (warm winters that increase survival, MDNR population management through hunting permits) that are outside the control of the Forest Service, and are the result of factors over which Forest Service has control (forest vegetation management for suitable deer habitat). With increasing deer populations and increasing numbers of road-killed deer, and forest management that promotes increasing deer habitat, this could result in greater potential for eagles to be killed or harmed along highways.

The Project could have minor cumulative effects, as there is mature forest habitat on the Mine Site that could be used by bald eagles. Bald eagles, however, were not observed using this habitat during wildlife surveys on the Mine Site. Both PolyMet and the Forest Service could conduct timber and other land management activities on their acquired lands. Cumulative effects from timber and other land management should be negligible if the Forest Service follows guidance in its 2004 Forest Plan (USDA Forest Service 2004a), and PolyMet and/or private landowners follow national bald eagle management guidelines developed by the USDO IUSFWS (2007).

Summary

Project activities associated with the Proposed Action and Alternative B should have no adverse direct or indirect effects on individual bald eagles or their habitat. There could be minor cumulative effects to bald eagle habitat, primarily from loss of mature forest habitat due to mining, but it is unlikely that these trees would be used by eagles in the near future. There would also be a cumulative loss of bald eagle habitat elsewhere in the CESA due to timber management, lakeside and other development, and other land use activities. Timber management and road construction could occur on the federal and non-federal lands in the reasonably foreseeable future, but only a small acreage of federal and non-federal lands would be affected.

Determination

The Proposed Action and Alternative B **may impact individuals but are not likely to cause a trend to federal listing or loss of viability** for bald eagle. The No Action Alternative would have **no impact** to individuals of bald eagle.

Mitigation and Recommendations

No mitigation measures are recommended for the bald eagle.

5.2.6.2 Northern Goshawk (*Accipter gentilis*)

Environmental Baseline

Northern goshawk is a large forest raptor that is found on boreal and temperate forests throughout the holarctic. Squires and Reynolds (1997) state that *Accipter gentilis atricapillus*, the subspecies occurring in Minnesota, is widely distributed across the northern half of eastern North America and in many parts of western North America. Northern goshawks are generally uncommon throughout their range. Population productivity and nesting densities coincide with populations of snowshoe hare and grouse. Populations in the Great Lakes Region may have declined in the past due to early logging and settlement and extermination of passenger pigeons, a prey species for northern goshawk. In Wisconsin, the reintroduced fisher is blamed for increased nest failure and adult female mortality. Northern goshawk populations may be increasing with the recovery and maturing of forests in recent times in some parts of the U.S.

Northern goshawk is a forest dwelling raptor whose habitat preferences are mature deciduous or mixed coniferous/deciduous forest in fairly contiguous blocks intermixed with younger forests and openings for prey species habitat. Goshawks are adapted to flying beneath the forest canopy and use primarily mature forest with sufficient open space between the bottom live tree branches and understory for the birds to fly easily. Some understory (e.g., forbs) and downed logs are needed for prey species habitat. Adults and fledglings use large downed logs as feeding and plucking perches. Goshawks may use forest edge if large-bodied prey is more common there.

Boal et al. (2001 in USDA Forest Service 2010b) studied habitat use by nesting goshawks in northern Minnesota. Eighty-one percent of 46 nests were built in aspen trees, 11% in paper birch trees, 4% in white pine trees, and 2% each in red oak and red pine trees. On the Laurentian District, red pine plantations were the most common nest stands (four nests), followed by trembling aspen-black spruce-balsam fir (two nests), trembling aspen (one nest), jack pine (one nest), paper birch (one nest), and maple (one nest).

While goshawks do not always use the same nest for more than a year, they typically have two and up to nine alternate nest sites that are usually within a mile of the present nest. It is important to also protect these alternate nest sites that may be used in subsequent years.

Boal et al. (2001 in USDA Forest Service 2010b) found that foraging stands, regardless of stand type, were consistent in having high stand densities of tall, large canopy trees, with horizontal open spaces of 3 to 12 feet between the bottom of the overstory and top of the understory trees, and up to 3 feet between the bottom of the understory canopy and top of the shrub layer. They suggested that these relatively unobstructed spaces between vegetation layers may serve as important flight paths through forest stands, and the heights in which they occurred was consistent among stand types.

Calling surveys were conducted for northern goshawks on the federal lands (ENSR 2000, 2005, AECOM 2009, 2011a) and on Hay Lake Lands and McFarland Lake Lands (AECOM 2010b). One nest was found within the federal lands within the Mine Site in March 2000 (One Hundred Mile Swamp Territory; Ryan 2013a). The northern goshawk pair observed on the Mine Site used a large, 14 inches dbh trembling aspen tree as a nest, and

the midstory was mostly open in the vicinity of the nest. The surrounding forest stand was a mixture of deciduous and coniferous trees, and was near a recent clear-cut stand and a shrub swamp wetland. No goshawks were detected at the site during a 2004 survey (ENSR 2005). The territory was actively used by northern goshawks in 2005, but they did not nest. In 2006, the site was occupied by a great gray owl and there was a possible nest attempt by great gray owls in 2010 (Ryan 2013b).

In April 2009, a goshawk nest with a pair of goshawks at the nest was found near the boundary of the Mine Site (Wetlegs Creek Territory; AECOM 2009, Ryan 2013b). The occupied nest was located in the fork of a 12 inches dbh trembling aspen tree. The nest site area was characterized as a mixed coniferous/deciduous forest habitat, with numerous mature trembling aspen trees found in the forest stand. The nest site was in close proximity to a large bog wetland. In 2010, a barred owl used the nest at this location. In 2011, the nest was again used by northern goshawks. The nest was not occupied by goshawks during 2012, but in 2013 was again used by northern goshawks, although the nest attempt failed. A second nest was also found near the boundary of the Mine Site in 2009, but the nest was unoccupied and may have been an alternate goshawk nest or nest of another raptor or common raven.

A northern goshawk territory (Pike Mountain 2 Territory) is found near the southwestern boundary of Hay Lake Lands, and are probably used by the same pair (Ryan 2013b). The pair produced young in 2010, 2011, and 2013. No other northern goshawk nests have been found on or within a mile of the other non-federal lands, although northern goshawks have been seen within 3 miles of Lake County Lands South.

Direct and Indirect Effects

Proposed Action

There could be direct and indirect effects to northern goshawk from the Project. Two northern goshawk territories have been found on the federal lands, and northern goshawks nested on the federal lands in 2000, 2009, 2011, and 2013. Under the Proposed Action, the northern goshawk nest tree within the One Hundred Mile Swamp Territory on the Mine Site would no longer be available to northern goshawks, although the tree has not been used by northern goshawks since at least 2005.

Project noise would potentially have an impact on northern goshawk utilization of habitat in the vicinity of the Mine Site. Existing ambient steady equivalent noise levels for most of the Mine Site are in the range of 35 to 45 decibels (dBA), which is a range comparable to secluded woods or a quiet bedroom (MPCA 1999). The Peter Mitchell Mine, north of the Mine Site, and traffic along Dunka Road and the existing railway, along the south edge of the Mine Site, also contribute brief, episodic noise impacts.

The primary sources of Project noise from the Mine Site would be blasting, haul trucks, and train horns, with noise levels ranging from 89-115 dBA. Equipment such as graders, bull dozers, and support trucks would be less dominant sources of noise, ranging from 75-95 dBA (EPA 1971). Blasting at the Mine Site is expected to occur once every two to three days. Typically, rock blasting generates a single event noise level ranging from 111- 115 dBA at 50 feet from the blasting site (Table 5.5-7 of Madera County 2005). Within most of the Mine Site, the sound from the blast would be similar to a loud clap of thunder.

Noise and other disturbances on the Mine Site and Dunka Road and Utility Corridor could disturb northern goshawks nesting just off the Mine Site and on federal lands (Wetlegs Creek Territory), and possible cause them to abandon the territory. The Wetlegs Creek Territory nest site is about 0.75 miles from the Mine Site and

Dunka Road, and is buffered by forestland, which should help to minimize disturbance to the pair. Both territories are about 0.75 miles from the Northshore Mine property, where there is active mining, suggesting that northern goshawks nesting on the federal lands have habituated to disturbance from that mining operation.

Northern goshawks favor mature upland forest habitat (MIH 1). There are 557 acres of mature upland forest habitat within the federal lands that could provide habitat for the northern goshawks (**Table 6**). In addition, there are about 773 acres of young and immature upland forest habitat that could be used by northern goshawks in the future. The Project would affect about 158 acres of mature upland forest habitat, including mature trembling aspen habitat used by northern goshawks. In addition, about 375 acres of young and immature upland forest habitat would be lost to mining.

There are 591 acres of mature and 2,104 acres of young and immature upland forest habitat on the non-federal lands (**Table 6**). The non-federal lands would not be directly affected by the Project, but should benefit from Forest Service management that favors longer harvest rotations than typically occurs on private forestlands. Under the Proposed Action, the Forest Service would survey for northern goshawks and associated habitat prior to conducting land-disturbing activities; areas of known or potential habitat would be avoided when feasible.

Alternative B

Potential direct and indirect effects to northern goshawk from the Project under Alternative B would be similar to those under the Proposed Action. Under Alternative B, there are about 326 acres of mature and 628 acres of young and immature upland forest habitat on the federal lands (**Table 6**). About 230 fewer acres of mature and 145 acres of young and immature upland forest habitat on the federal lands would be transferred to PolyMet from the Forest Service under Alternative B than under the Proposed Action. Habitat loss to mining activities under Alternative B would be the same as under the Proposed Action.

The Forest Service would acquire Hay Lake Lands under Alternative B. There is a northern goshawk territory on Hay Lake Lands (Ryan 2013a). There are about 460 acres of mature and 1,906 acres of young and immature upland forest on Hay Lake Lands that could provide habitat for northern goshawk (**Table 6**). About 78% of mature, and 91% of young and immature, upland forest habitat that occurs on the non-federal lands is found on Hay Lake Lands. Thus, the Forest Service would receive most of the land that could provide habitat for northern goshawk on the non-federal lands under both the Proposed Action and Alternative B.

No Action Alternative

There would be no direct or indirect effects to northern goshawk under the No Action Alternative.

Cumulative Effects

Destruction or modification of habitat, habitat fragmentation, changes in vegetative structure and composition, and effects of activities associated with habitat modification are considered the primary threats to breeding northern goshawks (USDA Forest Service 2010b). Niemi and Hanowski (1992 *in* Jaakko Poyry Consulting, Inc. 1994)) suggested that northern goshawk prefer larger tracts of forest for foraging and are affected by fragmentation of forested areas. The species seldom uses recently cut areas for foraging, presumably because prey is hard to detect and capture in the dense understory. Another threat to northern goshawk is creation of landscape patterns (e.g., large openings from clear-cutting or increased edge habitat) that favor predators such as

red-tailed hawk, great-horned owl, fisher, or raccoon. In one study, stands larger than 50 acres were used more consistently by northern goshawk rather than stands smaller than 25 acres (Estabrook 2000).

State, county, and private forest management will likely reduce the present level of large blocks of mature upland forest found in the CESA. A 2008 Geographic Information System analysis shows a slight increase in mature upland forest on the Superior National Forest in recent decades, but the amount of mature/old upland forest is expected to decrease over the next several decades (USDA Forest Service 2010b). Fragmentation of larger blocks of habitat would make northern goshawks more vulnerable to predators and affect species distribution. Boal et al. (2001 *cited in* USDA Forest Service 2010b) documented up to 30% nest predation in northern Minnesota. Wide ranging pairs of northern goshawks may not successfully breed if they are forced to expand their home ranges to compensate for further loss of high quality foraging habitat.

There would be cumulative effects to northern goshawk habitat from the Project. About 158 acres of mature upland forest habitat that could be used by northern goshawk on the federal lands would be directly affected by the Project, including mature and other upland forest associated with the One Hundred Mile Swamp Territory, which was last used by northern goshawks in 2005 (**Table 6**). However, there are about 625,000 acres of upland forest within the CESA that could now, or in the reasonably foreseeable future, provide habitat for northern goshawk (Emmons and Olivier, Inc. 2006:30, 38). Thus, habitat loss from the Project would have a negligible cumulative effect on northern goshawks in the CESA.

Summary

Project activities associated with the Proposed Action and Alternative B would have no direct effects, but could have adverse indirect and cumulative effects to individual northern goshawks and their habitat. In particular, mining activities could disturb northern goshawks nesting on the Wetlegs Creek Territory, and remove habitat and prey and cause disturbance in areas where these birds may forage. Upland forest habitat used by northern goshawks is abundant in the CESA, and northern goshawks, although uncommon in the region, seem to have increased in numbers over the past several decades.

Timber management and road construction could occur on the federal and non-federal lands in the reasonably foreseeable future, but only a small acreage of federal and non-federal lands would be affected. It is more likely that production of mature upland forest habitat on the non-federal lands would occur if these lands are federally administered rather than under private ownership.

Determination

The Proposed Action and Alternative B **may impact individuals but are not likely to cause a trend to federal listing or loss of viability** for northern goshawk. The No Action Alternative would have **no impact** to individuals of northern goshawk.

Mitigation and Recommendations

No mitigation measures are recommended for the northern goshawk.

5.2.6.3 Boreal Owl (*Aegolius funereus*)

Environmental Baseline

Hayward (1994) states that boreal owls occupy boreal forests throughout the northern hemisphere. East of the Rocky Mountains, breeding by boreal owls has only been confirmed in Minnesota and primarily in northeastern Minnesota. Nesting boreal owls are uncommon west of Highway 53 or the Vermillion River, or within 8 miles of Lake Superior. The prime area for boreal owls appears to be the eastern portion of the Forest Service Laurentian Ranger District, southern portion of the Kawishiwi Ranger District, and the middle portion of the Tofte Ranger District.

Boreal owls are rarely seen in Minnesota. The first one reported nesting in Minnesota was in 1978. Boreal owls have been documented as breeding in the Superior National Forest (USDA Forest Service 1999, Green 2003, Catton 2007), including a failed boreal owl nest in 2013 that was about 8 miles east/southeast of Wolf Lands 2 and 3 in Township 58 North, Range 9 West, Lake County, Minnesota (Ryan 2013c).

While attempts have been made to monitor boreal owl populations, present survey techniques are not sufficiently precise to detect population trends for northern Minnesota. Boreal owl populations fluctuate with winter snow depth and prey availability, and winter population irruptions occur periodically. There appears to be an influx of boreal owls into northern Minnesota every 4 years, perhaps due to a decline in their prey (vole) populations further north in Canada. The latest influx was in winter 2013, with several boreal owls sighted near Duluth. The population on the Superior National Forest is part of a larger Canadian population and may not be viable by itself at present.

Boreal owls prefer forests dominated by black spruce, white spruce, balsam fir, balsam poplar, trembling aspen, and paper birch. They favor mature forest during winter because snow conditions (un-crusting snow) facilitate access to prey. In summer, mature forest sites have less herbaceous cover than open sites, allowing greater access to prey. Following spring thaw, before herbaceous vegetation becomes dense, owls shift to openings where densities of voles exceed densities in forested stands.

Nesting habitat is mixed coniferous/deciduous upland forest usually older than 70 years. Nest trees are typically trembling aspen and paper birch with an average 16 to 18 inches dbh. Cavities excavated by pileated woodpeckers are often used for nesting by the boreal owl. Within 8 acres centered on each nest site, another important habitat component is six or more dominant or co-dominant conifers that are used as calling perches. Nest sites are usually within 200 yards of large areas of productive mature lowland conifers, primarily black spruce, which are preferred for foraging and roosting. Nests that are further than 200 yards from lowland conifer forest typically have a mature forest corridor to that lowland coniferous forest. Populations are limited by availability of cavities for nesting and food supply. Limiting factors may be the right combination of nesting and foraging/roosting habitat, and possibly the distribution of these habitats and cavity trees. Fragmentation has been a primary factor causing the isolation of lowland coniferous forests. Other limiting factors include automobile collisions and low prey density.

Night calling surveys for boreal owls were conducted on the federal lands during winter and early spring 2000, summer 2004, summer 2008, and spring 2009 by broadcasting pre-recorded boreal owl calls; no boreal owls were heard during the surveys (ENSR 2000, 2005, AECOM 2009, 2011a). A boreal owl was heard along the Dunka Road during surveys in 1988 to 1989 (ENSR 2000). Surveys were also conducted on the non-federal

lands, but no boreal owls were heard (AECOM 2011b, c), although a boreal owl nest was found by the Forest Service in 2013 about 8 miles east/southeast of Wolf Lands 2 and 3 (Ryan 2013c).

Direct and Indirect Effects

Proposed Action

There should be no direct effects to boreal owls on the federal lands from the Project as no boreal owls are known to use the federal lands. Boreal owls could use the federal lands, however, and mining activities could disturb boreal owls on or near the Mine Site and Dunka Road and Utility Corridor and indirectly affect their habitat use.

The Project would cause the loss of potential boreal owl foraging habitat (lowland black spruce and mixed swamp coniferous stands greater than 50 years old) and nesting habitat (upland deciduous forest habitat greater than 70 years old; USDA Forest Service 2010b). There are about 3,040 acres of mature lowland coniferous forest (MIH 9) and about 557 acres of mature upland forest habitat (MIH 1) on the federal lands that could provide habitat for boreal owls (**Table 6**). In addition, there are about 773 acres of young and immature upland forest habitat that could be used by boreal owls in the future. The Project would affect about 482 acres of mature lowland coniferous forest, 158 acres of mature upland forest, and 375 acres of young and immature upland forest habitat (**Table 6**). No young or immature lowland coniferous forest habitat would be affected by the Project.

Boreal owls have not been recorded on the non-federal lands in recent years, but a boreal owl nest was found by the Forest Service in 2013 about 8 miles east/southeast of Wolf Lands 2 and 3 (Ryan 2013c). There are about 1,208 acres of mature and 2,101 acres of young and immature lowland coniferous forest habitat, and about 591 acres of mature and 2,104 acres of young and immature upland forest habitat, on the non-federal lands (**Table 6**). Thus, there could be suitable boreal owl foraging habitat (mature lowland coniferous forest) and nesting habitat (mature upland forest) on the non-federal lands. These lands would not be directly affected by the Project. This habitat could be maintained through the retention of mature patches greater than 300 acres, limited black spruce harvest, riparian management, and by leaving large trembling aspen/paper birch as reserve trees and positioning reserve areas along the wetland/upland interface. Under the Proposed Action, the Forest Service would survey for boreal owls and associated habitat prior to conducting land-disturbing activities and areas of known or potential habitat would be avoided when feasible. The Forest Service would also monitor boreal owl use of these lands and seek to protect larger patches of high quality habitat for boreal owls.

Alternative B

Effects to boreal owl under Alternative B should be similar to those under the Proposed Action. Under Alternative B, there are about 2,063 acres of mature and 16 acres of young and immature lowland coniferous forest habitat and 326 acres of mature and 628 acres of young and immature upland forest on the federal lands (**Table 6**). About 977 fewer acres of mature lowland coniferous forest and 231 fewer acres of mature upland forest would be transferred to PolyMet from the Forest Service than under the Proposed Action. Habitat loss to mining activities would be the same under Alternative B as under the Proposed Action.

The Forest Service would acquire Hay Lake Lands under Alternative B. No boreal owls have been observed in recent years on these lands. There are 0 acres of mature and 1,818 acres of young and immature lowland coniferous forest habitat, and 460 acres of mature and 1,906 acres of young and immature upland deciduous

forest habitat on Hay Lake Lands. About 87% of the lowland coniferous forest habitat and 78% of the mature upland forest habitat that occurs on the non-federal lands are found on Hay Lake Lands.

No Action Alternative

There would be no direct or indirect effects to boreal owl under the No Action Alternative.

Cumulative Effects

The Final Generic Environmental Impact Statement Study on Timber Harvesting and Forest Management in Minnesota (Jaakko Poyry Consulting Inc. 1994) projected a decrease in the Minnesota boreal owl population if statewide timber harvest increased over 1 million cords overall or about 25% higher than at present. On federal lands, there is anticipated to be a reduction in mature upland patches (less than 300 acres) and a reduction in interior forest, but also an increase in mature lowland patches greater than 300 acres. Harvest by other landowners has the potential to further reduce boreal owl nesting, and to a lesser extent, foraging habitat.

The 2008 Superior National Forest-wide monitoring showed a slight increase in mature upland deciduous and coniferous habitat, and a slight decrease in mature lowland coniferous forest for the Superior National Forest (USDA Forest Service 2010b). Monitoring also showed a slight increase in mature upland forest on the Superior National Forest in recent decades, but the amount of mature upland forest is expected to decrease over the next several decades. State, county, and private forest management will probably reduce the present level of large blocks of mature upland forest found on the CESA.

There should be no cumulative effects to individual boreal owls from the Project, but there would be a cumulative loss of potential boreal owl habitat. About 640 acres of mature lowland coniferous forest and upland deciduous forest habitat that could be used by this species on the federal lands would be directly affected by the Project. However, there are about 820,000 acres of upland deciduous and lowland coniferous forest within the CESA that could now, or in the reasonably foreseeable future, provide habitat for boreal owls (Emmons and Olivier, Inc. 2006; 30, 38). Thus, habitat loss from the Project would have a negligible cumulative effect on boreal owls in the CESA.

Summary

Project activities associated with the Proposed Action and Alternative B should have no adverse direct or cumulative effects on individual boreal owls, but could have direct, indirect, or cumulative effects on their habitat. Mining activities could disturb boreal owls on or near the Mine Site and Dunka Road and Utility Corridor and indirectly affect their habitat use. Timber management and road construction could occur on lands within the CESA in the reasonably foreseeable future, but only a small acreage of federal and non-federal lands would be affected. It is more likely that production of mature lowland and upland forest habitat on the non-federal lands would occur if these lands are federally administered rather than under private ownership.

Determination

The Proposed Action and Alternative B **may impact individuals but are not likely to cause a trend to federal listing or loss of viability** for boreal owl. The No Action Alternative would have **no impact** to individuals of boreal owl.

Mitigation and Recommendations

No mitigation measures are recommended for boreal owl.

5.2.6.4 Great Gray Owl (*Strix nebulosa*)

Environmental Baseline

The great gray owl has a holarctic distribution and breeds in the western U.S. and in the northern Great Lakes Region. Great gray owls forage anywhere meadow voles are abundant and available. Meadow vole abundance is influenced by season (more numerous in late summer and fall), a 3- to 5-year cycle in Minnesota, and habitat capacity. The great gray owl prefers moist soils and relatively open areas with high primary production of prey. Nesting commonly occurs in mature trembling aspen adjacent to muskegs. Minimum nest stand size was 10 acres in Manitoba and 27 acres in Alberta. Foraging occurs in open habitat, including bogs, selective and clear-cut logged areas with residual perches, natural meadows, and open forests within 1.5 miles of the nest. Perches need not be tall and can be high stumps, broken-off trees, and the short black spruce found in peatland bogs. Meadow voles that are 50 feet or more from a perch or forest edge are usually not available to great gray owls. Great gray owls avoid jack pine, taller black spruce, dense forest cover, large open treeless areas without perches, and habitats with a dense shrub layer. They also avoid concentrations of predators such as great horned owls. Average home range size for breeding adults was 1.7 square miles (mi²) in Oregon. A Minnesota study found eight nests in 20 mi².

Kozie (1999) recommended the following forestry practices to maintain or enhance great gray owl habitat: 1) restriction of harvest unit size to less than 25 acres with a mosaic of multi-sized units, 2) retention of forest stands within 900 feet of known or potential nest trees or sites, 3) provision of hunting perches in clearcuts, 4) ensuring irregularly shaped harvest units with a maximum distance across the cut of less than 300 feet, and 5) maintenance of forested travel corridors, 150 to 300 feet wide, between cut areas. In the Pacific Northwest, the Forest Service recommended providing a no-harvest buffer of about 300 feet around meadows and natural openings and establishment of a 1,320-foot protection zone (125 acres) around nest trees. Kozie (1999) also recommended placing priority on maintaining nesting habitat within 0.5 to 1.5 miles of natural openings rather than clear-cuts.

Night calling surveys did not identify great gray owls on the federal lands (ENSR 2000, 2005, AECOM 2009, 2011a). During 2009 surveys, however, a great gray owl was observed hunting along Dunka Road south of the Mine Site. Based on Forest Service observations, a great gray owl pair was seen using a nest site on the Mine Site in 2006, and possibly in 2010. The nesting effort(s) were unsuccessful. This was the same nest site used by northern goshawks in 2000 (ENSR 2000; Ryan 2013b). In 2011, a great gray owl was seen using a nest site on the federal lands surrounding the Mine Site and near a nest used by northern goshawks (Wetlegs Creek Territory).

Calling surveys did not identify great gray owls on the non-federal lands (AECOM 2011b, c). Great gray owls were surveyed on the Tracks Project area in 2007 and 2008 using both call playback and listening stops. Five survey routes were run and consisted of 50 survey points along roads. These routes were run two to four times in the spring both years. No great gray owls were detected within the Tracks Project area.

Direct and Indirect Effects

Proposed Action

Great gray owls were seen nesting on the Mine Site in 2006, and foraging along the Dunka Road in 2009. If the Mine Site is part of the territory of a great gray owl, mining activities could directly affect great gray owls by disrupting their use of this area, and indirectly affect owls through removal of a tree that has provided a nest site for great gray owls in the past, removal of foraging habitat and prey, and from Mine Site and Dunka Road and Utility Corridor disturbances. Great gray owls have been seen perching near the Plant Site entrance on light poles, and foraging and perching on trees within 100 feet of the Dunka Road. Thus, great gray owls seem tolerant of some human disturbance (AECOM 2009).

Project noise would potentially have an impact on eagle utilization of habitat in the vicinity of the Mine Site. Existing ambient steady equivalent noise levels for most of the Mine Site are in the range of 35 to 45 decibels (dBA), which is a range comparable to secluded woods or a quiet bedroom (MPCA 1999). The Peter Mitchell Mine, north of the Mine Site, and traffic along Dunka Road and the existing railway, along the south edge of the Mine Site, also contribute brief, episodic noise impacts.

The primary sources of Project noise from the Mine Site would be blasting, haul trucks, and train horns, with noise levels ranging from 89-115 dBA. Equipment such as graders, bull dozers, and support trucks would be less dominant sources of noise, ranging from 75-95 dBA (EPA 1971). Blasting at the Mine Site is expected to occur once every two to three days. Typically, rock blasting generates a single event noise level ranging from 111- 115 dBA at 50 feet from the blasting site (Table 5.5-7 of Madera County 2005). Within most of the Mine Site, the sound from the blast would be similar to a loud clap of thunder.

The impacts of noise on great gray owl utilization of habitat near the Mine Site are largely unknown and the assessment of impacts remains subjective, although as noted above, great gray owls appear to be tolerant of human disturbance. Impacts may also vary between individual owls. Some may adapt to predictable human activities, so if the activity generally occurs at predictable time periods at the same places or along the same routes, individual great gray owls may become habituated to the activity (ENSR/AECOM 2006).

Mature upland forest (MIH 1) is indicative of nesting habitat, while foraging habitat consists of young upland forest and lowland coniferous forest (MIH 9). Non-forest (upland and lowland) also provides foraging habitat. There are about 233 acres of young and 557 acres of mature upland forest habitat, 3,060 acres of lowland coniferous habitat, and 492 acres of lowland shrubland (MIH – other lowland shrub) on the federal lands that could provide habitat for great gray owls (**Table 6**). The Project would affect about 144 acres of young and 158 acres of mature upland forest habitat. In addition, about 482 acres of lowland coniferous forest habitat and 141 acres of shrubland would be lost to mining (**Table 6**).

There are about 607 acres of young and 591 acres of mature upland forest habitat, 3,309 acres of lowland coniferous forest habitat, and 332 acres of lowland shrubland habitat on the non-federal lands (**Table 6**).

There is abundant great gray owl foraging habitat and nesting habitat on the non-federal lands. These lands would not be directly affected by the Project. This habitat would be maintained through the retention of mature patches greater than 300 acres, limited black spruce harvest, riparian management, and in harvest units by leaving large trembling aspen/paper birch as reserve trees and positioning reserve areas along the wetland/upland interface. Under the Proposed Action, the Forest Service would survey for great gray owls and

associated habitat prior to conducting land-disturbing activities and areas of known or potential habitat would be avoided when feasible.

Alternative B

Potential direct and indirect effects to great gray owl from the Project would be similar to those under the Proposed Action. Under Alternative B, there are about 233 acres of young and 326 acres of mature upland forest, 2,079 acres of lowland coniferous forest, and 385 acres of lowland shrubland on the federal lands (**Table 6**). About 230 fewer acres of upland forest, 982 fewer acres of lowland coniferous forest, and 107 fewer acres of lowland shrubland would be transferred to PolyMet from the Forest Service under Alternative B than under the Proposed Action. This area would provide habitat for great gray owls, although noise and other disturbance associated with mining may discourage use of the area by great gray owls.

The Forest Service would acquire Hay Lake Lands under Alternative B. No great gray owls have been reported on these lands. There are about 519 acres of young and 460 acres of mature upland forest, 1,818 acres of lowland coniferous forest, and 113 acres of lowland shrubland habitat on Hay Lake Lands (**Table 6**). About 85% of young and 78% of mature upland forest, 55% of lowland coniferous forest habitat, and 34% of lowland shrubland habitat that occurs on the non-federal lands are found on Hay Lake Lands. A portion of Hay Lake Lands could be administered as a Candidate Research Natural Area, to the potential benefit of great gray owls. As noted in Section 5.2.6.2, a northern goshawk territory is found in the southwestern portion of Hay Lake Lands. Great gray owls show a propensity to use northern goshawk nests, and could use the nest sites on Hay Lake Lands in the future.

No Action Alternative

There would be no direct or indirect effects to great gray owl under the No Action Alternative.

Cumulative Effects

As discussed for boreal owls, reasonably foreseeable future land and timber management activities in the CESA could result in a loss of some habitat for owls in Minnesota. Logging in nesting habitat could affect the great gray owl under the Proposed Action, Alternative B, and No Action Alternative by removing suitable nesting structure. Despite the fact that timber harvest can remove nesting habitat, harvest can create more temporary foraging habitat in some coniferous forest types. Maintaining large mature patches of upland forest would help to ensure suitable interior nesting habitat would be available across the landscape. Implementation of Minnesota Forest Resources Council's (1999) Voluntary Site-Level Forest Management Guidelines would help to ensure that snags, reserve trees, and downed wood are provided in all harvested stands.

Roads and recreation projects should have a minimal effect on great gray owls. Owls readily forage along roadsides. Many of the proposed roads use existing road corridors which are not owl nesting habitat. Wetlands would be avoided whenever possible. Prescribed burning should not have an effect on great gray owls unless there was a nest present in the stand.

About 925 acres of young and mature upland forest, lowland coniferous forest, and shrubland that could be used as nesting and foraging habitat for this species on the federal lands would be directly affected by the Project (**Table 6**). However, there are about 980,000 acres of upland forest, and lowland coniferous forest and shrubland, within the CESA that could now, or in the reasonably foreseeable future, provide habitat for great

gray owls (Emmons and Olivier, Inc. 2006:30, 38). Thus, habitat loss from the Project would have a negligible cumulative effect on great gray owls in the CESA.

Summary

Project activities associated with the Proposed Action and Alternative B should have no adverse direct, indirect, or cumulative effects on individual great gray owls, but could have direct, indirect, or cumulative effects on their habitat. Timber management and road construction could occur on the lands within the CESA in the reasonably foreseeable future, but only a small acreage of federal and non-federal lands would be affected. It is more likely that production of mature lowland and upland forest habitat on the non-federal lands would occur if these lands are federally administered rather than under private ownership.

Determination

The Proposed Action and Alternative B **may impact individuals but are not likely to cause a trend to federal listing or loss of viability** for great gray owl. The No Action Alternative would have **no impact** to individuals of great gray owl.

Mitigation and Recommendations

No mitigation measures are recommended for great gray owl.

5.2.6.5 Three-toed Woodpecker (*Picoides tridactylus*)

Environmental Baseline

Three-toed woodpecker is a species of boreal and montane coniferous forests and is primarily a resident species throughout its range (Burdett 2002 and references cited therein). It usually inhabits mature or old-growth lowland coniferous stands with abundant insect-infected dead and dying trees. Even in predominately living forests, three-toed woodpeckers forage mainly on dead and dying timber. Three-toed woodpeckers breed throughout lowland coniferous forests in Canada and the western U.S., and in northern Minnesota and Wisconsin. Population trends are unknown. In the Superior National Forest, they seem to nest mainly in black spruce and balsam fir snags and mature trees. This dependence on insect-infected dead and dying timber frequently results in populations showing an association with forest disturbances such as fire, wind-throw, floods, insect outbreaks, and disease. In particular, three-toed woodpecker populations often show an increased abundance in early post-fire successional areas (Burdett 2002). Black spruce and tamarack stands are the vegetation community most likely to contain three-toed woodpeckers in Minnesota.

Habitat for the three-toed woodpecker is conifers killed by fire, beetles, partial wind-throw, or flooding. The bird keys in on beetles that feed on dead trees 1 to 5 years after trees are killed. A limiting factor for the three-toed woodpecker is foraging habitat where sufficient insects can be found to feed its young during the breeding season. This species can be nomadic and shift over large portions of the landscape depending on habitat conditions. Promotion of conifers and retaining residual trees (preferably long-lived, wind-firm conifers) in large openings may maintain or enhance habitat conditions for three-toed woodpeckers. Studies have also found that they are more likely to occur in larger areas of virgin forest versus smaller patches, suggesting forest fragmentation may adversely affect the three-toed woodpecker population.

ENSR (2000, 2005) and AECOM (2011a) conducted visual and calling surveys for woodpeckers on the federal lands. One three-toed woodpecker was observed foraging on black spruce snags during winter field surveys on the Mine Site in 2000 (ENSR 2000). A three-toed woodpecker was also seen on the Mine Site by Forest Service personnel in 2007. AECOM (2011b, c) conducted calling and visual surveys for three-toed woodpeckers on the non-federal lands, but no three-toed woodpeckers were seen or heard.

The Natural Resources Research Institute's (NRRI) Breeding Bird Monitoring effort surveys 169 forest stands on the Superior National Forest. The Institute did not detect three-toed woodpeckers on the Superior National Forest; however, timing and location of survey routes are such that this species is not adequately surveyed (USDA Forest Service 2010b). No three-toed woodpeckers were observed on the Tracks Project area.

Direct and Indirect Effects

Proposed Action

A three-toed woodpecker was identified on the federal lands during surveys in 2000 and was observed on the lands again in 2007. Though not surveyed, the Transportation and Utility Corridors and Plant Site lack the old-growth forest or recent burn habitat preferred by the three-toed woodpecker. This species is sensitive to disturbance and would not be expected to use the Mine Site, Transportation and Utility Corridors, or the Plant Site, although observations of three-toed woodpecker in 2000 were made within one-half mile of an active exploration drill rig (ENSR 2005).

Project noise would potentially have an impact on eagle utilization of habitat in the vicinity of the Mine Site. Existing ambient steady equivalent noise levels for most of the Mine Site are in the range of 35 to 45 decibels (dBA), which is a range comparable to secluded woods or a quiet bedroom (MPCA 1999). The Peter Mitchell Mine, north of the Mine Site, and traffic along Dunka Road and the existing railway, along the south edge of the Mine Site, also contribute brief, episodic noise impacts.

The primary sources of Project noise from the Mine Site would be blasting, haul trucks, and train horns, with noise levels ranging from 89-115 dBA. Equipment such as graders, bull dozers, and support trucks would be less dominant sources of noise, ranging from 75-95 dBA (EPA 1971). Blasting at the Mine Site is expected to occur once every two to three days. Typically, rock blasting generates a single event noise level ranging from 111- 115 dBA at 50 feet from the blasting site (Table 5.5-7 of Madera County 2005). Within most of the Mine Site, the sound from the blast would be similar to a loud clap of thunder.

The impacts of noise on three-toed woodpecker utilization of habitat near the Mine Site are largely unknown and the assessment of impacts remains subjective, although as noted above, three-toed woodpeckers appear to be sensitive to human disturbance. Impacts may also vary between individual three-toed woodpeckers.

Three-toed woodpeckers favor lowland black spruce forest and areas with snags. There are about 3,040 acres of mature lowland coniferous habitat (MIH 9) on the federal lands that could provide habitat for three-toed woodpeckers (**Table 6**). AECOM (2005) found about 80 acres associated with the Partridge River that had been flooded, killing spruce trees and creating snag habitat. The Project would affect about 482 acres of mature lowland coniferous habitat. This includes pockets of snag habitat within wetlands.

There are about 1,208 acres of mature lowland coniferous forest habitat on the non-federal lands (**Table 6**). AECOM found about 45 acres of black spruce snags associated with forests that had been flooded by beavers,

which kills trees (AECOM 2011b, c). These lands would not be directly affected by the Project. Under the Proposed Action, the Forest Service would survey for three-toed woodpeckers and associated habitat prior to conducting land-disturbing activities and areas of known or potential habitat would be avoided when feasible.

Alternative B

Potential direct and indirect effects to three-toed woodpeckers from the Project would be similar to those under the Proposed Action. Under Alternative B, there are about 2,063 acres of mature lowland forest on the federal lands (**Table 6**). About 977 fewer acres of mature lowland coniferous forest would be transferred to PolyMet from the Forest Service under Alternative B than under the Proposed Action. This area could provide habitat for three-toed woodpeckers, although noise and other disturbance associated with mining could discourage use of the area by three-toed woodpeckers.

The Forest Service would acquire Hay Lake Lands under Alternative B. No three-toed woodpeckers were seen on these lands during wildlife surveys. There are about 1,818 acres of lowland coniferous forest habitat on Hay Lake Lands, although none of this habitat contains mature forest (**Table 6**). About 55% of the lowland coniferous forest that occurs on the non-federal lands is found on Hay Lake Lands. There are about 45 acres of black spruce snag habitat on Hay Lake Lands (AECOM 2011b). Thus, there would be limited foraging and nesting habitat for three-toed woodpeckers on Hay Lake Lands.

No Action Alternative

There would be no direct or indirect effects to three-toed woodpecker under the No Action Alternative.

Cumulative Effects

Threats facing the three-toed woodpecker include habitat loss and fragmentation, fire suppression, salvage logging, conifer conversion to aspen, beaver control, and poor snag retention policies. Historically, natural fire regimes in mature conifer and large amounts of old-growth forest would have created abundant foraging habitat for three-toed woodpeckers prior to European settlement. Clearing of the forests and fire suppression after settlement would have started to reduce habitat for this species.

Forest management that removes conifers that have the potential to have high populations of insects, especially wood-boring beetles, is detrimental to the three-toed woodpecker. Practices that increase the amount of mature lowland coniferous forest would benefit this species.

Other ownerships (especially the State of Minnesota) have started converting some trembling aspen stands to coniferous stands, which should help increase habitat. Beaver populations may increase and thereby increase three-toed woodpecker habitat (flood-killed trees). Recent large fires on the Superior National Forest in the past few years have produced good habitat. Prescribed burning may be beneficial to this species if it leads to some mortality of overstory trees.

About 482 acres of mature lowland coniferous forest that could be used by this species on the federal lands would be directly affected by the Project (**Table 6**). However, there are about 356,000 acres of lowland coniferous forest/shrubland within the CESA that could now, or in the reasonably foreseeable future, provide habitat for three-toed woodpeckers (Emmons and Olivier, Inc. 2006:30, 38). Thus, habitat loss from the Project would have a negligible cumulative effect on three-toed woodpeckers in the CESA.

Summary

Project activities associated with the Proposed Action and Alternative B could have adverse direct, indirect, or cumulative effects on three-toed woodpeckers and their habitat. Few three-toed woodpeckers use the federal lands. Timber management and road construction could occur on the lands in the reasonably foreseeable future, but only a small acreage of federal and non-federal lands would be affected. It is more likely that production of mature lowland habitat on the non-federal lands would occur if these lands are federally administered rather than under private ownership.

Determination

The Proposed Action and Alternative B **may impact individuals but are not likely to cause a trend to federal listing or loss of viability** for three-toed woodpecker. The No Action Alternative would have **no impact** to individuals of three-toed woodpecker.

Mitigation and Recommendations

No mitigation measures are recommended for three-toed woodpecker.

5.2.6.6 Olive-sided flycatcher (*Contopus cooperi*)

Environmental Baseline

The olive-sided flycatcher has a large breeding range that includes the wooded areas of Canada, Alaska, and the western and northeastern U.S. While secure in some places, the Breeding Bird Survey data for North America shows the species declined 5% per year between 1986 and 1998 nationally, and more than 1.5% per year in northern Minnesota between 1966 and 1996 (USDA Forest Service 2010b, Sauer et al. 2012).

No olive-sided flycatchers were seen during surveys of the federal and non-federal lands, although surveys were conducted on the Hunting Club, Lake County, and Wolf Lands during late fall after flycatchers had migrated south for the winter (ENSR 2000, 2005, AECOM 2011a, b, c). A few individuals are detected each year on songbird monitoring plots in the Superior National Forest, but numbers are not large enough to estimate population trends. An average of 1.7 and 0.2 olive-sided flycatchers have been recorded on the Jordan and Hart Lake Breeding Bird Survey routes, respectively, each year since 1966. The Jordan route is about 20 miles southeast of the federal lands and the Hart Lake route is about 20 miles south of the federal lands; these routes are the closest survey routes to the federal lands. Two olive-sided flycatchers were recorded during the Tracks Project area Breeding Bird Surveys in 2008.

The NRRI's Breeding Bird Monitoring effort surveys 169 forest stands on the Superior National Forest. Olive-sided flycatchers have been detected in 37 forest stands on the Superior National Forest. However, detections are rare and irregular, with only 1 detection in 20 forest stands during the period between 1991 and 2005. A nesting olive-sided flycatcher was reported on the Gunflint Ranger District in 2005.

Olive-sided flycatchers nest most frequently in larger black spruce-tamarack bogs or in large openings with scattered trees. MacLean (1999) found olive-sided flycatchers using burned or cleared areas with standing trees, primarily conifers. Beaver ponds provide important habitat with flood-killed trees. Timber harvest does not provide habitat if it results in an even-aged stand with little variation in canopy height, or few dead standing

trees. At least 50 acres of habitat may be needed to support a single territorial pair of olive-sided flycatchers. The primary threat to the species, however, appears to be destruction of wintering habitats in the Andes of South America.

Direct and Indirect Effects

Proposed Action

Olive-sided flycatchers favor lowland black spruce/tamarack bogs, but also use upland coniferous forest. There are 3,060 acres of lowland coniferous forest (MIH 9) and 1,252 acres of upland coniferous habitat (MIH 5) on the federal lands that could provide habitat for the olive-sided flycatchers (**Table 6**). The Project would affect about 482 acres of lowland coniferous and 505 acres of upland coniferous habitat. After mining, about 397 acres would be reclaimed to wetland/grassland/shrubland habitat that, over time, would become upland and lowland coniferous and deciduous habitat that could be used by olive-sided flycatchers (MDNR et al. 2013).

There are about 3,309 acres of lowland coniferous forest, but only 80 acres of upland coniferous forest habitat on the non-federal lands (**Table 6**). These lands would not be directly affected by the Project. Under the Proposed Action, the Forest Service would survey for olive-sided flycatchers and associated habitat prior to conducting land-disturbing activities and areas of known or potential habitat would be avoided when feasible.

Alternative B

Potential direct and indirect effects to olive-sided flycatchers from the Project would be similar to those under the Proposed Action. Under Alternative B, there are 2,079 acres of lowland coniferous forest and 1,139 acres of upland coniferous habitat on the federal lands (**Table 6**). About 981 fewer acres of lowland coniferous forest and 113 fewer acres of upland coniferous forest on the federal lands would be transferred to PolyMet under Alternative B. This area could provide habitat for olive-sided flycatchers, although noise and other disturbance associated with mining may discourage use of the area by olive-sided flycatchers.

The Forest Service would acquire Hay Lake Lands under Alternative B. There are about 1,818 acres of lowland coniferous forest and 54 acres of upland coniferous forest habitat on Hay Lake Lands (**Table 6**). About 55% of the lowland coniferous forest and 68% of the upland coniferous forest that occurs on the non-federal lands is found on Hay Lake Lands. No olive-sided flycatchers were seen on these lands during wildlife surveys, although olive-sided flycatchers were seen on the nearby Tracks Project area and Breeding Bird Survey routes.

No Action Alternative

There would be no direct or indirect effects to olive-sided flycatcher under the No Action Alternative.

Cumulative Effects

Threats facing this species are similar to those for species, such as the three-toed woodpecker and boreal owl, that use lowland black spruce/tamarack bog habitat, including habitat loss and fragmentation, fire suppression, salvage logging of fire-killed trees, conifer conversion to aspen, beaver control, and clear-cutting that leaves few residual trees or little variety in canopy structure. Historically, natural fire regimes in mature coniferous forest and large amounts of old-growth forest would have created abundant foraging habitat for olive-sided

flycatchers prior to European settlement. Clearing of the forests and fire suppression after settlement would have started to reduce habitat for this species.

Other ownerships (especially the State) have started converting some trembling aspen stands to coniferous stands, which should help increase habitat. Beaver populations may increase and thereby increase olive-sided flycatchers' habitat (flood-killed trees). Recent large fires on the Superior National Forest in the past few years have produced good habitat. Prescribed burning may be beneficial to this species if it leads to some mortality of overstory trees.

About 482 acres of lowland coniferous forest (MIH 9) and 505 acres of upland coniferous forest habitat (MIH 5) that could be used by this species on the federal lands would be lost due to the Project (**Table 6**). However, there are about 356,000 acres of lowland coniferous forest and about 161,000 acres of upland coniferous forest within the CESA that could now, or in the reasonably foreseeable future, provide habitat for olive-sided flycatchers (Emmons and Olivier, Inc. 2006:30, 38). Thus, habitat loss from the Project would have a negligible cumulative effect on olive-sided flycatchers in the CESA.

Summary

Project activities associated with the Proposed Action and Alternative B should have no adverse direct, indirect, or cumulative effects on individual olive-sided flycatchers, but could have direct, indirect, or cumulative effects on their habitat. Timber management and road construction could occur on the lands in the reasonably foreseeable future, but only a small acreage of federal and non-federal lands would be affected. It is more likely that production of immature and mature lowland habitat, prescribed burnings that leave standing dead trees, and partial cuts, on the non-federal lands could occur if these lands are federally administered rather than under private ownership.

Determination

The Proposed Action and Alternative B **may impact individuals but are not likely to cause a trend to federal listing or loss of viability** for olive-sided flycatcher. The No Action Alternative would have **no impact** to individuals of olive-sided flycatcher.

Mitigation and Recommendations

No mitigation measures are recommended for olive-sided flycatcher.

5.2.6.7 Bay-breasted Warbler (*Dendroica castanea*)

Environmental Baseline

Bay-breasted warbler is a neotropical migrant that breeds throughout the black spruce-balsam fir forest of Canada and the northernmost parts of the U.S., following the range of spruce budworm (*Choristoneura fumiferana*). The Project area is at the very edge of its range in Minnesota, although vegetation data from the time of European settlement shows that most of the area was black spruce/balsam fir forest. Bay-breasted warbler populations are closely tied to outbreaks and declines in spruce budworm (Mayasich and Niemie 2002 and references cited therein), and have been decreasing range-wide (4.5% per year in North America between 1986 and 1998). An average of 0.2 bay-breasted warblers have been recorded on the Hart Lake Breeding Bird

Survey route each year since 1966, but none have been recorded on the Jordan Breeding Bird Survey route (Sauer et al. 2012). No bay-breasted warblers were observed on the nearby Tracks Project area. The NRRI's Breeding Bird Monitoring effort has detected bay-breasted warblers in 21 of 169 forest stands, but sightings have been rare. Loss of habitat, change in vegetation composition, management to control spruce budworm, fire suppression, and deforestation in wintering habitat all contribute to the population decline of the bay-breasted warbler.

Bay-breasted warbler breeds primarily in old spruce-fir forests, sometimes pine, and also in spruce bogs and coniferous riparian areas (Maxson 1999). They breed in forests where the conifers are dominant or co-dominant trees. There is little information about their use of black spruce lowlands in Minnesota. They need patches of spruce budworm outbreak over a large area. Birds often move to such an area in large groups. It is possible that maintenance of a viable and well-distributed population may require patches of relatively un-fragmented old spruce-fir forest of more than 3,000 acres capable of hosting a large enough spruce budworm outbreak. Robbins et al. (1989) suggested that some warblers may require extensive areas of interior forest habitat, but research has not been done to find out to determine its applicability to bay-breasted warbler in northeastern Minnesota.

No bay-breasted warblers were seen during wildlife surveys on the federal and non-federal lands, although surveys on Hunting Club Lands, Lake County Lands, and Wolf Lands occurred during late fall after bay-breasted warblers had migrated south for the winter (ENSR 2000, 2005, AECOM 2011a, b, c).

Direct and Indirect Effects

Proposed Action

Bay-breasted warblers favor lowland and upland mature spruce forest. There are about 3,040 acres of mature lowland (MIH 9) and 235 acres of mature upland coniferous forest habitat (MIH 5) on the federal lands that could provide habitat for the bay-breasted warblers. The Project would affect about 482 acres of mature lowland and 24 acres of mature upland coniferous forest habitat (**Table 6**).

There are 1,208 acres of mature lowland coniferous forest and 26 acres of mature upland coniferous forest habitat on the non-federal lands (**Table 6**). These lands would not be directly affected by the Project. Under the Proposed Action, the Forest Service would survey for bay-breasted warblers and associated habitat prior to conducting land-disturbing activities and areas of known or potential habitat would be avoided when feasible.

Alternative B

Potential direct and indirect effects to bay-breasted warblers from the Project under Alternative B would be similar to those under the Proposed Action. Under Alternative B, there are about 2,063 acres of mature lowland and 186 acres of mature upland coniferous forest habitat on the federal lands (**Table 6**). About 977 fewer acres of mature lowland coniferous forest and 49 fewer acres of mature upland coniferous forest on the federal lands would be transferred to PolyMet from the Forest Service under Alternative B than under the Proposed Action. This area could provide habitat for bay-breasted warblers, although noise and other disturbance associated with mining and use of the Dunka Road and Utility Corridor may discourage use of the area by bay-breasted warblers.

The Forest Service would acquire Hay Lake Lands under Alternative B. No bay-breasted warblers were seen on these lands during wildlife surveys, and observations of bay-breasted warblers are extremely rare in the vicinity

of Hay Lake Lands. There is no mature lowland or upland coniferous forest habitat on Hay Lake Lands (**Table 6**). Thus, there would be limited foraging and nesting habitat for bay-breasted warblers on Hay Lake Lands.

No Action Alternative

There would be no direct or indirect effects to bay-breasted warbler under the No Action Alternative.

Cumulative Effects

The greatest threat to the breeding range of the bay-breasted warbler is the reduction in the area of old-growth black spruce and balsam fir of the boreal forest. Both nesting habitat and food supply (spruce budworm) are at risk when reductions or alterations of these forest types occur. Spraying insecticides to control spruce budworm can have direct toxic effect on this warbler (inhibition of brain acetylcholinesterase activity). Winter habitat degradation and loss is also a threat, as commercial and residential development activity continues to reduce the forested habitats in the tropics (Mayasich and Niemie 2002). Green (1995) stated that coniferous forest-dominated stands have decreased and been replaced by trembling aspen over the past 100 years, indicating that less habitat is available at present compared to 100 years ago. Black spruce-balsam fir forest is currently below 2004 Forest Plan objectives and the Minnesota Forest Resources Council Landscape Committee set a goal to increase black spruce-balsam fir forest in Minnesota (USDA Forest Service 2004a). Forest Service data show that spruce budworm defoliation in the eastern U.S. dropped substantially in 1986 from 5 to 8 million acres per year prior to that to less than 1 million acres per year after 1985. In Minnesota, there were about 70,000 of spruce-budworm defoliation in 1999 compared to a million acres in 1958.

About 482 acres of mature lowland coniferous forest and 24 acres of mature upland coniferous forest habitat that could be used by this species on the federal lands would be directly affected by the Project (**Table 6**). However, there are about 356,000 acres of lowland coniferous forest and about 161,000 acres of upland coniferous forest within the CESA that could now, or in the reasonably foreseeable future, provide habitat for bay-breasted warblers (Emmons and Olivier, Inc. 2006:30, 38). Thus, habitat loss from the Project would have a negligible cumulative effect on bay-breasted warblers in the CESA.

Summary

Project activities associated with the Proposed Action and Alternative B should have no adverse direct, indirect, or cumulative effects on individual bay-breasted warblers, but could have direct, indirect, or cumulative effects on their habitat. Bay-breasted warblers were not seen on the federal lands during wildlife surveys for the FEIS, and are rare in the Superior National Forest, although habitat is present. Timber management and road construction could occur on the federal and non-federal lands in the reasonably foreseeable future, but only a small acreage of federal and non-federal lands would be affected. It is more likely that production of immature and mature lowland habitat, prescribed burnings that leave standing dead trees, and partial cuts on the non-federal lands could occur if these lands are federally administered rather than under private ownership.

Determination

The Proposed Action and Alternative B **may impact individuals but are not likely to cause a trend to federal listing or loss of viability** for bay-breasted warbler. The No Action Alternative would have **no impact** to individuals of bay-breasted warbler.

Mitigation and Recommendations

No mitigation measures are recommended for bay-breasted warbler.

5.2.6.8 Connecticut Warbler (*Oporornis agilis*)

Environmental Baseline

The Connecticut warbler has the most restricted breeding distribution of any northern warbler, aside from the Kirtland's warbler, ranging from eastern British Columbia east across south-central Canada to Quebec and south to northern Minnesota, Wisconsin, and the Upper Peninsula and northern Lower Peninsula of Michigan. Eighty-five percent of the North American breeding range of the Connecticut warbler is in Canada (Kudell-Ekstrum 2002 and references cited therein).

The bird is very secretive and difficult to detect. Breeding Bird Survey data showed a 5% per year population decline between 1986 and 1998 in North America. The NRRI's Breeding Bird Monitoring effort detected Connecticut warblers in 41 of 169 forest stands on the Superior National Forest during 1991 through 2005. An average of 0.3 Connecticut warblers have been recorded on the Hart Lake, and two Connecticut warblers on the Jordan Breeding Bird Survey routes each year since 1966 (Sauer et al. 2012). Two Connecticut warblers were seen on the nearby Tracks Project area.

Typical habitat consists of wet areas with black spruce, tamarack, mosses, speckled alder, dogwood, Labrador tea, bog rosemary, bog laurel, and leatherleaf. Breeding habitat consists of black spruce-tamarack bogs, muskeg, poplar woodlands and moist deciduous forests, and jack pine. The Connecticut warbler has been found in 15 forest types in the U.S. consisting of jack pine, red pine, black spruce, mixed swamp conifer, northern white cedar, sugar maple/basswood, tamarack, paper birch, and trembling aspen, and wetland bog and wetland sedge meadow. They may also be found in jack pine with a dense blueberry understory. They forage on the ground and in low shrubs. Boreal bogs that are 100 acres or larger are typical habitat in northeastern Minnesota. Territories of a breeding pair of birds are about 1.2 acres. Connecticut warblers nest on the ground in a small hollow, on moss mound in a bog, or in grasses or weeds, or at the base of a shrub and sometimes forming loose "colonies."

No Connecticut warblers were seen during wildlife surveys of the federal and non-federal lands, although surveys on the Hunting Club, Lake County, and Wolf Lands occurred during late fall after Connecticut warblers had migrated south for the winter (ENSR 2000, 2005, AECOM 2011a, b, c).

Direct and Indirect Effects

Proposed Action

Connecticut warblers favor lowland spruce forest and upland jack pine forest. There are about 3,060 acres of lowland (MIH 9) and 1,252 acres of upland coniferous (MIH 5) forest on the federal lands that could provide habitat for the Connecticut warbler. Approximately 482 acres of lowland coniferous forest and 505 acres of upland coniferous forest habitat would be lost due to mining (**Table 6**). Forest Service MIH mapping did not specifically identify jack pine forest (MIH 8) on the Mine Site, but it is present on the eastern portion of the Mine Site in association with black spruce and trembling aspen.

There are about 3,309 acres of lowland coniferous and 80 acres of upland coniferous forest habitat on the non-federal lands (**Table 6**). These lands would not be directly affected by the Project. Under the Proposed Action, the Forest Service would survey for Connecticut and associated habitat prior to conducting land-disturbing activities and areas of known or potential habitat would be avoided when feasible.

Alternative B

Potential direct and indirect effects to Connecticut warblers from the Project would be similar to those under the Proposed Action. Under Alternative B, there are about 2,079 acres of lowland and 1,139 acres of upland coniferous forest on the federal lands (**Table 6**). About 981 fewer acres of lowland coniferous forest and 113 fewer acres of upland coniferous forest would be transferred to PolyMet from the Forest Service than under the Proposed Action. This area could provide habitat for Connecticut warblers, although noise and other disturbance associated with mining may discourage use of the area by Connecticut warblers.

The Forest Service would acquire Hay Lake Lands under Alternative B. No Connecticut warblers were seen on these lands during wildlife surveys (AECOM 2011b, c), although two Connecticut warblers were observed on the nearby Tracks Project area. There are about 1,818 acres of lowland and 54 acres of upland coniferous forest habitat on Hay Lake Lands (**Table 6**). About 55% of the lowland coniferous forest and 68% of upland coniferous forest that occurs on the non-federal is found on Hay Lake Lands. There would be suitable foraging and nesting habitat for Connecticut warblers on Hay Lake Lands. This habitat should benefit from Forest Service management that favors longer harvest rotations than typically occurs on private forestlands.

No Action Alternative

There would be no direct or indirect effects to Connecticut warbler under the No Action Alternative.

Cumulative Effects

The Connecticut warbler may be sensitive to habitat fragmentation due to increases in nest predation and parasitism that may accompany decreases in forest interior habitat. Loss and fragmentation of jack pine forests was identified as the biggest threat to Connecticut warbler. However Connecticut warblers have been found in association with open forest habitats. Cowbird parasitism may also be a threat.

Peat mining may pose a threat to Connecticut warbler habitat. Peat mining is a large industry in Canada and has started in the U.S. at Pine Island in Koochiching County, Minnesota. Towers and structures have been reported as specific threats. Three hundred Connecticut warblers were killed in one season from collision with towers in Eau Claire, Wisconsin (Kudell-Ekstrum 2002 and references cited therein). Rieck (1999) stated that wintering habitat in northern South America is declining and breeding habitat may also be in decline range-wide.

About 482 acres of lowland coniferous forest and 505 acres of upland coniferous forest habitat that could be used by this species on the federal lands would be directly affected by the Project (**Table 6**). However, there are about 356,000 acres of lowland coniferous forest and 161,000 acres of upland coniferous forest within the CESA that could now, or in the reasonably foreseeable future, provide habitat for Connecticut warblers (Emmons and Olivier, Inc. 2006:30, 38). Thus, habitat loss from the Project would have a negligible cumulative effect on Connecticut warblers in the CESA. Noise and other disturbance from the Project could also cumulatively affect Connecticut warblers, although Connecticut warbler use of the Project area is likely very rare.

Summary

Project activities associated with the Proposed Action and Alternative B should have no adverse direct, indirect, or cumulative effects on individual Connecticut warblers, but could have direct, indirect, or cumulative effects on their habitat. Connecticut warblers have not been seen on the federal lands, and are rare in the Superior National Forest. Timber management and road construction could occur on the federal and non-federal lands in the reasonably foreseeable future, but only a small acreage of federal and non-federal lands would be affected. It is more likely that production of immature and mature lowland habitat and partial cuts that benefit Connecticut warbler would occur on the non-federal lands if these lands are federally administered rather than under private ownership.

Determination

The Proposed Action and Alternative B **may impact individuals but are not likely to cause a trend to federal listing or loss of viability** for Connecticut warbler. The No Action Alternative would have **no impact** to individuals of Connecticut warbler.

Mitigation and Recommendations

No mitigation measures are recommended for Connecticut warbler.

5.2.7 Mammals

5.2.7.1 Eastern Heather Vole (*Phenacomys ungava*)

Environmental Baseline

In eastern North America, the range of the eastern heather vole reaches its southernmost point in the Upper Midwest on the Superior National Forest. A long-term (1995-2006) study of small mammal populations documented 64 eastern heather voles on the Superior National Forest (Jannett 2006 *cited* in USDA Forest Service 2010b).

Eastern heather voles are found in a wide variety of habitats, including coniferous forests and forest borders, heath shrublands, willow thickets, rocky hillsides, and moist meadows (Coffin and Pfannmuller 1988, McAllister and Hofmann 1988). *Vaccinium* species (ericaceous shrubs) are often present where eastern heather voles are found. Naylor et al. (1985) found high densities of eastern heather voles in Ontario in jack pine monocultures with a dense, relatively continuous understory of ericaceous shrubs. Eastern heather voles' preferred habitat appears to be upland forests and openings with ericaceous ground cover not far from water. Anything that encourages grasses encourages meadow voles, which are detrimental to the eastern heather vole.

No eastern heather voles were seen during wildlife surveys of the federal and non-federal lands (ENSR 2000, 2005, AECOM 2011a, b, c). The MDNR NHIS database documents the nearest known eastern heather vole location as 24 miles north of the Project area off of the Tomahawk Road. No eastern heather voles were found on the nearby Tracks Project area.

Direct and Indirect Effects

Proposed Action

Forest Service MIH 8, which is primarily mature jack pine forest, is considered indicative of eastern heather vole habitat. Forest Service MIH mapping did not specifically identify jack pine forest on the federal lands, but jack pine forest is on present across the Mine Site, especially on the eastern portions of the site, and often in association with black spruce and trembling aspen (ENSR 2000, 2005, AECOM 2011a). However, there is no mature jack pine habitat on the Mine Site. There are about 1,252 acres of upland coniferous forest (MIH 5) on the federal lands, including about 235 acres of mature upland coniferous forest that could be used as habitat by the eastern heather vole (**Table 6**). The Project would affect about 505 acres of upland coniferous forest habitat.

The eastern heather vole was not identified on the non-federal lands during wildlife surveys or in the MDNR NHIS database (MDNR 2006, AECOM 2011b, c). There are about 80 acres of upland coniferous forest habitat on the non-federal lands, and jack pine is a component in these forests (**Table 6**). There are only 26 acres of mature coniferous forest habitat found on the non-federal lands. The majority of mature coniferous forest habitat, which consists primarily of eastern white pine, is found on Hunting Club Lands. These lands would not be directly affected by the Project. Under the Proposed Action, the Forest Service would survey for eastern heather vole and associated habitat prior to conducting land-disturbing activities and areas of known or potential habitat would be avoided when feasible.

Alternative B

Potential direct and indirect effects to eastern heather voles from the Project would be similar to those under the Proposed Action. Under Alternative B, there are about 1,252 acres of upland coniferous forest on the federal lands (**Table 6**). About 113 fewer acres of upland coniferous forest on the federal lands would be transferred to PolyMet from the Forest Service under Alternative B than under the Proposed Action. This area could provide habitat for eastern heather vole.

The Forest Service would acquire Hay Lake Lands under Alternative B. No eastern heather voles were seen on these lands during wildlife surveys (AECOM 2011b). Coniferous forest is rare on Hay Lake Lands. There are about 54 acres of upland coniferous forest habitat on Hay Lake Lands, although none of this habitat contains mature forest (**Table 6**). About 68% of the upland coniferous forest that occurs on the non-federal lands is found on Hay Lake Lands. Forest cover was 60 to 70% and was comprised of red pine and jack pine (AECOM 2011b). There would be little suitable habitat for eastern heather vole on Hay Lake Lands, but upland coniferous forest habitat should benefit from Forest Service management that favors longer harvest rotations than typically occurs on private forestlands.

No Action Alternative

There would be no direct or indirect effects to eastern heather vole under the No Action Alternative.

Cumulative Effects

The biggest negative effect to eastern heather vole habitat has likely come from fire suppression. Timber harvest potentially perpetuates habitat for this species, however, an increase of trembling aspen and a decrease of jack pine has likely reduced the amount of suitable habitat for the species. Based on analysis done for the Tracks

Project, the amount of mature jack pine forest should increase in the Superior National Forest during the next 10 years and would benefit eastern heather vole. The Superior National Forest goals are to increase the amount of jack pine forest over time. The cumulative effects analysis for the 2004 Forest Plan BE concluded that habitat conditions in the future are predicted to continue to provide a patchy distribution for eastern heather vole (USDA Forest Service 2004d).

About 505 acres of upland coniferous forest habitat that could be used by this species on the federal lands would be directly affected by the Project, but none of this habitat consists of mature coniferous trees (**Table 6**). There are about 161,000 acres of upland coniferous forest within the CESA that could now, or in the reasonably foreseeable future, provide habitat for eastern heather vole (Emmons and Olivier, Inc. 2006:30, 38). Thus, habitat loss from the Project would have a negligible cumulative effect on eastern heather vole in the CESA. In addition, about 397 acres of the 1,719-acre mine disturbance area would be reclaimed and could become upland coniferous forest habitat 20 years or more after reclamation (MDNR et al. 2013).

Summary

Project activities associated with the Proposed Action and Alternative B should have no adverse direct, indirect, or cumulative effects on individual eastern heather vole, but could have cumulative effects on their habitat. Eastern heather vole has not been seen on the federal lands, and is rare in the Superior National Forest, although habitat is present. Timber management and road construction could occur on the lands in the reasonably foreseeable future, but only a small acreage of federal and non-federal lands would be affected.

Determination

The Proposed Action and Alternative B **may impact individuals but are not likely to cause a trend to federal listing or loss of viability** for eastern heather vole. The No Action Alternative would have **no impact** to individuals of eastern heather vole.

Mitigation and Recommendations

No mitigation measures are recommended for eastern heather vole.

5.2.7.2 Northern Long-eared Bat (*Myotis septentrionalis*), Tri-colored Bat (*Perimyotis subflavus*), and Little Brown Myotis (*Myotis lucifugus*)

Environmental Baseline

The northern long-eared bat, tri-colored bat (synonym: eastern pipistrelle), and little brown myotis bat species were added to the 2011 RFSS list due to the spread of white-nose syndrome, which is a fungal disease affecting bats. In addition, the northern long-eared bat was recently listed by the USFWS as threatened species under the ESA (USDOI USFWS 2013, USACE, and USDA Forest Service 2013). The disease carries a high mortality rate for all bat species, and the Superior National Forest is closely watching the RFSS bat species to identify signs of white-nose syndrome. White-nosed syndrome has been reported at the Tower/Soudan Underground Mine State Park in St. Louis County, 15 miles northwest of the Project area, and in Fillmore County in southeastern Minnesota (USDOI USFWS 2013, U.S. Geological Survey National Wildlife Health Center 2013).

The northern long-eared bat prefers forests and riparian areas. It may hibernate in caves, mines, overhangs, crevices, drill holes, and similar sites. As noted in Section 1.1, the *NorthMet Mining Project and Land Exchange Biological Assessment Draft* was prepared to evaluate project effects to northern long-eared bat, a RFSS species that was recently listed as a federally threatened species (USACE and USDA Forest Service 2013). Additional information on the northern long-eared bat is available in the BA.

The tri-colored bat prefers open areas with large trees and woodland edges. It avoids open fields and deep woods. It may hibernate in caves and mines and roosts in trees and man-made structures. The little brown myotis is the most abundant bat in Minnesota. It is a habitat generalist and its preferred habitat includes boreal forests, bogs and fens, open fields, shrublands, and urban areas. It may hibernate in caves, tunnels, and abandoned mines and roosts in trees and man-made structures. Both the tri-colored bat and the little brown bat generally avoid large open areas, but do forage over or near water and prefer aquatic, soft-bodied insects (e.g., moths, flies, beetles, gnats, mosquitos).

Between 2008 and 2010, acoustic surveys for bats were conducted as part of wildlife surveys for the federal and non-federal lands (AECOM 2011a, b, c). No effort was made to determine the species of bat making the echolocation. Along with the three RFSS bats, four other bat species could occur in the Project area: the big brown bat, the silver-haired bat, the eastern red bat, and the hoary bat. Echolocations recorded during the surveys could have come from any of these seven bat species.

Echolocation surveys were conducted at five stations on the federal lands, although only four stations gave usable information due to rainfall during the survey at one station. Recordings indicated the presence of bats at all sites, with the greatest number of echolocations occurring at open water sites associated with the Partridge River and an unnamed creek, and the fewest echolocations at emergent wetlands covered with water and some aquatic vegetation.

Recordings on Hay Lake Lands showed that most echolocations occurred at an emergent wetland with open water (814 echolocations, mostly feeding activity). Moderate numbers of echolocations were recorded at the two sites along the Pike River (164 echolocations at the north Pike River site, 230 echolocations at the middle Pike River site; feeding activity was moderate), and at two small emergent wetland ponds with limited open water (64 and 181 echolocations; AECOM 2011b). An echolocation site to the south of Hay Lake Lands was located at a small patch of open water associated with an old beaver pond; 72 echolocations were recorded at this site. No echolocation surveys were made on Hunting Club Lands, Lake County Lands, and Wolf Lands as surveys were conducted in November and bats would have already migrated from the area. Surveys were also not conducted at McFarland Lake Lands, although bats likely forage over McFarland Lake.

In the summer of 2013, Superior National Forest staff initiated a pilot project to document forest bat occupancy and collect demographic and habitat data (Grandmaison et al. 2013). Across eight locations on the Kawishiwi District, 34 bats were collected over nine nights. Northern long-eared bats comprised 38% of the captured bats, while little brown bats comprised 62% of the captured bats. No tri-colored bats were documented in the survey (Grandmaison et al. 2013).

In the spring of 2014, the Superior National Forest staff and MDNR staff, with additional funding from USFWS, conducted a pilot project to describe summer habitat use by northern long-eared bats in Minnesota. Surveys were conducted at 12 sites, five of which were on the Superior National Forest. The survey captured six of the seven species of bats known to occur in Minnesota; tri-colored bat was the only species not captured. The most

frequently captured bats were little brown bats (45%) and northern long-eared bats (22%) (USDA Forest Service 2014b).

Superior National Forest staff conducted surveys for the northern long-eared bat and the little brown bat at three general locations in the Project area in July and August 2014 (USDA Forest Service 2014a; Personal Communication, Dan Ryan, USDA Forest Service, January 9, 2015). The three Project locations included the Mine Site, the Plant Site, and the Dunka Road and Utility Corridor. Survey methods utilized passive sonic (Anabat) detectors on the Mine Site and transportation corridor. At the Plant Site, the methods were primarily direct observation of bat species, supplemented by passive sonic detectors when feasible. The surveys found northern long-eared bats, little brown bats, silver-haired bats, big brown bats, hoary bats and eastern red bats present at the Mine Site with little brown bat accounting for 78% of all calls and northern long-eared bat accounting for 14% of all calls (USDA Forest Service 2014a). The eastern red bat was the only species whose calls were not identified during the driving surveys. Emergence surveys at the Plant Site in conjunction with the sonic detectors identified the presence of little brown bat, northern long-eared bat, silver-haired bat and big brown bat. The tri-color bat was not detected in any of the surveys (USDA Forest Service 2014a). The 2014 surveys suggested that the Mine Site may contain roost sites, however, there have been no surveys specifically targeted for identification of roost sites.

Bats were seen during wildlife surveys of the federal and non-federal lands, but were not identified to species. As noted above, bats foraged and drank water on wetlands and other aquatic habitats with some open water. There are no caves or mine shafts that could be used for hibernation on the federal lands, but bats could also roost in tree hollows and under tree bark, or under railroad trestles near the Mine Site. Bats have occasionally been observed in Plant Site buildings, but do not hibernate or roost in great numbers at the Plant Site.

Direct and Indirect Effects

Proposed Action

There are about 210 acres of open bog, 31 acres of open water, 36 acres of sedge/wet meadow, and 97 acres of shallow marsh habitat that could be used by bats for feeding and drinking on the federal lands (**Table 8**). There are about 4,312 acres of lowland and upland coniferous forest habitat (MIH 5 and 9) that could be used by bats for roosting on the federal lands (**Table 6**). The Project would directly affect 65 acres of open bog, open water, sedge/wet meadow, and shallow marsh habitat and 987 acres of lowland and upland coniferous forest habitat (**Tables 6 and 8**).

Potential indirect affects to the tri-color and little brown bat from drinking water from Project ponds and from the consumption of insects that may inhabit or drink from the ponds is qualitatively assessed. MnDNR (2015) identifies that the tri-color bat is typically found in the southeast corner of the state and the occurrence in the northeast portion of the state is considered rare. Even though the tri-color bat was not detected in the 2014 Forest Service surveys, it is assumed to have the potential to be present in the Project area. A qualitative assessment of potential affects to the northern long-eared bat is provided in the Biological Assessment Report.

The tri-color bat and the little brown bat are considered habitat generalists by some researchers (Ford et al. 2005). Studies have identified the little brown bat to have a preference for foraging along the forest edge (Broders et al. 2006; Jantzen 2012). Both the tri-color and little brown bat have an affinity for water and feed above open water (Fenton and Barclay 1980; Broders et al. 2006; Lookingbill et al. 2010), and using water sources within the forest for drinking (woodland seasonal pools and beaver ponds) (Francl 2008). Other studies identify that the little brown bat has some affinity for open upland areas (meadow, prairie, and savanna) (Buckman-Sewald et al. 2014). Jantzen (2012) found bat activity (little brown bat, northern long-eared bat) to be concentrated within about 40 meters of the forest/open edge and Fulton et al. (2014) found that bats were more active in hydric habitats (riparian areas and wetlands) than in the surrounding forest. Lookingbill et al. (2010) identified a foraging radius of 500 meters for the little brown bat and 100 meters for the tri-color bat. Tri-colored bats tend to avoid deep woods or open fields (Ford et al. 2005). The Wisconsin DNR (2013) identified that little brown bats would preferentially follow a forest edge rather than fly across a large open area such as a field. Common summer roosting habitat is in older forest stands that provide more opportunities for roosting in cavities, but because they are common to a wide range of areas they also roost in human-made structures (Wisconsin DNR 2013).

In comparison, the northern long-eared bat is a forest specialist (Henderson and Broders 2008; Chapman et al. 2014). As a forest specialist, the weight of evidence in the literature (Henderson and Broders 2008; Jantzen 2012; Chapman et al. 2014) indicates it would be highly unlikely for the northern long-eared bat to be present in the large open area at the future Mine Site or near the ponds within the Plant Site.

About 57% of the 3,015 acre Mine Site would be affected by the Project. Much of this affected area would be cleared of vegetation to accommodate the mine pits and associated infrastructure (e.g., haul roads, stockpile, stormwater ponds, waste water ponds) and would become a large open area during operations. The existing Plant Site is primarily an open area dominated by the LTVSMC Tailings Basin and would continue as an open area during Project operations. Overall, the peer-reviewed literature identifies that bats will forage at those locations where insect density is highest (Jantzen 2012; Lookingbill et al. 2010) and the large area of existing wetlands around the Tailings Basin and the future Mine Site would likely attract a large portion of the

local population of bats. Further, Francl (2008) has identified the little brown bat's predominance at woodland seasonal pools. Based on the peer-reviewed literature and the existing wetland and riparian areas immediately adjacent to the Mine Site, there is a low probability that either species would use the operational Mine Site to any great extent. However, because both species of bat are known to feed over open water and because the 2014 Forest Service bat surveys identified the little brown bat presence within the existing Tailings Basin (Forest Service 2014a: Figure 4), it is possible that some number of bats may be present within the active Flotation Tailings Basin during mining operations although it is uncertain if bats would use an active tailings basin in the same manner or frequency that they currently use the reclaimed LTVSMC Tailings Basin.

The Project's water management is expected to limit the potential exposure of bats to indirect effects from the various water features at the Plant Site or Mine Site and consumption of insects that may use these water features. Project water features include stormwater ponds, process water ponds, water in active mine pits, constructed wetlands, the Hydrometallurgical Facility pond (operations), the Flotation Tailings Basin Pond and wetland (reclamation and long-term closure), and the West Pit lake (long-term closure). Each water feature is qualitatively evaluated for potential indirect effects to bats.

1. Stormwater from precipitation and runoff would be directed to sedimentation ponds to remove total suspended solids prior to being discharged off-site. Water in the ponds prior to discharge is expected to reflect background concentrations of water quality parameters (including metals and mercury) and any aquatic insects inhabiting stormwater ponds should have metal and mercury concentrations that reflect background conditions, and therefore, similar to existing conditions. Therefore, any consumers of aquatic insects (including bats) from Project stormwater ponds should not be exposed to metal or mercury concentrations in those insects above background levels.
2. Process water would be collected and stored in a number of ponds at the Mine Site (e.g., Overburden Storage and Laydown Area Pond) and the Flotation Tailings Basin Pond and Hydrometallurgical Residue Facility Pond at the Plant Site and be actively managed for re-use. The probability of insects inhabiting or using a process water pond as a source of drinking water is expected to be low because: 1) these ponds would tend to be turbid and limit the establishment and growth of plants and in turn limit organic materials and the establishment of macroinvertebrates (Nelms et al. 2012); 2) mining-related water is low in organic carbon (Berndt and Bavin 2012) and nutrients and would limit growth and reproduction of algae, macroinvertebrates, and other biota (Nelms et al. 2012; Seger et al. 2012); 3) the use of liners and/or compacted bottoms to maximize water retention would not likely provide a suitable substrate for the larval stages of most aquatic insects (Flake and Cieminski 1996); and 4) fine mineral sediments that have little silt or clay are poor media for plant establishment and growth (Nelms et al. 2012) and further limits the presence of aquatic insects that require organic materials for food (Seger et al. 2012). The above listed factors likely limit the aquatic life in process water ponds. Insects from Project process water ponds would likely represent a very small percent of the diet of consumers of aquatic insects when compared to the large acreage of existing wetlands around the Plant Site and Mine Site that currently provide the forage base for bats and other consumers. Overall, limited pond productivity likely reduces the potential effect of process water ponds on insects and consumers of those insects such as bat species.

Similar to taconite processing, mercury in process water sent to the Flotation Tailings Basin Pond

and the Hydrometallurgical Residue Facility Pond is expected to be associated with the solids and sequestered with those solids in the respective ponds and result in relatively low concentrations of mercury in the water column (Barr 2007b; PolyMet 2015). Mercury associated with solids such as tailings is sequestered within the basin and is typically not released from the basin (Berndt 2003) and not readily bioavailable. The continual deposition of solids in these ponds is likely to limit sediment-dwelling organisms (Nelms et al. 2012), as would the lack of organic material for food (Flake and Cieminski 1996; Nelms et al. 2012). Limited pond productivity and sequestration of mercury with solids likely reduces the potential effect of process water ponds on bat species.

3. Mine pit dewatering would occur during Mine Years 1 through 20 and this process water would be routed to the Waste Water Treatment Facility for initial treatment and then pumped to the Flotation Tailing Basin Pond for use in ore processing (Poly Met 2014c). A minimal amount of water is expected to be present in an active mine pit, therefore the probability of aquatic insects inhabiting or using a sump area is low. The continual removal of water is likely to limit the presence of aquatic organisms (Nelms et al. 2012), as would the lack of organic material for food (Flake and Cieminski 1996; Nelms et al. 2012). Limited productivity reduces the potential effect of mine pit watering on bat species, including the northern long-eared bat which is a forest specialist (Henderson and Broders 2008; Jantzen 2012; Chapman et al. 2014) and not expected to be present within the mine pits.
4. As part of reclamation, some stormwater ponds and process water ponds would be filled and converted to terrestrial habitat (.e.g., Hydrometallurgical Residue Facility Pond) (Poly Met 2014b; 2014e; 2014f). Ponds filled and reclaimed to terrestrial vegetation would have the potential to produce runoff water that would be expected to reflect background conditions. Reclaiming ponds to terrestrial vegetation is not expected to produce runoff that would adversely affect aquatic insects.

A part of the East Pit (after backfilling is completed) and some stormwater and process water ponds would be converted to wetlands (Poly Met 2014b, 2014c, 2014d). These constructed wetlands are expected to receive precipitation and stormwater runoff. The accumulating water should reflect background concentrations for various parameters (including mercury). Any aquatic insects inhabiting a constructed wetland or using it as a source of drinking water should have metal or mercury concentrations that reflect background conditions. Therefore, any consumers of these aquatic insects (including bats) should not be exposed to metal or mercury concentrations in those insects above background levels.

In regard to the backfilling of the East Pit, the water level would be maintained below the level of the fill material to facilitate truck hauling (Poly Met 2014b). No visible ponding of water is expected during backfilling. Therefore, backfilling of the East Pit would have no potential to affect aquatic organisms.

5. The Flotation Tailings Basin Pond would be present after Mine Year 20 and a wetland would be constructed around the perimeter of the pond. The pond and wetland are expected to be present into long-term closure. After Mine Year 20, the Beneficiation Plant and Mine Site would no longer contribute water and the largest source of water to the pond would be precipitation and

runoff (Poly Met 2015). In long-term closure, the water in the pond would be primarily from precipitation and runoff (Poly Met 2015) and would be expected to reflect background conditions and parameter concentrations (including mercury). Any aquatic insects inhabiting the Flotation Tailings Basin Pond or using it as a source of drinking water during long-term closure should have metal or mercury concentrations that reflect background conditions. Therefore, any consumers of these aquatic insects (including bats) should not be exposed to metal or mercury concentrations in those insects above background levels.

6. The depth of the West Pit at the end of mining will be more than 600 feet. Flooding of the pit would result in rapid water level increases that are predicted to average about 17 feet per year (Poly Met 2014g). Rapidly rising water levels likely limits the aquatic life that would inhabit the lake during the years of pit flooding (Nelms et al. 2007). Therefore, the potential exposure of bats to any insects that might inhabit or use the West Pit lake during the early years of flooding is likely low.

The majority of water used to flood the West Pit would be primarily from precipitation and stormwater runoff (Poly Met 2014g) and as the pit fills the parameter concentrations in the upper portion of the water column (i.e., the epilimnion) should reflect background (including mercury). Flooding of the West Pit would produce a pit lake that is approximately 320 acres in size with a maximum depth of 630 feet (Poly Met 2014b). As an oligotrophic system with a small littoral area, aquatic insect diversity and numbers in the West Pit lake would be limited (Nelms et al. 2012; Gray et al. 2012). Data for pit lakes identifies they have low densities and diversity of invertebrates (MDNR 1989). In addition, pit lake waters are typically low in phosphorus, limiting primary production (MDNR 1989). For the above reasons, overall, the potential population of aquatic insects in the West Pit lake is expected to be small. In addition, these insects would likely represent only a small portion of the diet of consumers of aquatic insects. Therefore aquatic insects inhabiting the West Pit lake or using it as a source of drinking water would likely have no significant effect on insect consumers such as bats.

With regard to mercury, the West Pit lake is estimated to have a total mercury concentration of 0.3 to 0.9 ng/L during flooding and in long-term closure (Poly Met, 2014g). Because precipitation would be the main input of water to the West Pit lake, metal concentrations in long-term closure would likely reflect background conditions. Therefore, any aquatic insects inhabiting the West Pit lake or drinking from the West Pit lake would be exposed to background concentrations. Any consumers of these aquatic insects (including bats) should not be exposed to mercury concentrations in those insects above background levels.

Because existing wetlands at the Plant Site (e.g., north of the tailings basin) and the Mine Site (e.g., 100 Mile Swamp) would be providing an abundant supply of insects, the majority of bats and other consumers of insects would likely be focused in these areas and would not likely be relying solely on the Project water features for their food supply. Therefore, any insects inhabiting Project water features or using them as sources of drinking water are not expected to have a significant effect on the consumers of insects. Overall, the Project's water features are not expected to have adverse indirect effects on bats. Project noise would potentially have an impact on bat utilization of maternity and roosting habitat in the vicinity of the Mine Site. Existing ambient steady equivalent noise levels for most of the Mine Site are in the range of 35 to 45 decibels (dBA), which is a range comparable to secluded woods or a quiet bedroom (MPCA 1999). The Peter Mitchell Mine, north of the Mine

Site, and traffic along Dunka Road and the existing railway, along the south edge of the Mine Site, also contribute brief, episodic noise impacts.

The primary sources of Project noise from the Mine Site would be blasting, haul trucks, and train horns, with noise levels ranging from 89-115 dBA. Equipment such as graders, bull dozers, and support trucks would be less dominant sources of noise, ranging from 75-95 dBA (EPA 1971). Blasting at the Mine Site is expected to occur once every two to three days. Typically, rock blasting generates a single event noise level ranging from 111- 115 dBA at 50 feet from the blasting site (Table 5.5-7 of Madera County 2005). Within most of the Mine Site, the sound from the blast would be similar to a loud clap of thunder.

Bats were seen on the non-federal lands during wildlife surveys (AECOM 2011b, c). There are about 7 acres of open bog, 183 acres of open water, 0 acres of sedge/wet meadow, and 117 acres of shallow marsh on the non-federal lands (**Table 8**). There are about 3,389 acres of lowland and upland coniferous forest habitat (MIH 5 and 9) that could be used by bats for roosting on the non-federal lands (**Table 6**). These lands would not be directly affected by the Project. Under the Proposed Action, the Forest Service would survey for bats and associated habitat prior to conducting land-disturbing activities and areas of known or potential habitat would be avoided when feasible.

Alternative B

Potential direct and indirect effects to bats from the Project would be similar to those under the Proposed Action. Under Alternative B, there are 175 acres of open bog, 9 acres of open water, 35 acres of sedge/wet meadow, 81 acres of shallow marsh, and 3,218 acres of lowland and upland coniferous forest on the federal lands (**Tables 6 and 8**). About 74 fewer acres of open bog, open water, sedge/wet meadow, and shallow marsh habitat and 1,094 fewer acres of lowland and upland coniferous forest habitat on the federal lands would be transferred to PolyMet from the Forest Service under Alternative B than under the Proposed Action. This habitat could be used by bats. Habitat loss to mining activities would be the same as under the Proposed Action.

The Forest Service would acquire Hay Lake Lands under Alternative B. Bats were seen at several locations on the lands during wildlife surveys (AECOM 2011b). There are 2 acres of open bog, 177 acres of open water, 0 acres of sedge/wet meadow, 84 acres of shallow marsh, and 1,872 acres of lowland and upland coniferous forest (MIH 5 and 9) on Hay Lake Lands (AECOM 2011b). About 86% of the open bog, open water, sedge/wet meadow, and shallow marsh and 55% of the lowland and upland coniferous forest (MIH 5 and 9) that occurs on the non-federal lands is found on Hay Lake Lands (**Tables 6 and 8**). This habitat would benefit from Forest Service management that favors longer protection of wetlands and other aquatic resources.

No Action Alternative

There would be no direct or indirect effects to northern long-eared bat, tri-colored bat, or little brown myotis bat under the No Action Alternative.

Cumulative Effects

Bats are facing loss of habitat from fewer old houses, buildings, old open mines, and snags (dead and decaying trees). Loggers cut down snags because they can be a danger, and people target snags for firewood. However, protecting old open mines that provide habitat for bats, limiting human intrusion into these mines with bat gates,

and managing forests to protect snags has helped to slow the loss of bat hibernacula (hibernation) and roosting habitat.

As noted above, the Forest Service has added the northern long-eared bat, tri-colored bat, and little brown myotis to the RFSS list due to concerns about white-nosed syndrome. White-nose syndrome has killed more than a million bats in the northeastern U.S. A fungus that thrives in the same cold temperature range as hibernating bats causes a white fuzzy growth on their noses and wings. Scientists speculate the fungus interrupts sleep patterns and causes the hibernating bats to awaken, depleting their fat reserves and causing starvation.

Bats also have been found dead near wind energy towers. Most collision mortality involves migrating or dispersing bats, not resident, breeding bats (MDNR 2008). Future research should concentrate on determining the cause of bat collisions with wind turbines and methods to reduce and mitigate the mortality.

About 65 acres of wetland/aquatic habitat and 987 acres of lowland and upland coniferous habitat that could be used by bats on the federal lands would be directly affected by the Project (**Tables 6 and 8**). However, there are about 67,000 acres of open wetland and open wetland, and about 517,000 acres of lowland and upland coniferous forest habitat within the CESA that could now, or in the reasonably foreseeable future, provide habitat for northern long-eared bat, tri-colored bat, and little brown myotis (Emmons and Olivier, Inc. 2006:30, 38). Thus, habitat loss from the Project would have a negligible cumulative effect on northern long-eared bat, tri-colored bat, and little brown myotis in the CESA. In addition, about 516 acres that would be affected by mining would be reclaimed to wetland and open water habitat (MDNR et al. 2013). Reclaimed areas would likely provide feeding and drinking habitat for bats soon after reclamation, and could provide roosting habitat about 80 or more years after trees establish on the reclamation areas (USDA Forest Service 2004a). In addition, about 614 acres of mining disturbance would be reclaimed to grassland/herbaceous habitat and could provide roosting habitat about 80 or more years after trees establish on these reclamation sites (MDNR et al. 2013).

Summary

Project activities associated with the Proposed Action and Alternative B could have adverse direct, indirect, or cumulative effects on individual northern long-eared bat, tri-colored bat, and little brown myotis and their habitats. Bats are common on the federal and non-federal lands. About 65 acres of open bog, open water, sedge/wet meadow, and shallow marsh habitat that could be used by bats for foraging and drinking would be lost due to mining (**Table 8**). In addition, about 987 acres of lowland and upland coniferous forest habitat that could be used by bats for roosting would be lost due to mining (**Table 6**).

Timber management and road construction could occur on the federal and non-federal lands in the reasonably foreseeable future and could destroy bat habitat, but only a small acreage of federal and non-federal lands would be affected. It is more likely that production of immature and mature upland coniferous habitat that benefits roosting bats would occur on the non-federal lands if these lands are federally administered rather than under private ownership. PolyMet would follow the April 2015 interim 4(d) rules for the federally-threatened northern long-eared bat regarding tree removal (USFWS 2015), or would consult with the USFWS if tree removal activities do not meet the criteria of the exempted activities presented in the interim 4(d) rules. Wetland and other aquatic habitat would be about equally protected under Forest Service or private ownership because of federal and state laws.

Determination

The Proposed Action and Alternative B **may impact individuals but are not likely to cause a trend to federal listing or loss of viability** for northern long-eared bat, tri-colored bat, and little brown myotis. The No Action Alternative would have **no impact** to individuals of northern long-eared bat, tri-colored bat, and little brown myotis.

Mitigation and Recommendations

No mitigation measures are recommended for northern long-eared bat, tri-colored bat, and little brown myotis.

5.2.7.3 Gray Wolf

As noted in Section 1.1, the *NorthMet Mining Project and Land Exchange Biological Assessment Draft* was prepared to evaluate project effects to gray wolf, a RFSS species that has been federally listed as threatened in the past, delisted in 2011, and relisted December 19, 2014, following a federal court reversal of the USFWS decision to delist the gray wolf. The following summarizes the results of the BA.

Environmental Baseline

The gray wolf is the largest wild member of the dog family (*Canidae*) and is common on and near the federal and non-federal lands. In 1967, the gray wolf was determined to be endangered under the Endangered Species Preservation Act of 1966, in response to their vastly declining numbers range wide. In 1974, the species was formally listed as endangered through the authority of the ESA, and the Minnesota population was reclassified to threatened in 1977. In April 2003, gray wolf populations in the U.S. were separated into three Distinct Population Segments (DPS) to more effectively manage the species; the Minnesota population was a designated portion of the Eastern DPS. In 1978, critical habitat was designated for the Eastern DPS of gray wolf. That rule identified critical habitat at Isle Royale National Park, Michigan, and Minnesota wolf management zones 1, 2, and 3. Wolf management zones 1, 2, and 3 comprised approximately 9,800 mi² in northeastern and north central Minnesota and included all of the Superior National Forest and portions of the Chippewa National Forest. Hunting Club Lands and McFarland Lake Lands were in Zone 1, while the federal lands, and other non-federal lands were in Zone 2.

On December 28, 2011, the USFWS revised the 1978 listing of the Minnesota population of gray wolf to conform to statutory and policy requirements. The USFWS renamed what was previously listed as the Minnesota population of the gray wolf as the Western Great Lakes DPS, and delineated the boundaries of the expanded Minnesota population segment to include all of Minnesota, Wisconsin, and Michigan and portions of the adjacent states. The USFWS removed the Western Great Lakes DPS from the list of endangered and threatened wildlife. The USFWS took this action because the best available scientific and commercial information indicated that the Western Great Lakes DPS does not meet the definitions of threatened or endangered under the ESA. This final rule also removed the designated critical habitat for the gray wolf in Minnesota and Michigan and the special regulations under Section 4(d) of the ESA for gray wolves in Minnesota. In 2012, the MDNR established a regulated hunting and trapping season for wolves in Minnesota. On December 19, 2014, a federal court reversed the USFWS decision to delist the gray wolf, restoring federal threatened status and critical habitat designation in Minnesota.

Six comparable surveys of gray wolf numbers and range in Minnesota have been carried out since 1979. Gray wolf populations in Minnesota were estimated at 1,235 in 1979; 1,500 to 1,750 in 1989; 2,440 in 1998; 3,020 in 2004, and 2,920 in 2008 (Berg and Kuehn 1982, Fuller et al. 1992, Berg and Benson 1999, Erb 2008). The 1998 and later surveys revealed that the number of gray wolves in Minnesota was two times greater than the planning goal (1,400 gray wolves) as specified in the Recovery Plan for Minnesota. However, the 2012 survey showed that gray wolf numbers have declined statewide from 2,920 in 2008 to about 2,200 in 2012 (Erb and Samson 2013).

Gray wolves are carnivorous predators that prefer a diet of medium and large mammals. Prey species in Minnesota include white-tailed deer, moose, beaver, and snowshoe hare, with small mammals, birds, and large invertebrates sometimes being taken (Mech 1974, Wisconsin DNR 1999). Gray wolves are habitat generalists that do not depend on the type, age, or structure of vegetation. Instead, they are indirectly influenced by vegetative condition through the distribution of their primary prey species.

Potential and favorable gray wolf habitat is defined by several elements such as low human population density, sufficient prey density, low road density, vegetation cover, and special landscape patterns (Mladenoff et al. 1995). Gray wolves can live in most any habitat that supports ungulate prey. Gray wolf densities are directly related to the densities of their primary ungulate prey (Fuller 1989). Thus, forested areas occupied by white-tailed deer and moose are important habitat. Additionally, the habitat should be suitable for smaller prey such as beaver and snowshoe hare that may be seasonally important (Mech 1970). Moose, deer, and snowshoe hare tend to forage in areas of regenerating upland forest, and coniferous forest is an important component of thermal cover for all. Riparian trembling aspen forest is important for beavers. Patch structure is only important in that it may alter prey densities or include areas of high road and human densities thereby indirectly altering gray wolf distribution (Fuller 1997).

The Forest Service identified young forest (MIH by age class - young) that is less than 10 years old as providing important foraging habitat for wolves (USDA Forest Service 2004b). Immature and mature forest habitat provides important cover habitat for wolves (MIH by age class - immature and mature).

Gray wolf tracks, scat, and signs of gray wolf kills were seen during wildlife studies on the federal lands, Dunka Road and Utility Corridor, and Plant Site during 2000, 2004, 2008, and 2009 (ENSR 2000, 2005, AECOM 2009, 2011a). Tracks were commonly seen on the Dunka Road, on mine exploration roads, along railroad grades and utility ROW, and north of the Mine Site on Northshore Mine roads during all seasons. In addition, several wolves responded to calls from the Mine Site during 2004. The wolves were located to the south of the calling station, and likely south of the property boundary based on call intensity and direction.

Gray wolf tracks and scat were recorded on the Hay Lake Lands, Wolf Lands 3 and 4, and Lake County Lands North during the survey. Gray wolf scat was seen on several abandoned logging roads. No wolves or their sign were seen on the other non-federal lands, although conditions for surveys were not favorable for detecting tracks and scat at the Hunting Club Lands.

Until 2012, International Wolf Center posted on their website a database summary of gray wolf radiotelemetry observations in northeastern Minnesota. Of the over 11,000 records in the monitoring database between 1994 and 2010, 10 records were for wolves recorded on the federal lands; however, there were no records for the Plant Site or Transportation and Utility Corridors (International Wolf Center 2012). Radiocollared wolves have been recorded on the townships of the Hay Lake Lands. A gray wolf was observed in Section 6 of Township 58

North, Range 16 West in September 1994, just south of Hay Lake. Wolves were observed in Sections 1, 19, 22, and 23 of Township 59 North, Range 16 West, in and around the Hay Lake Lands, between 1994 and 1997. Radiocollared wolves have been recorded in the vicinity of Wolf Lands 2 and 3. There are no recorded observations of wolves in the township of the McFarland Lake Lands, although the McFarland Lake Lands and other non-federal lands that would be involved in the land exchange are within the current range of the gray wolf (Erb and Sampson 2013).

Direct and Indirect Effects

Proposed Action

There are 271 acres of gray wolf foraging habitat and 5,393 acres of gray wolf cover habitat on the federal lands that could be used as habitat by the gray wolf (**Table 6**). The Project would affect about 181 acres of gray wolf foraging habitat and 1,333 acres of gray wolf cover habitat (**Table 6**). Loss of this habitat would reduce the availability of prey and cover for gray wolf traveling through the Project area. Loss of habitat would also make it less likely that a gray wolf pack would establish a territory within the Project area, especially areas directly affected by the Project. The primary effects to gray wolf prey habitat from the Project would result from habitat loss and disturbance.

Project noise would potentially have an impact on gray wolf utilization of habitat in the vicinity of the Mine Site. Existing ambient steady equivalent noise levels for most of the Mine Site are in the range of 35 to 45 decibels (dBA), which is a range comparable to secluded woods or a quiet bedroom (MPCA 1999). The Peter Mitchell Mine, north of the Mine Site, and traffic along Dunka Road and the existing railway, along the south edge of the Mine Site, also contribute brief, episodic noise impacts.

The primary sources of Project noise from the Mine Site would be blasting, haul trucks, and train horns, with noise levels ranging from 89-115 dBA. Equipment such as graders, bull dozers, and support trucks would be less dominant sources of noise, ranging from 75-95 dBA (EPA 1971). Blasting at the Mine Site is expected to occur once every two to three days. Typically, rock blasting generates a single event noise level ranging from 111- 115 dBA at 50 feet from the blasting site (Table 5.5-7 of Madera County 2005). Within most of the Mine Site, the sound from the blast would be similar to a loud clap of thunder.

The impacts of noise on gray wolf utilization of habitat near the Mine Site are largely unknown and the assessment of impacts remains subjective. Impacts may also vary between individual gray wolves. Some may adapt to predictable human activities, so if the activity generally occurs at predictable time periods at the same places or along the same routes, individual gray wolves may become habituated to the activity (ENSR/AECOM 2006).

There are 778 acres of gray wolf foraging habitat and 5,365 acres of gray wolf cover habitat on the non-federal lands (**Table 6**). The Forest Service has not determined the suitability of these lands to provide habitat for wolves or their prey. However, wildlife habitat surveys conducted on these lands give an indication of the suitability of these lands for these species. Portions of the non-federal lands have been harvested for timber during the past 20 years, with much of the harvest occurring on Lake County Lands and Wolf Lands 2 and 3. Under the Proposed Action, the Forest Service would survey for gray wolves and associated habitat prior to conducting land-disturbing activities and areas of known or potential habitat would be avoided when feasible.

Alternative B

Potential direct and indirect effects to wolves from the Project would be similar to those under the Proposed Action. Under Alternative B, there are 271 acres of gray wolf foraging habitat and 3,901 acres of gray wolf cover habitat on the federal lands. The same acreage of gray wolf foraging habitat and 1,492 fewer acres of gray wolf cover habitat would be transferred to PolyMet from the Forest Service under Alternative B than under the Proposed Action.

The Forest Service would acquire Hay Lake Lands under Alternative B. Gray wolf howling surveys were conducted at night on Hay Lake Lands. No gray wolves were heard during howling surveys, but sign of gray wolf was seen on Hay Lake Lands. Gray wolf scat was seen on several abandoned logging roads (AECOM 2011b). There are about 534 acres of gray wolf foraging habitat and 3,720 acres of gray wolf cover habitat on Hay Lake Lands (**Table 6**). About 69% of the gray wolf forage habitat and 69% of the gray wolf cover habitat that occurs on the non-federal lands is found on Hay Lake Lands. Lowland and upland coniferous forest habitat would benefit from Forest Service management that favors longer harvest rotations than typically occurs on private forestlands.

No Action Alternative

There should be no direct or indirect effects to gray wolf under the No Action Alternative.

Cumulative Effects

The Project and other nearby proposed mine projects would increase the amount of habitat fragmentation in the area, changing wooded/forested and other vegetated habitats to disturbed/developed areas with limited habitat value. Development of iron mines along the Iron Range has made portions of this area of limited value to the gray wolf, especially areas with pits, tailings, and waste rock piles. Historic waste rock piles and tailings have begun to revegetate and provide some habitat for gray wolf and their prey.

The Project would increase the amount of human access and disturbance in the area. Increased human populations in the Project area may also lead to increased risk to wolves from collisions with vehicles and trains, increased levels of recreation activities and use of backcountry roads and trails, and increased mortality from illegal hunting and trapping.

Minnesota's Wolf Management Plan will ensure the gray wolf's long-term survival. The plan gives owners of livestock and domestic pets more protection from gray wolf depredation. It splits the state into two management zones with more protective regulations in the northern third, considered the gray wolf's core range. The MDNR has not established a maximum population goal and wolves are allowed to naturally expand their range. A statewide winter population of 1,600 wolves is the minimum goal. If Minnesota's gray wolf population falls below this minimum, the MDNR will take immediate and appropriate management actions to reverse the decline and restore the population to its minimum level in the shortest possible time. The MDNR implemented a conservative and regulated hunting and trapping season in fall 2012. Hunters and trappers harvested 413 wolves in 2012 (MDNR 2013a). The MDNR expects the 2013 season to follow a similar framework with a harvest goal of 220 wolves (MDNR 2013b).

Given that the number of miles of roads associated with the federal and non-federal lands after mining is expected to be similar to or less than current levels, effects associated with road mileage are not expected to accumulate from the Project. The potential for wolves to be killed from vehicle/rail collisions was estimated using the methodology described in Section 6.1.2.1 of the BA (USACE and USDA Forest Service 2013). Assuming that there is about 0.04 gray wolf/km², that vehicle/rail collisions could occur along the 8-mile Transportation and Utility Corridors and railroad, and that vehicles and rail traffic have equal potential for collisions with wolves, it was estimated that approximately 0.05 gray wolf could be killed annually by vehicle/train traffic between the Mine Site and Plant Site, or about one gray wolf during the estimated 20-year life of the Project (assuming that mortalities due to collisions with vehicles and trains were twice the estimated level).

Using the same assumptions and methodology used to estimate gray wolf mortality on Project roads and railroads (see Section 6.1.2.1 of the BA), approximately 0.3 gray wolf could be killed annually by vehicle/train traffic on off-Project access roads/rail lines to the Plant Site, or about six wolves during the estimated 20-year life of the Project (assuming that mortalities due to collisions with vehicles and trains were twice the estimated level).

Hunting and trapping of wolves would not be allowed on lands administered by PolyMet. Thus, there should be no illegal or accidental take due to the Project. Loss of wolves to illegal trapping and hunting should remain near current levels on the non-federal lands, while the number of wolves harvested on non-federal lands during legal hunting seasons will vary based on gray wolf population levels. Thus, there should be negligible or no cumulative effect to legal, illegal, and accidental take of wolves from the Project and land exchange.

About 181 acres of gray wolf foraging habitat and 1,333 acres of gray wolf cover habitat would be lost due to mining (**Table 6**). Development of the Mine Site would add to habitat fragmentation by eventually converting habitat on the Mine Site to an open water pit lake (321 acres) and waste rock stockpiles (526 acres) of limited value to wolves. The Mine Site would account for about 0.4% of habitat affected by future mining activity within the next 30 years (Barr 2009b).

Although the Project would result in habitat loss and fragmentation on about 1,719 acres for about 20 years (until the Project is reclaimed), in the context of available habitat, and habitat that would be available to wolves in the reasonably foreseeable future, cumulative effects of the Project on habitat loss and fragmentation would be minor.

Summary

Project activities associated with the Proposed Action and Alternative B would have adverse direct, indirect, and cumulative effects on wolves and their habitat. Wolves have been seen on or near the federal and non-federal lands. Timber management and road construction could occur on the federal and non-federal lands in the reasonably foreseeable future and could destroy gray wolf habitat, but only a small acreage of federal and non-federal lands would be affected. It is more likely that production of immature and mature lowland and upland coniferous habitat that benefits gray wolf cover would occur on the non-federal lands if these lands are federally administered rather than under private ownership, although more gray wolf foraging habitat could be created on the non-federal lands under private ownership.

Determination

The Proposed Action and Alternative B **may impact individuals but are not likely to cause a trend to federal listing or loss of viability** for gray wolves. The No Action Alternative would have **no impact** to individual gray wolves.

Mitigation and Recommendations

Mitigation measures recommended for gray wolf would be primarily designed to reduce the likelihood of vehicle collisions with wolves by increasing visibility and improving wolf identification by employees. These include:

1. Reduce speed limits on Dunka Road and on haul roads.

2. Clear trees and shrubs along the inside of curves in Dunka Road to increase sight distance.
3. Promptly remove (within 48 hours of their discovery) any deer or moose killed by vehicles on Dunka Road and the haul roads to limit the likelihood of wolves feeding on carrion on or near the road. Carcasses should be taken at least one-quarter mile away from Dunka Road or the haul roads.
4. Provide site safety training on identification of gray wolves to contractors and employee who would drive on the haul road.
5. Report any vehicle collisions with gray wolves to the local Superior National Forest office. These reports shall include all known information regarding the incident, including the species involved, date of incident, fate of the animal (e.g., dead, injured), location of the carcass, geographic coordinates of the accident location, sex of the animal, and approximate age (i.e., adult, juvenile).

APPENDIX A

Common and Scientific Names of Plants and Animals Given in this Biological Evaluation

Common Name	Scientific Name
Plants	
A Lichen	<i>Caloplaca parvula</i>
A Lichen	<i>Cetraria aurescens</i>
American Shoreweed	<i>Littorella uniflora</i>
American Waterawlwort	<i>Subularia aquatica</i>
Alpine Milkvetch	<i>Astragalus alpinus</i>
Appalachian Clubmoss	<i>Huperzia appalachiana</i>
Arctoparmelia Lichen	<i>Arctoparmelia centrifuga</i>
Arctoparmelia Lichen	<i>Arctoparmelia subcentrifuga</i>
Arrowhead	<i>Sagittaria latifolia</i>
Auricled Twayblade	<i>Listera auriculata</i>
Balsam Fir	<i>Abies balsamea</i>
Barren Strawberry	<i>Waldsteinia fragariodes</i>
Basswood	<i>Tilia americana</i>
Beaked Hazel	<i>Corylus cornuta</i>
Beard Lichen	<i>Usnea longissima</i>
Black Ash	<i>Fraxinus nigra</i>
Black Spruce	<i>Picea mariana</i>
Blueberry	<i>Vaccinium angustifolium</i>
Bog Birch	<i>Betula pumila</i>
Bog Labrador-tea	<i>Ledum groenlandicum</i>
Bog Muhly	<i>Muhlenberia uniflora</i>
Bog Rosemary	<i>Andromedia polifolia</i>
Bog White Violet	<i>Viola lanceolata</i>
Braun's Holly Fern	<i>Polystichum braunii</i>
Bullrush	<i>Scirpus</i> sp.
Canada Bluejoint	<i>Calamagrostis canadensis</i>
Canada Ricegrass	<i>Piptatherum canadense</i>
Canada Yew	<i>Taxus canadensis</i>
Cartilage Lichen	<i>Ramalina thrausta</i>
Cattail	<i>Typha</i> spp.
Chilean Sweet-cicely	<i>Osmorhiza berteroi</i>
Cloudberry	<i>Rubus chamaemorus</i>
Clubmoss	<i>Lycopodium</i> spp.
Common Moonwort	<i>Botrychium lunaria</i>
Creeping Rush	<i>Juncus subtilis</i>
Creeping Snowberry	<i>Gaultheria hispidula</i>
Douglas' Hawthorn	<i>Crataegus douglasii</i>

APPENDIX A (Cont.)

Common and Scientific Names of Plants and Animals Given in the Report

Common Name	Scientific Name
Plants (Cont.)	
Dwarf Bilberry	<i>Vaccinium cespitosum</i>
Eastern White Pine	<i>Pinus strobus</i>
Encrusted Saxifrage	<i>Saxifraga paniculata</i>
Fairy Slipper	<i>Calypso bulbosa</i>
Fan Lichen	<i>Peltigera venosa</i>
Floating Marsh Marigold	<i>Caltha natans</i>
Honeycombed Lichen	<i>Menegazzia terebrata</i>
Jack Pine	<i>Pinus banksiana</i>
Lanceleaf Grapefern	<i>Botrychium lanceolatum</i> var. <i>angustisegmentum</i>
Largeleaf Sandwort	<i>Moehringia macrophylla</i>
Least Moonwort	<i>Botrychium simplex</i>
Leatherleaf	<i>Chamaedaphne calyculata</i>
Leiberg's Waterlily	<i>Nymphaea leibergii</i>
Linear-leaved Sundew	<i>Drosera linearis</i>
Little Goblin Moonwort	<i>Botrychium mormo</i>
Long-leaved Arnica	<i>Arnica lonchophylla</i>
Maidenhair Spleenwort	<i>Asplenium trichomanes</i>
Michigan Moonwort	<i>Botrychium michiganense</i>
Moor Rush	<i>Juncus stygius</i>
Moschatel	<i>Adoxa moschatellina</i>
Narrow-leaved Cattail	<i>Typha latifolia</i>
New England Sedge	<i>Carex novae-angliae</i>
Nodding Saxifrage	<i>Saxifraga cernua</i>
Northern White Cedar	<i>Thuja occidentalis</i>
Oakes' Pondweed	<i>Potamogeton oakesianus</i>
Pale Moonwort	<i>Botrychium pallidum</i>
Paper Birch	<i>Betula papyrifera</i>
Peppered Moon Lichen	<i>Sticta fuliginosa</i>
Pussywillow	<i>Salix discolor</i>
Quill Spikerush	<i>Eleocharis nitida</i>
Ram's Head Lady Slipper	<i>Cypripedium arietinum</i>
Raspberry	<i>Rubus</i> spp.
Red Oak	<i>Quercus rubra</i>
Red-osier Dogwood	<i>Cornus stolonifera</i>
Red Pine	<i>Pinus resinosa</i>
Roughfruit Fairybells	<i>Prosartes trachycarpa</i>
Scotch False Asphodel	<i>Tofieldia pusilla</i>

APPENDIX A (Cont.)

Common and Scientific Names of Plants and Animals Given in the Report

Common Name	Scientific Name
Plants (Cont.)	
Sedge	<i>Carex</i> spp.
Selwyn's Scalewort	<i>Frullania selwyniana</i>
Shining Clubmoss	<i>Lycopodium lucidulum</i>
Short Sedge	<i>Carex rossii</i>
Small Beggerticks	<i>Bidens discoidea</i>
Small-fruited Bog Cranberry	<i>Vaccinium oxycoccus</i>
Smooth Woodsia	<i>Woodsia glabella</i>
Snowline Wintergreen	<i>Pyrola minor</i>
Sphagnum Moss	<i>Sphagnum</i> spp.
Speckled Alder	<i>Alnus rugosa</i>
Sticky Locoweed	<i>Oxytropis borealis</i> var. <i>viscida</i>
Sugar Maple	<i>Acer saccharum</i>
Tamarack	<i>Larix laricina</i>
Ternate Grapefern	<i>Botrychium rugulosum</i>
Three-seeded Bog Sedge	<i>Carex trisperma</i>
Three-leaved False Solomon's Seal	<i>Smilacia trifolia</i>
Trembling Aspen	<i>Populus tremuloides</i>
Triangle Grapefern	<i>Botrychium lanceolatum</i>
Wain's Cup Lichen	<i>Cladonia wainioi</i>
Western Jacob's-ladder	<i>Polemonium occidentale</i> ssp. <i>lacustre</i>
White Pine	<i>Pinus strobus</i>
White Spruce	<i>Picea glauca</i>
Wild Rice	<i>Zizania</i> spp.
Willow	<i>Salix</i> spp.
Woolgrass	<i>Scirpus cyperinus</i>
Yellow Specklebelly	<i>Pseudocypbellaria crocata</i>
Animals	
Bald Eagle	<i>Haliaeetus leucocephalus</i>
Bay-breasted Warbler	<i>Dendroica castanea</i>
Beaver	<i>Castor canadensis</i>
Big Brown Bat	<i>Eptesicus fuscus</i>
Black Sandshell	<i>Ligumia recta</i>
Boreal Owl	<i>Aegolius funereus</i>
Brown-headed Cowbird	<i>Molothrus ater</i>
Canada Lynx	<i>Lynx canadensis</i>
Common Raven	<i>Corvus corax</i>
Connecticut Warbler	<i>Oporornis agilis</i>

APPENDIX A (Cont.)

Common and Scientific Names of Plants and Animals Given in the Report

Common Name	Scientific Name
Animals (Cont.)	
Creek Heelsplitter	<i>Lasmigona compressa</i>
Eastern Heather Vole	<i>Phenacomys ungava</i>
Eastern Red Bat	<i>Lasiurus borealis</i>
Ebony Boghaunter	<i>Williamsonia fletcheri</i>
Fisher	<i>Martes pennanti</i>
Freija' Grizzled Skipper	<i>Pyrgus centaureae freija</i>
Gray Wolf	<i>Canis lupus</i>
Great Gray Owl	<i>Strix nebulosa</i>
Great Horned Owl	<i>Bubo virginianus</i>
Headwaters Chilostigman Caddisfly	<i>Chilostigma itascae</i>
Hoary Bat	<i>Lasiurus cinereus</i>
Moose	<i>Alces alces</i>
Lake Sturgeon	<i>Acipenser fulvescens</i>
Little Brown Myotis	<i>Myotis lucifugus</i>
Nabokov's Blue	<i>Plebejus idas nabokovi</i>
Nipigon Cisco	<i>Coregonus nipigon</i>
Northern Brook Lamprey	<i>Ichthyomyzon fossor</i>
Northern Goshawk	<i>Accipiter gentilis</i>
Northern Long-eared Bat	<i>Myotis septentrionalis</i>
Olive-sided Flycatcher	<i>Contopus cooperi</i>
Passenger Pigeon	<i>Ectopistes migratorius</i>
Quebec Emerald	<i>Somatochlora brevicincta</i>
Raccoon	<i>Procyon lotor</i>
Red-tailed Hawk	<i>Buteo jamaicensis</i>
Ruffed Grouse	<i>Bonasa umbellus</i>
Shortjaw Cisco	<i>Coregonus zenithicus</i>
Silver-haired Bat	<i>Lasionycteris noctivagans</i>
Snowshoe Hare	<i>Lepus canadensis</i>
Spruce Budworm	<i>Choristoneura fumiferana</i>
Taiga Alpine	<i>Erebia mancinus</i>
Three-toed Woodpecker	<i>Picoides tridactylus</i>
Tri-colored Bat	<i>Perimyotis subflavus</i>
White-tailed Deer	<i>Odocoileus virginianus</i>
Wood Turtle	<i>Glyptemys insculpta</i>
